To my wife Jeri, my son Kyle, and grandson Tucker
To my late mother Dorothy, who instilled values in my brother Steve and myself that have
helped us throughout life
To family and animals who represent the purity of life.

Larry P. Tilley

To my wife, May, my son, Ben, and my daughter, Jade, who are a constant source of inspiration, love and joy. To my late father, Frank, who was my perfect role model. To Kaylee (dog) and Centie (cat) who remind me each day to make time to play.

Francis W.K. Smith, Jr.

PREFACE

Keeping abreast of advances in veterinary internal medicine is extremely difficult, especially for the busy general practitioner. To keep current with all the veterinary journals while practicing medicine is impossible. The veterinarian in practice can be overwhelmed by all of the findings and conclusions of thousands of studies conducted by veterinary specialists. *Blackwell's Five-Minute Veterinary Consult* is designed to provide the busy veterinary practitioner and student of veterinary medicine with concise practical reviews of almost all the diseases and clinical problems in dogs and cats. Our goal in creating this textbook was also to provide up-to-date information in an easy-to-use format. Emphasis is placed on diagnosis and treatment of problems and diseases likely to be seen by veterinarians.

Our fondest dream was realized when the first five editions of this book were chosen as a comprehensive reference source for canine and feline medicine by veterinary students, practicing veterinarians, and board-certified specialists. The format has proven easy to use and very popular with busy practitioners. The scope of the book and the number of consulting editors and authors have been expanded. We have also increased the number of authors from outside North America, to provide the best advice in the world. The number of topics has been increased, and every topic has been updated to provide you with the most current information possible in a textbook. The appendixes have also been expanded to include more useful tables, and the Drug Formulary has been updated and expanded. New medications have also been added.

Several good veterinary internal medicine textbooks are available. The uniqueness and value of *Blackwell's Five-Minute Veterinary Consult* as a quick reference is the consistency of presentation, the breadth of coverage, the contribution of large numbers of experts, and the timely preparation of the manuscript. The format of every topic is identical, making it easy to find information. An extensive list of topic headings ensures complete coverage of each topic.

As the title implies, one objective of this book is to make information quickly available. To this end, we have organized topics alphabetically from A to Z. Most topics can be found without using the index. A table of contents broken out by organ system and a detailed index are provided. Large volumes of useful information are summarized in charts in the appendixes. Also included in the appendixes are an extensive and detailed drug formulary, toxicology tables, endocrine testing protocols, normal laboratory values, new genetic epilepsy classification table, pain management tables, information page with important resources for veterinarians, and conversion tables.

We are delighted and privileged to have had the assistance of numerous experts in veterinary internal medicine from around the world. More than 300 veterinary specialists contributed to this text, allowing each chapter to be written by an expert on the subject. In addition to providing outstanding information, this large pool of experts allowed us to publish this major text in a timely manner.

Many large textbooks take several years to write, making some of the information outdated by the time the book is published. We are indebted to the many contributors and consulting editors whose hard work allowed us to write, edit, and publish this work in 2 years, with most chapters completed within a year of publication. Our goal is to revise the text every 3 years, so that the contents will always be current.

Blackwell's Five-Minute Veterinary Consult : Canine and Feline, Sixth Edition is available in a variety of digital formats. Visit www.wiley.com/go/5MVC for more information. This edition also includes client education handouts based on the content of *Blackwell's Five-Minute Veterinary Consult*. The complimentary client education handouts are available on a companion website at www.fiveminutevet.com/canineandfeline featuring more than 352 Client Handouts for you to customize and use in practice. These handouts can be edited to reflect your practice preferences and then printed on your letterhead to distribute to your clients.

The book will also be published as an e-book as a downloadable ePub/ePDF. Now veterinarians can quickly access information about necessary clinical skills and new developments in diagnosis and treatment on their computers or mobile versions. Our *Blackwell's Five-Minute Veterinary Consult* website, mobile applications offer fast, affordable access to much of the accumulated wisdom in veterinary medicine by use of a simple search-and-retrieval process. This interactive computer technology brings to the clinic examination room and doctor's office an easy-to-use "dynamic textbook" that will markedly improve the quality of continuing education and clinical practice.

The sixth edition of this textbook constitutes an important, up-to-date medical reference source for your practice and clinical education. We strived to make it complete yet practical and easy to use. Our dreams are realized if this text helps you to quickly locate and use the "momentarily important" information that is essential to the practice of high-quality veterinary medicine. We would appreciate your input so that we can make future editions even more useful. If you would like to see any changes in content or format, additions, or deletions, please let us know. Send comments to the following:

ACKNOWLEDGMENTS

The completion of this textbook provides a welcome opportunity to recognize in writing the many individuals who have helped along the way. The editors gratefully acknowledge the consulting editors and the contributors who, by their expertise, have so unmistakably enhanced the quality of this textbook.

We would also like to acknowledge and thank our families for their support of this project and the sacrifices they made to allow us the time to complete the book.

In addition to thanking veterinarians who have referred patients to us, we would like to express our gratitude to each of the veterinary students, interns, and residents whom we have had the privilege of teaching. Their curiosity and intellectual stimulation have enabled us to grow and have prompted us to undertake the task of writing this book.

Finally, a special acknowledgment goes to everyone at Wiley-Blackwell. The marketing and sales departments also must be acknowledged for generating such an interest in this book. They are all meticulous workers and kind people who have made the final stages of preparing this book both inspiring and fun. We would also like to thank copy-editor Heather Addison, and Erica Judisch, Executive Editor. A special thank you goes to Mirjana Misina, Editorial Project Manager, who spent hours and days keeping track of all the contributors and the deadline dates for manuscripts. This edition would not have taken place without her. A special thank you goes to Kathy Cavanagh, who edited the client education handouts available with this textbook and Naomi Burtnick who helped edit the Drug Formulary. An important life goal of ours has been fulfilled: to provide expertise in small animal internal medicine worldwide and to teach the principles contained in this textbook to veterinarians and students everywhere.

Larry P. Tilley and Frank W.K. Smith, Jr

KEITH RICHTER, DVM, MSEL Diplomate ACVIM (Small Animal Internal Medicine) Hospital Director and Staff Internist Veterinary Specialty Hospital of San Diego San Diego, California USA		

GRETCHEN LEE SCHOEFFLER, DVM Diplomate ACVECC Chief, Companion Animal Emergency & Critical Care Section Department of Clinical Sciences College of Veterinary Medicine Cornell University Ithaca, New York USA	KIM A. SELTING, DVM, MS Diplomate ACVIM (Oncology) Assistant Teaching Professor Department of Veterinary Medicine & Surgery University of Missouri Columbia, Missouri USA	DAVID D. SISSON, DVM Diplomate ACVIM (Cardiology) Professor Department of Clinical Sciences College of Veterinary Medicine Oregon State University Corvallis, Oregon USA
JOHAN P. SCHOEMAN, BVSc, MMedVet(Med), PhD, DSAM Diplomate ECVIM Professor and Head Department of Companion Animal Clinical Studies Faculty of Veterinary Science University of Pretoria Onderstepoort South Africa	LINDA G. SHELL, DVM Diplomate ACVIM (Neurology) Professor, Small Animal Internal Medicine Ross University School of Veterinary Medicine St. Kitts West Indies	FRANCIS W.K. SMITH, Jr., DVM Diplomate ACVIM (Small Animal Internal Medicine & Cardiology) Clinical Assistant Professor Department of Medicine Cummings School of Veterinary Medicine Tufts University North Grafton, Massachusetts and Vice President, VetMed Consultants Lexington, Massachusetts USA
DONALD P. SCHROPE, DVM Diplomate ACVIM (Cardiology) Clinical Cardiologist Oradell Animal Hospital Paramus, New Jersey USA	G. DIANE SHELTON, DVM, PhD Diplomate ACVIM (Internal Medicine) Professor Department of Pathology School of Medicine University of California, San Diego La Jolla, California USA	JO R. SMITH, MA, VetMB, PhD Diplomate ACVIM (Small Animal Internal Medicine) Associate Professor Department of SA Medicine & Surgery College of Veterinary Medicine University of Georgia Athens, Georgia USA
FRED W. SCOTT, DVM, PhD Diplomate ACVM Professor Emeritus Department of Microbiology & Immunology College of Veterinary Medicine Cornell University Ithaca, New York USA	BARBARA L. SHERMAN, MS, PhD, DVM Diplomate ACVB (Behavior) & ACAW (Animal Welfare) Clinical Professor Department of Clinical Sciences College of Veterinary Medicine North Carolina State University Raleigh, North Carolina USA	PATRICIA J. SMITH, MS, DVM, PhD Diplomate American College of Veterinary Ophthalmologists Animal Eye Care Fremont, California USA
J. CATHARINE R. SCOTT-MONCRIEFF, MA Vet MB MS Diplomate ACVIM (Small Animal Internal Medicine); ECVIM (companion animal) Head, Department of Veterinary Clinical Sciences Professor Small Animal Internal Medicine College of Veterinary Medicine, Purdue University West Lafayette, Indiana USA	TRACI A. SHREYER, MA Applied Animal Behaviorist Veterinary Medical Center Community Practice & Dentistry The Ohio State University College of Veterinary Medicine Columbus, Ohio USA	PAUL W. SNYDER, DVM, PhD Diplomate ACVP (Anatomic Pathology) Professor College of Veterinary Medicine Purdue University West Lafayette, Indiana USA
LYNNE M. SEIBERT, DVM, MS, PhD Diplomate ACVB Veterinary Behavior Consultants Roswell, Georgia USA	DEBORAH C. SILVERSTEIN, DVM, DACVECC Associate Professor of Critical Care Department of Clinical Studies-Philadelphia University of Pennsylvania Matthew J. Ryan Veterinary Teaching Hospital Philadelphia, Pennsylvania USA	MITCHELL D. SONG, DVM Diplomate ACVD Animal Dermatology, PC Phoenix, Arizona Adjunct Assistant Clinical Professor Midwestern University College of Veterinary Medicine Glendale, Arizona USA
LAURA E. SELMIC, BVetMed (Hons.), MPH, MRCVS Diplomate ACVS-SA ACVS Founding Fellow, Surgical Oncology Assistant Professor Department of Veterinary Clinical Medicine University of Illinois Urbana, Illinois USA	ALLEN FRANKLIN SISSON, DVM, MS Diplomate ACVIM (Neurology) Staff Neurologist Department of Neurology Angell Animal Medical Center-Boston Boston, Massachusetts USA	JÖRG M. STEINER, med.vet., Dr.med.vet., PhD, Diplomate ACVIM; Diplomate ECVIM-CA, AGAF Professor Gastrointestinal Laboratory Department of Small Animal Clinical Sciences College of Veterinary Medicine & Biomedical Sciences Texas A&M University College Station, Texas USA

MEREDITH E. STEPITA, DVM Diplomate ACVB (Behavior) Owner Veterinary Behavior Specialists Clayton, California USA	JANE E. SYKES, BVSc (Hons), PhD Diplomate ACVIM (Small Animal Internal Medicine) Professor Department of Medicine & Epidemiology School of Veterinary Medicine University of California Davis, California USA	JUSTIN D. THOMASON, DVM Diplomate ACVIM Assistant Professor of Cardiology Department of Clinical Sciences Veterinary Health Center Kansas State University Manhattan, Kansas USA
JOSHUA A. STERN, DVM, PhD Diplomate ACVIM (Cardiology) Assistant Professor Department of Medicine & Epidemiology School of Veterinary Medicine University of California Davis, California USA	JOSEPH TABOADA, DVM Diplomate ACVIM (Small Animal Internal Medicine) Professor of Small Animal Internal Medicine and Associate Dean Office of Veterinary Education and Student Affairs Department of Veterinary Clinical Sciences School of Veterinary Medicine Louisiana State University Baton Rouge, Louisiana USA	CRAIG A. THOMPSON, DVM Diplomate ACVP (Clinical Pathology) Clinical Assistant Professor – Clinical Pathology Department of Comparative Pathobiology Purdue University – College of Veterinary Medicine West Lafayette, Indiana USA
REINHARD K. STRAUBINGER, Dr.med.vet., PhD Professor of Bacteriology und Mycology Institute for Infectious Diseases & Zoonoses Faculty of Veterinary Medicine Ludwig-Maximilians-Universität Munich Germany	PATRICIA A. TALCOTT, MS, DVM, PhD Diplomate ABVT Professor Department of Integrative Physiology & Neuroscience Toxicology Section Head, WADDL Washington State University College of Veterinary Medicine Pullman, Washington USA	MARY F. THOMPSON, BVSc (Hons.) Diplomate ACVIM (Small Animal Internal Medicine); MACVSc Lecturer Companion Animal Medicine The University of Queensland Gatton, Queensland Australia
JAN S. SUCHODOLSKI, MedVet, DrVetMed, PhD, AGAF Diplomate ACVM (Immunology) Associate Professor & Associate Director Gastrointestinal Laboratory Department of Small Animal Clinical Sciences College of Veterinary Medicine & Biomedical Sciences Texas A&M University College Station, Texas USA	INGE TARNOW, DVM, PhD Professor Department of Veterinary Clinical & Animal Studies The Faculty of Health & Medical Sciences University of Copenhagen Denmark	JERRY A. THORNHILL, DVM, DACVIM Director, Nephrology and Dialysis Veterinary Specialty Center Buffalo Grove, Illinois USA
STEFFEN O. SUM, DVM Assistant Professor Department of Small Animal Medicine & Surgery College of Veterinary Medicine University of Georgia Athens, Georgia USA	SUSAN M. TAYLOR, DVM Diplomate ACVIM (Small Animal Internal Medicine) Professor Department of Small Animal Clinical Sciences Western College of Veterinary Medicine University of Saskatchewan Saskatoon, Saskatchewan Canada	MARY ANNA THRALL, BA, DVM, MS Diplomate ACVP (Clinical Pathology) Professor Head, Department of Biomedical Sciences Ross University School of Veterinary Medicine Basseterre, St. Kitts West Indies
STEVEN E. SUTER, VMD, MS, PhD Diplomate ACVIM (Oncology) Associate Professor Department of Clinical Sciences College of Veterinary Medicine North Carolina State University Raleigh, North Carolina USA	JENNIFER S. THOMAS, DVM, PhD Diplomate ACVP (Clinical Pathology) Associate Professor Department of Pathobiology & Diagnostic Investigation College of Veterinary Medicine Michigan State University East Lansing, Michigan USA	LARRY P. TILLEY, DVM Diplomate, ACVIM (Small Animal Internal Medicine) President, VetMed Consultants, Inc. Santa Fe, New Mexico USA
CHERYL L. SWENSON, DVM, PhD Diplomate ACVP (Clinical Pathology) Associate Professor Department of Pathobiology & Diagnostic Investigation College of Veterinary Medicine Michigan State University East Lansing, Michigan USA		ANDREA TIPOLD, Prof. Dr. Diplomate ECVN Department of Small Animal Medicine & Surgery University of Veterinary Medicine Hannover Hannover Germany

SHEILA M.F. TORRES, DVM, MS, PhD Diplomate ACVD Professor of Veterinary Dermatology Department of Veterinary Clinical Sciences College of Veterinary Dermatology University of Minnesota St. Paul, Minnesota USA	SHELLY L. VADEN, DVM, PhD Diplomate ACVIM Professor, Internal Medicine Department of Clinical Sciences College of Veterinary Medicine North Carolina State University Raleigh, North Carolina USA	ALEXANDER H. WERNER, VMD Diplomate ACVD Animal Dermatology Center Studio City & Westlake Village, California and Reno, Nevada USA
SANDRA P. TOU, DVM Diplomate ACVIM (Cardiology and Internal Medicine) Clinical Assistant Professor Department of Clinical Sciences College of Veterinary Medicine North Carolina State University Raleigh, North Carolina USA	MARIA VIANNA, DVM Diplomate DACVS Veterinary Specialty Hospital of Palm Beach Gardens Palm Beach Gardens, Florida USA	MICHAEL D. WILLARD, DVM, MS Diplomate ACVIM (Small Animal) Professor Department of Small Animal Clinical Sciences College of Veterinary Medicine Texas A&M University College Station, Texas USA
WILLIAM J. TRANQUILLI, DVM, Bs.in Ed., MS Diplomate ACVAA Professor Emeritus University of Illinois-Urbana Urbana, Illinois President Veterinary Outdoor Education and Continuing Education Inc. Illinois USA	LORI S. WADDELL, DVM Diplomate ACVECC Adjunct Associate Professor, Critical Care Department of Clinical Studies Matthew J. Ryan Veterinary Hospital University of Pennsylvania Philadelphia, Pennsylvania USA	HEATHER M. WILSON-ROBLES, DVM Diplomate ACVIM (Oncology) Associate Professor Department of Small Animal Clinical Sciences College of Veterinary Medicine Texas A&M University College Station, Texas USA
DAVID C. TWEDT, DVM Diplomate ACVIM Professor Department of Clinical Sciences College of Veterinary Medicine & Biomedical Sciences Colorado State University Fort Collins, Colorado USA	LIORA WALDMAN, BVM&S, CertSAD, MRCVS Veterinary Dermatology & Allergy Clinic Haifa Israel	TINA WISMER, DVM Diplomate ABVT; Diplomate ABT Medical Director ASPCA Animal Poison Control Center Urbana, Illinois USA
VALARIE V. TYNES, DVM Diplomate ACVB Veterinary Services Specialist Ceva Animal Health Sweetwater, Texas USA	KIRSTEN E. WARATUKE, DVM Consulting Veterinarian in Clinical Toxicology ASPCA Animal Poison Control Center Urbana, Illinois USA	R. DARREN WOOD, DVM, DVSc Diplomate ACVP (Clinical Pathology) Associate Professor Department of Pathobiology Ontario Veterinary College University of Guelph Guelph, Ontario Canada
YU UEDA, DVM Resident Small Animal Emergency & Critical Care William R. Pritchard Veterinary Medical Teaching Hospital University of California Davis, California USA	MICHAEL WEH, DVM Diplomate ACVS Assistant Professor of Orthopedic Surgery Small Animal Medicine and Surgery Veterinary Teaching Hospital College of Veterinary Medicine University of Georgia Athens, Georgia USA	J. PAUL WOODS, DVM, MS Diplomate ACVIM (Internal Medicine, Oncology) Professor of Internal Medicine and Oncology Department of Clinical Studies Ontario Veterinary College Co-Director, Institute for Comparative Cancer Investigation University of Guelph Guelph, Ontario Canada
LISA K. ULRICH, CVT Certified Veterinary Technician Veterinary Clinical Sciences Department Minnesota Urolith Center College of Veterinary Medicine University of Minnesota St. Paul, Minnesota USA	GLADE WEISER, DVM Diplomate ACVP (Clinical Pathology) Professor, Special Appointment Department of Microbiology, Immunology, & Pathology College of Veterinary Medicine & Biomedical Sciences Colorado State University Fort Collins, Colorado USA	JACKIE M. WYPIJ, DVM, MS Diplomate ACVIM (Oncology) Assistant Professor Department of Veterinary Clinical Medicine University of Illinois, Urbana-Champaign Urbana, Illinois USA
	SHARON LYNN WELCH, DVM, ABVT, ABT Pet Poison Helpline and SafetyCall International, PLLC Minneapolis, Minnesota USA	

HANY YOUSSEF, BVSc, MS, DVM
Diplomate ABT, Diplomat ABVT
Owner of Watseka Animal Hospital
Iroquois County Animal Control
Watseka, Illinois
USA

DEBRA L. ZORAN, DVM, PhD
Diplomate ACVIM (Small Animal Internal
Medicine)
Professor & Chief of SA Medicine
Medical Operations Chief, VET
Department of SA Clinical Sciences
College of Veterinary Medicine &
Biomedical Sciences
Texas A&M University
College Station, Texas
USA

ABOUT THE COMPANION WEBSITE

This book is accompanied by a companion website:

www.fiveminutevet.com/canineandfeline

The website includes:

- Videos
- Images
- Client Education Handouts
- Additional references and internet resources

The password for the companion website: bwc837gx4d

CONTENTS

TOPIC	
Abortion, Spontaneous (Early Pregnancy Loss)—Cats	2
Abortion, Spontaneous (Early Pregnancy Loss)—Dogs	4
Abortion, Termination of Pregnancy	6
Abscessation	8
Acetaminophen (APAP) Toxicosis	10
Acidosis, Metabolic (Traditional Approach)	12
Acne—Cats	14
Acne—Dogs	15
Acral Lick Dermatitis	16
Acromegaly—Cats	17
Actinomycosis	19
Acute Abdomen	20
Acute Respiratory Distress Syndrome	23
Adenocarcinoma, Anal Sac	25
Adenocarcinoma, Lung	26
Adenocarcinoma, Nasal	27
Adenocarcinoma, Pancreas	29
Adenocarcinoma, Prostate	30
Adenocarcinoma, Renal	31
Adenocarcinoma, Salivary Gland	32
Adenocarcinoma, Skin (Sweat Gland, Sebaceous)	33
Adenocarcinoma, Stomach, Small and Large Intestine, Rectal	34
Adenocarcinoma, Thyroid—Dogs	35
Aggression to Unfamiliar People and Unfamiliar Dogs	37
Aggression Toward Children—Dogs	39
Aggression Toward Familiar People—Dogs	40
Aggression Toward Humans—Cats	42
Aggression, Food and Resource Guarding—Dogs	44
Aggression, Intercat Aggression	46
Aggression, Overview—Cats	49
Aggression, Overview—Dogs	51
Aggression—Between Dogs in the Household	55
Alkalosis, Metabolic (Traditional Approach)	57
Alopecia—Cats	59
Alopecia—Dogs	61
Alopecia, Non-Inflammatory—Dogs	63
Amebiasis	65

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Ameloblastoma	66
Amitraz Toxicosis	67
Amphetamines and ADD/ADHD Medication Toxicosis	69
Amyloidosis	71
Anaerobic Infections	73
Anal Sac Disorders	74
Anaphylaxis	75
Anemia of Chronic Kidney Disease	77
Anemia, Aplastic	79
Anemia, Heinz Body	80
Anemia, Immune-Mediated	81
Anemia, Iron-Deficiency	83
Anemia, Metabolic (Anemias with Spiculated Red Cells)	84
Anemia, Nonregenerative	85
Anemia, Nuclear Maturation Defects (Anemia, Megaloblastic)	87
Anemia, Regenerative	88
Anisocoria	90
Anorexia	92
Antebrachial Growth Deformities	94
Anterior Uveitis—Cats	96
Anterior Uveitis—Dogs	98
Antidepressant Toxicosis—SSRIs and SNRIs	100
Antidepressant Toxicosis—Tricyclic	102
Aortic Stenosis	104
Aortic Thromboembolism	106
Apudoma	109
Arteriovenous Fistula and Arteriovenous Malformation	110
Arteriovenous Malformation of the Liver	111
Arthritis (Osteoarthritis)	113
Arthritis, Septic	115
Ascites	117
Aspergillosis, Nasal	119
Aspergillosis, Systemic	121
Aspirin Toxicosis	123
Asthma, Bronchitis—Cats	124
Astrocytoma	126
Astrovirus Infection	127
Ataxia	128
Atherosclerosis	130
Atlantoaxial Instability	131
Atopic Dermatitis	133
Atrial Fibrillation and Atrial Flutter	135
Atrial Premature Complexes	138
Atrial Septal Defect	140
Atrial Standstill	141
Atrial Wall Tear	143
Atrioventricular Block, Complete (Third Degree)	145

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Atrioventricular Block, First Degree	147
Atrioventricular Block, Second Degree—Mobitz I	149
Atrioventricular Block, Second Degree—Mobitz II	151
Atrioventricular Valve Dysplasia	153
Atrioventricular Valve (Myxomatous) Disease	155
Atrioventricular Valvular Stenosis	158
Azotemia and Uremia	161
Babesiosis	164
Baclofen Toxicosis	166
Bartonellosis	167
Basal Cell Tumor	168
Battery Toxicosis	169
Baylisascariasis	170
Benign Prostatic Hyperplasia (BPH)	171
Benzodiazepine and Other Sleep Aids Toxicosis	172
Beta Blocker Toxicosis	174
Beta-2 Agonist Inhaler Toxicosis	175
Bile Duct Carcinoma	176
Bile Duct Obstruction (Extrahepatic)	177
Bile Peritonitis	180
Bilious Vomiting Syndrome	182
Blastomycosis	183
Blepharitis	185
Blind Quiet Eye	187
Blood Transfusion Reactions	189
Blue-Green Algae Toxicosis	190
Botulism	191
Brachial Plexus Avulsion	192
Brachycephalic Airway Syndrome	193
Brain Injury	195
Brain Tumors	197
Breeding, Timing	199
Bronchiectasis	201
Bronchitis, Chronic	202
Brucellosis	204
Calcium Channel Blocker Toxicosis	206
Campylobacteriosis	207
Candidiasis	208
Canine Coronavirus Infections	209
Canine Distemper	210
Canine Infectious Respiratory Disease	212
Canine Influenza	214
Canine Parvovirus Infection	216
Canine Schistosomiasis (Heterobilharziasis)	218
Capillariasis (Pearsonema)	219
Car Ride Anxiety—Dogs and Cats	220
Carbon Monoxide Toxicosis	223

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Carcinoid and Carcinoid Syndrome	224
Cardiac Glycoside Plant Toxicosis	225
Cardiomyopathy—Boxer (Arrhythmogenic Right Ventricular)	226
Cardiomyopathy, Dilated—Cats	227
Cardiomyopathy, Dilated—Dogs	230
Cardiomyopathy, Hypertrophic—Cats	233
Cardiomyopathy, Hypertrophic—Dogs	235
Cardiomyopathy, Restrictive—Cats	236
Cardiopulmonary Arrest	238
Carnitine Deficiency	240
Cataracts	241
Cerebellar Degeneration	243
Cerebellar Hypoplasia	244
Cerebrovascular Accidents	245
Ceruminous Gland Adenocarcinoma, Ear	247
Cervical Spondylomyelopathy (Wobbler Syndrome)	248
Chagas Disease (American Trypanosomiasis)	250
Chediak-Higashi Syndrome	251
Chemodectoma	252
Cheyletiellosis	253
Chlamydiosis—Cats	254
Chocolate (Methylxanthine) Toxicosis	256
Cholangitis/Cholangiohepatitis Syndrome	259
Cholecystitis and Choledochitis	262
Cholelithiasis	264
Chondrosarcoma, Bone	266
Chondrosarcoma, Larynx and Trachea	267
Chondrosarcoma, Nasal and Paranasal Sinus	268
Chondrosarcoma, Oral	269
Chorioretinitis	270
Chylothorax	272
Cirrhosis and Fibrosis of the Liver	274
Clostridial Enterotoxicosis	277
Coagulation Factor Deficiency	279
Coagulopathy of Liver Disease	281
Cobalamin Deficiency	283
Coccidioidomycosis	285
Coccidiosis	287
Cognitive Dysfunction Syndrome	288
Cold Agglutinin Disease	290
Colibacillosis	291
Colitis and Proctitis	293
Colitis, Histiocytic Ulcerative	296
Compulsive Disorders—Cats	297
Compulsive Disorders—Dogs	299
Congenital and Developmental Renal Diseases	301
Congenital Ocular Anomalies	303

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Congenital Spinal and Vertebral Malformations	305
Congestive Heart Failure, Left-Sided	307
Congestive Heart Failure, Right-Sided	309
Conjunctivitis—Cats	311
Conjunctivitis—Dogs	313
Constipation and Obstipation	315
Contact Dermatitis	317
Coonhound Paralysis (Acute Polyradiculoneuritis)	318
Copper Associated Hepatopathy	320
Coprophagia and Pica	324
Corneal and Scleral Lacerations	326
Corneal Opacities—Degenerations and Infiltrates	328
Corneal Opacities—Dystrophies	329
Corneal Sequestrum—Cats	330
Cough	331
Craniomandibular Osteopathy	333
Cruciate Ligament Disease, Cranial	334
Cryptococciosis	336
Cryptorchidism	338
Cryptosporidiosis	339
Crystalluria	340
Cutaneous Drug Eruptions	342
Cuterebriasis	343
Cyanosis	344
Cyclic Hematopoiesis	346
Cylindruria	347
Cysticercosis	348
Cytauxzoonosis	349
Deafness	350
Deciduous Teeth, Persistent	352
Degenerative Myelopathy	353
Demodicosis	355
Dental Caries	357
Dentigerous Cyst	359
Dermatomyositis	360
Dermatophilosis	362
Dermatophytosis	363
Dermatoses, Depigmenting Disorders	365
Dermatoses, Erosive or Ulcerative	367
Dermatoses, Exfoliative	369
Dermatoses, Neoplastic	371
Dermatoses, Papulonodular	373
Dermatoses, Sterile Nodular/Granulomatous	375
Dermatoses, Sun-Induced	377
Dermatoses, Vesiculopustular	378
Dermatoses, Viral (Non-Papillomatosis)	380
Destructive and Scratching Behavior—Cats	381

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Destructive Behavior—Dogs	382
Diabetes Insipidus	383
Diabetes Mellitus with Hyperosmolar Coma	384
Diabetes Mellitus with Ketoacidosis	386
Diabetes Mellitus without Complication—Cats	388
Diabetes Mellitus without Complication—Dogs	390
Diabetic Hepatopathy	392
Diaphragmatic Hernia	394
Diarrhea, Acute	395
Diarrhea, Antibiotic Responsive	397
Diarrhea, Chronic—Cats	398
Diarrhea, Chronic—Dogs	400
Digoxin Toxicity	402
Diisocyanate Glue (Gorilla Glue) Toxicosis	403
Diocophyema Renale (Giant Kidney Worm)	404
Discolored Tooth/Teeth	406
Discospondylitis	408
Disseminated Intravascular Coagulation	410
Drowning (Near Drowning)	412
Ductal Plate Malformation (Congenital Hepatic Fibrosis)	413
Dysautonomia (Key-Gaskell Syndrome)	416
Dyschezia and Hematochezia	417
Dysphagia	419
Dyspnea and Respiratory Distress	422
Dystocia	424
Dysuria and Pollakiuria	426
Ear Mites	428
Ebstein's Anomaly	429
Eclampsia	430
Ectopic Ureter	431
Ectropion	432
Ehrlichiosis (Anaplasma)	433
Elbow Dysplasia	435
Electric Cord Injury	437
Enamel Hypoplasia/Hypocalcification	438
Encephalitis	439
Encephalitis Secondary to Parasitic Migration	441
Endocarditis, Infective	442
Endomyocardial Diseases—Cats	444
Entropion	446
Eosinophilic Granuloma Complex	447
Epididymitis/Orchitis	449
Epilepsy, Genetic (Idiopathic)—Dogs	450
Epiphora	452
Episcleritis	454
Epistaxis	455
Epulis	457

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Esophageal Diverticula	459
Esophageal Foreign Bodies	460
Esophageal Stricture	462
Esophagitis	464
Ethanol Toxicosis	467
Ethylene Glycol Toxicosis	468
Excessive Vocalization and Waking at Nights	470
Exercise-Induced Weakness/Collapse in Labradors	472
Exocrine Pancreatic Insufficiency	474
Eyelash Disorders (Trichiasis/Distichiasis/Ectopic Cilia)	476
Facial Nerve Paresis and Paralysis	477
False Pregnancy	479
Familial Shar-Pei Fever	481
Fanconi Syndrome	483
Fear and Aggression in Veterinary Visits	484
Fears, Phobias, and Anxieties—Cats	488
Fears, Phobias, and Anxieties—Dogs	490
Feline Calicivirus Infection	492
Feline Foamy Virus Infection (FFV)	494
Feline Herpesvirus Infection	495
Feline Hyperesthesia Syndrome	497
Feline Idiopathic Lower Urinary Tract Disease	498
Feline Immunodeficiency Virus Infection (FIV)	500
Feline Infectious Peritonitis (FIP)	502
Feline Ischemic Encephalopathy	504
Feline Leukemia Virus Infection (FeLV)	506
Feline Panleukopenia	508
Feline Paraneoplastic Alopecia	510
Feline Symmetrical Alopecia	511
Fever	512
Fiber-Responsive Large Bowel Diarrhea	514
Fibrocartilaginous Embolic Myelopathy	515
Fibrosarcoma, Bone	517
Fibrosarcoma, Gingiva	518
Fibrosarcoma, Nasal and Paranasal Sinus	519
Fipronil Toxicosis	520
Flatulence	521
Flea Bite Hypersensitivity and Flea Control	523
Food Reactions, Dermatologic	525
Food Reactions (Gastrointestinal), Adverse	527
Gallbladder Mucocele	529
Gastric Dilation and Volvulus Syndrome	531
Gastric Motility Disorders	533
Gastritis, Atrophic	535
Gastritis, Chronic	536
Gastroduodenal Ulceration/Erosion (GUE)	538
Gastroenteritis, Eosinophilic	540

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Gastroenteritis, Hemorrhagic	542
Gastroenteritis, Lymphocytic-Plasmacytic	544
Gastroesophageal Reflux	546
Gastrointestinal Obstruction	547
Giardiasis	549
Gingival Hyperplasia/Enlargement	550
Glaucoma	551
Glomerulonephritis	553
Glucagonoma	555
Glucosuria	557
Gluten Enteropathy in Irish Setters	559
Glycogen Storage Disease	560
Glycogen-Type Vacuolar Hepatopathy	561
Grape, Raisin, and Currant Toxicosis	564
Hair Follicle Tumors	565
Halitosis	566
Head Pressing	568
Head Tilt	570
Head Tremors (Bobbing), Idiopathic—Dogs	572
Heartworm Disease—Cats	573
Heartworm Disease—Dogs	574
Heat Stroke and Hyperthermia	576
Helicobacter spp	578
Hemangiosarcoma, Bone	580
Hemangiosarcoma, Heart	581
Hemangiosarcoma, Skin	582
Hemangiosarcoma, Spleen and Liver	584
Hematemesis	586
Hematuria	588
Hemoglobinuria and Myoglobinuria	590
Hemothorax	592
Hemotropic Mycoplasmosis (Also Hemoplasmosis)	593
Hepatic Amyloid	595
Hepatic Encephalopathy	597
Hepatic Failure, Acute	600
Hepatic Lipidosis	603
Hepatic Nodular Hyperplasia and Dysplastic Hyperplasia	606
Hepatitis, Chronic	608
Hepatitis, Granulomatous	612
Hepatitis, Infectious (Viral) Canine	614
Hepatitis, Suppurative and Hepatic Abscess	616
Hepatocellular Adenoma	618
Hepatocellular Carcinoma	619
Hepatomegaly	620
Hepatoportal Microvascular Dysplasia	623
Hepatotoxins	626
Hepatozoonosis	628

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Herpesvirus Infection—Dogs	629
Hiatal Hernia	630
Hip Dysplasia	631
Histiocytic Diseases	633
Histoplasmosis	635
Hookworms (Ancylostomiasis)	637
Horner's Syndrome	638
Housesoiling—Cats	639
Housesoiling—Dogs	643
Hydrocephalus	645
Hydronephrosis	647
Hyperadrenocorticism (Cushing's Syndrome)—Cats	649
Hyperadrenocorticism (Cushing's Syndrome)—Dogs	650
Hypercalcemia	654
Hypercapnia	656
Hyperchloremia	658
Hypercoagulability	660
Hypereosinophilic Syndrome (HES)	661
Hyperestrogenism (Estrogen Toxicity)	662
Hyperglycemia	664
Hyperkalemia	666
Hyperlipidemia	668
Hypermagnesemia	670
Hypermetria and Dysmetria	672
Hypernatremia	674
Hyperosmolarity	676
Hyperparathyroidism	678
Hyperparathyroidism, Renal Secondary	680
Hyperphosphatemia	682
Hypertension, Portal	684
Hypertension, Pulmonary	687
Hypertension, Systemic	689
Hyperthyroidism	692
Hypertrophic Osteodystrophy	694
Hypertrophic Osteopathy	696
Hypertrophic Pyloric Gastropathy, Chronic	697
Hyperviscosity Syndrome	699
Hyphema	700
Hypoadrenocorticism (Addison's Disease)	702
Hypoalbuminemia	705
Hypocalcemia	707
Hypochloremia	709
Hypoglycemia	710
Hypokalemia	712
Hypomagnesemia	714
Hypomyelination	716
Hyponatremia	717

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Hypoparathyroidism	719
Hypophosphatemia	722
Hypopituitarism	724
Hypopyon	725
Hypothenuria	726
Hypothermia	727
Hypothyroidism	729
Hypoxemia	733
Icterus	735
Idioventricular Rhythm	737
Illeus	739
Illicit/Club Drug Toxicosis	741
Immunodeficiency Disorders, Primary	742
Immunoproliferative Enteropathy of Basenjis	744
Incontinence, Fecal	745
Incontinence, Urinary	747
Infertility, Female—Dogs	749
Infertility, Male—Dogs	751
Inflammatory Bowel Disease	753
Insoluble Oxalate Plant Toxicosis	755
Insulinoma	756
Interstitial Cell Tumor, Testicle	758
Intervertebral Disc Disease—Cats	759
Intervertebral Disc Disease, Cervical	760
Intervertebral Disc Disease, Thoracolumbar	763
Intussusception	766
Iris Atrophy	768
Iron Toxicosis	769
Irritable Bowel Syndrome	770
Ivermectin and Other Macrocylic Lactones Toxicosis	771
Joint Luxations	772
Keratitis, Eosinophilic—Cats	774
Keratitis, Nonulcerative	775
Keratitis, Ulcerative	777
Keratoconjunctivitis Sicca	779
Lactic Acidosis (Hyperlactatemia)	780
Lameness	783
Laryngeal Diseases	784
Lead Toxicosis	786
Left Anterior Fascicular Block	788
Left Bundle Branch Block	790
Legg-Calvé-Perthes Disease	792
Leiomyoma, Stomach, Small and Large Intestine	794
Leiomyosarcoma, Stomach, Small and Large Intestine	795
Leishmaniasis	796
Lens Luxation	797
Leptospirosis	798

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Leukemia, Acute Lymphoblastic	800
Leukemia, Chronic Lymphocytic	801
Leukoencephalomyopathy in Rottweilers	802
L-Form Bacterial Infections	803
Lily Toxicosis	804
Lipoma	805
Lipoma, Infiltrative	806
Liver Fluke Infestation	807
Lizard Venom Toxicosis	809
Lower Urinary Tract Infection, Bacterial	810
Lower Urinary Tract Infection, Fungal	812
Lumbosacral Stenosis and Cauda Equina Syndrome	813
Lung Lobe Torsion	815
Lupus Erythematosus, Cutaneous (Discoid)	816
Lupus Erythematosus, Systemic (SLE)	817
Lyme Borreliosis	819
Lymphadenitis	821
Lymphadenopathy	823
Lymphangiectasia	825
Lymphedema	827
Lymphoma—Cats	828
Lymphoma—Dogs	830
Lymphoma, Cutaneous Epitheliotropic	832
Lymphomatoid Granulomatosis	833
Lysosomal Storage Diseases	834
Malassezia Dermatitis	835
Malignant Fibrous Histiocytoma	836
Malocclusion—Skeletal and Dental	837
Mammary Gland Hyperplasia—Cats	839
Mammary Gland Tumors—Cats	840
Mammary Gland Tumors—Dogs	842
Marijuana Toxicosis	844
Marking, Roaming, and Mounting Behavior—Cats	845
Marking, Roaming, and Mounting Behavior—Dogs	847
Mast Cell Tumors	849
Mastitis	851
Maternal Behavior Problems	852
Maxillary and Mandibular Fractures	854
Mediastinitis	856
Megacolon	857
Megaesophagus	859
Melanocytic Tumors, Oral	861
Melanocytic Tumors, Skin and Digit	863
Melena	865
Meningioma—Cats and Dogs	867
Meningitis/Meningoencephalitis/Meningomyelitis, Bacterial	870
Meningoencephalomyelitis, Eosinophilic	872

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Meningoencephalomyelitis of Unknown Origin (MUO)	873
Mesothelioma	875
Metaldehyde Toxicosis	876
Metformin Toxicosis	877
Methemoglobinemia	878
Metritis	880
Microsporidiosis (Encephalitozoonosis)	881
Movement Disorders	882
Mucopolysaccharidoses	883
Multiple Myeloma	885
Mumps	886
Murmurs, Heart	887
Muscle Rupture (Muscle Tear)	889
Mushroom Toxicoses	891
Myasthenia Gravis	895
Mycobacterial Infections	897
Mycoplasmosis	899
Mycotoxicosis—Aflatoxin	901
Mycotoxicosis—Deoxynivalenol	902
Mycotoxicosis—Tremorgenic Toxins	903
Myelodysplastic Syndromes	904
Myelomalacia, Spinal Cord (Ascending, Descending)	905
Myelopathy—Paresis/Paralysis—Cats	906
Myeloproliferative Disorders	908
Myocardial Infarction	909
Myocardial Tumors	910
Myocarditis	911
Myoclonus	913
Myopathy, Focal Inflammatory	914
Myopathy, Generalized Inflammatory	916
Myopathy, Noninflammatory—Endocrine	918
Myopathy, Noninflammatory—Hereditary Labrador Retriever	920
Myopathy, Noninflammatory—Hereditary Muscular Dystrophy	921
Myopathy, Noninflammatory—Hereditary Myotonia	922
Myopathy, Noninflammatory—Hereditary Scotty Cramp	923
Myopathy, Noninflammatory—Metabolic	924
Myxedema and Myxedema Coma	926
Nail (Claw) and Nailbed (Clawfold) Disorders	927
Narcolepsy and Cataplexy	928
Nasal and Nasopharyngeal Polyps	929
Nasal Dermatoses—Canine	930
Nasal Discharge	932
Nasopharyngeal Stenosis	934
Neck and Back Pain	935
Necrotizing Encephalitis	937
Neonatal Mortality (Fading Syndrome)	938
Neonicotinoid Toxicosis	940

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Neosporosis	941
Nephrolithiasis	942
Nephrotic Syndrome	945
Nephrotoxicity, Drug-Induced	947
Nerve Sheath Tumors	949
Neuroaxonal Dystrophy	950
Neutropenia	951
Nocardiosis	953
Nonsteroidal Anti-Inflammatory Drug Toxicosis	954
Notoedric Mange	956
Nystagmus	957
Obesity	959
Odontoma	961
Oliguria and Anuria	962
Ollulanus Infection	964
Ophthalmia Neonatorum	965
Optic Neuritis and Papilledema	966
Oral Cavity Tumors, Undifferentiated Malignant Tumors	968
Oral Masses	969
Oral Ulceration	973
Orbital Diseases (Exophthalmos, Enophthalmos, Strabismus)	975
Organophosphorus and Carbamate Toxicosis	977
Oronasal Fistula	979
Osteochondrodysplasia	980
Osteochondrosis	981
Osteomyelitis	983
Osteosarcoma	985
Otitis Externa and Media	987
Otitis Media and Interna	989
Ovarian Remnant Syndrome	992
Ovarian Tumors	994
Ovulatory Failure	995
Pain (Acute, Chronic, and Postoperative)	996
Pancreatitis—Cats	1000
Pancreatitis—Dogs	1002
Pancytopenia	1004
Panniculitis/Steatitis	1006
Panosteitis	1007
Panting and Tachypnea	1009
Papillomatosis	1011
Paralysis	1012
Paraneoplastic Syndromes	1014
Paraphimosis, Phimosis, and Priapism	1017
Paraproteinemia	1018
Patellar Luxation	1019
Patent Ductus Arteriosus	1021
Pectus Excavatum	1024

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Pediatric Behavior Problems and Training—Dogs	1025
Pediatric Behavior Problems—Cats	1027
Pelger-Hüet Anomaly	1029
Pelvic Bladder	1030
Pemphigus	1032
Perianal Fistula	1034
Pericardial Effusion	1035
Pericarditis	1038
Perineal Hernia	1040
Periodontal Diseases	1042
Peripheral Edema	1044
Perirenal Pseudocysts	1046
Peritoneopericardial Diaphragmatic Hernia	1047
Peritonitis	1048
Petechia, Ecchymosis, Bruising	1051
Petroleum Hydrocarbon Toxicoses	1053
Pheochromocytoma	1055
Phlebitis	1057
Phosphofructokinase Deficiency	1059
Physalopterosis	1060
Plague	1061
Plasmacytoma, Mucocutaneous	1062
Pleural Effusion	1063
Pneumocystosis	1065
Pneumonia, Aspiration	1066
Pneumonia, Bacterial	1067
Pneumonia, Eosinophilic	1069
Pneumonia, Fungal	1071
Pneumonia, Interstitial	1073
Pneumothorax	1075
Pododermatitis	1077
Poisoning (Intoxication) Therapy	1079
Polioencephalomyelitis—Cats	1081
Polyarthritis, Immune-Mediated	1082
Polycystic Kidney Disease	1084
Polycythemia	1085
Polycythemia Vera	1087
Polyneuropathies (Peripheral Neuropathies)	1088
Polyphagia	1090
Polypoid Cystitis	1092
Polyuria and Polydipsia	1094
Portosystemic Shunting, Acquired	1096
Portosystemic Vascular Anomaly, Congenital	1099
Poxvirus Infection—Cats	1102
Premature Labor	1103
Primary Ciliary Dyskinesia	1104
Prolapsed Gland of the Third Eyelid (Cherry Eye)	1105

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Proptosis	1106
Prostate Disease in the Breeding Male Dog	1107
Prostatic Cysts	1109
Prostatitis and Prostatic Abscess	1110
Prostomatomegaly	1112
Protein-Losing Enteropathy	1114
Proteinuria	1116
Protothecosis	1119
Pruritus	1120
Pseudoephedrine/Phenylephrine Toxicosis	1122
Pseudorabies Virus Infection	1123
Ptyalism	1124
Pulmonary Contusions	1126
Pulmonary Edema, Noncardiogenic	1127
Pulmonary Thromboembolism	1129
Pulmonic Stenosis	1131
Puppy Strangles (Juvenile Cellulitis)	1133
Pyelonephritis	1134
Pyoderma	1136
Pyoderma—Methicillin-Resistant	1138
Pyometra	1139
Pyothorax	1142
Pyrethrin and Pyrethroid Toxicosis	1144
Pyruvate Kinase Deficiency	1145
Pythiosis	1146
Pyuria	1148
Q Fever	1150
Quadrigeminal Cyst	1151
Rabies	1152
Rectal and Anal Prolapse	1154
Rectal Stricture	1155
Rectoanal Polyps	1156
Red Eye	1157
Regurgitation	1159
Renal Failure, Acute	1161
Renal Failure, Chronic	1164
Renal Tubular Acidosis	1167
Renomegaly	1168
Reovirus Infections	1170
Respiratory Parasites	1171
Retained Placenta	1173
Retinal Degeneration	1174
Retinal Detachment	1176
Retinal Hemorrhage	1178
Rhinitis and Sinusitis	1180
Rhinosporidiosis	1182
Right Bundle Branch Block	1183

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Rocky Mountain Spotted Fever	1185
Rodenticide Toxicosis—Anticoagulants	1187
Rodenticide Toxicosis—Bromethalin	1189
Rodenticide Toxicosis—Phosphides	1190
Rotavirus Infections	1191
Roundworms (Ascariasis)	1192
Sago Palm Toxicosis	1193
Salivary Mucocele	1194
Salmon Poisoning Disease	1196
Salmonellosis	1197
Sarcoptic Mange	1199
Schiff-Sherrington Phenomenon	1200
Schwannoma	1201
Sebaceous Adenitis, Granulomatous	1202
Seizures (Convulsions, Status Epilepticus)—Cats	1203
Seizures (Convulsions, Status Epilepticus)—Dogs	1205
Seminoma	1207
Separation Distress Syndrome	1208
Sepsis and Bacteremia	1211
Sertoli Cell Tumor	1213
Sexual Development Disorders	1214
Shaker/Tremor Syndrome, Corticosteroid Responsive	1216
Shock, Cardiogenic	1217
Shock, Hypovolemic	1219
Shock, Septic	1221
Shoulder Joint, Ligament, and Tendon Conditions	1223
Sick Sinus Syndrome	1225
Sinus Arrest and Sinoatrial Block	1227
Sinus Arrhythmia	1229
Sinus Bradycardia	1231
Sinus Tachycardia	1233
Sjögren-Like Syndrome	1235
Skin Fragility Syndrome, Feline	1236
Small Intestinal Dysbiosis	1237
Smoke Inhalation	1239
Snake Venom Toxicosis—Coral Snakes	1240
Snake Venom Toxicosis—Pit Vipers	1241
Sneezing, Reverse Sneezing, Gagging	1243
Soft Tissue Sarcoma	1245
Spermatocele/Sperm Granuloma	1247
Spermatozoal Abnormalities	1248
Spider Venom Toxicosis—Black Widow	1249
Spider Venom Toxicosis—Brown Recluse	1250
Spinal Dysraphism	1251
Splenic Torsion	1252
Splenomegaly	1253
Spondylosis Deformans	1255

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Sporotrichosis	1256
Squamous Cell Carcinoma, Digit	1257
Squamous Cell Carcinoma, Ear	1258
Squamous Cell Carcinoma, Gingiva	1259
Squamous Cell Carcinoma, Lung	1260
Squamous Cell Carcinoma, Nasal and Paranasal Sinuses	1261
Squamous Cell Carcinoma, Nasal Planum	1262
Squamous Cell Carcinoma, Skin	1263
Squamous Cell Carcinoma, Tongue	1265
Squamous Cell Carcinoma, Tonsil	1266
Staphylococcal Infections	1267
Steroid-Responsive Meningitis-Arteritis—Dogs	1269
Stertor and Stridor	1270
Stomatitis	1272
Stomatitis, Caudal—Cat	1274
Streptococcal Infections	1275
Strongyloidiasis	1276
Stupor and Coma	1277
Subarachnoid Cysts (Arachnoid Diverticulum)	1279
Subinvolution of Placental Sites	1281
Submissive and Excitement Urination—Dogs	1282
Superficial Necrolytic Dermatitis	1283
Supraventricular Tachycardia	1284
Syncope	1286
Synovial Sarcoma	1288
Syringomyelia and Chiari-Like Malformation	1289
Tapeworms (Cestodiasis)	1291
Taurine Deficiency	1292
Temporomandibular Joint Disorders	1293
Testicular Degeneration and Hypoplasia	1294
Tetanus	1295
Tetralogy of Fallot	1297
Third Eyelid Protrusion	1298
Thrombocytopathies	1300
Thrombocytopenia	1302
Thrombocytopenia, Primary Immune-Mediated	1304
Thunderstorm and Noise Phobias	1306
Thymoma	1307
Tick Bite Paralysis	1308
Ticks and Tick Control	1310
Toad Venom Toxicosis	1313
Tooth Formation/Structure, Abnormal	1314
Tooth Fracture	1315
Tooth Luxation or Avulsion	1317
Tooth—Missing	1318
Tooth Resorption—Cat	1319
Tooth Root Abscess (Apical Abscess)	1320

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Toxoplasmosis	1322
Tracheal and Airway Collapse	1324
Tracheal Perforation	1326
Transitional Cell Carcinoma	1327
Transmissible Venereal Tumor	1329
Traumatic Myocarditis	1330
Tremors	1331
Trichinosis	1333
Trichomoniasis	1334
Trigeminal Neuritis, idiopathic	1335
Tularemia	1336
Tyzzer Disease	1338
Unruly Behaviors: Jumping, Pulling, Chasing, Stealing—Dogs	1339
Ureterolithiasis	1341
Urethral Prolapse	1343
Urinary Retention, Functional	1345
Urinary Tract Obstruction	1347
Urolithiasis, Calcium Oxalate	1349
Urolithiasis, Calcium Phosphate	1352
Urolithiasis, Cystine	1353
Urolithiasis, Struvite—Cats	1355
Urolithiasis, Struvite—Dogs	1357
Urolithiasis, Urate	1359
Urolithiasis, Xanthine	1361
Uterine Inertia	1362
Uterine Tumors	1363
Uveal Melanoma—Cats	1364
Uveal Melanoma—Dogs	1365
Uveodermatologic Syndrome (VKH)	1366
Vaginal Discharge	1367
Vaginal Hyperplasia and Prolapse	1369
Vaginal Malformations and Acquired Lesions	1370
Vaginal Tumors	1372
Vaginitis	1373
Vascular Ring Anomalies	1375
Vasculitis, Cutaneous	1376
Vasculitis, Systemic	1377
Ventricular Arrhythmias/Sudden Death in German Shepherds	1378
Ventricular Fibrillation	1379
Ventricular Premature Complexes	1381
Ventricular Septal Defect	1383
Ventricular Standstill (Asystole)	1385
Ventricular Tachycardia	1387
Vertebral Column Trauma	1390
Vesicourachal Diverticula	1392
Vestibular Disease, Geriatric—Dogs	1393
Vestibular Disease, Idiopathic—Cats	1395

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Vitamin D Toxicosis	1397
Vomiting, Acute	1399
Vomiting, Chronic	1401
Von Willebrand Disease	1404
Weight Loss and Cachexia	1406
West Nile Virus Infection	1409
Whipworms (Trichuriasis)	1410
Wolff-Parkinson-White Syndrome	1411
Xylitol Toxicosis	1413
Zinc Toxicosis	1414
 Appendix I Normal Reference Ranges for Laboratory Tests	1416
Table I-A Normal hematologic values	1416
Table I-B Normal biochemical values	1416
Table I-C Conversion table for hematologic units	1417
Table I-D Conversion table for clinical biochemical units	1418

BEHAVIOR

Aggression to Unfamiliar People and Unfamiliar Dogs	37
Aggression Toward Children—Dogs	39
Aggression Toward Familiar People—Dogs	40
Aggression Toward Humans—Cats	42
Aggression, Food and Resource Guarding—Dogs	44
Aggression, Intercat Aggression	46
Aggression, Overview—Cats	49
Aggression, Overview—Dogs	51
Aggression—Between Dogs in the Household	55
Car Ride Anxiety—Dogs and Cats	220
Cognitive Dysfunction Syndrome	288
Compulsive Disorders—Cats	297
Compulsive Disorders—Dogs	299
Coprophagia and Pica	324
Destructive and Scratching Behavior—Cats	381
Destructive Behavior—Dogs	382
Excessive Vocalization and Waking at Nights	470
Fear and Aggression in Veterinary Visits	484
Fears, Phobias, and Anxieties—Cats	488
Fears, Phobias, and Anxieties—Dogs	490
Housesoiling—Cats	639
Housesoiling—Dogs	643
Marking, Roaming, and Mounting Behavior—Cats	845
Marking, Roaming, and Mounting Behavior—Dogs	847
Maternal Behavior Problems	852
Pediatric Behavior Problems and Training—Dogs	1025
Pediatric Behavior Problems—Cats	1027
Polyphagia	1090
Separation Distress Syndrome	1208
Submissive and Excitement Urination—Dogs	1282
Thunderstorm and Noise Phobias	1306
Unruly Behaviors: Jumping, Pulling, Chasing, Stealing—Dogs	1339

CARDIOLOGY

Aortic Stenosis	104
Aortic Thromboembolism	106
Arteriovenous Fistula and Arteriovenous Malformation	110
Ascites	117
Atherosclerosis	130
Atrial Fibrillation and Atrial Flutter	135
Atrial Premature Complexes	138
Atrial Septal Defect	140
Atrial Standstill	141

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Atrial Wall Tear	143
Atrioventricular Block Complete (Third Degree)	145
Atrioventricular Block, First Degree	147
Atrioventricular Block, Second Degree—Mobitz I	149
Atrioventricular Block, Second Degree—Mobitz II	151
Atrioventricular Valve Dysplasia	153
Atrioventricular Valve (Myxomatous) Disease	155
Atrioventricular Valvular Stenosis	158
Cardiomyopathy—Boxer (Arrhythmogenic Right Ventricular)	226
Cardiomyopathy, Dilated—Cats	227
Cardiomyopathy, Dilated—Dogs	230
Cardiomyopathy, Hypertrophic—Cats	233
Cardiomyopathy, Hypertrophic—Dogs	235
Cardiomyopathy, Restrictive—Cats	236
Cardiopulmonary Arrest	238
Carnitine Deficiency	240
Congestive Heart Failure, Left-Sided	307
Congestive Heart Failure, Right-Sided	309
Digoxin Toxicity	402
Ebstein's Anomaly	429
Electric Cord Injury	437
Endocarditis, Infective	442
Endomyocardial Diseases—Cats	444
Fever	512
Heartworm Disease—Cats	573
Heartworm Disease—Dogs	574
Heat Stroke and Hyperthermia	576
Hypertension, Pulmonary	687
Hypertension, Systemic	689
Hypothermia	727
Idioventricular Rhythm	737
Left Anterior Fascicular Block	788
Left Bundle Branch Block	790
Lymphedema	827
Murmurs, Heart	887
Myocardial Infarction	909
Myocarditis	911
Patent Ductus Arteriosus	1021
Pericardial Effusion	1035
Pericarditis	1038
Peripheral Edema	1044
Peritoneopericardial Diaphragmatic Hernia	1047
Phlebitis	1057
Pleural Effusion	1063
Pulmonary Thromboembolism	1129
Pulmonic Stenosis	1131
Right Bundle Branch Block	1183

DERMATOLOGY

Tooth-Missing	1318
Tooth Resorption—Cat	1319
Tooth Root Abscess (Apical Abscess)	1320

Acne—Cats	14
Acne—Dogs	15
Acral Lick Dermatitis	16
Alopecia—Cats	59
Alopecia—Dogs	61
Alopecia, Non-Inflammatory—Dogs	63
Anal Sac Disorders	74
Atopic Dermatitis	133
Cheyletiellosis	253
Contact Dermatitis	317
Cutaneous Drug Eruptions	342
Demodicosis	355
Dermatomyositis	360
Dermatophilosis	362
Dermatophytosis	363
Dermatoses, Depigmenting Disorders	365
Dermatoses, Erosive or Ulcerative	367
Dermatoses, Exfoliative	369
Dermatoses, Neoplastic	371
Dermatoses, Papulonodular	373
Dermatoses, Sterile Nodular/Granulomatous	375
Dermatoses, Sun Induced	377
Dermatoses, Vesiculopustular	378
Dermatoses, Viral (Non-Papillomatosis)	380
Ear Mites	428
Eosinophilic Granuloma Complex	447
Feline Paraneoplastic Alopecia	510
Feline Symmetrical Alopecia	511
Flea Bite Hypersensitivity and Flea Control	523
Food Reactions, Dermatologic	525
Lupus Erythematosus, Cutaneous (Discoid)	816
Lymphoma, Cutaneous Epitheliotropic	832
Malassezia Dermatitis	835
Mycobacterial Infections	897
Nail (Claw) and Nailbed (Clawfold) Disorders	927
Nasal Dermatoses—Canine	930
Notoedric Mange	956
Otitis Externa and Media	987
Panniculitis/Steatitis	1006
Papillomatosis	1011
Pemphigus	1032

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Pododermatitis	1077
Protothecosis	1119
Pruritus	1120
Puppy Strangles (Juvenile Cellulitis)	1133
Pyoderma	1136
Pyoderma—Methicillin-Resistant	1138
Sarcoptic Mange	1199
Sebaceous Adenitis, Granulomatous	1202
Skin Fragility Syndrome, Feline	1236
Sporotrichosis	1256
Superficial Necrolytic Dermatitis	1283
Ticks and Tick Control	1310
Uveodermatologic Syndrome (VKH)	1366
Vasculitis, Cutaneous	1376

ENDOCRINOLOGY AND METABOLISM

Acromegaly—Cats	17
Apudoma	109
Carcinoid and Carcinoid Syndrome	224
Diabetes Insipidus	383
Diabetes Mellitus with Hyperosmolar Coma	384
Diabetes Mellitus with Ketoacidosis	386
Diabetes Mellitus without Complication—Cats	388
Diabetes Mellitus without Complication—Dogs	390
Glucagonoma	555
Hyperadrenocorticism (Cushing's Syndrome)—Cats	649
Hyperadrenocorticism (Cushing's Syndrome)—Dogs	650
Hypercalcemia	654
Hyperchloremia	658
Hyperestrogenism (Estrogen Toxicity)	662
Hyperglycemia	664
Hyperkalemia	666
Hyperlipidemia	668
Hypermagnesemia	670
Hypernatremia	674
Hyperosmolarity	676
Hyperparathyroidism	678
Hyperphosphatemia	682
Hyperthyroidism	692
Hypoadrenocorticism (Addison's Disease)	702
Hypocalcemia	707
Hypochloremia	709
Hypoglycemia	710
Hypokalemia	712
Hypomagnesemia	714
Hyponatremia	717

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

GASTROENTEROLOGY

Hypoparathyroidism	719
Hypophosphatemia	722
Hypopituitarism	724
Hypothenuria	726
Hypothyroidism	729
Insulinoma	756
Lactic Acidosis (Hyperlactatemia)	780
Myxedema and Myxedema Coma	926
Pheochromocytoma	1055

Acute Abdomen	20
Anorexia	92
Bilious Vomiting Syndrome	182
Canine Parvovirus Infection	216
Clostridial Enterotoxicosis	277
Cobalamin Deficiency	283
Coccidiosis	287
Colitis and Proctitis	293
Colitis, Histiocytic Ulcerative	296
Constipation and Obstipation	315
Diarrhea, Acute	395
Diarrhea, Antibiotic Responsive	397
Diarrhea, Chronic—Cats	398
Diarrhea, Chronic—Dogs	400
Dyschezia and Hematochezia	417
Dysphagia	419
Esophageal Diverticula	459
Esophageal Foreign Bodies	460
Esophageal Stricture	462
Esophagitis	464
Exocrine Pancreatic Insufficiency	474
Fiber-Responsive Large Bowel Diarrhea	514
Flatulence	521
Food Reactions (Gastrointestinal), Adverse	527
Gastric Dilation and Volvulus Syndrome	531
Gastric Motility Disorders	533
Gastritis, Atrophic	535
Gastritis, Chronic	536
Gastroduodenal Ulceration/Erosion (GUE)	538
Gastroenteritis, Eosinophilic	540
Gastroenteritis, Hemorrhagic	542
Gastroenteritis, Lymphocytic-Plasmacytic	544
Gastroesophageal Reflux	546
Gastrointestinal Obstruction	547
Gluten Enteropathy in Irish Setters	559

Helicobacter spp	578
Hematemesis	586
Hiatal Hernia	630
Hypertrophic Pyloric Gastropathy, Chronic	697
Ileus	739
Immunoproliferative Enteropathy of Basenjis	744
Incontinence, Fecal	745
Inflammatory Bowel Disease	753
Intussusception	766
Irritable Bowel Syndrome	770
Lymphangiectasia	825
Megacolon	857
Megaesophagus	859
Melena	865
Obesity	959
Pancreatitis—Cats	1000
Pancreatitis—Dogs	1002
Perianal Fistula	1034
Perineal Hernia	1040
Protein-Losing Enteropathy	1114
Ptyalism	1124
Pythiosis	1146
Rectal and Anal Prolapse	1154
Rectal Stricture	1155
Rectoanal Polyps	1156
Regurgitation	1159
Salivary Mucocele	1194
Small Intestinal Dysbiosis	1237
Vomiting, Acute	1399
Vomiting, Chronic	1401
Weight Loss and Cachexia	1406

HEMATOLOGY/IMMUNOLOGY

Anaphylaxis	75
Anemia, Aplastic	79
Anemia, Heinz Body	80
Anemia, Immune-Mediated	81
Anemia, Iron-Deficiency	83
Anemia, Metabolic (Anemias with Spiculated Red Cells)	84
Anemia, Nonregenerative	85
Anemia, Nuclear Maturation Defects (Anemia, Megaloblastic)	87
Anemia, Regenerative	88
Blood Transfusion Reactions	189
Chediak-Higashi Syndrome	251
Coagulation Factor Deficiency	279
Cold Agglutinin Disease	290

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Cyclic Hematopoiesis	346
Disseminated Intravascular Coagulation	410
Familial Shar-Pei Fever	481
Hemotropic Mycoplasmosis (Also Hemoplasmosis)	593
Hypercoagulability	660
Hypereosinophilic Syndrome (HES)	661
Hyperviscosity Syndrome	699
Immunodeficiency Disorders, Primary	742
Lupus Erythematosus, Systemic (SLE)	817
Lymphadenitis	821
Lymphadenopathy	823
Methemoglobinemia	878
Mucopolysaccharidoses	883
Neutropenia	951
Pancytopenia	1004
Paraproteinemia	1018
Pelger-Huet Anomaly	1029
Petechia, Ecchymosis, Bruising	1051
Phosphofructokinase Deficiency	1059
Polycythemia	1085
Pyruvate Kinase Deficiency	1145
Sjögren-Like Syndrome	1235
Splenic Torsion	1252
Thrombocytopathies	1300
Thrombocytopenia	1302
Thrombocytopenia, Primary Immune-Mediated	1304
Von Willebrand Disease	1404

HEPATOTOLOGY

Arteriovenous Malformation of Liver	111
Bile Duct Obstruction (Extrahepatic)	177
Bile Peritonitis	180
Cholangitis/Cholangiohepatitis Syndrome	259
Cholecystitis and Choledochitis	262
Cholelithiasis	264
Cirrhosis and Fibrosis of the Liver	274
Coagulopathy of Liver Disease	281
Copper Associated Hepatopathy	320
Diabetic Hepatopathy	392
Ductal Plate Malformation (Congenital Hepatic Fibrosis)	413
Gallbladder Mucocele	529
Glycogen Storage Disease	560
Glycogen-Type Vacuolar Hepatopathy	561
Hepatic Amyloid	595
Hepatic Encephalopathy	597
Hepatic Failure, Acute	600

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Hepatic Lipidosis	603
Hepatic Nodular Hyperplasia and Dysplastic Hyperplasia	606
Hepatitis, Chronic	608
Hepatitis, Granulomatous	612
Hepatitis, Infectious (Viral) Canine	614
Hepatitis, Suppurative and Hepatic Abscess	616
Hepatomegaly	620
Hepatoportal Microvascular Dysplasia	623
Hepatotoxins	626
Hypertension, Portal	684
Hypoalbuminemia	705
Icterus	735
Liver Fluke Infestation	807
Portosystemic Shunting, Acquired	1096
Portosystemic Vascular Anomaly, Congenital	1099
Splenomegaly	1253

INFECTIOUS DISEASE

Abscessation	8
Actinomycosis	19
Amebiasis	65
Anaerobic Infections	73
Aspergillosis, Systemic	121
Astrovirus Infection	127
Babesiosis	164
Bartonellosis	167
Baylisascariasis	170
Blastomycosis	183
Brucellosis	204
Campylobacteriosis	207
Candidiasis	208
Canine Coronavirus Infections	209
Canine Distemper	210
Canine Influenza	214
Canine Schistosomiasis (Heterobilharziasis)	218
Chagas Disease (American Trypanosomiasis)	250
Chlamydiosis—Cats	254
Coccidioidomycosis	285
Colibacillosis	291
Cryptococciosis	336
Cryptosporidiosis	339
Cuterebriasis	343
Cysticercosis	348
Cytauxzoonosis	349
Ehrlichiosis (Anaplasma)	433
Feline Calicivirus Infection	492

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Feline Foamy Virus Infection (FFV)	494
Feline Herpesvirus Infection	495
Feline Immunodeficiency Virus Infection (FIV)	500
Feline Infectious Peritonitis (FIP)	502
Feline Leukemia Virus Infection (FeLV)	506
Feline Panleukopenia	508
Giardiasis	549
Hepatozoonosis	628
Herpesvirus Infection—Dogs	629
Histoplasmosis	635
Hookworms (Ancylostomiasis)	637
Leishmaniasis	796
Leptospirosis	798
L-Form Bacterial Infections	803
Lyme Borreliosis	819
Microsporidiosis (Encephalitozoonosis)	881
Mumps	886
Mycoplasmosis	899
Neonatal Mortality (Fading Syndrome)	938
Neosporosis	941
Nocardiosis	953
Ollulanus Infection	964
Peritonitis	1048
Physalopterosis	1060
Plague	1061
Pneumocystosis	1065
Poxvirus Infection—Cats	1102
Pseudorabies Virus Infection	1123
Q Fever	1150
Rabies	1152
Reovirus Infections	1170
Rhinosporidiosis	1182
Rocky Mountain Spotted Fever	1185
Rotavirus Infections	1191
Roundworms (Ascariasis)	1192
Salmon Poisoning Disease	1196
Salmonellosis	1197
Sepsis and Bacteremia	1211
Staphylococcal Infections	1267
Streptococcal Infections	1275
Strongyloidiasis	1276
Tapeworms (Cestodiasis)	1291
Tetanus	1295
Toxoplasmosis	1322
Trichinosis	1333
Trichomoniasis	1334
Tularemia	1336

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Tyzzer Disease	1338
West Nile Virus Infection	1409
Whipworms (Tricuriasis)	1410

MUSCULOSKELETAL

Antebrachial Growth Deformities	94
Arthritis (Osteoarthritis)	113
Arthritis, Septic	115
Atlantoaxial Instability	131
Craniomandibular Osteopathy	333
Cruciate Ligament Disease, Cranial	334
Discospondylitis	408

Lower Urinary Tract Infection, Fungal	812
Nephrolithiasis	942
Nephrotic Syndrome	945
Nephrotoxicity, Drug-Induced	947
Oliguria and Anuria	962
Pelvic Bladder	1030
Perirenal Pseudocysts	1046
Polycystic Kidney Disease	1084
Polypoid Cystitis	1092
Polyuria and Polydipsia	1094
Prostatic Cysts	1109
Prostatitis and Prostatic Abscess	1110
Prostomatomegaly	1112
Proteinuria	1116
Pyelonephritis	1134
Pyuria	1148
Renal Failure, Acute	1161
Renal Failure, Chronic	1164
Renal Tubular Acidosis	1167
Renomegaly	1168
Ureterolithiasis	1341
Urethral Prolapse	1343
Urinary Retention, Functional	1345
Urinary Tract Obstruction	1347
Urolithiasis, Calcium Oxalate	1349
Urolithiasis, Calcium Phosphate	1352
Urolithiasis, Cystine	1353
Urolithiasis, Struvite—Cats	1355

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

NEUROLOGY

Urolithiasis, Struvite—Dogs	1357
Urolithiasis, Urate	1359
Urolithiasis, Xanthine	1361
Vesicourachal Diverticula	1392

Ataxia	128
Botulism	191
Brachial Plexus Avulsion	192
Brain Injury	195
Brain Tumors	197
Cerebellar Degeneration	243
Cerebellar Hypoplasia	244
Cerebrovascular Accidents	245
Cervical Spondylomyelopathy (Wobbler Syndrome)	248
Congenital Spinal and Vertebral Malformations	305
Coonhound Paralysis (Acute Polyradiculoneuritis)	318
Deafness	350
Degenerative Myelopathy	353
Dysautonomia (Key-Gaskell Syndrome)	416
Encephalitis	439
Encephalitis Secondary to Parasitic Migration	441
Epilepsy, Genetic (Idiopathic)—Dogs	450
Exercise-Induced Weakness/Collapse in Labradors	472
Facial Nerve Paresis and Paralysis	477
Feline Hyperesthesia Syndrome	497
Feline Ischemic Encephalopathy	504
Fibrocartilaginous Embolic Myelopathy	515
Head Pressing	568
Head Tilt	570
Head Tremors (Bobbing), Idiopathic—Dogs	572
Hydrocephalus	645
Hypermetria and Dysmetria	672
Hypomyelination	716
Intervertebral Disc Disease—Cats	759
Leukoencephalomyopathy in Rottweilers	802
Lumbosacral Stenosis and Cauda Equina Syndrome	813
Lysosomal Storage Diseases	834
Meningioma—Cats and Dogs	867
Meningitis/Meningoencephalitis/Meningomyelitis, Bacterial	870
Meningoencephalomyelitis, Eosinophilic	872
Meningoencephalomyelitis of Unknown Origin (MUO)	873
Movement Disorders	882
Myelomalacia, Spinal Cord (Ascending, Descending)	905
Myelopathy—Paresis/Paralysis—Cats	906
Myoclonus	913

354 client education handouts are available at www.fiveminutevet.com/canineandfeline for you to download and use in practice

Narcolepsy and Cataplexy	928
Neck and Back Pain	935
Necrotizing Encephalitis	937
Nerve Sheath Tumors	949
Neuroaxonal Dystrophy	950
Nystagmus	957
Otitis Media and Interna	989
Pain (Acute, Chronic, and Postoperative)	996
Paralysis	1012
Polioencephalomyelitis—Cats	1081
Polyneuropathies (Peripheral Neuropathies)	1088
Quadrigeminal Cyst	1151
Schiff-Sherrington Phenomenon	1200
Seizures (Convulsions, Status Epilepticus)—Cats	1203
Seizures (Convulsions, Status Epilepticus)—Dogs	1205
Shaker/Tremor Syndrome, Corticosteroid Responsive	1216
Spinal Dysraphism	1251
Spondylosis Deformans	1255
Steroid-Responsive Meningitis-Arteritis—Dogs	1269
Stupor and Coma	1277
Subarachnoid Cyst (Arachnoid Diverticulum)	1279
Syringomyelia and Chiari-Like Malformation	1289
Tick Bite Paralysis	1308
Tremors	1331
Trigeminal Neuritis, Idiopathic	1335
Vertebral Column Trauma	1390
Vestibular Disease, Geriatric—Dogs	1393
Vestibular Disease, Idiopathic—Cats	1395

ABORTION, SPONTANEOUS (EARLY PREGNANCY LOSS)—CATS

BASICS

DEFINITION

- Spontaneous abortion—natural expulsion of fetus(es) prior to the point at which they can sustain life outside the uterus.
- Early pregnancy loss—generalized term for any loss of conceptus including early embryonic death and resorption.

PATOPHYSIOLOGY

- Infectious causes result in pregnancy loss directly by affecting the embryo, fetus, or fetal membranes, or indirectly by creating debilitating systemic disease in the queen.
- Non-infectious causes of pregnancy loss result from any factor other than infection that leads to the death or premature expulsion of the conceptus (e.g., uterine disease, inadequate maternal nutrition, endocrine dysfunction, toxicity, genetic defects).

SYSTEMS AFFECTED

- Endocrine
- Reproductive
- Other systems—any debilitating illness can result in pregnancy loss.

GENETICS

Genetic defects are more prevalent in highly inbred individuals; heritability of susceptibility to FIPV thought to be very high.

INCIDENCE/PREVALENCE

Unknown—pregnancy frequently not confirmed, owners may not recognize late pregnancy loss if the queen is fastidious; early embryonic death is difficult to document.

SIGNALMENT

Species

Cat

Breed Predilections

Purebred cats—higher incidence of non-infectious abortion; inbreeding increases risk of genetic disease. Predisposition to developing FIP increased in some breeds including Bengal, Birman, and Himalayan.

Mean Age and Range

Infectious abortion seen in all ages; non-infectious abortion seen more commonly in young and aged queens.

SIGNS

General Comments

Early embryonic death and resorption frequently have no clinical symptoms; any combination of historical and physical examination findings may occur, with some queens displaying no symptoms.

Historical Findings

Failure to deliver litter at expected time, return to estrus sooner than expected, decrease in abdominal diameter and weight loss, discovery of fetal material, behavior change, anorexia, vomiting, diarrhea.

Physical Examination Findings

Purulent, mucoid, watery, or sanguineous vaginal discharge; dehydration, fever, abdominal straining, abdominal discomfort.

CAUSES

Infectious

- Bacterial—organisms implicated in causing abortion via ascending infection include *Escherichia coli*, *Staphylococcus* spp., *Streptococcus* spp., *Chlamydia* spp., *Pasteurella* spp., *Klebsiella* spp., *Pseudomonas* spp., *Salmonella* spp., *Mycoplasma* spp., and *Ureaplasma* spp.
- Protozoal—*Toxoplasma gondii*
- Viral—FHV-1, FIV, FIP, FeLV, FPLV.

Non-infectious

- Uterine—cystic endometrial hyperplasia, pyometra, chronic endometritis, anatomical abnormalities of the uterus, mechanical trauma to uterus or fetus.
- Ovarian—early termination of corpora lutea function causes a decline in serum progesterone concentrations resulting in early parturition/abortion. Primary hypoluteoidism is rare but secondary hypoluteoidism may result from certain drugs, prolonged stress and uterine inflammation.
- Fetal—chromosomal abnormalities resulting in abnormal or arrested development and embryonic or fetal death.
- Systemic—malnutrition or nutritional disorders such as taurine deficiency; vitamin A deficiency or toxicity; severe non-reproductive illness; exogenous drug administration: estrogens, glucocorticoids, PGF_{2α}, and dopamine agonists (cabergoline, bromocriptine) will disrupt normal corpora lutea function; fetotoxic or teratogenic drugs: chemotherapeutic agents, antifungal agents, some antibiotics (trimethoprim-sulfonamides, tetracyclines, gentamicin); modified live vaccines.

RISK FACTORS

- Previous history of pregnancy loss
- Concurrent systemic disease
- Recent trauma
- Purebred cat with high degree of inbreeding
- Very young or old queen
- Previous use of progestins to suppress estrus
- Malnourishment
- Homemade and raw diets
- Overcrowded or unsanitary environment

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Early pregnancy loss—failure to conceive, disorder of sexual development, anovulatory cycle
- Vulvar discharge—pyometra, mucometra, uterine stump pyometra; vaginitis, metritis, cystitis; impending parturition or dystocia; neoplasia or trauma of urinary bladder, urethra, vagina, or uterus;
- Estrus—very little discharge typically seen
- Abdominal straining or discomfort: urethral obstruction; intestinal foreign body;

peritonitis; trauma; impending parturition or dystocia

CBC/BIOCHEMISTRY/URINALYSIS

- May be normal.
- Inflammatory leukogram or stress leukogram depending on systemic disease response.
- Hemoconcentration and azotemia with dehydration.

OTHER LABORATORY TESTS

Infectious Causes

- Cytology and bacterial culture of vaginal discharge, fetus, fetal membranes, or uterine contents (aerobic, anaerobic, and mycoplasma).
- FeLV—test for antigens in queens using ELISA or IFA.
- FHV-1—IFA or PCR from corneal or conjunctival swabs, viral isolation from conjunctival, nasal, or pharyngeal swabs.
- FIP—submit fetal tissue for histopathology and immunohistochemistry.
- FIV—ELISA: confirm positive results with Western blot.
- FPLV—viral isolation from fetuses submitted for necropsy; document seroconversion in the queen.

Non-infectious Causes

- To rule out anovulatory cycle, confirm progesterone rise > 1.5 ng/mL one week following mating.
- Hypoluteoidism—serum progesterone level < 1.0 ng/mL prior to abortion indicates luteal failure but does not determine whether the luteal failure was primary or secondary.
- Disorder of sexual development can be evaluated with description of external genitalia, karyotype, and histopathology of reproductive tract.

IMAGING

- Abdominal ultrasound in early gestation (21–25 days post-breeding) to confirm pregnancy and screen for evidence of resorption. Later pregnancy, evaluate health and viability of fetus(es) and associated fluid and membranes; abnormal uterine fluid accumulation and non-reproductive disease.
- Radiograph—evaluates relative size, number, and position of fetal skeletons; can also be used to screen for fetal monsters, fetal malpresentation, and non-reproductive disease.

DIAGNOSTIC PROCEDURES

- Genetic defects—necropsy aborted fetus(es); submit samples from aborted and stillborn fetus for karyotyping.
- Nutrition—submit sample of diet for nutritional analysis: of particular importance when queen is fed a homemade and/or raw diet.
- Pedigree analysis to evaluate inbreeding coefficient
- Evaluate cattery for vaccination protocols, feeding regime, general sanitation procedures, and quarantine procedures for pregnant queens and new arrivals.
- Submit reproductive tract (uterus, ovaries, uterine tubes) and aborted, stillborn, mummified fetus(es) and fetal membranes (fresh, refrigerated, on wet ice) for evaluation of anatomic and pathologic changes, gross

(CONTINUED) ABORTION, SPONTANEOUS (EARLY PREGNANCY LOSS)—CATS

necropsy, histopathology, cultures, and viral isolation.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Outpatient management: typically no medical management required for non-infectious stable queens; primary hypoluteoidism—can be managed on an outpatient basis with tocolytic drugs in combination with tocodynamometry.
- Surgical management: OHE for queens with severe illness due to pyometra or metritis.

ACTIVITY

- Isolation for queens with infectious disease.
- No activity restrictions for most non-infectious pregnancy losses.
- Restrict activity as indicated for pregnancy loss due to trauma.

DIET

Feed commercially available diet labeled for use in pregnancy. Correct diets with inappropriate taurine or vitamin A concentrations. Avoid feeding raw meats or allowing queens to hunt during pregnancy to reduce risk for ingestion of pathogenic bacteria and *T. gondii*.

CLIENT EDUCATION

- Infectious diseases—verify client is following good vaccination protocols and disease surveillance measures and is utilizing quarantine facilities for pregnant queens and new arrivals.
- Breeding management—discuss normal reproductive behavior and good breeding management; advise clients to keep detailed records related to reproductive performance, pedigree analysis, and social behavior of queens within the cattery.
- Nutrition—discuss routine diet recommendations for breeding queens; advise homemade diets undergo nutritional analysis.
- Genetic disease—increase in inbred individuals; many reproductive traits are heritable.
- Discuss risk of zoonotic disease from *Toxoplasma gondii*.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Will depend on etiology.
- Amoxicillin-clavulanic acid 13.75 mg/kg PO q12h or enrofloxacin 5 mg/kg/day PO based on bacterial culture results.
- Tocolytic therapy to prevent uterine contractions and help maintain pregnancy: Terbutaline 0.03–1.0 mg PO as needed based on tocodynamometry; 0.03 mg/kg PO q8h if tocodynamometry not available.
- Hypoluteoidism: progesterone in oil—2.0–3.0 mg/kg IM as needed based on

serum progesterone concentration and tocodynamometry.

CONTRAINDICATIONS

- Terbutaline—cardiac or respiratory disease, pyometra, infectious disease, hypertension.
- Progesterone in oil—diabetes, pyometra, infectious disease, CEH.

PRECAUTIONS

• Use of tocolytics to maintain pregnancy requires accurate documentation of breeding dates to know when treatment should be discontinued; tocolytics used most successfully in combination with tocodynamometry to establish desired dosing interval based on increasing preterm uterine activity.

• Terbutaline can cause hypertension leading to increased hemorrhage from the placental sites during parturition or at the time of c-section.

POSSIBLE INTERACTIONS

- Progesterone administration during pregnancy is associated with masculinization of female fetuses; do not administer in the first half of pregnancy and use with informed consent thereafter.
- Use of tocolytics to maintain pregnancy is associated with increased risk of dystocia, failure of normal placental separation at parturition, lack of mammary gland development and milk production, and poor maternal behavior for the first few days postpartum.

**FOLLOW-UP****PATIENT MONITORING**

- Serial ultrasound evaluation q 5–7 days to evaluate fetal viability for queens receiving tocolytics.

PREVENTION/AVOIDANCE

- Institute infectious disease prevention, control, and surveillance plan.
- Replace infertile queens with more reproductively fit individuals.
- Avoid exposure to abortifacient, teratogenic, or fetotoxic drugs.

POSSIBLE COMPLICATIONS

- Depends on etiology.
- Metritis, endometritis, uterine rupture, sepsis, shock.
- Diabetes, CEH, masculinization of female fetuses with progesterone treatment.

EXPECTED COURSE AND PROGNOSIS

- Infectious disease—normal pregnancy, repeated abortion, or infertility possible with viral disease.
- Poor prognosis for normal pregnancy in queens with severe CEH.
- Fair prognosis for successful pregnancy with treatment for primary hypoluteoidism; significant monitoring required for good outcome.
- Pregnancy loss due to genetic abnormalities likely to recur if queen is bred to tom with similar pedigree.

**MISCELLANEOUS****AGE-RELATED FACTORS**

- Queens > 6 years old have higher incidence of infertility.
- Pregnancy loss seen most frequently in very young and old queens.

ZOONOTIC POTENTIAL*Toxoplasma gondii***SEE ALSO**

- Breeding, Timing • Sexual Development Disorders

ABBREVIATIONS

- CEH = cystic endometrial hyperplasia

ABORTION, SPONTANEOUS (EARLY PREGNANCY LOSS)—DOGS

BASICS

DEFINITION

Loss of a fetus because of resorption in early stages or expulsion in later stages of pregnancy.

PATHOPHYSIOLOGY

- Direct causes—congenital abnormality, infectious disease, trauma.
- Indirect causes—infectious placentitis, abnormal ovarian function, abnormal uterine environment.

SYSTEMS AFFECTED

- Reproductive. • Any dysfunction of a major body system can adversely affect pregnancy.

GENETICS

- No genetic basis for most causes of abortion.
- Lymphocytic hypothyroidism—single-gene recessive trait in borzois.

INCIDENCE/PREVALENCE

- True incidence unknown. • Resorption estimated between 11–13%, some estimates up to 30% of at least one resorption.
- Incidence of stillbirth reported as 2.2–4.4%; increases with dystocia up to 22.3%.

SIGNALMENT

Species

Dog

Breed Predilections

- Familial lymphocytic hypothyroidism reported in borzoi—prolonged interestrus interval, poor conception rates, abortion midgestation, stillbirths. • Many breeds considered at risk for familial hypothyroidism (see Hypothyroidism).

Mean Age and Range

- Infectious causes, pharmacologic agents causing abortion, fetal defects—seen in all ages. • Cystic endometrial hyperplasia—usually > 6 years old.

Predominant Sex

Intact bitches

SIGNS

Historical Findings

- Failure to whelp on time. • Expulsion of recognizable fetuses or placental tissues.
- Decrease in abdominal size; weight loss.
- Anorexia. • Vomiting, diarrhea.
- Behavioral changes.

Physical Examination Findings

- Sanguineous or purulent vulvar discharge.
- Disappearance of vesicles or fetuses previously documented by palpation, ultrasonography, or radiography.
- Abdominal straining, discomfort.
- Depression. • Dehydration. • Fever in some patients.

CAUSES

Infectious

- *Brucella canis*. • Canine herpesvirus.
- *Toxoplasma gondii*, *Neospora caninum*.

- *Mycoplasma* and *Ureaplasma*.
- Miscellaneous bacteria—*E. coli*, *Streptococcus*, *Campylobacter*, *Salmonella*.
- Miscellaneous viruses—distemper virus, parvovirus, adenovirus.

Uterine

- Cystic endometrial hyperplasia and pyometra. • Trauma—acute and chronic.
- Neoplasia. • Embryotoxic drugs.
- Chemotherapeutic agents. • Estrogens.
- Glucocorticoids—high dosages.

Ovarian

- Prostaglandins—lysis of corpora lutea.
- Dopamine agonists—lysis of corpora lutea via suppression of prolactin; bromocryptine, cabergoline. • Hypoluteoidism—abnormal luteal function in the absence of fetal, uterine, or placental disease; progesterone concentrations < 1–2 ng/mL, most often seen at 40–45 days gestation.

Hormonal Dysfunction

- Hypothyroidism; new data shows this is less common than previously thought.
- Hyperadrenocorticism. • Environmental factors—endocrine disrupting contaminants have been documented in human and wildlife instances of fetal loss.

Fetal Defects

- Lethal chromosomal abnormality. • Lethal organ defects.

RISK FACTORS

- Exposure of the brood bitch to carrier animals • Old age • Hereditary factors

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differentiate infectious from non-infectious causes—*B. canis* of immediate and zoonotic concern. • Differentiate resorption from infertility—helped by early diagnosis of pregnancy. • History of drug use during pregnancy—particularly during the first trimester, or use of drugs (e.g., dexamethasone, prostaglandins, ketoconazole, griseofulvin, doxycycline, tetracycline, dantralene, among others) known to cause fetal death. • Vulvar discharges during diestrus—may mimic abortion; evaluate discharge and origin to differentiate uterine from distal reproductive tract disease.
- Necropsy of aborted fetus, stillborn puppies, and placenta(s)—enhances chances of a definitive diagnosis, refrigerate but do not freeze prior to submission. • History of systemic or endocrine disease—may indicate problems with the maternal environment.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal. • Systemic disease, uterine infection, viral infection, or endocrine abnormalities—may produce changes in CBC, biochemistries, or urinalysis.

OTHER LABORATORY TESTS

- Serologic testing—*B. canis*, canine herpesvirus, and *Toxoplasma*, *Neospora*; collect serum as soon as possible after abortion; repeat testing for raising titers for canine herpesvirus, *Toxoplasma*, *Neospora*. • Slide test for *B. canis*—very sensitive; negative results reliable; prevalence of false positives as high as 60% (D-Tec CB®, Synbiotics Corp., (800)733-5500); • PCR for *B. canis* now available; • Definitive diagnosis made via culture. • Tube agglutination test for *B. canis*—gives titers; titers > 1:200 considered positive; titers from 1:50–1:200 considered suspicious. • Agar gel immunodiffusion test for *B. canis*—effectively differentiates between false positives and true positives in agglutination tests; detects cytoplasmic and cell surface antigens (Cornell University Animal Health Diagnostic Laboratory, (607)253-3900). • Baseline T₄ serum concentration (when no infectious agents are identified)—hypothyroidism is a common endocrine disease and has been suggested as a cause for fetal wastage; role in pregnancy loss unclear; subnormal T₄ concentrations indicate need for further testing (see Hypothyroidism). • Serum progesterone concentration (when no infectious agents are identified)—hypoluteoidism may cause fetal wastage; dogs depend on ovarian progesterone production throughout gestation (minimum of 2 ng/mL required to maintain pregnancy); collect sample and determine as soon as possible after abortion; in subsequent pregnancies, start weekly monitoring at week 3, which may be before pregnancy can be documented with ultrasound; start biweekly sampling around the gestational age of previous loss. Pregnancy loss typically occurs during the seventh week of gestation (see Premature Labor). • Vaginal culture—*B. canis* with positive serologic test; *Mycoplasma*, *Ureaplasma*, other bacterial agents; all except *B. canis* can be normal flora, therefore diagnosis difficult from vaginal cultures alone; *Salmonella* associated with systemic illness in the bitch.

IMAGING

- Radiography—identifies fetal structures after 45 days of gestation; earlier, can determine uterine enlargement but cannot assess uterine contents.
- Ultrasonography—identifies uterine size and contents; assesses fluid and its consistency; assesses fetal remains or fetal viability by noting heartbeats (normal, > 200 bpm; stress, < 150 or > 280 bpm).

DIAGNOSTIC PROCEDURES

- Vaginoscopy—identify source of vulvar discharges and vaginal lesions; use a scope of sufficient length (16–20 cm) to examine the entire length of the vagina. • Cytologic examination and bacterial culture—vagina may reveal an inflammatory process (e.g., uterine infection); technique for culture: use a

(CONTINUED) ABORTION, SPONTANEOUS (EARLY PREGNANCY LOSS)—DOGS

guarded swab culture instrument to ensure an anterior sample (distal reproductive tract is normally heavily contaminated with bacteria), or collection of secretions via transcervical catheterization.

PATHOLOGIC FINDINGS

Histopathologic examination and culture of fetal and placental tissue—may reveal infectious organisms; tissue culture, particularly of stomach contents, to identify infectious bacterial organisms.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Most bitches should be confined and isolated pending diagnosis.
- Hospitalization of infectious patients preferred.
- *B. canis*—highly infective to dogs; shed in high numbers during abortion; suspected cases should be isolated.
- Outpatient medical management—medically stable patients with non-infectious causes of pregnancy loss, endocrinopathies, or endometrial disease.
- Partial abortion—may attempt to salvage the live fetuses; administer antibiotics if a bacterial component is identified.

NURSING CARE

Dehydration—use replacement fluids, supplemented with electrolytes if imbalances are identified by serum biochemistries.

ACTIVITY

Partial abortion—cage rest generally recommended, although the positive effect on reducing further abortion is unknown.

DIET

No special dietary considerations for uncomplicated cases

CLIENT EDUCATION

- Critical for *B. canis*—if confirmed, euthanasia recommended due to lack of successful treatment and to prevent spread of infection; may try OHE and long-term antibiotics; discuss surveillance program for kennel situations: monthly serology for all individuals, culling any positive animals, until three consecutive negative tests are obtained; discuss zoonotic potential.
- Primary uterine disease—OHE is indicated in patients with no breeding value; cystic endometrial hyperplasia is an irreversible change.
- Infertility or pregnancy loss—may recur in subsequent estrous cycles despite successful immediate treatment.
- Prostaglandin treatment—discuss side effects (see Abortion, Termination of Pregnancy).
- Infectious diseases—establish surveillance and control measures.

SURGICAL CONSIDERATIONS

OHE—preferred for stable patients with no breeding value.

**MEDICATIONS****DRUG(S) OF CHOICE**

- PGF_{2α} (Lutalyse, dinoprost tromethamine)—uterine evacuation after abortion; 0.05–0.1 mg/kg SC q8–24h; cloprostenol (Estrumate, cloprostenol)—1–5 µg/kg SC q24h; not approved for use in dogs, but adequate documentation legitimizes its use; use only if all living fetuses have been expelled.
- Antibiotics—for bacterial disease; initially institute broad-spectrum agent; specific agent depends on culture and sensitivity testing of vaginal tissue or necropsy of fetus.
- Progesterone (Regu-Mate) at 0.088 mg/kg (1 mL/25 kg PO q24h); progesterone in oil at 2 mg/kg IM q48–72h; progesterone (Prometrium®; 10 mg/kg PO q24h, adjust daily dosage based on serum progesterone)—for documented hypoluteodism only to maintain pregnancy, must have accurate due date to know when to discontinue therapy— inadvertently prolonging gestation will result in fetal death.

CONTRAINdications

Progesterone supplementation—contraindicated in dogs with endometrial or mammary gland disease.

PRECAUTIONS

PGF_{2α}—metabolized in the lung; side effects are related to smooth muscle contraction, are dose-related, and diminish with each injection; panting, salivation, vomiting, and defecation common; dosing critical (LD₅₀ for dinoprost—5 mg/kg).

ALTERNATIVE DRUG(S)

Oxytocin—1 U/5 kg SC q6–24h for uterine evacuation; should only be considered in cases where uterine evacuation is desired solely through uterine contraction.

**FOLLOW-UP****PATIENT MONITORING**

- Partial abortion—monitor viability of remaining fetuses with ultrasonography; monitor systemic health of the dam for remainder of pregnancy.
- Vulvar discharges—daily; for decreasing amount, odor, and inflammatory component; for consistency (increasing mucoid content is prognostically good).
- PGF_{2α}—continued for 5 days or until most of the discharge ceases (range 3–15 days).
- *B. canis*—monitor after neutering and antibiotic therapy; yearly serologic testing to identify recrudescence.
- Hypothyroidism—treat appropriately; neutering recommended (hereditary nature); see Hypothyroidism.

PREVENTION/AVOIDANCE

- Brucellosis and other infectious agents—surveillance programs to prevent introduction to kennel.
- OHE—for bitches with no breeding value.
- Use of modified-live vaccines (e.g., some distemper, parvovirus, etc., vaccines).

POSSIBLE COMPLICATIONS

- Untreated pyometra—septicemia, toxemia, death.
- Brucellosis—discospondylitis, endophthalmitis, recurrent uveitis.

EXPECTED COURSE AND PROGNOSIS

- Pyometra—recurrence rate during subsequent cycle is high (up to 70%) unless pregnancy is established.
- CEH—recovery of fertility unlikely; pyometra common complication.
- Hormonal dysfunction—often manageable; familial aspects should be considered.
- Brucellosis—guarded; extremely difficult to successfully eliminate infection even if combined with neutering.

**MISCELLANEOUS****AGE-RELATED FACTORS**

Older bitches more likely to have CEH

ZOONOTIC POTENTIAL

B. canis—can be transmitted to humans, especially when handling the aborting bitch and expelled tissues; massive numbers of organisms expelled during abortion. Pathologists should be warned when *B. canis* is suspected. People that are immunocompromised are at greatest risk for infection.

SEE ALSO

- Brucellosis
- Hypothyroidism
- Infertility, Female—Dogs
- Premature Labor
- Pyometra

ABBREVIATIONS

- CEH = cystic endometrial hyperplasia
- OHE = ovariohysterectomy
- PGF_{2α} = prostaglandin F_{2α}

ABORTION, TERMINATION OF PREGNANCY

BASICS

DEFINITION

Termination of an unwanted pregnancy. May be accomplished by drugs that alter embryo transport in the oviduct impeding establishment of a pregnancy, and/or cause luteal regression, terminating an established pregnancy. Due to their possible side effects (CEH, aplastic anemia and bone marrow suppression), drugs that impair embryonic transit through the oviduct (estrogens) are not commonly used or recommended.

PATHOPHYSIOLOGY

After fertilization the embryo travels the oviduct in a timely manner before entering the uterus. Impaired embryo transport through the oviduct leads to embryonic degeneration and implantation abnormalities. In the dog and cat, pregnancy maintenance is dependent on progesterone production from the corpora lutea. In dogs and cats, maintenance of the corpora lutea during the second half of gestation is also supported by prolactin. Drugs that cause luteal regression, antagonize PRL, and/or compete with progesterone receptors will terminate pregnancy.

SYSTEMS AFFECTED

- Cardiovascular • Digestive • Neurologic (caused by drugs used for treatment)
- Reproductive • Respiratory

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog and cat

Breed Predilections

N/A

Mean Age and Range

Postpubertal bitch and queen

Predominant Sex

Pregnant bitch or queen

SIGNS

- Depends on stage of gestation: ° None
- ° Vaginal discharge ° Fetal expulsion

CAUSES

- Impaired oviductal transport • Luteal regression • Progesterone receptor antagonism

RISK FACTORS

N/A

DIAGNOSIS

- Confirm pregnancy first, less than 40% of mated bitches become pregnant:
 - Abdominal palpation (bitch: 31–33 days after LH surge; queen: 21–25 days after breeding).
 - Transabdominal ultrasound (bitch: > 25 days after LH surge; queen: > 16 days after breeding).
 - Abdominal radiographs (bitch: > 45 days after LH surge; queen: > 38 days after breeding).
 - Serum relaxin concentration in the bitch (> 28 days after LH surge) (Witness® Relaxin, Synbiotics/ Zoetis Corp., <http://synbiotics.com/index.html>; (800)733-5500).
- Ascertain that a breeding took place; a tie in the bitch and coital “after-reaction” in the queen.

DIFFERENTIAL DIAGNOSIS

- Hydrometra • Mucometra • Hematometra
- Pyometra • Pseudopregnancy

CBC/BIOCHEMISTRY/URINALYSIS

- Within normal limits during first half of pregnancy in healthy patients.
- Decrease in PCV during second half of pregnancy in bitches and queens is normal.
- Recommended as screening test prior to treatment in patients with suspected underlying disease.

OTHER LABORATORY TESTS

- Vaginal cytology—determines stage of estrous cycle and presence of sperm (absence does not rule out a previous breeding). Methods to increase detection of sperm: infuse and recover 5–10 mL of saline from anterior vagina using standard AI pipette, centrifuge, examine pellet; collect routine cytology and allow swab to sit in 1–2 mL of saline, express fluid, centrifuge, examine pellet.
- Serum progesterone concentration determines if the female is in diestrus and monitors luteal regression during treatment.

IMAGING

- Transabdominal ultrasound (method of choice): diagnose pregnancy and monitor uterine evacuation during treatment.
- Abdominal radiographs.

PATHOLOGIC FINDINGS

N/A

TREATMENT

APPROPRIATE HEALTH CARE

- Physical examination before initiation of treatment.
- Monitor 30–60 minutes after treatment for side effects (vomiting, defecation, hypersalivation, hyperpnea, micturition, tachycardia).
- Pregnancy status in early diestrus is unknown; ultrasound confirmation of pregnancy is not possible until ~4 weeks after breeding.
- Treatment on day 6–10 of diestrus—may have reduced

efficacy compared to midgestation but can be less distasteful to client (less discharge and recognizable fetuses are not passed).

- PGF_{2α} and bromocriptine given in combination—improves efficacy of either drug given alone.

NURSING CARE

N/A

ACTIVITY

Normal

DIET

Avoid feeding prior to each treatment and for 1–2 hours after treatments (reduces nausea and vomiting).

CLIENT EDUCATION

- Discuss patient's reproductive future with owner. If no litters are desired, then OHE is the best option.
- Discuss with the client the potential side effects of the treatment options; reach a mutual agreement on the treatment plan.

SURGICAL CONSIDERATIONS

OHE is recommended for patients with no reproductive value or when owners do not desire future litters.

MEDICATIONS

DRUG(S) OF CHOICE

- Confirmation of pregnancy before initiating any of the treatment protocols suggested below is recommended. Lengths of treatment suggested may vary; treatments should be continued until abortion is complete.

- PGF_{2α}: causes luteal regression with subsequent decline in progesterone concentration, cervical relaxation, and uterine contractions; bitches and cats low dose protocol: 10 µg/kg SC q6h for 7–10 days or until pregnancy terminated (in the bitch), then 25 µg/kg q6h for 1–2 days; then 50 µg/kg q6h for 3–4 days (the queen is more resistant to the luteolytic effects of PGF_{2α} than bitches—often higher doses for longer periods are required); bitch standard dose protocol: 100 µg/kg SC q8h for 2 days, then 200 µg/kg SC q8h until pregnancy termination; queens: 0.5–1 mg/kg SC q12h every other day > day 40, or 2 mg/cat IM q24h for 5 days > day 33.

- Cloprostenol (prostaglandin analogue): bitches: 2.5 µg/kg SC q8 or q12h every 48 hours until pregnancy termination (~6 days after start of treatment).

- Dexamethasone: mode of action is unknown; bitches: 0.2 mg/kg PO q8–12h for 5 days, then decreasing from 0.16 to 0.02 mg/kg over the last five days; treatment failures not uncommon.

- Cabergoline (PRL antagonist): causes luteal regression; bitches: 1.65 µg/kg SC q24h for 5 days or 5 µg/kg PO q24h for 5 days > day 40; queens: 1.65 µg/kg SC for

(CONTINUED)

ABORTION, TERMINATION OF PREGNANCY

- 5 days > day 30 or 5 µg/kg PO q24h for 5 days > day 35.
- Bromocriptine (PRL antagonist): causes luteal regression; bitches: 50–100 µg/kg q12h IM or PO for 4–7 days > day 35 (50% effective); vomiting common side effect, reduce dose and give with meal.
 - Cloprostenol and cabergoline combination: bitches: cabergoline 5 µg/kg PO q24h for 10 days plus cloprostenol 2.5 µg/kg SC at start of treatment or 1 µg/kg SC at start of treatment and at day 5 of treatment; treatment should be initiated > 28 days post-LH surge; queen: cabergoline 5 µg/kg PO q24h plus cloprostenol 5 µg/kg SC q48h (> 30 days after breeding) until abortion is complete (~ 9 days).
 - Cloprostenol and bromocriptine combination: bitches; bromocriptine 30 µg/kg q8h PO for 10 days plus cloprostenol 2.5 µg/kg SC or 1 µg/kg SC at start of treatment and at day 5 of treatment; treatment should be initiated > 28 days post-LH surge.

CONTRAINDICATIONS

- PGF_{2α} and analogues: animals with respiratory disease (bronchoconstriction); do not administer intravenously.
- Cabergoline and bromocriptine: avoid administration in animals hypersensitive to ergot alkaloids; use with caution in patients with significantly impaired liver function.
- Estrogens may cause cystic endometrial hyperplasia, pyometra, and bone marrow suppression leading to pancytopenia.

PRECAUTIONS

- PGF_{2α} and analogues: side effects are dose-dependent and include vomiting, defecation, dyspnea, tachycardia, salivation, restlessness, and anxiety; side effects subside within 60 minutes; the severity of effects can be attenuated with premedication (> 15 minutes) with a combination of atropine (0.025 mg/kg); use extreme caution in dogs and cats with preexisting cardiopulmonary, liver, and renal diseases.
- Dexamethasone: polydipsia, polyuria, and polyphagia are reported side effects. Long-term administration has been associated with hyperadrenocorticism.
- Cabergoline and bromocriptine: should be administered with caution in patients with impaired liver function. Side effects may include vomiting and anorexia; prolonged use (> 2 weeks) may cause coat color changes.

POSSIBLE INTERACTIONS

- PGF_{2α} and analogues: effect may be reduced by concomitant administration of progestins; use may enhance effects of oxytocin.
- Cabergoline and bromocriptine: cabergoline effects may be reduced with concomitant treatment with dopamine (D₂) antagonists; avoid concomitant treatment with hypotensive drugs.

ALTERNATIVE DRUG(S)

- The following drugs are recommended for use in bitches but not available in the United States:
 - Mifepristone (RU486; progestin and glucocorticoid receptor antagonist): 2.5 mg/kg PO q12h for 4–5 days > day 32 of pregnancy (dog); no side effects have been reported.
 - Aglepristone (progestin and glucocorticoid receptors antagonists): 10 mg/kg SC q24h for 2 days > 32 days post-LH surge (dog); pregnancy is terminated in 4–7 days; mild reaction at injection site have been reported; mild vaginal discharge may be observed.
 - Aglepristone and cloprostenol combination: aglepristone (10 mg/kg SC) combined with cloprostenol (1 µg/kg SC) q24h for 2 days > 25 days pregnancy; pregnancy is terminated within 6 days. Side effects after treatment include vomiting and diarrhea. Vaginal discharge may be observed.
 - Aglepristone (10 mg/kg SC, q24h for 2 days) with intravaginal misoprostol (200–400 µg, depending on body size) daily until abortion complete; abortion complete within 7 days. Vomiting, diarrhea, polydipsia, anorexia not observed with this regimen.
 - GnRH antagonists (Acyline; blocks GnRH receptors at the pituitary gland, causing a decline in gonadotropins concentration): a single treatment with 110–330 µg/kg SC is recommended (dog); pregnancy is terminated within 6–10 days after treatment; prepartum-like behavior has been observed; abortion may be followed by serosanguineous vaginal discharge for 2–3 days; not yet available in the US (currently in Phase I clinical trials for prostate cancer in men).

**FOLLOW-UP****PATIENT MONITORING**

In animals treated with luteolytic drugs (prostaglandins and PRL antagonists), progesterone assays and transabdominal ultrasound examinations should be performed to monitor decrease of serum progesterone concentration and complete evacuation of uterine contents. In patients treated with progesterone receptor antagonist drugs, transabdominal ultrasound examinations are recommended to monitor complete evacuation of the uterus.

PREVENTION/AVOIDANCE

- OHE for bitches and queens not intended for breeding.
- Estrus suppression or confinement of bitches and queens intended for breeding during a later cycle to avoid mismating.

POSSIBLE COMPLICATIONS

Pregnancy termination may not be achieved after one treatment protocol and continuation or change in treatment protocol may be necessary.

EXPECTED COURSE AND PROGNOSIS

- The interestrous interval in bitches treated with prostaglandins and PRL inhibitors may be shortened (~1 month). Queens may resume estrous behavior 7–10 days after pregnancy termination.
- Subsequent estrus fertility is not affected.

ABSCESSTION

BASICS

DEFINITION

An abscess is a localized collection of purulent exudate contained within a cavity.

PATHOPHYSIOLOGY

- Bacteria are often inoculated under the skin via a puncture wound; the wound surface then seals.
- When bacteria and/or foreign objects persist in the tissue, purulent exudate forms and collects.
- Accumulation of purulent exudates—if not quickly resorbed or discharged to an external surface, stimulates formation of a fibrous capsule; may eventually lead to abscess rupture.
- Prolonged delay of evacuation—formation of a fibrous abscess wall; to heal, the cavity must be filled with granulation tissue from which the causative agent may not be totally eliminated; may lead to chronic or intermittent discharge of exudate from a draining sinus tract.

SYSTEMS AFFECTED

- Skin/Exocrine—percutaneous (cats > dogs); anal sac (dogs > cats)
- Reproductive—prostate gland (dogs > cats); mammary gland
- Ophthalmic—periocular tissues
- Hepatobiliary—liver parenchyma
- Gastrointestinal—pancreas (dogs > cats)

Cat and dog

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

Mammary glands (female); prostate gland (male)

SIGNS

General Comments

- Determined by organ system and/or tissue affected.
- Associated with a combination of inflammation (pain, swelling, redness, heat, and loss of function), tissue destruction, and/or organ system dysfunction caused by accumulation of exudates.

Historical Findings

- Often presented for nonspecific signs such as lethargy and anorexia.

- History of traumatic insult or previous infection.
- A rapidly appearing painful swelling with or without discharge, if affected area is visible.

Physical Examination Findings

- Determined by the organ system or tissue affected.
- Classic signs of inflammation (heat, pain, swelling, and loss of function) are associated with specific anatomic location of the abscess.
- Inflammation and discharge from a fistulous tract may be visible if the abscess is superficial and has ruptured to an external surface.
- A variably sized, painful mass of fluctuant to firm consistency attached to surrounding tissues may be palpable.
- Fever if abscess is not ruptured and draining.
- Sepsis occasionally, especially if abscess ruptures internally.

CAUSES

- Foreign objects.
- Pyogenic bacteria—*Staphylococcus* spp.; *Escherichia coli*; β -hemolytic *Streptococcus* spp.; *Pseudomonas*; *Mycoplasma* and *Mycoplasma*-like organisms (L-forms); *Pasteurella multocida*; *Corynebacterium*; *Actinomyces* spp.; *Nocardia*; *Bartonella*.
- Obligate anaerobes—*Bacteroides* spp.; *Clostridium* spp.; *Peptostreptococcus*; *Fusobacterium*.

RISK FACTORS

- Anal sac—impaction; anal sacculitis.
- Brain—otitis interna sinusitis oral infection.
- Liver—omphalophlebitis sepsis.
- Lung—foreign object aspiration bacterial pneumonia.
- Mammary gland—mastitis.
- Periorbital—dental disease; chewing of wood or other plant material.
- Percutaneous—fighting, trauma, or surgery.
- Prostate gland—bacterial prostatitis.
- Immunosuppression—FeLV/FIV infection, immunosuppressive chemotherapy, acquired or inherited immune system dysfunctions, underlying predisposing disease (e.g., diabetes mellitus, chronic renal failure, hyperadrenocorticism).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Mass Lesions

- Cyst—less or only transiently painful; slower growing.
- Fibrous scar tissue—firm; non-painful.
- Granuloma—less painful; slower growing; generally firmer without fluctuant center.
- Hematoma/seroma—variable pain (depends on cause); non-encapsulated; rapid initial growth but slow increase once full size is attained; unattached to surrounding tissues; fluctuant and fluid filled initially but more firm with organization.

- Neoplasia—variable growth; consistent; painful.

Draining Tracts

- Mycobacterial disease
- Mycetoma—botryomycosis, actinomycotic mycetoma, eumycotic mycetoma
- Neoplasia
- Phaeohyphomycosis
- Sporotrichosis
- Systemic fungal infection—blastomycosis, coccidioidomycosis, cryptococcosis, histoplasmosis, trichosporosis

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—normal or neutrophilia with or without regenerative left shift. Neutropenia and degenerative left shift if sepsis present.
- Urinalysis and serum chemistry profile—depends on system affected.
- Prostatic—pyuria.
- Liver and/or pancreatic—high liver enzymes and/or total bilirubin.
- Pancreatic (dogs)—high amylase/lipase.
- Diabetes mellitus—persistent hyperglycemia and glucosuria.

OTHER LABORATORY TESTS

- FeLV and FIV—for cats with recurrent or slow-healing abscesses.
- CSF evaluation—increase in cellularity and protein expected with brain abscess.
- Adrenal function—evaluate for hyperadrenocorticism.

IMAGING

- Radiography—soft-tissue density mass in affected area; may reveal foreign body.
- Ultrasonography—determine if mass is fluid filled or solid; determine organ system affected; reveal flocculent-appearing fluid characteristic of pus; may reveal foreign object.
- Echocardiography—helpful for diagnosis of pericardial abscess.
- CT or MRI—helpful for diagnosis of brain abscess.

DIAGNOSTIC PROCEDURES

Aspiration

- Reveals a red, white, yellow, or green liquid.
- Protein content $> 2.5\text{--}3.0 \text{ g/dL}$.
- Nucleated cell count—3,000–100,000 (or more) cells/ μL ; primarily degenerative neutrophils with lesser numbers of macrophages and lymphocytes.
- Pyogenic bacteria—may be seen in cells and free within the fluid.

- If the causative agent is not readily identified with a Romanowsky-type stain, specimens should be stained with an acid-fast stain to detect mycobacteria or *Nocardia* and PAS stain to detect fungus.

Biopsy

- Sample should contain both normal and abnormal tissue in the same specimen.
- Impression smears—stained and examined.
- Tissue—submit for histopathologic examination and culture.

(CONTINUED)

- Contact the diagnostic laboratory for specific instructions.

Culture

- Affected tissue and/or exudate— aerobic and anaerobic bacteria and fungus.
- Blood and/or urine—isolate bacterium responsible for possible sepsis.
- Bacterial sensitivity.

PATHOLOGIC FINDINGS

- Pus-containing mass lesion accompanied by inflammation.
- Palpable—variably firm or fluctuant mass.
- Ruptured—may see pus draining directly from the mass or an adjoining tract.
- Exudate—large numbers of neutrophils in various stages of degeneration; other inflammatory cells; necrotic tissue.
- Surrounding tissue—congested; fibrin; large number of neutrophils; variable number of lymphocytes; plasma cells; macrophages.
- Causative agent variably detectable.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Depends on location of abscess and treatment required.
- Outpatient—bite-induced abscesses.
- Inpatient—sepsis; extensive surgical procedures; treatment requiring extended hospitalization.
- Establish and maintain adequate drainage.
- Surgical removal of nidus of infection or foreign object(s) if necessary.
- Institution of appropriate antimicrobial therapy.

NURSING CARE

- Depends on location of abscess.
- Apply hot packs to inflamed area as needed.
- Use protective bandaging and/or Elizabethan collars as needed.
- Accumulated exudate—drain abscess; maintain drainage by medical and/or surgical means.
- Sepsis or peritonitis—aggressive fluid therapy and support.

ACTIVITY

Restrict until the abscess has resolved and adequate healing of tissues has taken place.

DIET

- Sufficient nutritional intake to promote a positive nitrogen balance.
- Depends on location of abscess and treatment required.

CLIENT EDUCATION

- Discuss need to correct or prevent risk factors.
- Discuss need for adequate drainage and continuation of antimicrobial therapy for an adequate period of time.

SURGICAL CONSIDERATIONS

- Appropriate debridement and drainage—may need to leave the wound open to an external surface; may need to place surgical drains.
- Early drainage—to prevent further tissue damage and formation of abscess wall.
- Remove any foreign objects(s), necrotic tissue, or nidus of infection.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Antimicrobial drugs—effective against the infectious agent; gain access to site of infection.
- Broad-spectrum agent—bactericidal and with both aerobic and anaerobic activity; until results of culture and sensitivity are known. Dogs and cats: amoxicillin (11–22 mg/kg PO q8–12h); amoxicillin/clavulanic acid (12.5–25 mg/kg PO q12h); clindamycin (5 mg/kg PO q12h); and trimethoprim/sulfadiazine (15 mg/kg PO IM q12h). Cats with *Mycoplasma* and l-forms: doxycycline (5 mg/kg PO q12h).
- Aggressive antimicrobial therapy—sepsis or peritonitis.

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

Monitor for progressive decrease in drainage, resolution of inflammation, and improvement of clinical signs.

PREVENTION/AVOIDANCE

- Percutaneous abscesses—prevent fighting.
- Anal sac abscesses—prevent impaction; consider anal saculectomy for recurrent cases.
- Prostatic abscesses—castration possibly helpful.
- Mastitis—prevent lactation (spaying).
- Periorbital abscesses—do not allow chewing on foreign object(s).

POSSIBLE COMPLICATIONS

- Sepsis.
- Peritonitis/pleuritis if intra-abdominal or intrathoracic abscess ruptures.
- Compromise of organ function.
- Delayed evacuation may lead to chronically draining fistulous tracts.

EXPECTED COURSE AND PROGNOSIS

Depends on organ system involved and amount of tissue destruction.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- FeLV or FIV infection
- Immunosuppression

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

- Minimal for pyogenic bacteria.
- Mycobacteria and systemic fungal infections carry some potential.

PREGNANCY/FERTILITY/BREEDING

Teratogenic agents—avoid use in pregnant animals.

ACETAMINOPHEN (APAP) TOXICOSIS

BASICS

DEFINITION

Results from accidental animal ingestion or owner administration of over-the-counter acetaminophen-containing analgesic and antipyretic medications.

PATHOPHYSIOLOGY

When the normal biotransformation mechanisms for detoxification (glucuronidation and sulfation) are saturated, cytochrome P450-mediated oxidation produces a toxic metabolite (*N*-acetyl-p-benzoquinone imine) that is electrophilic, conjugates with glutathione, and binds to sulphydryl groups leading to hepatic necrosis.

Dogs

- Liver is most susceptible to toxicity.
- Signs commonly observed at exposures > 100 mg/kg.
- Methemoglobinemia may develop at doses > 200 mg/kg.

Cats

- Cannot effectively glucuronidate; more limited capacity for acetaminophen elimination than dogs.
- Saturate glucuronidation and sulfation biotransformation routes.
- RBCs are most susceptible to oxidative injury following glutathione depletion.
- Develop toxic cytochrome P450 metabolite at much lower doses than dogs.
- Poisoned by as little as 50–60 mg/kg (often as little as one-half tablet); deacetylation of acetaminophen to p-aminophenol (PAP) causes oxidative damage to RBCs, rapidly producing methemoglobinemia by binding to sulphydryl groups on hemoglobin.
- Slower-developing hepatotoxicosis may not be fully expressed before development of fatal methemoglobinemia.

SYSTEMS AFFECTED

- Hemic/Lymph/Immune—RBCs are damaged by glutathione depletion, allowing oxidation of hemoglobin to methemoglobin.
- Hepatobiliary—liver necrosis (more common in dogs).
- Cardiovascular (primarily cats)—edema of the face, paws, and (to a lesser degree) forelimbs through an undefined mechanism.

GENETICS

Cats—genetic deficiency in the glucuronide conjugation pathway makes them vulnerable.

INCIDENCE/PREVALENCE

Common drug toxicity in cats; less frequent in dogs.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Cats more often than dogs

SIGNS

General Comments

Relatively common—owing to widespread human use.

Historical Findings

- Depression
- Hyperventilation
- Darkened mucous membranes
- Signs may develop 1–4 hours after dosing

Physical Examination Findings

- Progressive depression
- Salivation
- Vomiting
- Abdominal pain
- Tachypnea and cyanosis or muddy mucous membranes—reflect methemoglobinemia
- Edema—face, paws, and possibly forelimbs; after several hours
- Chocolate-colored urine—hematuria and methemoglobinuria; especially in cats
- Icterus
- Hypothermia
- Shock
- Death

CAUSES

Acetaminophen toxicosis

RISK FACTORS

- Nutritional deficiencies of glucose and/or sulfate
- Simultaneous administration of other glutathione-depressing drugs

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of liver injury

- Hepatotoxic mushrooms
- Blue-green algae
- Aflatoxins
- Iron, copper, zinc
- Xylitol
- Cycad palms
- NSAIDs

Other causes of methemoglobinemia

- Onions/garlic
- Naphthalene
- Chlorates
- Nitrites
- Sulfites
- Phenol
- Benzocaine
- Propylene glycol (cats)

CBC/BIOCHEMISTRY/URINALYSIS

- Methemoglobinemia and progressively rising serum concentrations of liver enzymes (ALT, AST)—characteristic.
- As hepatic function becomes impaired—decreased BUN, cholesterol, and albumin, and increased serum bilirubin.
- Heinz bodies (cats)—prominent in RBCs within 72 hours.
- Anemia, hemoglobinemia, and hemoglobinuria or hematuria.

OTHER LABORATORY TESTS

Acetaminophen plasma, serum, or urine concentrations

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Methemoglobinemia.
- Pulmonary edema.
- Centrilobular necrosis and congestion of the liver.
- Renal tubular edema and degeneration with proteinaceous tubular casts.

TREATMENT

APPROPRIATE HEALTH CARE

- With methemoglobinemia—must evaluate promptly.
- With dark or bloody colored urine or icterus—inpatient.

NURSING CARE

- Gentle handling—imperative for clinically affected patients.
- Induced emesis and gastric lavage—useful within 4–6 hours of ingestion.
- Anemia, hematuria, or hemoglobinuria—may require whole blood transfusion.
- Fluid therapy—maintain hydration and electrolyte balance.
- Oxygen therapy may be needed.
- Drinking water—available at all times.
- Food—offered 24 hours after initiation of treatment.

(CONTINUED)

ACETAMINOPHEN (APAP) TOXICOSIS**ACTIVITY**

Restricted

DIET

N/A

CLIENT EDUCATION

- Warn client that treatment in clinically affected patients may be prolonged and expensive.
- Inform client that patients with liver injury may require prolonged and costly management.

SURGICAL CONSIDERATIONS

N/A

**MEDICATIONS****DRUG(S) OF CHOICE**

- Activated charcoal 2 g/kg PO; immediately after completion of emesis or gastric lavage.
- N*-acetylcysteine (Mucomyst) 140 mg/kg diluted in D5W as loading dose PO, IV; then 70 mg/kg diluted in D5W PO, IV, q6h for 5–7 additional treatments.
- S-adenosylmethionine (SAMe) as a glutathione donor; 40 mg/kg PO × 1 dose, then 20 mg/kg q24h PO × 7 days.
- Added benefit of using methylene blue, cimetidine, and/or ascorbic acid is controversial.

CONTRAINDICATIONS

Drugs that contribute to methemoglobinemia or hepatotoxicity.

PRECAUTIONS

Drugs requiring extensive liver metabolism or biotransformation—use with caution; expect their half-lives to be extended.

POSSIBLE INTERACTIONS

Drugs requiring activation or metabolism by the liver have reduced effectiveness.

**FOLLOW-UP****PATIENT MONITORING**

- Continual clinical monitoring of methemoglobinemia—vital for effective management; laboratory determination of methemoglobin percentage every 2–3 hours.
- Serum liver enzyme activities (ALT, ALP) every 12 hours; monitor liver damage.

PREVENTION/AVOIDANCE

- Never give acetaminophen to cats.
- Give careful attention to the acetaminophen dose in dogs.

POSSIBLE COMPLICATIONS

Liver necrosis and resulting fibrosis—may compromise long-term liver function in recovered patients.

EXPECTED COURSE AND PROGNOSIS

- Rapidly progressive methemoglobinemia—serious sign.
- Methemoglobin concentrations ≥ 50%—grave prognosis.
- Progressively rising serum liver enzymes 12–24 hours after ingestion—serious concern.
- Expect clinical signs to persist 12–48 hours; death owing to methemoglobinemia possible at any time.
- Dogs and cats receiving prompt treatment that reverses methemoglobinemia and prevents excessive liver necrosis—may recover fully.
- Dogs—death as a result of liver necrosis may occur within 72 hours.
- Cats—death as a result of methemoglobinemia occurs 18–36 hours after ingestion.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Keratoconjunctivitis sicca (KCS) may develop in small-breed dogs as a sequela.

AGE-RELATED FACTORS

Young and small dogs and cats—greater risk from owner-given single-dose acetaminophen medications.

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

Imposes additional stress and higher risk on exposed animals.

SYNONYMS

- Paracetamol
- Tylenol

SEE ALSO

Poisoning (Intoxication) Therapy

ABBREVIATIONS

- PAP = p-aminophenol
- ALT = alanine aminotransferase
- AST = aspartate transaminase

ACIDOSIS, METABOLIC (TRADITIONAL APPROACH)

BASICS

DEFINITION

A process in the body that leads to a decrease in pH below the reference interval for that species. A decline in blood pH is specifically termed acidemia. Associated with a decrease in plasma bicarbonate concentration (HCO_3^-) (dogs, > 18 mEq/L; cats, > 16 mEq/L) and base excess (BE) (< -4 mmol/L) with a compensatory decrease in carbon dioxide tension (PCO_2).

PATOPHYSIOLOGY

- Metabolic acidosis may develop either from a loss of HCO_3^- (hyperchloremic acidosis) or a gain in acid (high anion gap acidosis). It is usually secondary to an accumulation of metabolically produced strong anions (strong ion gap or high anion gap acidosis), accumulation of weak acids (hyperphosphatemia), corrected hyperchloremia (hyperchloremic acidosis), or as a compensatory mechanism for respiratory alkalosis.
- High anion gap acidosis:** Increase in the concentration of other strong anions through addition (e.g., ethylene glycol toxicity), excessive production (e.g., lactate produced by prolonged anaerobic metabolism), or renal retention (e.g., renal failure) of strong anions other than chloride causes metabolic acidosis without increasing chloride concentration (so-called normochloremic or high AG metabolic acidosis).
- Hyperphosphatemic acidosis:** Increase in plasma weak acids (e.g., inorganic phosphate) is associated with metabolic acidosis and increased anion gap. At pH of 7.4, a 1 mg/dL increase in phosphate concentration is associated with a 0.58 mEq/L decrease in HCO_3^- and a 0.58 mEq/L increase in AG. Hyperphosphatemia commonly develops with decreased renal phosphorous excretion (e.g., renal failure, hypoparathyroidism, etc), cellular lysis (e.g., tumor lysis syndrome, trauma, rhabdomyolysis), bone neoplasms (increased bone resorption), and hypervitaminosis D.
- Hyperchloremic acidosis:** Hyperchloremic acidosis may be caused by chloride retention (e.g., renal failure, renal tubular acidosis) that typically occurs in response to HCO_3^- loss. Chloride and HCO_3^- are reciprocally related; a loss of HCO_3^- generally results in retention of chloride. Other mechanisms for hyperchloremic acidosis include: excessive loss of sodium relative to chloride (e.g., diarrhea, Addison's) and administration of substances containing more chloride than sodium as compared with normal extracellular fluid composition (e.g., administration of KCl, 0.9% NaCl). Acidemia is usually not severe in patients with hyperchloremic acidosis.

SYSTEMS AFFECTED

• **Cardiovascular**—a fall in pH results in an increase in sympathetic discharge but simultaneously causes a decrease in the responsiveness of the cardiac myocytes and vascular smooth muscle to the effects of catecholamines. In mildly acidemic conditions (pH > 7.2), the effects of increased sympathetic stimulation predominate and result in a mild increase in heart rate and cardiac output. More severe acidemia (pH < 7.1), especially if acute, may decrease cardiac contractility and predispose the heart to ventricular arrhythmias and ventricular fibrillation.

• **Respiratory**—increased $[\text{H}^+]$ stimulates peripheral and central chemoreceptors to increase alveolar ventilation; hyperventilation decreases PCO_2 , which counters the effects of low plasma HCO_3^- on pH. In dogs, a decrease of approximately 0.7 mmHg in PCO_2 is expected for each 1 mEq/L decrease in plasma HCO_3^- . Little is known about compensation in cats, but it appears to be almost nonexistent.

• **Renal/Urologic**—the kidneys increase net acid excretion, primarily by increasing excretion of NH_4^+ and chloride. This compensatory mechanism is not very effective in cats.

SIGNALMENT

Any breed, age, or sex of dog and cat

SIGNALMENT

Historical Findings

- Chronic disease processes that lead to metabolic acidosis (e.g., renal failure, diabetes mellitus, and hypoadrenocorticism), acute circulatory shock (hemorrhagic), exposure to toxins (e.g., ethylene glycol, salicylate, and paraldehyde), diarrhea, administration of carbonic anhydrase inhibitors (e.g., acetazolamide and dichlorphenamide).

Physical Examination Findings

- Generally relate to the underlying disease.
- Depression, stupor, seizures, and/or generalized muscle weakness in severely acidotic patients.
- Tachypnea in some patients results from compensatory increase in ventilation.
- Kussmaul's respiration, typically seen in human beings with metabolic acidosis, is not commonly observed in dogs and cats.
- Vomiting and/or diarrhea.

CAUSES

Associated with Hyperchloremia (Hyperchloremic Metabolic Acidosis)

- Renal:** Renal tubular acidosis; carbonic anhydrase inhibitors.
- GI:** Diarrhea.
- Other:** Chloride-rich fluids (e.g., 0.9% NaCl, KCl supplementation); total parenteral nutrition with cationic amino acids: lysine, arginine, and histidine; rapid correction of hypocapnia (chronic respiratory alkalosis); NH_4Cl or HCl.

Associated with Normochloremia (High Anion Gap Metabolic Acidosis)

- Renal:** uremic acidosis, acute renal failure.
- Ketoacidosis:** diabetic ketoacidosis, starvation liver disease.
- Lactic acidosis:** impaired perfusion, impaired carbohydrate metabolism.
- Toxins:** ethylene glycol, salicylate, paraldehyde, and methanol intoxication.
- Hyperphosphatemia (see Hyperphosphatemia):** raises the anion gap. At a pH of 7.4, each 1 mg/dL increase in phosphate concentration is associated with a 0.58 mEq/L increase in anion gap.

RISK FACTORS

- Chronic renal failure, diabetes mellitus, and hypoadrenocorticism
- Poor tissue perfusion or hypoxia—lactic acidosis
- Tumor lysis syndrome or osteosarcoma—hyperphosphatemia
- Trauma, snake envenomation, or malignant hyperthermia—rhabdomyolysis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Low plasma HCO_3^- and hyperchloremia may also be compensatory in animals with chronic respiratory alkalosis, in which PCO_2 is low and pH is high or near normal, despite decreased HCO_3^- and increase in chloride concentration. Blood gas determination is required to differentiate.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

Potassium bromide is measured as chloride in most analyzers, so potassium bromide administration artificially decreases the anion gap.

Disorders That May Alter Laboratory Results

- Too much heparin (> 10% of the sample) decreases HCO_3^- .
- Blood samples stored at room temperature for > 15 minutes have low pH because of increased PCO_2 .
- Hypoalbuminemia lowers AG; negative charges of albumin are the main component of the anion gap.

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- Low total CO_2 —total CO_2 in serum samples handled aerobically closely approximates the serum HCO_3^- concentration; unfortunately, patients with chronic respiratory alkalosis also have low total CO_2 , and the distinction cannot be made without blood gas analysis.
- Metabolic acidoses are traditionally divided into hyperchloremic and high anion gap by means of the anion gap. Anion gap, the difference between the measured cations and the

(CONTINUED)

ACIDOSIS, METABOLIC (TRADITIONAL APPROACH)

A

measured anions, is calculated as $AG = [Na^+] - (HCO_3^- + Cl^-)$ or $AG = ([Na^+] + [K^+]) - (HCO_3^- + Cl^-)$, depending on the preference of the clinician or laboratory. Normal values with potassium included in the calculation are usually 12–24 mEq/L in dogs and 13–27 mEq/L in cats. The negative charges of albumin are the major contributors to the normal anion gap; this should be taken into account when evaluating anion gap in patients with hypoalbuminemia. At pH 7.4 in dogs, a decrease of 1 g/dL in albumin is associated with a decrease of 4.1 mEq/L in the anion gap. • Normal anion gap (i.e., hyperchloremic metabolic acidosis). • High anion gap (i.e., normochloremic metabolic acidosis). • Hyperglycemia—see Hyperglycemia. • Azotemia—see Azotemia. • Hyperphosphatemia—see Hyperphosphatemia. • High lactate concentration—see Lactic Acidosis. • Hyperkalemia—see Hyperkalemia (*formulas to adjust potassium concentration based on pH changes should not be used*).

OTHER LABORATORY TESTS

Blood gas analysis reveals low HCO_3^- , low PCO_2 , and low pH.

DIAGNOSTIC PROCEDURES

None

**TREATMENT**

- Acid-base disturbances are secondary phenomena; successful resolution depends on diagnosis and treatment of the underlying disease process.
- Restore blood volume and perfusion deficits before considering $NaHCO_3$.
- Treat patients with blood pH ≤ 7.1 aggressively while pursuing the definitive diagnosis.
- Discontinue drugs that may cause metabolic acidosis.
- Nursing care—Isotonic, *buffered* electrolyte solution is the fluid of choice for patients with mild metabolic acidosis and normal liver function.

**MEDICATIONS****DRUG(S) OF CHOICE**

- $NaHCO_3$ may help patients with hyperchloremic, hyperphosphatemic, or uremic acidosis, but not patients with lactic acidosis or diabetic ketoacidosis.
- $NaHCO_3$ may be considered for alkaline diuresis in salicylate toxicity.
 - Estimation of HCO_3^- dose: dogs, $0.3 \times$ body weight (kg) $\times (21 - \text{patient } HCO_3^-)$; cats, $0.3 \times$ body weight (kg) $\times (19 - \text{patient } HCO_3^-)$. Give half of this dose slowly IV and reevaluate blood gases before deciding on the need for additional administration. An empirical dose of 1–2 mEq/kg followed

by reevaluation of blood gas status is safe in most patients.

- Potential complications of $NaHCO_3$ administration: volume overload resulting from administered sodium, tetany from low ionized calcium concentration, increased affinity of hemoglobin for oxygen, paradoxical CNS acidosis, overshoot metabolic alkalosis, and hypokalemia.
- Hyperchloremic acidosis: $NaHCO_3$ may be effective and considered whenever pH < 7.1 .
- Uremic acidosis: efficacy of $NaHCO_3$ in acute therapy of uremic acidosis is related to the shift of phosphate inside the cells and consequent amelioration of hyperphosphatemic acidosis.
- Lactic acidosis: $NaHCO_3$ increases lactate production and is of little to no value in lactic acidosis. Therapy should be directed at augmenting oxygen delivery to the tissues and reestablishing cardiac output. Small titrated doses of $NaHCO_3$ can be used as a temporizing measure to maintain HCO_3^- above 5 mEq/L, if needed.
- Diabetic ketoacidosis: $NaHCO_3$ adversely affects outcome in humans with diabetic ketoacidosis even when pH < 7.0 .
- Administration of $NaHCO_3$ to ketoacidotic patients cannot be recommended at any pH. Therapy should be direct at insulin and fluid administration. Reestablishing plasma volume and renal perfusion will allow the kidneys to excrete ketoanions, replacing them with chloride.

CONTRAINdications

- Avoid $NaHCO_3$ in patients with respiratory acidosis because it generates CO_2 .
- Patients with respiratory acidosis cannot adequately excrete CO_2 , and increased PCO_2 will further decrease the pH.
- Avoid diuretics that act in the distal nephron (e.g., spironolactone).
- Avoid carbonic anhydrase inhibitors (e.g., acetazolamide, dichlorphenamide).
- Avoid $NaHCO_3$ in acute (< 10 minutes) cardiac arrest as it may impair tissue oxygen unloading.

PRECAUTIONS

Use $NaHCO_3$ cautiously in patients with congestive heart failure because the sodium load may cause decompensation of the heart failure.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

None

**FOLLOW-UP****PATIENT MONITORING**

Recheck acid-base status; frequency dictated by the underlying disease and patient response to treatment.

POSSIBLE COMPLICATIONS

- Hyperkalemia in acute hyperchloremic acidosis
- Myocardial depression and ventricular arrhythmias

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Hyperkalemia
- Hyperchloremia

AGE-RELATED FACTORS

None

PREGNANCY/FERTILITY/BREEDING

ACNE—CATS

BASICS

OVERVIEW

- Inflammatory dermatitis affecting the chin and lips
- Symptoms may be recurrent or persistent
- Precise etiology unknown

SIGNALMENT

- Cats
- Prevalence for sex, age, or breed not reported

SIGNS

- Cats may have a single episode, a life-long recurrent problem, or a continual disease.
- Frequency and severity of each occurrence varies with the individual.
- Comedones, mild erythematous papules, serous crusts, and dark keratin debris develop on the chin and less commonly on the lips.
- Swelling of the chin.
- Severe cases—nodules, hemorrhagic crusts, pustules, cysts, fistulae, severe erythema, alopecia, and pain.
- Pain often associated with bacterial furunculosis.

CAUSES & RISK FACTORS

Precise etiology unknown; may be a disorder of keratinization, poor grooming, abnormal sebum production, immunosuppression, viral infection, or stress.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bacterial folliculitis
- Demodicosis
- Malassezia* infection
- Dermatophytosis
- Neoplasia of sebaceous or apocrine glands
- Eosinophilic granuloma
- Contact hypersensitivity

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Skin scrapings—demodicosis.
- Fungal culture—dermatophytosis.
- Cytology—bacteria, *Malassezia*.
- Biopsy—rarely needed; necessary in selected cases to characterize changes such as cystic follicles, to differentiate acne from other diseases such as demodicosis, infections (bacterial, yeast, or dermatophytes), or to diagnose neoplasia.

PATHOLOGIC FINDINGS

- Mild disease—follicular distention with keratin (comedo), hyperkeratosis, and follicular plugging.
- Severe disease—mild to severe folliculitis and perifolliculitis with follicular pustule formation leading to furunculosis and pyogranulomatous dermatitis.
- Bacteria and *Malassezia* in these lesions are considered secondary invaders and not causative agents.
- Demodex* mites can be primary agents of this disease.

TREATMENT

- Initial treatment—gentle clipping and soakings to soften crusts.
- Continue one or a combination of the therapies listed below until all lesions have resolved.
- Discontinue treatment by tapering medication over a 2- to 3-week period.
- Recurrent episodes—once the recurrence rate is determined, an appropriate maintenance protocol can be designed for each individual.
- Continual episodes—life-long maintenance treatment necessary.

MEDICATIONS

DRUG(S)

Topical

- Shampoo—once or twice weekly with antiseborheic (sulfur-salicylic acid, benzoyl peroxide, or ethyl lactate).
- Cleansing agents—benzoyl peroxide, salicylic acid, chlorhexidine-phthosphingosine.
- Wet wipes—Douxo Chlorhexidine pads®, Malaseb® wipes, MalAcetic® wipes, GlycoZoo® wipes.
- Antibiotic ointment—mupirocin 2%.
- Other topicals—clindamycin or erythromycin solution or ointment.
- Combination topicals—benzoyl peroxide-antibiotic gels (e.g., Benzamycin).
- Topical retinoids—Tretinoin (Retin-A 0.01% gel).
- In severe inflammatory periods 10–14 days of oral prednisolone (1–2 mg/kg q24h) may help to reduce scar tissue formation.

Systemic

- Antibiotics—amoxicillin with clavulanate, cephalosporin, or fluoroquinolone.
- Severe cases may warrant treatment with isotretinoin (Accutane) or cyclosporine, modified (Atopica).
- Demodicosis—oral ivermectin 400 µg/kg daily until mites are cleared.

CONTRAINdications/POSSIBLE INTERACTIONS

- Benzoyl peroxide and salicylic acids—can be irritating.
- Some wipes contain alcohols that can be irritating.
- Systemic isotretinoin—use with caution, if animal will not allow application of topical medications; potential deleterious side effects in human beings (drug interactions and teratogenicity); container should be labeled for animal use only and kept separate from human medications to avoid accidental use; currently difficult to obtain for animal patients.

FOLLOW-UP

- Monitor for relapses.
- Maintenance cleansing programs can be used to reduce relapses. Affected cats are likely to have variable numbers of comedones life-long, often are just cosmetic and treatment is not necessary.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Systemic isotretinoin should not be used on breeding animals.

Author David D. Duclos

Consulting Editor Alexander H. Werner

BASICS

OVERVIEW

- Also called muzzle folliculitis and furunculosis.
- Chronic inflammatory disorder of the chin and lips of young animals.
- Characterized by folliculitis and furunculosis; rarely comedogenic as seen in “true acneiform” lesions of human beings.
- Recognized almost exclusively in short-coated breeds.
- Genetic predisposition and local trauma may play a more important role than hormonal effects.

SIGNALMENT

- Dogs.
- Predisposed short-coated breeds—boxer, Doberman pinscher, English bulldog, Great Dane, Weimaraner, mastiff, rottweiler, German shorthaired pointer, pit bull terrier.

SIGNS

- Ventral chin and lip margins may be minimally to markedly swollen with numerous erythematous papules and pustules.
- Initial lesions are sterile; bacteria may not be isolated and lesions may not respond to antibiotics.
- Advanced stages—lesions may be exudative, indicating secondary deep bacterial folliculitis-furunculosis.
- Lesions may be painful on palpation; most are non-painful and non-pruritic.
- Chronic resolved lesions may be scarred and lichenified.

CAUSES & RISK FACTORS

Some short-coated breeds appear to be genetically predisposed to follicular hyperkeratosis and secondary bacterial infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dermatophytosis
- Demodicosis
- Foreign body
- Contact dermatitis

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Bacterial culture and sensitivity testing—in patients with suppurative folliculitis and furunculosis that are non-responsive to initial antibiotic selection.
- Biopsy—histologic confirmation for cases in which diagnosis is in question.
- Skin scrape—demodicosis.
- Dermatophyte culture—dermatophytosis.

PATHOLOGIC FINDINGS

- Clinical signs and histopathologic findings are diagnostic.
- Initial lesions—hairless follicular papules; characterized histopathologically by marked follicular keratosis, plugging, dilatation, and perifolliculitis.
- Bacteria—not present and cannot be isolated from lesions in early stages.
- As disease progresses, papules enlarge and rupture, promoting a suppurative folliculitis and furunculosis.

TREATMENT

- Depends on the severity and chronicity of the disease.
- Reduce behavioral trauma to the chin (e.g., rubbing on the carpet, chewing bones that increase salivation).
- Frequent cleaning with benzoyl peroxide shampoo or gel.
- Mupirocin 2% ointment to reduce the bacterial numbers on the surface of the skin.
- Instruct owners to avoid expressing the lesions, which may cause internal rupture of the papule and massive inflammation.

MEDICATIONS

DRUG(S)

Topical

- Benzoyl peroxide shampoo or gel (antibacterial).
- Mupirocin 2% ointment (antibacterial-staphylococcus).
- Tretinoin (Retin-A)—may reduce follicular keratosis.
- Corticosteroids—may be necessary to reduce inflammation; limit frequency of use to avoid local and systemic effects.

Systemic

- Antibiotics appropriate for deep bacterial infection—when indicated (e.g., cephalaxin, 22 mg/kg PO q8-12h for 6–8 weeks).
- May need to perform bacterial culture and sensitivity test.
- Isotretinoin (Accutane)—1–2 mg/kg/day.
- Oral corticosteroids: tapering dosages of prednisolone (initial 0.5 mg/kg/day) to reduce significant inflammation; not for continued use.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Benzoyl peroxide—may bleach carpets and fabrics; may be irritating.
- Mupirocin ointments—greasy; may be prudent to reserve for use in multidrug-resistant cases.
- Topical retinoids—may be drying and irritating.
- Topical steroids—may cause adrenal suppression and thinning of skin with repeated use.
- Isotretinoin—may cause keratoconjunctivitis sicca, hyperactivity, ear pruritus, erythema of mucocutaneous junctions, lethargy with vomiting, abdominal distension, anorexia with lethargy, collapse, and swollen tongue; CBC and chemistry screen abnormalities include high platelet count, hypertriglyceridemia, hypercholesterolemia, and high alanine transaminase.

FOLLOW-UP

PATIENT MONITORING

- Continue antibiotics until lesions have healed.
- Repeat bacterial culture/sensitivity if lesions worsen.
- Discontinue topical corticosteroids when possible.

EXPECTED COURSE AND PROGNOSIS

- Long-term topical treatment may be required.
- Chronic scarring may be prevented by early and aggressive therapy.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Synthetic retinoids—teratogens; do not use in pregnant animals, animals intended for reproduction, or intact female animals; should not be handled by women of childbearing age.

Suggested Reading

Author Karen Helton Rhodes

Consulting Editor Alexander H. Werner

ACRAL LICK DERMATITIS

BASICS

OVERVIEW

- Chronic lesions directly caused by self-trauma.
- A cycle of licking, pruritus, and secondary infection develops.

SYSTEMS AFFECTED

Skin/Exocrine

SIGNALMENT

- Dogs.
- Most common in large breeds—especially Doberman pinschers, Labrador retrievers, Great Danes, Irish and English setters, golden retrievers, Akitas, Dalmatians, boxers, Shar-Peis, and Weimaraners.
- Age at onset—varies (especially with cause).
- No sex predilection.

SIGNS

- Excessive licking of the affected area.
- Alopecic, eroded, thickened, and raised firm plaques with scabs and exudation, usually located on the dorsal aspect of the carpus, metacarpus, tarsus, or metatarsus.
- Lesions often occur singly or may be multiple.

CAUSES & RISK FACTORS

- Focal trauma to the area initiating a lick-itch cycle.
- Anything causing a local irritation or lesion may initiate response.
- Associated diseases—staphylococcal furunculosis, hypersensitivity, endocrinopathy, demodicosis, dermatophytosis, foreign body reaction, neoplasia, underlying joint disease or arthritis, trauma, neuropathy, psychogenic, or sensory nerve dysfunction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Neoplasia
- Bacterial furunculosis
- Focal demodicosis
- Focal dermatophytosis

CBC/BIOCHEMISTRY/URINALYSIS

Normal except in cases of endocrinopathy.

OTHER LABORATORY TESTS

Endocrinopathy—free T₄/TSH; ACTH stimulation test or LDDST.

IMAGING

Radiology—neoplasia; local trauma; radiopaque foreign bodies; bony proliferation may be seen secondary to the chronic irritation; evidence of underlying arthritis if over a joint.

DIAGNOSTIC PROCEDURES

- Skin scrapings—demodicosis.

- Dermatophyte culture—fungal infection.
- Epidermal cytology—bacterial infection.
- Bacterial culture and sensitivity—tissue cultures may differ from surface culture.
- Food-elimination diet—determine food allergy.
- Intradermal allergy testing—atopy.
- Biopsy—to rule out neoplasia, other infections.
- Behavioral history.
- Neurologic and orthopedic evaluation.

PATHOLOGIC FINDINGS

Histopathology—epidermal hyperplasia, plasmacytic dermal inflammation, folliculitis, furunculosis, perihidradenitis, hidradenitis, and vertical streaking fibrosis.

TREATMENT

- Behavioral therapy: attempt to identify psychological causes and remediate.
- Physical restraints—Elizabethan collars and bandaging permit healing.
- Therapeutic laser—one controlled study did not demonstrate efficacy.
- Diet—no modification unless food hypersensitivity is suspected.
- Difficult to treat, especially if no underlying cause is found; warn owner that patience and time are necessary.
- Surgery (laser or standard)—may cause increased licking and attention to a larger affected area; if underlying causes are not addressed, recurrence is likely.

MEDICATIONS

DRUG(S)

Antibiotics

- Based on bacterial culture and sensitivity.
- Administer until infection is completely resolved; often at least 6 weeks.

Systemic

- Antihistamines—e.g., hydroxyzine (1–2 mg/kg PO q12h); chlorpheniramine (4–8 mg/dog PO q12h; maximum of 0.5 mg/kg q12h).
- SSRIs: e.g., fluoxetine (1 mg/kg PO q24h); paroxetine (0.5–1 mg/kg PO q24h).
- Dopamine antagonists: e.g., naltrexone (2.2 mg/kg PO q12–24h).
- TCAs: e.g., amitriptyline (1.1–2.2 mg/kg PO q12h; doxepin (3–5 mg/kg PO q12h; maximum 150 mg q12h); clomipramine (1–3.5 mg/kg PO q12–24h).
- Combine and/or withdraw administration of these medications carefully.

Topical

- Flunixin meglumine and flucinolone in dimethyl sulfoxide (combined).
- Topical capsaicin products.
- Intralesional corticosteroids rarely helpful.

- Topical medications should be applied with gloves.
- Animals should be kept from licking the area for 10–15 minutes.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Doxepin—caution using with monoamine oxidase inhibitors, clonidine, anticonvulsants, oral anticoagulants, steroid hormones, antihistamines, or aspirin.
- Antihistamines—may cause sedation.
- Psychotropic medications should be combined and/or withdrawn carefully.
- Cardiotoxicity and hepatotoxicity—rare cases in animals on TCAs. Routine monitoring recommended.

FOLLOW-UP

- Monitor level of licking and chewing closely.
- Treat underlying disease to prevent recurrence.
- If no underlying disease is detected, suspect psychogenic causes (compulsive or self-mutilation disorder); prognosis is guarded.

MISCELLANEOUS

AGE-RELATED FACTORS

Dogs < 5 years old—strongly consider allergy

ZOONOTIC POTENTIAL

- Transmitted to humans only if dermatophytosis is the underlying cause; exceedingly rare.
- Methicillin resistant *Staphylococcus aureus* may have zoonotic implications.

ABBREVIATIONS

- ACTH = adrenocorticotropin hormone
- LDDST = low-dose dexamethasone suppression test
- SSRI = selective serotonin reuptake inhibitor
- TCA = tricyclic antidepressant
- TSH = thyroid stimulating hormone

Acknowledgment The author and editors acknowledge the prior contribution of Jean S. Greek.

BASICS

OVERVIEW

- Syndrome resulting from growth hormone (somatotropin) hypersecretion by tumorous or hyperplastic somatotrophs in the anterior pituitary.
- Clinical signs are due to growth hormone's direct catabolic/diabetogenic effects and its indirect anabolic effects mediated through insulin-like growth factor I, which is secreted by the liver in response to growth hormone stimulation.
- Elevated IGF1 activity induces excessive soft tissue growth, visceral organomegaly, bone remodeling and thickening (especially in bones formed from membranous ossification) resulting in arthropathy, broad facial features, and enlarged "clubbed" paws.
- Myocardial hypertrophy occurs in many cats, but heart failure is uncommon.
- The catabolic actions of GH result from insulin antagonism leading eventually to pancreatic β cell exhaustion and DM. Between 25 and 33% of diabetic cats may have acromegaly.
- Like most diabetic cats the potential for remission remains if the excessive GH production can be normalized; likelihood of remission is inversely related to the duration of DM.

SIGNALMENT

- Cat
- Median age—11 years (range of 6–17 years)
- Approximately 80% are males

SIGNS

- Initial signs relate to unregulated DM with the vast majority of cases presenting with polyuria, polydipsia, and often profound polyphagia accompanied with concurrent weight gain (weight loss has also been reported).
- Many patients gain weight and have increased body size due to increased bone and soft tissue mass, not from increased adipose tissue. Weight gain in an unregulated diabetic cat strongly suggests acromegaly.
- Broadening of facial features, prognathia inferior, and increased paw size reflect long-standing or severe disease.
- Organomegaly—most commonly bilateral renomegaly and hepatomegaly.
- Murmur and/or gallop rhythm occasionally present; signs of heart failure uncommon.
- Lameness may develop.
- Neurologic signs referable to intracranial disease through an expanding pituitary mass lesion possible.
- Recent reports suggest the majority of acromegalic cats are indistinguishable phenotypically from non-acromegalic diabetic cats.

CAUSES & RISK FACTORS

- GH hypersecretion.
- Progestins do not cause GH secretion and acromegaly in cats as they do in dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Uncomplicated DM or DM secondary to hyperadrenocorticism
- Pituitary-dependent hyperadrenocorticism and acromegaly can both produce insulin-resistant DM with an associated pituitary mass lesion. Differentiation may require use of a low-dose dexamethasone suppression test to rule out PDH.
- Acromegaly and PDH can occur concurrently.
- Other disorders causing weight loss with polyphagia, polyuria, and polydipsia such as hyperthyroidism are not usually associated with significant glucose intolerance.
- Insulin-resistant DM (> 2.0 U of insulin/kg/12h) is to be expected in all acromegalic cats and the dose tends to increase over time, with doses of 12–50 U/cat/12h not uncommon.
- Acromegaly should be suspected in any diabetic cat demonstrating signs of otherwise unexplained insulin resistance.

CBC/BIOCHEMISTRY/URINALYSIS

- Most abnormalities attributed to poorly controlled DM—hyperglycemia, glucosuria, and elevated fructosamine levels are consistent findings in most acromegalic cats.
- Hyperproteinemia.
- Traditionally associated with renal failure and hypertension, but more recent studies suggest this is not the case.

OTHER LABORATORY TESTS

- IGF1—diabetic cats receiving insulin can have higher IGF1 levels than normal; hence there is significant potential for overlap between acromegalic and non-acromegalic diabetic cats; however, dramatically elevated IGF1 levels (e.g., $> 1,000$ ng/ml) are strongly suggestive of the acromegaly.
- IGF1 is well preserved across the species, so valid assays are commonly available.
- GH—elevated basal serum levels are diagnostic. However, as GH is not well preserved across the species, a validated fGH assay has limited availability.

IMAGING

- Intracranial imaging to demonstrate a pituitary mass lesion; MRI is more sensitive than contrast-enhanced CT, although the difference is modest and from a cost-benefit perspective CT is generally preferred.
- Echocardiographic abnormalities may include left atrial enlargement, asymmetric

septal and left ventricular free-wall thickening, systolic anterior motion of the mitral valve, and diastolic dysfunction.

- Radiographic changes include increased oropharyngeal soft tissue, degenerative arthropathy with periarticular osteophytosis, spinal spondylosis deformans, and variable abdominal organomegaly.

TREATMENT

RADIOTHERAPY

- The only currently available means of reducing autonomous overproduction of GH from the anterior pituitary. Unfortunately, radiotherapy is more suited to reducing the size of the tumor than achieving clinically significant reductions in GH secretion.
- A total dose of between 3,500 and 5,000 cGy, administered in variably fractionated doses is often suggested. Recent reports suggest that the greatest success may be achieved with a total dose of 3,700 cGy administered as an incremental hypofractionated dosage protocol of 10 doses. Using this method, 13 of 14 acromegalic cats had markedly improved diabetic control.

SURGERY

- Hypophysectomy is considered the treatment of choice in human hypersomatotropism. It has also proven to be the only consistently effective and reliable method to cure HS in cats.
- An experienced neurosurgeon and appropriate pre-, peri- and postoperative care are essential for success. A transsphenoidal approach is currently preferred (incising the soft palate).
- In the long run, cats need to be supplemented with thyroid hormone and a glucocorticoid; synthetic ADH (DDAVP) supplementation can often be ceased 6–8 weeks postoperatively. When performed early in the disease process, diabetic remission is a realistic outcome and often occurs within 2 months after the procedure.

MEDICATIONS

Somatostatin and dopamine agonists have been used to try to inhibit GH secretion by the pituitary, mostly without success. Recently, a novel somatostatin analog, pasireotide (Novartis, Basel, Switzerland) has been shown to be effective at achieving this, although further research is required to evaluate the use of this drug, including dosing regimes, in the long run.

PALLIATIVE TREATMENT

- When definitive treatment is not possible, the focus should lie on gaining more control of the diabetes mellitus and treating possible comorbidities.
- Eventually most cats tend to need high dosages of insulin and/or combinations of short-acting and long-acting insulin types to ensure an adequate quality of life for both pet and owner.
- Nevertheless, a minority achieve an adequate quality of life.
- Regular veterinary assessment is recommended.
- Iatrogenic hypoglycemia is a major concern given the pulsatile nature of GH secretion (and therefore associated insulin resistance).

**FOLLOW-UP**

- Clinical signs that might be attributed to poor diabetic control (e.g., profound polyphagia) will not improve with improved diabetic control; thus levels of glycated proteins or blood glucose levels are better indicators of diabetic control than clinical signs.
- Serum IGF1 levels are not suitable for monitoring therapy as they do not change during or after radiotherapy.
- Reported survival times vary enormously—from a few months to many years, and dying from causes unlikely to be related to acromegaly.

**MISCELLANEOUS***Suggested Reading*

Consulting Editor Deborah S. Greco

BASICS

OVERVIEW

- An infectious disease caused by Gram-positive, branching, pleomorphic, rod-shaped bacteria of the genus *Actinomyces*.
- *A. viscosus* and *A. hordeovulnaris*—most commonly identified isolates (though most isolates are not identified to the species level); survives in microaerophilic or anaerobic conditions.
- Rarely found as the single bacterial agent in a lesion; more commonly, it is a component of a polymicrobial infection.
- There may be synergism between *Actinomyces* and other organisms.
- Organ systems affected may include:
 - Skin
 - Respiratory
 - Cardiovascular
 - Musculoskeletal
 - Nervous

SIGNALMENT

- Dogs and cats (uncommon).
- Most common in young male dogs of sporting breeds.

SIGNS

- Infections—usually localized; may be disseminated; cervicofacial area commonly involved.
- Cutaneous swellings or abscesses with draining tracts—yellow granules (“sulfur granules”) may be seen in associated exudates.
- Pain, fever, and weight loss.
- Exudative pleural or peritoneal effusions; occasionally pericardial effusion noted.
- Cough, dyspnea, decreased ventral lung sounds (empyema).
- Retroperitonitis—lumbar pain; rear limb paresis or paralysis.
- Osteomyelitis of vertebrae or long bones—probably secondary to extension of cutaneous infection; lameness or a swollen extremity may develop.
- Motor and sensory deficits—reported with spinal cord compression by granulomas.
- Pyothorax and subcutaneous bite wounds are the most common presenting signs in cats.

CAUSES & RISK FACTORS

- *Actinomyces* spp. normal inhabitants of the oral cavity of dogs and cats.
- Loss of normal protective barriers (mucosa, skin), immunosuppression, or change in the bacterial microenvironment can predispose; thought to occur as an opportunistic infection.
- Specific risk factors—trauma (bite wound), migrating foreign body (grass awn or, in the western United States, a foxtail), and periodontal disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Nocardiosis—primary differential diagnosis; *Actinomyces* not reliably distinguished from *Nocardia* spp. by Gram staining, cytology, or clinical signs.
- Other causes of chronic

draining tracts and pleural or peritoneal effusions must be addressed.

CBC/BIOCHEMISTRY/URINALYSIS

- Nonspecific changes.
- Leukocytosis with a left shift and monocytosis—reported.
- Nonregenerative anemia—may develop.
- Hypoglycemia and hyperglobulinemia—reported.

IMAGING

- Radiographs of infected bone—periosteal new bone production, reactive osteosclerosis, and osteolysis.
- Thoracic radiographs—alveolar and interstitial lung patterns with possible lung consolidation; pleural effusion; pericardial effusion; subcutaneous masses on lateral thorax.
- Abdominal radiographs—peritoneal effusion; mass effect in abdomen.
- Vertebral column radiographs—periosteal new bone formation, especially T13–L3.

DIAGNOSTIC PROCEDURES

- Pus or osteolytic bone fragments submitted in anaerobic specimen containers for culture (see *Anaerobic Infections*) can provide a definitive diagnosis; inform the lab to check for actinomycosis; advisable to submit aerobic culture, as well.
- Fresh smears—Gram staining, cytology, and acid-fast staining; staining does not preclude the need for culture; *Actinomyces* does not stain acid-fast; *Nocardia* is variable.

PATHOLOGIC FINDINGS

Histopathologic examination—sulfur granules can be difficult to find so multiple tissue sections should be submitted; special stains may enhance visualization of organisms; granules are a useful diagnostic tool when present; pyogranulomatous or granulomatous cellulitis with colonies of filamentous bacteria is characteristic.

TREATMENT

- Exudative fluid (thorax, abdomen, subcutaneous tissue) should be drained and lavaged.
- A chest tube with continuous suction is needed for cats with pyothorax; dogs are best served with surgical exploration of the chest prior to tube placement in order to identify and remove any grass awns.
- Diseased lung lobes may need to be removed.
- Dogs with solitary masses involving the thoracic or abdominal wall may experience cure with radical surgical excision.

MEDICATIONS

DRUG(S)

- Important to distinguish between *Actinomyces* and *Nocardia* for appropriate antimicrobial selection.

- Antibiotics—a retrospective study suggests administration for a minimum of 3–4 months after resolution of all signs; may need to be directed against other associated microbes.
- Penicillins—considered the drug of choice; in most cases, oral therapy can be initiated and parenteral is not needed; amoxicillin should be administered at 20–22 mg/kg q8h PO.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Metronidazole—avoid use; actinomycosis unlikely to respond.
- Aminoglycosides—do not use; ineffective against anaerobic infections.
- *A. hordeovulnaris*—cell-wall deficient variant (l-phase); does not usually respond well to penicillin; consider clindamycin, erythromycin, and chloramphenicol.

FOLLOW-UP

PATIENT MONITORING

Monitor patients closely for recurrence in the months after therapy discontinued.

PREVENTION/AVOIDANCE

Avoidance of contact with grass awns and prevention of bite wounds.

POSSIBLE COMPLICATIONS

Concurrent immune-suppressive disease or therapy may complicate management.

EXPECTED COURSE AND PROGNOSIS

Redevelopment of infection at the initial site may be expected in about half of all cases.

MISCELLANEOUS

AGE-RELATED FACTORS

Young outdoor dogs.

ZOONOTIC POTENTIAL

There are no reported cases of actinomycosis being transmitted from animals to man; transmission by bite wound may be possible so appropriate attention should be given to bite wounds.

ACUTE ABDOMEN

BASICS

DEFINITION

An emergency condition characterized by historical and physical examination findings of a tense, painful abdomen. May represent a life-threatening condition.

PATHOPHYSIOLOGY

- A patient with an acute abdomen has pain associated with either distention of an organ, inflammation, traction on the mesentery or peritoneum, or ischemia.
- The abdominal viscera are sparsely innervated, and diffuse involvement is often necessary to elicit pain; nerve endings also exist in the submucosa-muscularis of the bowel wall.
- Any process that causes fluid or gaseous distension (i.e., intestinal obstruction, gastric dilatation-volvulus, ileus) may produce pain.
- Inflammation produces abdominal pain by releasing vasoactive substances that directly stimulate nerve endings.
- Many nerves in the peritoneum are sensitive to a diffuse inflammatory response.

SYSTEMS AFFECTED

- Behavioral—trembling, inappetence, vocalizing, lethargy, and abnormal postural changes such as the praying position to achieve comfort.
- Cardiovascular—severe inflammation, ischemia, and sepsis may lead to acute circulatory collapse (shock). May be associated with SIRS and septic shock.
- Gastrointestinal—vomiting, diarrhea, inappetence, generalized functional ileus; pancreatic inflammation, necrosis, and abscesses may lead to cranial abdominal pain, vomiting, and ileus.
- Hepatobiliary—jaundice associated with extrahepatic cholestasis from biliary obstruction (including pancreatitis) and bile peritonitis. Hyperbilirubinemia may occur secondary to sepsis.
- Renal/Urologic—azotemia can be due to prerenal causes (dehydration, hypovolemia, and shock), renal causes (acute pyelonephritis and acute renal failure), and post-renal causes (ureteral obstruction, urethral obstruction and uroperitoneum from bladder rupture).
- Respiratory—increased respiratory rate due to pain or metabolic/acid-base disturbances.

SIGNALMENT

- Dogs and cats.
- Dogs more commonly.
- Younger animals tend to have a higher incidence of trauma-related problems, intussusceptions, and acquired diet- and infection-related diseases; older animals have a greater frequency of malignancies.
- Male cats and dogs are at higher risk for urethral obstruction.

- Male Dalmatians in particular have a higher risk of urethral obstruction because of the high incidence of urate urinary calculi.
- German shepherds with pancreatic atrophy have a higher risk of mesenteric volvulus.
- Patients treated with corticosteroids and non-steroidal anti-inflammatory drugs are at higher risk for gastrointestinal ulceration and perforation.

SIGNS

General Comments

Clinical signs vary greatly depending on the type and severity of the disease leading to an acute abdomen.

Historical Findings

- Trembling, reluctance to move, inappetence, vomiting, diarrhea, vocalizing, and abnormal postures (tucked up or praying position)—signs that the owner may notice.
- Question owner carefully to ascertain what system is affected; for example, melena with a history of NSAID treatment may suggest GI mucosal disruption (ulceration).

Physical Examination Findings

- Abnormalities include abdominal pain, splinting of the abdominal musculature, gas- or fluid-filled abdominal organs, abdominal mass, ascites, pyrexia or hypothermia, tachycardia, and tachypnea.
- Once abdominal pain is confirmed, attempt to localize the pain to cranial, middle, or caudal abdomen.
- Perform a rectal examination to evaluate the colon, pelvic bones, urethra, and prostate, as well as for the presence of melena.
- Rule out extra-abdominal causes of pain by careful palpation of the kidneys and thoracolumbar vertebrae.
- Pain associated with intervertebral disc disease often causes referred abdominal guarding and is often mistaken for true abdominal pain. Renal pain can be associated with pyelonephritis.

CAUSES

Gastrointestinal

- Stomach—gastritis, ulcers, perforation, foreign bodies, gastric dilatation-volvulus.
- Intestine—obstruction (foreign bodies, intussusception, hernias), enteritis, ulcers, perforations.
- Rupture after obstruction, ulceration, or blunt or penetrating trauma, or due to tumor growth.
- Vascular compromise from infarction, mesenteric volvulus, or torsion.

Pancreas

- Pain associated with inflammation, abscess, ischemia.
- Pancreatic masses or inflammation obstructing the biliary duct/papilla may cause jaundice.

Hepatic and Biliary System

- Rapid distention of the liver and its capsule can cause pain.

- Biliary obstruction, rupture, or necrosis may lead to bile leakage and peritonitis. Gallbladder mucocele may be identified on ultrasound examination.

Hepatic abscess

Spleen

- Splenic torsion, splenic masses, splenic thrombus, splenic abscess.

Urinary Tract

- Distention is the main cause of pain in the urinary tract.
- Lower urinary tract obstruction can be due to tumors of the trigone area of the bladder or urethra, urinary calculi, or granulomatous urethritis.
- Traumatic rupture of the ureters or bladder are associated with blunt trauma and increased intra-abdominal pressure.
- Urethral tears can be associated with pelvic fractures from acute trauma.
- Free urine in the peritoneal cavity leads to a chemical peritonitis.
- Acute pyelonephritis, acute renal failure, nephroliths, and ureteroliths are uncommon causes of acute abdomen.

Genital Tract

- Prostatitis and prostatic abscess, pyometra; a ruptured pyometra or prostatic abscess can cause endotoxemia, sepsis, and cardiovascular collapse.
- Infrequent causes include ruptures of the gravid uterus after blunt abdominal trauma, uterine torsion, ovarian tumor or torsion, and intra-abdominal testicular torsion (cryptorchid).

Abdominal Wall/Diaphragm

- Umbilical, inguinal, scrotal, abdominal, or peritoneal hernias with strangulated viscera.
- Trauma or congenital defects leading to organ displacement or entrapment in the hernia will lead to abdominal pain if the vascular supply of the organs involved becomes impaired or ischemic.

RISK FACTORS

- Exposure to NSAIDs or corticosteroid treatment (increased risk when used concurrently)—gastric, duodenal, or colonic ulcers.
- Garbage or inappropriate food ingestion—pancreatitis.
- Foreign body ingestion—intestinal obstructions.
- Abdominal trauma—hollow viscus rupture.
- Hernias—intestinal obstruction/strangulation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Renal-associated pain, retroperitoneal pain, spinal or paraspinal pain, and disorders causing diffuse muscle pain may mimic abdominal pain; careful history and physical

(CONTINUED)

examination are essential in pursuing the appropriate problem.

- Parvoviral enteritis can present similarly to intestinal obstructive disease; fecal parvoviral antigen assay and CBC (leukopenia) are helpful differentiating diagnostic tests.

CBC/BIOCHEMISTRY/URINALYSIS

- Inflammation or infection may be associated with leukocytosis or leukopenia.
- Anemia may be seen with blood loss associated with GI ulceration.
- Azotemia is associated with prerenal, renal, and post-renal causes.
- Electrolyte abnormalities can help to evaluate GI disease (i.e., hypochloremic metabolic alkalosis with gastric outflow obstruction) and renal disease (i.e., hyperkalemia with acute renal failure or post-renal obstruction).
- Hyperbilirubinemia and elevated hepatic enzymes help localize a problem to the liver or biliary system.
- Urine specific gravity (before fluid therapy) is needed to help differentiate prerenal, renal, and post-renal problems.
- Urine sediment may be helpful in acute renal failure, ethylene glycol intoxication, and pyelonephritis.

OTHER LABORATORY TESTS

- Venous blood gas analysis including lactate concentration may indicate acid-base abnormalities, and increased lactate may be associated with hypoperfusion.
- Canine and feline pancreatic lipase immunoreactivity can be useful in evaluating pancreatitis.

IMAGING

Abdominal Radiography

- May see abdominal masses or changes in shape or shifting of abdominal organs.
- Loss of abdominal detail with abdominal fluid accumulation is an indication for abdominocentesis.
- Free abdominal gas is consistent with a ruptured GI viscus or infection with gas-producing bacteria and is an indication for emergency surgery.
- Use caution when interpreting radiographs following abdominocentesis with an open needle. Free gas may be introduced with this technique.
- Use caution when evaluating postoperative radiographs; free gas is a normal postoperative finding.
- Ileus is a consistent finding with peritonitis.
- Characterize ileus as functional (due to metabolic or inflammatory causes) or mechanical (due to obstruction).
- Foreign bodies may be radiopaque.
- Upper GI barium contrast radiographs are useful in evaluating the GI tract, particularly for determination of GI obstruction.
- Loss of contrast or radiographic detail in the area of the pancreas can be observed with pancreatic inflammation.

Abdominal Ultrasound

- A sensitive diagnostic tool for the detection of abdominal masses, abdominal fluid, abscesses, cysts, lymphadenopathy, and biliary or urinary calculi.
- FAST ultrasound is a published technique meaning Focused Assessment with Sonography in Trauma.

Abdominal CT

- Very sensitive diagnostic tool that may be used especially when surgeon requires additional information.

DIAGNOSTIC PROCEDURES

Abdominocentesis/Abdominal Fluid Analysis

- Perform abdominocentesis on all patients presenting with acute abdomen. Four-quadrant approach may improve yield. Fluid can often be obtained for diagnostic evaluation even when only a small amount of free abdominal fluid exists, well before detectable radiographic sensitivity. Ultrasound is much more sensitive than radiography for the detection of fluid and can be used to direct abdominocentesis. Blind abdominocentesis can be performed safely without ultrasound guidance. Abdominal fluid analysis with elevated WBC count, degenerate neutrophils, and intracellular bacteria is consistent with septic peritonitis and is an indication for immediate surgery.
- Diagnostic peritoneal lavage can be performed by introducing sterile saline (10–20 mL/kg) and performing abdominocentesis with or without ultrasound guidance.
- Measurement of glucose concentration in abdominal effusion in comparison with peripheral blood may aid in the diagnosis of septic abdomen. A blood-to-abdominal fluid glucose difference of > 20 mg/dL is consistent with septic effusion.
- Pancreatitis patients may have an abdominal effusion characterized as a non-septic (sterile) peritonitis.
- Creatinine concentration higher in abdominal fluid than in serum indicates urinary tract leakage.
- Similarly, higher bilirubin concentration in abdominal fluid than in serum indicates bile peritonitis.

Sedation and Abdominal Palpation

- Because of abdominal splinting associated with pain, thorough abdominal palpation is often not possible without sedation; this is particularly useful for detecting intestinal foreign bodies that do not appear on survey radiographs.

Exploratory Laparotomy

- Surgery may be useful diagnostically (as well as therapeutically) when ultrasonography (or other advanced imaging) is not available or when no definitive cause of the acute abdomen has been established with appropriate diagnostics.

ACUTE ABDOMEN

A

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient management with supportive care until decision about whether the problem is to be treated medically or surgically. Early intervention with surgery is important when indicated.
- Aggressive therapy and prompt identification of the underlying cause is very important.
- Many causes of acute abdominal pain require emergency surgical intervention.
- Keep patient NPO if vomiting, until a definitive cause is determined and addressed.
- Intravenous fluid therapy is usually required because of the large fluid loss associated with an acute abdomen; the goal is to restore the normal circulating blood volume.
- If severe circulatory compromise (shock) exists, supplement initially with isotonic crystalloid fluids (90 mL/kg, dogs; 70 mL/kg, cats) over 1–2 hours; hypertonic fluids or colloids may also be beneficial if refractory to isotonic crystalloids or hypoproteinemic.
- Evaluate hydration and electrolytes (with appropriate treatment adjustments) frequently after commencement of treatment.

DIET

Early nutritional support important, especially in order to maintain GI mucosal barrier. Nutritional support can be enteral (oral, nasoesophageal, esophageal tube, gastrostomy tube, enterostomy tube) or parenteral.

SURGICAL CONSIDERATIONS

- Many different causes of an acute abdomen (with both medical and surgical treatments) exist; make a definitive diagnosis whenever possible prior to surgical intervention.
- This can prevent both potentially unnecessary and expensive surgical procedures and associated morbidity and mortality.
- It will also allow the surgeon to prepare for the task and to educate the owner on the prognosis and financial investment.

MEDICATIONS

DRUG(S)

Analgesics

- Pain medication may be indicated for control of abdominal discomfort.
- Opioids, such as hydromorphone or fentanyl, are often good choices.

Histamine H₂ Antagonists

- Reduce gastric acid production.
- Famotidine 0.5–1.0 mg/kg IV, SC or IM q12h.
- Ranitidine 2 mg/kg IV q12h

Proton Pump Inhibitor

Pantoprazole 1–1.5 mg/kg IV as a CRI over 24 hours.

Protectants

Sucralfate 0.25–1 g PO q8h.

Antiemetics

- Metoclopramide 0.2–0.4 mg/kg IV q6–8h (or 24-hour continuous rate infusion 1–2 mg/kg/24h).
- Maropitant: dogs, 1–2 mg/kg SC; cats, 1 mg/kg SC
- Ondansetron 0.5–1 mg/kg IV slowly q6–12h.
- Dolasetron 1 mg/kg IV q24h.

Antibiotics

- Antibiotics may be indicated if signs of infection (fever, elevated white blood cell count, positive culture) are seen or hemorrhagic diarrhea is present.
- Broad spectrum for Gram-positive, Gram-negative, and anaerobic bacteria.
- Gram stain and cultures prior to treatment if possible, but do not delay intervention pending results.

CONTRAINDICATIONS

Do not use metoclopramide if GI obstruction is suspected. Do not use barium if gastrointestinal perforation is suspected. Use iodinated contrast agent instead.

PRECAUTIONS

Gentamicin and most NSAIDs can be nephrotoxic and should be used with caution in hypovolemic patients and those with renal impairment. Opiates are preferred to NSAIDs for pain management as NSAIDs may cause GI complications.

**FOLLOW-UP****PATIENT MONITORING**

Patients usually require intensive medical care and frequent evaluation of vital signs and laboratory parameters.

ACUTE RESPIRATORY DISTRESS SYNDROME

BASICS

DEFINITION

• Acute respiratory distress syndrome (ARDS) is a syndrome of acute onset of respiratory failure typified by diffuse bilateral pulmonary infiltrates on a dorsoventral thoracic radiograph with no clinical evidence of left atrial hypertension or volume overload. ARDS results from an overwhelming inflammatory reaction in the alveolocapillary membrane in response to a systemic or pulmonary inflammatory insult. The end result is increased vascular permeability leading to edema. • The 2012 Berlin Definition of ARDS defines three categories of severity based on $\text{PaO}_2/\text{FiO}_2$ ratio and level of PEEP employed during ventilation, with mild ARDS defined by a PF ratio of 200–300 mmHg with PEEP ≥ 5 mmHg, moderate ARDS as a PF ratio of 100–200 mmHg with PEEP ≥ 5 mmHg, and severe ARDS as a PF ratio < 100 mmHg with PEEP ≥ 5 mmHg.

PATOPHYSIOLOGY

• ARDS is due to a diffuse inflammatory insult that causes widespread damage to alveolar endothelial and epithelial cells resulting in thickening of the membrane and impaired gas exchange. This inflammatory insult can be triggered by primary pulmonary disease or it can be of non-pulmonary origin, and leads to exudative, proliferative, and fibrotic changes within the lung: • First, excessive accumulation and activation of neutrophils, monocytes, and platelets in the pulmonary microvasculature leads to increased alveolar endothelial permeability. This causes protein-rich edema fluid and inflammatory cells to leak into the interstitial and alveolar spaces. • Alveolar epithelial injury results from release of cytokines and other inflammatory mediators from leukocytes and platelets. • Epithelial injury involves both type I and type II alveolar epithelial cells, and results in alveolar flooding and surfactant dysfunction. This causes collapse and consolidation of alveoli with development of severe hypoxemia, and hyaline membrane formation in the alveolar spaces. • Microthrombi in the pulmonary vasculature, hypoxic pulmonary vasoconstriction, and release of endogenous vasoconstrictors lead to pulmonary arterial hypertension, which can lead to right-sided heart failure. • Proliferation of type 2 alveolar epithelial cells and pulmonary fibrosis occurs in the late stages of ARDS.

SYSTEMS AFFECTED

• Respiratory. • Cardiovascular—right-sided heart failure secondary to pulmonary hypertension; hemodynamic compromise may be associated with aggressive mechanical ventilator settings.

GENETICS

Certain humans are more prone to developing ARDS than others due to specific gene polymorphisms. This has not been investigated in the veterinary population.

INCIDENCE/PREVALENCE

Unknown

SIGNALMENT

Species

Dog and cat

Breed Predilections

A familial form of ARDS has been reported in a group of related Dalmatian dogs; it is clinically indistinguishable from ARDS.

Mean Age and Range

Unknown

SIGNS

Historical Findings

• Acute onset of respiratory distress in a patient with a significant underlying disease or exposure to known risk factors. • The patient is often hospitalized for its primary disease when it develops ARDS.

Physical Examination Findings

- Severe respiratory distress
- Crackles (if present) heard bilaterally on auscultation
- Fever—depends on underlying disease
- Cyanosis in more severe cases
- Signs relevant to the primary disease process.

CAUSES

Primary Pulmonary Causes

- Aspiration pneumonia
- Pneumonia
- Pulmonary contusion
- Near drowning
- Smoke inhalation
- An idiopathic form of ARDS associated with acute interstitial pneumonia or idiopathic pulmonary fibrosis has been reported in humans and dogs.

Non-pulmonary Causes

- SIRS
- Sepsis
- Neoplasia
- Pancreatitis
- Severe trauma and shock
- Severe bee sting envenomation

RISK FACTORS

- SIRS
- Sepsis
- Severity of illness
- Multiple transfusions

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Left-sided congestive heart failure
- Fluid overload
- Diffuse pneumonia
- Pulmonary hemorrhage

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis or leukopenia
- Other changes dependent on the underlying disease process

OTHER LABORATORY TESTS

• Arterial blood gases—low $\text{PaO}_2/\text{FiO}_2$ ratio (where PaO_2 is measured in mmHg and FiO_2 is 0.21–1.0). Normal $\text{PaO}_2/\text{FiO}_2$ ratio = 500; comparison of this ratio allows evaluation of severity of lung disease and allows direct

comparison of blood gases taken at different FiO_2 . PaCO_2 is often low; hypercapnia tends to be a late (preterminal) development.

- Total protein of airway edema fluid compared with serum total protein—ratio of edema fluid to serum total protein < 0.5 is supportive of low-protein hydrostatic pressure pulmonary edema (e.g., heart failure, fluid overload); edema fluid/serum total protein ratio > 0.7 suggests a high-protein, increased permeability pulmonary edema such as ARDS and pneumonia. • Coagulation panel may reveal hypocoagulable state supportive of DIC or cause of pulmonary hemorrhage.

IMAGING

Thoracic Radiographs

- Bilateral/diffuse pulmonary infiltrates.
- Severity of radiographic signs can lag behind clinical disease by 12–24 hours. • Can be difficult to distinguish from cardiogenic edema. Cardiac silhouette and pulmonary vascular size is usually normal in ARDS.

Echocardiography

- Attempt to rule out cardiogenic cause for pulmonary edema. • May be able to estimate degree of pulmonary hypertension.

DIAGNOSTIC PROCEDURES

Pulmonary artery catheter to measure pulmonary artery occlusion pressure can be used to rule out cardiogenic cause for edema; by definition, ARDS is associated with PAOP ≤ 18 mmHg.

PATHOLOGIC FINDINGS

Gross Pathology

Lungs are dark, heavy, and ooze fluid when cut.

Histopathology

- Acute phase—pulmonary vascular congestion with edema fluid and inflammatory cell accumulation in the interstitium and alveoli; epithelial cell damage, hyaline membrane formation, microthrombi, microatelectasis.
- Proliferative phase—hyperplasia of type 2 pneumocytes, interstitial mononuclear infiltration, organization of hyaline membranes, and fibroproliferation.

TREATMENT

APPROPRIATE HEALTH CARE

- There is no specific therapy. General aims are to maintain tissue oxygenation and to minimize iatrogenic lung injury while treating the underlying disease. • Oxygen therapy—no more than is required to maintain $\text{PaO}_2 > 60$ –80 mmHg to minimize oxygen toxicity. • Positive-pressure ventilation is essential in the management of ARDS patients. It is indicated in patients that are hypoxic despite oxygen therapy, patients requiring high levels of inspired oxygen for

ACUTE RESPIRATORY DISTRESS SYNDROME

(CONTINUED)

prolonged periods, or patients working so hard to breathe that they are at risk of exhaustion. • ARDS is thought to be exacerbated by ventilator-induced lung injury associated with alveolar overdistension compounded by cyclic opening and collapse of atelectatic alveoli. Therefore, lung-protective strategies of positive-pressure ventilation with moderate to high PEEP, low tidal volumes, and permissive hypercapnia are recommended to minimize ventilator-induced lung injury. Tidal volumes of 6 mL/kg have been found to increase survival significantly in human ARDS patients compared to tidal volumes of 12 mL/kg. • Recruitment maneuvers and high levels of PEEP can both cause significant hemodynamic compromise and patients should have constant direct arterial blood pressure monitoring.

- Intensive supportive care of the cardiovascular system and other organ systems is vital, as these patients are at high risk for development of multiple organ dysfunction.

NURSING CARE

- Monitor temperature closely, especially if using an oxygen cage, as animals with excessive work of breathing can easily become hyperthermic. • Ventilator patients require frequent position changes and physical therapy; regular oral care with a dilute chlorhexidine solution is important to reduce oral colonization with bacteria as a source of sepsis, and frequent endotracheal tube suctioning is needed to prevent occlusion. Inflate cuff carefully and change endotracheal cuff position regularly to prevent tracheal damage. • Blood pressure monitoring, as septic patients are prone to hypotension.
- Fluid therapy is important to support the cardiovascular system and to maintain normovolemia while avoiding fluid overload, as this will negatively affect lung function.

ACTIVITY

If not anesthetized for ventilation, strict cage confinement.

DIET

Nutritional support is important but challenging. Enteral feeding is desired over parenteral nutrition, but must consider high risk of regurgitation and aspiration in a recumbent patient.

CLIENT EDUCATION

Clients need to be aware of the guarded prognosis and high costs of therapy.

SURGICAL CONSIDERATIONS

The underlying disease may require surgery.

MEDICATIONS

DRUG(S) OF CHOICE

- No specific drug therapy.

- Antibiotics for the underlying disease where indicated.
- Vasoactive drugs to maintain blood pressure.
- Anesthetic drugs to allow positive-pressure ventilation.
- Analgesia as appropriate.
- Low-dose corticosteroid—use remains controversial with conflicting reports of efficacy for low-dose steroids in early or late ARDS.

ALTERNATIVE DRUG(S)

Furosemide may produce pulmonary venous dilation and improve lung function, as an intermittent bolus of 1 mg/kg IV q6–12h or as a CRI of 0.2 mg/kg/h IV. Beware dehydration and effects on organ function.

FOLLOW-UP

PATIENT MONITORING

Arterial blood gases, pulse oximetry, end-tidal carbon dioxide, thoracic radiographs, arterial blood pressure, ECG, temperature, urine output, CBC, coagulation profiles, serum chemistry, blood cultures, monitoring for other organ dysfunction.

PREVENTION/AVOIDANCE

- Aggressive therapy of primary disease processes to reduce the inflammatory insult to the lung. • Intensive cardiovascular monitoring and support of critically ill animals to ensure adequate tissue perfusion.
- Careful management of recumbent animals to reduce the chance of aspiration, especially if patient has neurologic disease or upper airway disorders that reduce the ability to protect the airway. • Judicious use of blood products in patients with inflammatory or severe systemic disease.

POSSIBLE COMPLICATIONS

- Multiorgan dysfunction syndrome—acute kidney injury, DIC, and gastrointestinal disease are the more common forms of organ dysfunction seen. • Barotrauma—can result in pneumothorax. Incidence is thought to be less with lower tidal volume ventilation strategies. • Ventilator-associated pneumonia—patients on PPV have increased risk of pneumonia that may be difficult to differentiate from worsening of the initial lung injury. Airway cultures should be considered in deteriorating patients.
- Oxygen toxicity may be unavoidable due to severity of hypoxemia in spite of PPV. Oxygen toxicity is indistinguishable from ARDS on histopathology making the incidence of this problem impossible to determine.

EXPECTED COURSE AND PROGNOSIS

- Mortality in human patients remains at 40–60%. • Mortality in veterinary patients likely approaches 100%.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Systemic inflammatory response syndrome, multiple organ dysfunction syndrome, sepsis.

SYNOMYMS

- Acute hypoxic respiratory failure • Acute interstitial pneumonia • Adult respiratory distress syndrome • High-protein pulmonary edema • Shock lung

SEE ALSO

- Dyspnea and Respiratory Distress • Panting and Tachypnea • Pulmonary Edema, Noncardiogenic • Sepsis and Bacteremia

ABBREVIATIONS

- ARDS = acute respiratory distress syndrome • CRI = constant rate infusion
- DIC = disseminated intravascular coagulation • PAOP = pulmonary artery occlusion pressure (formerly pulmonary capillary wedge pressure [PCWP]) • PEEP = positive end-expiratory pressure • PF ratio = $\text{PaO}_2/\text{FiO}_2$ ratio • PPV = positive-pressure ventilation • SIRS = systemic inflammatory response syndrome

Consulting Editor Lynelle R. Johnson

BASICS

OVERVIEW

- Malignant neoplasm derived from apocrine glands of the anal sac.
- Locally invasive.
- High metastatic rate, often to sublumbar lymph nodes.
- Frequently associated with hypercalcemia, secondary to parathyroid hormone-related peptide secretion.
- Prognosis guarded to fair.

SIGNALMENT

- Older dogs; extremely rare in cats.
- Females overrepresented in some studies.
- English cocker spaniels significantly overrepresented, springer and Cavalier King Charles spaniels also overrepresented.

SIGNS

Historical Findings

Signs may be due to physical obstructive nature of primary tumor (rectal mass, tenesmus) or enlarged local lymph node metastasis (tenesmus, constipation, stranguria), or systemic manifestations due to hypercalcemia (anorexia, polyuria/polydipsia, lethargy).

Physical Examination Findings

- Mass associated with anal sac; may be quite small despite massive metastatic disease.
- Sublumbar lymphadenopathy—on rectal or abdominal palpation.

CAUSES & RISK FACTORS

None definitively identified

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anal sac abscess
- Perianal adenoma/adenocarcinoma
- Mast cell tumor
- Lymphoma
- Squamous cell carcinoma
- Perineal hernias

CBC/BIOCHEMISTRY/URINALYSIS

- Hypercalcemia—25–50% of cases.
- Secondary renal failure may develop.

OTHER LABORATORY TESTS

If hypercalcemia is present, and tumor cannot be identified, parathyroid hormone and PTHrP levels can be assessed—high PTHrP support neoplasia as the cause of hypercalcemia.

IMAGING

- Abdominal radiography—to evaluate sublumbar lymph nodes and lumbar and pelvic bones.
- Thoracic radiography—to evaluate for pulmonary metastasis.
- Abdominal ultrasonography—may identify mildly enlarged sublumbar lymph nodes not visible radiographically, also nodules in liver/spleen.
- MRI—recently shown to identify lymphadenopathy with greater sensitivity than ultrasound.

DIAGNOSTIC PROCEDURES

- Fine-needle aspiration of anal sac mass to rule out conditions other than adenocarcinoma; while differentiation of benign versus malignant neoplasm of perianal masses is difficult, apocrine gland adenocarcinoma of the anal sac will have a neuroendocrine appearance and can be differentiated from perianal gland tumors.
- Fine-needle aspiration of enlarged lymph nodes, liver, or splenic nodules to confirm metastasis.
- Incisional biopsy for histopathology required for definitive diagnosis, although excisional biopsy may be appropriate if location of mass and cytology are supportive of anal gland neoplasia.

TREATMENT

- Surgical resection—treatment of choice.
- Resection of primary tumor and enlarged lymph nodes may prolong survival.
- If mass is large and regionally invasive at diagnosis, surgery often palliative, not curative.
- Debulking all disease present may control hypercalcemia until tumor recurrence.
- Saline diuresis (200–300 mL/kg/day) preoperatively if hypercalcemia is severe.
- Radiation may help delay local recurrence and control growth of sublumbar metastases.

MEDICATIONS

DRUG(S)

- Limited reports of partial responses to platinum compounds in dogs—cisplatin (70 mg/m^2 IV with 6-hour saline diuresis— 18.3 mL/kg/h), carboplatin (300 mg/m^2 IV as a slow bolus) every 3 weeks.
- Mitoxantrone (5 mg/m^2 IV every 3 weeks for five treatments) in combination with radiation therapy used in one small case series.
- Possible role for melphalan after debulking surgery (7 mg/m^2 PO q24h for 5 days every 3 weeks).
- Toceranib phosphate reported to have some benefit (partial response or stable disease) in 28 dogs with measurable tumor.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Avoid platinum chemotherapeutic agents in dogs with renal insufficiency.
- Do not use cisplatin in cats.

FOLLOW-UP

PATIENT MONITORING

- Complete resection—physical examination, thoracic radiography, abdominal ultrasonography, and serum biochemistry at 1, 3, 6, 9, and 12 months postoperatively,

then every 6 months thereafter.

- Incomplete resection—monitor tumor size and blood calcium and renal values.

EXPECTED COURSE AND PROGNOSIS

- Guarded prognosis with both local progression and metastasis occurring.
- Cures may occur if tumor is found early and treated aggressively.
- Growth of the tumor may be slow and debulking lymph node metastatic disease may significantly prolong survival.
- Hypercalcemia is variably associated with a poor prognosis.
- Four papers (involving 200 dogs) showed median survival times of 6 to 20 months, depending on stage and treatment.
- A recent report on 16 dogs without metastasis showed a median survival time not met with a follow-up of 33 months.
- Dogs with lymph node metastasis lived significantly longer if the nodes were extirpated.
- Ultimately, dogs that cannot have their tumors excised completely succumb to hypercalcemia-related complications or mass effect from primary tumor or sublumbar nodal metastases.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Hypercalcemia as a paraneoplastic syndrome

ABBREVIATION

PTHrP = parathyroid hormone-related peptide

Author Laura D. Garrett

Consulting Editor Timothy M. Fan

Client Education Handout
available online

ADENOCARCINOMA, LUNG

BASICS

OVERVIEW

- Comprises 75% of primary pulmonary tumors in dogs and cats.
- Strongest predictors of outcome are tumor grade, node involvement, and clinical signs.
- May metastasize.
- May be associated with hypertrophic osteopathy.

SIGNALMENT

Dogs

- 1% of all tumors
- Mean age of affected animals 10 years
- No sex predilection, though more females in some reports
- Medium to large breeds overrepresented

Cats

- Rarer than in dogs
- Mean age of affected animals 11 years
- No breed predilection

SIGNS

Historical Findings

- Related to presence of a lung mass
- Nonproductive cough (> 50% of dogs)
- Dyspnea (may be related to pneumothorax)
- Tachypnea ◦ Hemoptysis • Paraneoplastic signs:
 - Lameness—bone metastasis or hypertrophic osteopathy (dogs or cats), weight-bearing lytic digit metastasis (cats)
 - Polyuria or polydipsia—hypercalcemia or hyperadrenocorticism from ectopic production of ACTH ◦ Fever

Physical Examination Findings

- May be asymptomatic or lack respiratory signs
- Tachypnea and dyspnea
- Fever
- Limb swelling
- Ascites, pleural effusion
- Caval syndrome

CAUSES & RISK FACTORS

Some evidence correlates risk to urban environment; controversial

DIAGNOSIS

- Fine-needle aspirate cytology
- Tissue biopsy or definitive resection

DIFFERENTIAL DIAGNOSIS

- Granulomatous lesion (fungal, foreign body, parasitic)
- Pulmonary abscess
- Other primary lung tumor:
 - Squamous cell carcinoma
 - Sarcomas (osteo-, chondro-, lipo-)
- Metastatic lung tumor
- Pneumonia
- Asthma
- Pulmonary thromboembolism
- Congenital cyst
- Lung torsion or hematoma

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities

OTHER LABORATORY TESTS

Coagulation tests

IMAGING

- Thoracic radiography—usually demonstrates a focal, solitary,

well-circumscribed mass; must be performed in cats presenting with multiple digit tumors to screen for primary lung tumor (lung-digit syndrome).

- Ultrasonography—may help with obtaining an aspirate or biopsy specimen from lung, or to evaluate abdomen.
- CT—most accurate assessment of surgical feasibility, lymphadenopathy (93% accuracy), metastatic disease.
- Dogs—most common in right caudal lung lobe and accessory lobe; cats—most common in left caudal lung lobe.

DIAGNOSTIC PROCEDURES

- Thoracocentesis with cytologic examination (for pleural effusion).
- Cytology—transthoracic fine-needle aspiration (83% agreement with histopathology).
- Percutaneous tissue biopsy—use Tru-Cut instrument.
- Open lung biopsy—specimen via thoracotomy, or minimally invasive thoracoscopy.

PATHOLOGIC FINDINGS

- Adenocarcinoma—classified according to location (bronchial, bronchiolar, bronchiolar-alveolar, or alveolar) and degree of differentiation.
- Thyroid transcription factor-1 positivity may distinguish primary from metastatic carcinoma.
- Cats tend to have less differentiated tumors, corresponding to more aggressive behavior.

TREATMENT

- Surgery—mainstay of treatment: partial or complete lobectomy with tracheobronchial lymph node biopsy or removal; thoracoscopic removal possible at limited centers and offers less postoperative morbidity.
- Radiotherapy—reports are anecdotal, but certain patients may benefit.
- Chemotherapy should be considered following surgery for tumors that are high grade, undifferentiated, and/or have nodal involvement. Intracavitary chemotherapy can be used to treat malignant pleural effusion.

MEDICATIONS

DRUG(S)

- Chemotherapy—vinorelbine concentrates in lungs and responses have been seen.
 - Doxorubicin, cisplatin, carboplatin, mitoxantrone, vinorelbine, and/or vindesine—rational choices for palliation
 - Platinum based or gemcitabine chemotherapy may be superior
 - Toceranib Phosphate (Palladia) has shown some anecdotal success
- Chemotherapy can be toxic; seek advice if unfamiliar with cytotoxic drugs.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Doxorubicin—monitor patients with underlying cardiac disease carefully; consider pretreatment with diphenhydramine and serial echocardiograms and ECGs.
- Cisplatin—do not give to cats (fatal); do not use in dogs with pre-existing renal disease; never use without appropriate and concurrent diuresis.

FOLLOW-UP

PATIENT MONITORING

- Serial thoracic radiographs—consider every 3 months; administer a minimum of two cycles of chemotherapy before evaluating response to treatment.
- Perform CBC (with any chemotherapy), biochemical analysis (cisplatin), and urinalysis (cisplatin) before each chemotherapy treatment.

POSSIBLE COMPLICATIONS

- Following diagnostic procedures or thoracotomy: pneumo- or hemothorax
- Resulting from chemotherapy: myelosuppression, fever, sepsis, nausea

EXPECTED COURSE AND PROGNOSIS

- Metastasis to the tracheobronchial lymph nodes—single best prognostic indicator; median survival without metastasis approaches 1 year and with metastasis, 60 days. More common (75%) in cats.
- Postoperative survival in dogs (~1 yr) is better than in cats (~4 mo), but around 2 years in either species if positive prognostic factors are present.
- Other patient, tumor, and treatment factors influencing prognosis—complete surgical excision; size of the primary tumor (< 5 cm better); metastasis (better if none); degree of cell differentiation (histologic score, better if well differentiated), lack of clinical signs prior to surgery.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Chemotherapy is not advised in pregnant animals.

ABBREVIATIONS

ACTH = adrenocorticotrophic hormone

BASICS

DEFINITION

Malignant neoplasm involving the nasal cavity and paranasal sinuses.

PATHOPHYSIOLOGY

Progressive local and regional invasion of the nasal cavity, paranasal sinuses, and surrounding tissues by neoplastic epithelial and glandular epithelial cells.

SYSTEMS AFFECTED

- Respiratory—congestion, obstruction, dyspnea, epistaxis, mucopurulent nasal discharge
- Nervous—seizures, altered mentation
- Ophthalmic—exophthalmos, epiphora

INCIDENCE/PREVALENCE

- In dogs, less than 2% of all tumors are nasal tumors.
- In dogs, adenocarcinoma is more common than squamous cell carcinoma, chondrosarcoma, and other histologies, comprising 31.5% of all nasal tumors.
- In cats, nasal tumors comprise < 1% of all tumors. In cats, adenocarcinoma and lymphoma are most common.

GEOGRAPHIC DISTRIBUTION

Nasal adenocarcinomas are more commonly reported in urban areas.

SIGNALMENT

- Dog and cat.
- Median age in dogs is 10 years and 13 years in cats.
- In dogs, medium to large breeds affected more commonly with a possible overrepresentation of mesocephalic and dolichocephalic breeds.

SIGNS

Historical Findings

- Intermittent and progressive history of unilateral to bilateral epistaxis and/or mucopurulent discharge that initially responds to antibiotic therapy (median duration, 3 months).
- Sneezing and increased upper respiratory noises including reverse sneezing.
- Open-mouth breathing.
- Halitosis.
- Anorexia (more frequent in cats).
- Seizures (secondary to invasion of cranial vault).

Physical Examination Findings

- Nasal discharge (blood, mucopurulent)
- Decreased or absent airflow in the nasal passages (unilateral or bilateral)
- Facial deformity, exophthalmos, epiphora
- Pain upon nasal or paranasal sinus palpation or upon opening the mouth
- Regional lymphadenomegaly (rare)
- Abnormal mentation or other neurologic findings (rare)

CAUSES

Dolichocephalic morphology, p53 mutations, and COX-2 overexpression may all play a role.

RISK FACTORS

Urban environment and second-hand smoke may be risk factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other sinonasal tumors (e.g., squamous cell carcinoma, lymphoma, sarcomas, olfactory neuroblastoma)
- Intracranial neoplasia
- Viral infection—cats
- Fungal infections including aspergillosis (dogs) and cryptococcosis (cats)
- Bacterial sinusitis
- Parasites (e.g., nasal mites)
- Foreign body
- Trauma
- Tooth root abscess and oronasal fistula
- Coagulopathies
- Ehrlichiosis, leishmaniasis
- Systemic hypertension

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal
- Occasional blood loss anemia

OTHER LABORATORY TESTS

- Cytologic examination: occasionally helpful (e.g., aspirates of the subcutaneous mass if facial deformity)
- Coagulation profile

IMAGING

- Survey skull radiography—not sensitive; may show asymmetrical destruction of turbinates accompanied by a soft tissue mass effect; may see fluid density in the frontal sinuses secondary to outflow obstruction.
- Thoracic radiography—evaluate for lung metastasis (uncommon).
- CT or MRI best imaging method for local staging and observing integrity of cribriform plate or orbital invasion, and also used for therapeutic planning.

DIAGNOSTIC PROCEDURES

- Blood pressure.
- Oral exam under anesthesia.
- Rhinoscopy may permit visual observation of the mass and aid biopsy..
- Tissue biopsy necessary for definitive diagnosis. Biopsies may be performed blind, following advanced imaging, using pinch biopsy instrument including retroflex rhinoscopic biopsy of nasopharynx, cannula (closed suction), or hydropulsion techniques.
- Cytologic evaluation of regional lymph nodes to detect regional metastatic disease.

PATHOLOGIC FINDINGS

- Bilateral involvement and osteolysis common.

- Regional lymph node metastasis < 10% at time of diagnosis but up to 45% at necropsy.

TREATMENT

APPROPRIATE HEALTHCARE

- Radiation therapy is the standard of care.
- Radiation therapy can be administered with curative intent (definitive) or for palliation of clinical signs.
- Definitive radiation involves multiple fractions for a high total dose.
- Palliative radiation uses a low total dose to minimize toxicity while improving the quality of life through reduction of tumor size.
- Novel radiation techniques including IMRT and stereotactic radiation therapy may decrease risk of late toxicity while improving tumor control.
- Combining radiation therapy with novel drug therapy (toceranib phosphate (Palladia), others) appears safe and well tolerated.
- Radiation therapy followed by surgery to debulk residual mass may improve local control time but results in higher risk of late toxicity.
- Surgery alone considered ineffective with most tumors relapsing within 6 months.

NURSING CARE

- During radiation therapy, supportive care for radiation related mucositis may involve softening food, rinsing mouth with saline, dilute black tea, and administration of medications to control discomfort.
- These side effects are temporary but may cause discomfort for 10–14 days.

ACTIVITY

- Limit activity to minimize risk of epistaxis and dyspnea.
- Using a harness instead of a collar during walks may help minimize epistaxis.

DIET

- Soften food if needed during radiation therapy.
- Avoid extremes of temperatures and salty foods with radiation therapy-related mucositis.

CLIENT EDUCATION

Nasal adenocarcinoma may be painful even though the pet is not showing visible signs of pain.

- Consider the use of medications for discomfort and congestion.
- Radiation therapy is the most effective option and is well-tolerated using modern radiotherapy techniques.
- Radiation side effects may impact the patient's quality of life during treatment, but most pets enjoy a relatively normal quality of life following treatment.

ADENOCARCINOMA, NASAL

(CONTINUED)

- Intermittent congestion and sneezing may occur post therapy due to increased sensitivity from the tumors' destruction of the nasal turbinates.

SURGICAL/ANESTHETIC CONSIDERATIONS

Anesthetic recovery—ensure airway is maintained until animal is sternal to prevent apnea in patients with bilateral nasal obstruction.

MEDICATIONS

DRUG(S) OF CHOICE

- Chemotherapy is considered ineffective for durable tumor control, but may benefit some patients if radiation therapy is not a viable option. Various drugs have been described including cisplatin (dogs only), carboplatin, doxorubicin, and piroxicam. Toceranib phosphate (Palladia) exerts therapeutic activity against nasal carcinoma.
- Consult with an oncologist for more details.
- Adequate analgesic therapy should be employed as needed in patients suffering from invasive disease with bone destruction, signs of pain, and radiation therapy side effects.

CONTRAINDICATIONS

Cisplatin—never use in cats.

PRECAUTIONS

- Most chemotherapeutics have gastrointestinal, hematologic, and other potential side effects and should be administered and monitored by an oncologist.
- Piroxicam can cause gastric ulceration so careful monitoring of appetite, vomiting, and stool color (melena) is recommended.

POSSIBLE INTERACTIONS

Concurrent radiation therapy and chemotherapy will increase the risk of side effects but have not shown to significantly improve tumor control.

ALTERNATIVE DRUGS

- Palladia, a tyrosine kinase inhibitor, may have anticancer activity in some carcinomas including nasal adenocarcinomas. It is currently being investigated at the labeled dose alone and in combination with radiation therapy.
- Objective responses have been documented with use of Palladia alone.

FOLLOW-UP

PATIENT MONITORING

- CT or MRI are needed to assess response to therapy and are recommended 2–3 months post radiation treatment.
- Other staging tests including thoracic radiography or CT and lymph node evaluation are generally recommended in 3-month intervals during/following therapy.
- Routine staging with CT/MRI and monitoring of recurrent clinical signs can detect early recurrence.

POSSIBLE COMPLICATIONS

- Dyspnea
- Epistaxis
- Secondary infections
- Weight loss
- Anorexia
- Chemotherapy or radiation toxicity

EXPECTED COURSE AND PROGNOSIS

- Untreated—median survival around 2–6 months.
- Radiation therapy—median survival times around 12–18 months in dogs and 12–20 months in cats; 1-year survival rate 20–57% (dogs and cats); 2-year survival rate 20–48% (dogs and cats).
- Presence of cribriform lysis, brain involvement or metastatic disease (advanced stage) are poor prognostic indicators.
- Ophthalmic complications of radiation therapy—more likely in dogs than cats.
- Incidence and severity of ophthalmic toxicity are decreasing with advanced radiation therapy techniques now commonly used.
- Chronic rhinitis is possible following radiation therapy for sinonasal tumors and may require periodic symptomatic therapy.

MISCELLANEOUS

AGE-RELATED FACTORS

None

PREGNANCY/FERTILITY/BREEDING

Chemotherapeutic drugs and general anesthesia are a risk to the fetus and would not be recommended in pregnant animals.

SYNONYMS

- Nasal carcinoma
- Nasal tumor

SEE ALSO

- Squamous cell carcinoma, nasal
- Chondrosarcoma, nasal
- Lymphoma, nasal

BASICS

OVERVIEW

- Malignant tumor of ductal or acinar origin arising from the exocrine pancreas.
- Usually metastatic by the time of diagnosis, affecting regional lymph nodes and visceral abdominal organs (liver) and associated peritoneal cavity.

SIGNALMENT

- Rare in dogs—0.5–1.8% of all tumors
- Rare in cats—2.8% of all tumors
- Older female dogs and Airedale terriers at higher risk than others
- Median age (dogs)—9.2 years
- Mean age (cats)—11.6 years

SIGNS

- Nonspecific—fever; vomiting; weakness; anorexia; icterus; malabsorption syndrome; weight loss.
- Abdominal pain—variable.
- Abdominal effusion—malignant.
- Metastasis to bone and soft tissue common.
- Pathologic fractures secondary to metastasis reported.
- Palpable abdominal mass (cats).
- Paraneoplastic syndromes of epidermal necrosis, hyperinsulinemia, and hyperglucagonemia may be present.
- Average duration of clinical signs (cats): 41 days, range 2–180 days.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary pancreatitis; may be concurrent and complicate or delay early diagnosis
- Pancreatic pseudocyst
- Pancreatic nodular hyperplasia
- Hepatic neoplasia
- Other causes of vomiting and icterus
- Peritoneal carcinomatosis
- Other causes of abdominal effusion in cats

CBC/BIOCHEMISTRY/URINALYSIS

- Usually nonspecific changes (e.g., mild anemia and neutrophilia).
- Hyperamylasemia less reliable than hyperlipasemia.
- Lipase concentrations are often markedly elevated and may serve as a non-invasive biochemical marker of neoplasia in dogs.

OTHER LABORATORY TESTS

Rarely there may be significant metabolic alterations that affect glucagon, insulin, and amino acid concentrations.

IMAGING

- Abdominal radiographs may reveal a mass or loss of serosal detail associated with concurrent pancreatitis or peritoneal effusion.
- Ultrasonography may reveal one or more masses or concurrent pancreatitis (mixed echogenicity, large pancreas, hyperechoic peripancreatic fat). Pancreatic thickening, abdominal effusion, and single to multiple nodules of varying size may be identified. Sonographic findings may be impossible to distinguish from pancreatic nodular hyperplasia. Rarely the ultrasound of the pancreas may appear normal except for dilation of the pancreatic duct.

DIAGNOSTIC PROCEDURES

- Surgical biopsy—definitive.
- Fine-needle aspirate cytology—supportive. In many cases, where the tumor is not resectable, the fine-needle aspirates may provide strong enough evidence to start medical treatment.

TREATMENT

- None reported curative.
- Palliation of pain with aggressive analgesic combinations is necessary.
- Surgical intervention to alleviate intestinal and biliary obstruction, if necessary.
- Surgery is typically not a good option in many cases, due to the extent of the disease at the time of diagnosis.
- If surgery is an option, partial or total pancreatectomy may prolong survival.
- Treat concurrent pancreatitis.
- Antiemetics and supportive care (hydration and caloric requirements).

MEDICATIONS

DRUG(S)

- Gemcitabine is used in humans for the treatment of pancreatic carcinoma, and while used in dogs with cancer, it has not been established as the standard of care for dogs with pancreatic adenocarcinoma.
- Always consult a veterinary oncologist for updates in treating this rare neoplasm.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

POSSIBLE COMPLICATIONS

- Intestinal obstruction
- Biliary obstruction
- Pancreatic abscess
- Peritonitis
- Metastasis

EXPECTED COURSE AND PROGNOSIS

Progression to death is often rapid given that there is no successful curative treatment available. Despite the grave prognosis, individual patients treated with complete resection of their tumor and chemotherapy, in the absence of systemic metastasis, may have prolonged survival.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Gastrin-secreting pancreatic carcinoma (gastrinoma) has been reported in dogs and cats. Clinical signs are associated with hypergastrinemia, which results in inappropriate hydrochloric acid secretion by the stomach, leading to gastroduodenitis.

Suggested Reading

ADENOCARCINOMA, PROSTATE

BASICS

OVERVIEW

- Prostatic adenocarcinoma is a malignant tumor that occurs in both neutered and intact male dogs.
- Although this neoplasm represents < 1% of all canine malignancies, it is the most common prostatic disorder in neutered male dogs.
- Metastases to regional lymph nodes, lungs, and the lumbosacral skeleton are common. Skeletal metastases can adopt an osteoblastic appearance.

SIGNALMENT

- Dog and rarely cat
- Medium- to large-breed intact or neutered male dogs
- Median age of 9–10 years

SIGNS

Historical Findings

- Tenesmus (with the production of ribbon-like stool)
- Weight loss
- Stranguria and dysuria
- Rear limb lameness or neurologic weakness
- Lethargy
- Exercise intolerance

Physical Examination Findings

- A firm, asymmetrical, and immobile prostate gland.
- Prostatomegaly is common, but is not always present.
- Pain may be elicited in response to abdominal or rectal palpation.
- Caudal abdominal mass, cachexia, pyrexia, and dyspnea may also be identified in advanced cases of disease.

CAUSES & RISK FACTORS

Neutered males are at increased risk for prostatic neoplasia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other primary neoplasia (i.e., squamous cell carcinoma, transitional cell carcinoma).
- Metastatic or locally invasive neoplasia (i.e., transitional cell carcinoma).
- Acute or chronic prostatitis, benign prostatic hypertrophy, prostatic abscess, and prostatic cysts are possible differentials in intact male dogs but are highly unlikely in neutered dogs.

CBC/BIOCHEMISTRY/URINALYSIS

- Inflammatory leukogram possible.
- Alkaline phosphatase may be high if skeletal metastases exist.
- Post-renal azotemia may be present if urethral obstruction exists.
- It is prudent to evaluate urine samples via cystocentesis and free-catch techniques, as hematuria, pyuria, and malignant epithelial cells may be observed in free-catch samples but are unusual in samples obtained by cystocentesis.

OTHER LABORATORY TESTS

Serum and seminal plasma markers such as acid phosphatase, prostate specific antigen, and canine prostate specific esterase are not elevated in dogs with PAC.

IMAGING

- Thoracic radiography—metastases may appear as pulmonary nodules or increased interstitial markings.
- Abdominal radiography—sublumbar lymphadenomegaly, mineralization of the prostate, lytic lesions to the lumbar vertebrae or pelvis as a consequence of direct tumor extension from regionally infiltrated lumbar lymph nodes may be seen.
- Abdominal ultrasonography—focal to multifocal hyperechogenicity with asymmetry and irregular prostatic outline, ± prostatic mineralization.
- Contrast cystography may help differentiate prostatic from urinary bladder disease.

DIAGNOSTIC PROCEDURES

- Prostatic aspirate (percutaneous or transrectal).
- Prostatic wash.
- Prostatic biopsy performed percutaneously or surgically.
- Percutaneous biopsy has been associated with tumor seeding along the biopsy tract.

TREATMENT

- Prostatectomy if local disease (success of this procedure depends on the skill of the surgeon and extent of disease).
- Radiation therapy may palliate signs and prolong survival.
- Prostatic urethral stenting can alleviate urethral obstruction.
- Neutering—however, most tumors are not androgen responsive.

MEDICATIONS

DRUG(S)

- Chemotherapy—carboplatin, mitoxantrone, or doxorubicin; may offer short-term benefit.
- Pain relief with NSAIDs, morphine-derived drugs.
- Aminobisphosphonates for the relief of painful skeletal metastases.
- Stool softeners to relieve tenesmus.

CONTRAINdications/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Ability to urinate and defecate, pain secondary to skeletal metastases, quality of life.

PREVENTION/AVOIDANCE

Keeping dogs sexually intact may decrease risk.

POSSIBLE COMPLICATIONS

- Urethral obstruction
- Metastasis to regional lymph nodes, skeleton, and lungs

EXPECTED COURSE AND PROGNOSIS

Guarded to poor, survival of 2–6 months depending upon presenting clinical symptoms. Treatment early in the course of disease with curative-intent radiation and systemic chemotherapy can extend survival times to 12 months.

Consulting Editor Timothy M. Fan

BASICS

OVERVIEW

- Accounts for < 1% of all reported neoplasms in dogs.
- Renal tumors tend to be highly metastatic via hematogenous dissemination, locally invasive, and often bilateral.
- Renal cystadenocarcinoma, a rare heritable syndrome with a less aggressive behavior and better long-term prognosis than renal adenocarcinoma, has been described in German shepherd dogs.

SIGNALMENT

- Adenocarcinoma—older (8–9 years) dogs, 1.6:1 male-to-female ratio, no breed predilection.
- Cystadenocarcinoma—German shepherd dogs, often female.

SIGNS

- Adenocarcinoma—insidious, non-specific signs such as weight loss, inappetance, lethargy, hematuria, and pale mucous membranes. Possibility for paraneoplastic polycythemia.
- Cystadenocarcinoma—may present for nodular dermatofibrosis, a syndrome of painless, firm, fibrous lesions of the skin and subcutaneous tissues.

CAUSES & RISK FACTORS

- Adenocarcinoma—unknown.
- Cystadenocarcinoma—heritable in German shepherd dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other primary neoplasia (i.e., lymphoma, nephroblastoma)
- Metastatic neoplasia (i.e., hemangiosarcoma)
- Renal adenoma or cyst
- Pyelonephritis

CBC/BIOCHEMISTRY/URINALYSIS

- CBC may show paraneoplastic polycythemia or leukocytosis, or anemia.

- Biochemistry may be normal, or may reveal azotemia.
- Urinalysis may show hematuria, proteinuria, bacteriuria, or casts.

OTHER LABORATORY TESTS

Urine culture and sensitivity

IMAGING

- Thoracic radiographs—metastatic disease reported in up to 16% of patients.
- Abdominal radiographs—mass visualized in 81% of patients.
- Abdominal ultrasonography, CT, or contrast radiography—useful in identifying and staging the disease. Advanced imaging can guide decisions regarding surgical resectability.

DIAGNOSTIC PROCEDURES

- Renal biopsy (ultrasound-guided or surgical) for definitive diagnosis.
- Percutaneous fine-needle aspirate can be used for supportive diagnosis.

TREATMENT

- Aggressive surgical excision is the treatment of choice for unilateral disease.
- Successful chemotherapeutic management of either disease has not been described.
- Supportive management for patients in renal failure may be necessary.

MEDICATIONS

DRUG(S)

None

FOLLOW-UP

PATIENT MONITORING

- Renal failure—measure serum urea nitrogen and creatinine; urinalysis.
- Quality of life if bilateral or otherwise non-surgical disease.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Renal failure
- Metastatic disease
- Invasion of local vital structures (vena cava, aorta)

EXPECTED COURSE AND PROGNOSIS

- Adenocarcinoma—median reported survival of 49 dogs was 16 months (range 0–59 months).
- Cystadenocarcinoma—few large studies of this rare disease, reported median survival of 12+ months with no definitive therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- The paraneoplastic syndromes of hypertrophic osteopathy, polycythemia, and a neutrophilic leukocytosis have been reported in isolated cases.
- Renal failure.
- Nodular dermatofibrosis and uterine leiomyomas are commonly associated with cystadenocarcinoma.

ABBREVIATION

- CT = computed tomography

ADENOCARCINOMA, SALIVARY GLAND

BASICS

OVERVIEW

- Tumor arising from major (e.g., parotid, mandibular, sublingual, or zygomatic) or minor salivary glands.
- Mandibular or parotid glands constitute 80% of cases.
- Mandibular gland most frequently affected in dogs.
- Parotid gland most frequently affected in cats.
- Locally invasive and regionally metastatic.
- Cats typically have more advanced disease than dogs at time of diagnosis.
- Metastasis—regional lymph node involvement in 39% of cats and 17% of dogs at diagnosis; distant metastasis reported in 16% of cats and 8% of dogs at diagnosis but may be slow to develop.
- Other salivary gland neoplasms—carcinoma; squamous cell carcinoma; mixed neoplasia.
- Epithelial malignancies—constitute roughly 85% of salivary gland tumors.
- Fibrosarcomas, lipomas, mast cell tumors, and lymphomas have involved the salivary glands by direct extension and invasion. A concurrent malignant fibrous histiocytoma (giant cell type) and malignant mixed tumor (likely of ductal origin) within the salivary gland has also been described.
- Adenomas comprise only 5% of salivary tumors.

SIGNALMENT

- Dog and cat.
- Mean age, 10–12 years.
- Siamese cats—may be at relatively higher risk.
- Male cats affected twice as often as female cats.
- No other breed or sex predilection has been determined.

SIGNS

- Unilateral, firm, painless swelling of the upper neck (mandibular and sublingual), ear base (parotid), upper lip or maxilla (zygomatic), or mucous membrane of lip (accessory or minor salivary tissue).
- Other signs may include halitosis, weight loss, anorexia, dysphagia, exophthalmus, Horner's syndrome, sneezing, and dysphonia.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Squamous cell carcinoma
- Mucocele
- Abscess
- Soft tissue sarcoma, e.g., fibrosarcoma
- Lymphoma
- Sialadenosis

CBC/BIOCHEMISTRY/URINALYSIS

Results often normal

IMAGING

- Regional radiographs usually are normal; may see periosteal reaction on adjacent bones or displacement of surrounding structures.
- MRI or CT imaging allows superior discrimination of tumor for surgery and/or radiation treatment planning.
- Thoracic radiographs indicated to check for lung metastases.

DIAGNOSTIC PROCEDURES

- Cytologic examination of aspirate may differentiate salivary adenocarcinoma from mucocele and abscess.
- Needle core or wedge biopsy for histopathology—definitive diagnosis.

TREATMENT

- Aggressive surgical resection—when possible; most are invasive and difficult to excise completely.
- Radiotherapy—good local control and prolonged survival in three reported cases.
- Aggressive local resection (usually histologically incomplete) followed by adjuvant radiation can achieve local control and long-term survival, but further studies are needed to determine the most effective treatment, including the possible role for chemotherapy.

MEDICATIONS

DRUG(S)

Chemotherapy (mitoxantrone or carboplatin) efficacy is largely unreported; however, may

be indicated for treatment/palliation of metastatic disease.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Evaluations—physical examination and thoracic radiographs every 3 months reasonable if aggressive surgery and/or radiation therapy employed.

POSSIBLE COMPLICATIONS

Temporary acute side effects (e.g., moist dermatitis and alopecia) expected with definitive radiation therapy in dogs, but uncommon in cats. Consultation with a radiation oncologist is recommended regarding specific, anatomic site-related side effects associated with planned dose and field size.

EXPECTED COURSE AND PROGNOSIS

- Improved survival time in dogs without evidence of nodal or distant metastasis at diagnosis; clinical stage not prognostic for cats.
- Median survival 550 days for dogs and 516 days for cats in retrospective study.
- Local control obtained through radiation and/or surgery remains critical.

MISCELLANEOUS

ABBREVIATIONS

- CT = computed tomography
- MRI = magnetic resonance imaging

Consulting Editor Timothy M. Fan

ADENOCARCINOMA, SKIN (SWEAT GLAND, SEBACEOUS)

BASICS

OVERVIEW

Malignant growth originating from sebaceous or apocrine sweat glands of the skin.

SIGNALMENT

- Apocrine sweat gland—rare in dogs, uncommon in cats.
- Sebaceous gland—rare in both dogs and cats.
- Middle-aged to older pets.
- Female dogs overrepresented for apocrine adenocarcinoma in one study.

SIGNS

- May appear as solid, firm, raised, superficial skin lesions.
- May be ulcerated and bleeding and accompanied by inflammation of the surrounding tissue.
- Apocrine sweat gland—often poorly circumscribed, ulcerated; very invasive into underlying tissue; may occur anywhere on the body, frequently affecting the trunk in dogs.
- Sebaceous gland—often ulcerated and inflamed, moderate risk of lymph node involvement.
- Dermal and lymphatic tracking can be observed early in disease course.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other more frequent skin tumors
- Cutaneous histiocytic diseases
- Immune-mediated skin diseases
- Bacterial/fungal infections

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

N/A

IMAGING

Thoracic radiographs recommended at the time of diagnosis to assess for distant metastases.

DIAGNOSTIC PROCEDURES

- Biopsy for histopathology and definitive diagnosis
- Cytologic examination or biopsy of draining lymph nodes

PATHOLOGIC FINDINGS

- Apocrine gland adenocarcinomas are typically invasive into the underlying stroma and blood vessels, and often show poorly demarcated borders and a high mitotic index.
- Sebaceous gland adenocarcinomas often reveal lymphatic vessel invasion.

TREATMENT

- Aggressive *en bloc* surgical excision, including resection of draining lymph node, recommended for both types. Histopathologic analysis of lymph nodes assists with determining prognosis and establishing adjuvant treatment plan.
- Margins of entire tissue specimen must be evaluated histologically to assess completeness of resection.
- Radiation therapy may be recommended for treatment of draining lymph nodes after resection to prevent recurrence and development of regional metastasis; radiation therapy of primary tumor site recommended when wide and complete resection not possible.

MEDICATIONS

DRUG(S)

- Chemotherapy has been used anecdotally for the treatment of both tumor types, in both species.
- Contact a veterinary oncologist for any updated treatments that may be available.
- Nonsteroidal anti-inflammatory drugs and other analgesics are recommended, as indicated, for pain control.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None

FOLLOW-UP

- Sebaceous gland adenocarcinoma—little is known about the metastatic potential of this malignancy, but may be rapidly metastatic to regional lymph nodes in some patients; long-term prognosis is anecdotally good with multimodal therapy combining aggressive surgery, chemotherapy, and radiation therapy.
- Apocrine gland adenocarcinoma—fair to good long-term prognosis; the histologic finding of vascular invasion is a negative prognostic factor predicting systemic metastases; aggressive surgical resection (local and regional tumor control) followed by adjuvant chemotherapy is recommended to improve survival. A study reported a post-excisional median survival time of 30 months in dogs.

Author Louis-Philippe de Lorimier

Consulting Editor Timothy M. Fan

ADENOCARCINOMA, STOMACH, SMALL AND LARGE INTESTINE, RECTAL

BASICS

OVERVIEW

- Uncommon tumor arising from the epithelial lining of the gastrointestinal tract.
- Prognosis guarded to poor.

SIGNALMENT

- Dog more commonly affected than cat.
- Middle-aged to older (> 6 years) animals; age range 3–13 years.
- No breed predisposition.
- More common in males than females.

SIGNS

Historical Findings

- Stomach—vomiting, anorexia, weight loss, hematemesis, and melena.
- Small intestine—vomiting, weight loss, borborygmus, flatulence, and melena.
- Large intestine and rectum—mucus and blood-tinged feces and tenesmus.

Physical Examination Findings

- Stomach—nonspecific.
- Small intestine—may feel mid-abdominal mass; distended, painful loops of small bowel; melena on rectal exam.
- Large intestine and rectum—palpable mass per rectum, may form annular ring, or multiple nodular lesions protruding into the colon; bright red blood on feces.

CAUSES & RISK FACTORS

- Unknown.
- Nitrosamines—reported as causative agent in experimental literature.
- Possible genetic cause—gastric adenocarcinomas in related Belgian shepherds and Dutch Tervuren shepherds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Foreign body
- Inflammatory bowel disease
- Lymphoma
- Parasites
- Leiomyoma
- Leiomyosarcoma
- Pancreatitis

CBC/BIOCHEMISTRY/URINALYSIS

- Stomach and small intestine—may see microcytic, hypochromic anemia (iron-deficiency anemia). Mild and persistent elevations in blood urea nitrogen in the face of normal creatinine can support intestinal blood loss.
- Large intestine and rectum—no characteristic changes.

OTHER LABORATORY TESTS

Fecal occult blood may be positive; diet may affect results—can recheck to confirm after feeding non-meat diet for 3 days.

IMAGING

- Ultrasound—may reveal a thickened stomach or bowel wall; may see mass in the gastrointestinal tract, enlarged lymph nodes.
- Positive contrast radiography—filling defect (stomach); intraluminal space-occupying or annular constriction (small bowel); gastric neoplasm most often found in distal two-thirds of stomach.
- Double contrast radiography—large intestine and rectum; polypoid or annular space-occupying masses.
- Advanced imaging with contrast CT or MRI can provide highest quality images of gastrointestinal tract.

DIAGNOSTIC PROCEDURES

- Ultrasound-guided fine-needle aspirate of bowel mass or enlarged lymph node may reveal carcinoma cells on cytology, which can be useful to rule out lymphoma.
- Endoscopic biopsy may be non-diagnostic because tumors are frequently deep to the mucosal surface; thus surgical biopsy frequently required.

TREATMENT

- Surgical resection—treatment of choice; seldom curative.
- Gastric—usually non-resectable.
- Small intestine—remove by resection and anastomosis; metastasis to regional lymph nodes and the liver common.
- Large intestine and rectal—may occasionally be resected by a pull-through surgical procedure; metastasis common; transcolonic debulking may provide palliation of obstruction.

MEDICATIONS

DRUG(S)

- Chemotherapy—only anecdotal reports, usually unsuccessful.
- Piroxicam 0.3 mg/kg PO q24 h can provide palliation for large intestinal and rectal tumors.
- Aggressive combination analgesics should be instituted.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Seek advice before initiating treatment with cytotoxic drugs.

FOLLOW-UP

Physical examination, thoracic radiographs, and abdominal ultrasound—at 1, 3, 6, 9, and 12 months post-surgery.

EXPECTED COURSE AND PROGNOSIS

Dogs

- Overall poor; pedunculated rectal tumors do best; most cases recur locally, develop metastasis, or both rapidly.
- Median survival gastric—2 months.
- Median survival small intestinal—10 months.
- Mean survival large intestinal—annular 1.6 months versus pedunculated 32 months.

Cats

- Guarded.
- Few reported cases, but may have prolonged survival (> 1 year).

MISCELLANEOUS

ABBREVIATIONS

- CT = computed tomography
- MRI = magnetic resonance imaging

Author Laura D. Garrett

Consulting Editor Timothy M. Fan

BASICS

DEFINITION

A malignant tumor arising from the follicular or parafollicular cells (medullary/C-cells) of the thyroid gland.

PATHOPHYSIOLOGY

- About 60% of patients are euthyroid, 30% hypothyroid, and 10% hyperthyroid.
- Typically very invasive tumors with high rate of metastasis (lungs, retropharyngeal lymph nodes, liver), with up to 35–40% of dogs having metastasis at the time of diagnosis.
- Animals with bilateral tumors have a sixteen times greater risk of developing metastatic disease than animal with unilateral tumors.

SYSTEMS AFFECTED

- Cardiovascular**—hyperthyroid dogs are usually tachycardic and may have systemic hypertension; may see anemia and DIC in advanced disease.
- Endocrine/Metabolic**—affected dogs may be hypothyroid, euthyroid, or hyperthyroid; hypercalcemia may be seen as a paraneoplastic syndrome or secondary to concurrent parathyroid hyperplasia or parathyroid adenocarcinoma.
- Respiratory**—dogs may be dyspneic owing to a space-occupying mass adjacent to the trachea; metastasis to the lungs common. Large compressive masses can result in caval syndrome manifested as facial edema.

GENETICS

Unknown

INCIDENCE/PREVALENCE

Accounts for 1.2–3.8% of all canine tumors and represents 10–15% of all primary head and neck tumors.

GEOGRAPHIC DISTRIBUTION

May be more common in iodine-deficient areas.

SIGNALMENT

Species

Dog

Breed Predilections

Boxers, golden retrievers, Siberian huskies, and beagles at increased risk but seen in any breed.

Mean Age and Range

Older dogs (median 9–15 years; range 4–18 years)

Predominant Sex

No gender predilection.

SIGNS

General Comments

- Usually not diagnosed until a large mass is palpable.
- Approximately 65% are unilateral, 35% are bilateral.

Historical Findings

- Palpable mass/swelling in cervical neck, coughing, dyspnea, dysphagia, dysphonias, facial edema, neck pain.
- If functional thyroid tumor—may see polyuria, polydipsia, polyphagia, weight loss, restless behavior, diarrhea.
- If hypothyroid—may see poor hair coat, weight gain, lethargy.

Physical Examination Findings

- Freely movable or fixed cervical mass, unilateral or bilateral.
- Rarely may see Horner's syndrome, or cranial vena cava syndrome.
- If hyperthyroid—cardiac arrhythmias or murmurs.

CAUSES

Unknown

RISK FACTORS

- Untreated hypothyroidism has been shown to be a risk factor in a colony of beagles.
- Breed predilection.
- Iodine deficiency.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other primary neoplasms—lymphoma; soft tissue sarcoma; salivary gland adenocarcinoma; parathyroid carcinoma; carotid body tumor.
- Secondary tumors—metastatic oral squamous cell carcinoma; oral melanoma.
- Inflammatory—abscess or granuloma.
- Salivary mucocele.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- May see non-regenerative normocytic normochromic anemia of chronic disease, leukocytosis.
- Rare—hypercalcemia; isosthenuria; DIC.

OTHER LABORATORY TESTS

Thyroid hormone (T_4 and/or free T_4 levels) and endogenous TSH levels.

IMAGING

- Thoracic radiography (3 view)—evaluation of lungs and other thoracic structures for metastasis.
- Cervical ultrasonography, computed tomography, and magnetic resonance imaging—evaluation of tissue of origin, vascularity, invasion, and cervical lymph nodes.
- Technetium-99 m scintigraphy to evaluate for ectopic thyroid tissue or metastatic lesions.
- Radioiodine studies—may provide information about the tumor's ability to produce thyroid hormone.

DIAGNOSTIC PROCEDURES

Biopsy

Tru-Cut not recommended owing to high risk of severe hemorrhage; open biopsy usually

required and allows for controlled hemostasis in the event of bleeding.

Cytology

- Examination of fine-needle aspirates from tumor and palpable regional lymph nodes.
- Specimen almost always heavily contaminated with blood owing to highly vascular nature of tumor.
- Homogeneous population of epithelial cells, sometimes with colloid and/or tyrosine-containing granules.
- Unable to differentiate malignant from benign thyroid cells; but almost all thyroid neoplasms in dogs are malignant.

PATHOLOGIC FINDINGS

Gross

- Characterized by high vascularity with areas of hemorrhage and necrosis.
- Usually poorly encapsulated; often invade adjacent tissues (e.g., trachea and esophagus, and surrounding vasculature); may adhere to the jugular vein, carotid artery, and vagosympathetic trunk.

Histopathology

- Three main types—follicular, papillary, and compact (solid); mixed follicular and solid tumors most common in dogs.
- C-cell (e.g., parafollicular, medullary) carcinomas less common.

TREATMENT

APPROPRIATE HEALTH CARE

- Definitive treatment is dependent on tumor stage (tumor size, mobility, and evidence of metastatic disease).
- Complete surgical excision recommended for freely movable thyroid tumors.
- Full course external beam radiation therapy recommended preoperatively for large tumors, as a sole therapy for non-resectable tumors, or postoperatively for incompletely surgically removed tumors.
- Palliative radiation and/or chemotherapy recommended for tumors that are metastatic at presentation.
- Also can use iodine-131 but doses are very large (60–100 mCi) and therefore there are limited facilities that offer this therapy.
- Toceranib phosphate (Palladia) can exert cytoreductive activity.

NURSING CARE

Varies with signs on examination.

ACTIVITY

Restrict activity if dyspneic.

DIET

N/A

CLIENT EDUCATION

- Warn owners of the importance of controlling heart rate and rhythm in hyperthyroid patients and of the possibility of episodes of collapse.

ADENOCARCINOMA, THYROID—DOGS

(CONTINUED)

- Warn owners of possible postoperative laryngeal paralysis and intraoperative hemorrhage.
- Warn owners of acute radiation therapy toxicities—moist desquamation, laryngitis, tracheitis, esophagitis.

SURGICAL CONSIDERATIONS

See "Appropriate Health Care"

Risks

- Marked hemorrhage—tumors highly vascular and invasive into surrounding structures including vasculature; may need blood transfusion and intensive postoperative care.
- Laryngeal paralysis—owing to trauma to recurrent laryngeal nerve.
- Damaged parathyroid glands—may occur during surgery.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Chemotherapeutic agents:
 - Chemotherapy is recommended as a sole therapy, or possibly in combination with surgery and/or radiation therapy.
 - Cisplatin (60 mg/m^2 every 3 weeks), carboplatin (300 mg/m^2 every 3 weeks), or doxorubicin (30 mg/m^2 every 3 weeks)—reported to effect partial remission in approximately 50% of cases.
 - Toceranib (2.5–3 mg/kg 3 times a week)—had biologic activity in 80% of cases (26% partial remission, 53% stable disease).
 - Cisplatin—nephrotoxic; must use with saline diuresis (18.3 mL/kg/hour IV over 6 hours; give cisplatin after 4 hours).
- Antiemetics for cisplatin therapy:
 - Maropitant 1 mg/kg SC before cisplatin, or
 - Dolasetron 0.6–1 mg/kg IV or PO q24 h, or
 - Butorphanol 0.4 mg/kg IM before and after cisplatin.
- Thyroid management:
 - Thyroxine—maintenance doses to decrease TSH production have been recommended; some tumors contain TSH receptors; value of hormone replacement therapy in affected dogs not determined.
 - Methimazole 5 mg PO q8 h for medium to large dogs; may be beneficial for hyperthyroid patients.
 - β -blockers—may be indicated for tachycardia or hypertension in hyperthyroid patients.

CONTRAINdications

- Doxorubicin is cumulatively toxic to cardiac myocytes causing decreased myocardial function. Do not give to animals with poor cardiac function or dilated cardiomyopathy.

- Cisplatin is nephrotoxic; do not give to animals with renal disease.

PRECAUTIONS

Chemotherapy can cause gastrointestinal, bone marrow, cardiac, and other toxicities—seek advice from a medical oncologist if unfamiliar with cytotoxic drugs.

POSSIBLE INTERACTIONS

Verapamil—may potentiate doxorubicin-induced cardiotoxicity.

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

- Serum calcium concentration—if bilateral thyroidectomy was performed; signs of hypocalcemia (agitation, panting, muscle tremors, tetany, and seizures) may be observed.

- Treat with 10% calcium gluconate (1–1.5 mL/kg IV over 10–20 minutes).
- Maintain serum calcium with dihydrotachysterol (vitamin D) orally.
- Thyroid hormone—supplementation with thyroxine may be necessary after bilateral thyroidectomy.
- TSH concentration—a goal of thyroxin supplementation is to downregulate the body's secretion of TSH.
- Site of primary tumor—physical examination and cervical ultrasound; thoracic radiographs every 3 months to detect pulmonary metastasis.

PREVENTION/AVOIDANCE

Unknown

POSSIBLE COMPLICATIONS

- Tumor—anemia; thrombocytopenia; hypercalcemia; DIC; respiratory distress.
- Chemotherapy—dilated cardiomyopathy; renal failure; pancreatitis; sepsis; gastrointestinal upset.
- Surgery—hemorrhage; hypothyroidism; hypoparathyroidism leading to hypocalcemia; laryngeal paralysis.
- Radiotherapy—acute side effects—moist desquamation, pharyngeal mucositis; esophagitis; tracheitis; late side effects—alopecia, and skin or coat color change (at radiation site).

EXPECTED COURSE AND PROGNOSIS

- Prognosis—related to stage of disease (tumor size, mobility and evidence of metastatic disease) with small, non-attached unilateral, non-metastatic tumors having best prognosis.
- MST after surgical removal of unilateral thyroid tumors is 1462 days vs. 365 days for patients undergoing bilateral thyroidectomy.

- For animals treated with full course external beam radiation therapy—progression-free survival at 1 year—80%, and 72% at 3 years in one study and in another study MST 24.5 months.

- Palliative radiation therapy in 13 dogs—MST 24 months.

- ^{131}I therapy in combination with surgery—MST 34 months, or ^{131}I alone MST 30 months.

- Animals treated with cisplatin alone (13 dogs)—overall response rate was 53%, median progression-free interval for responders was 202 days and overall MST was 98 days.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Non-thyroidal malignancies common
- Multiple endocrine neoplasia reported

AGE-RELATED FACTORS

None

PREGNANCY/FERTILITY/BREEDING

It is not recommended to breed animals with cancer. Chemotherapy is teratogenic—do not give to pregnant animals.

SYNOMYS

Thyroid carcinoma

ABBREVIATIONS

- DIC = disseminated intravascular coagulation
- MST = median survival time
- TSH = thyroid stimulating hormone

AGGRESSION TO UNFAMILIAR PEOPLE AND UNFAMILIAR DOGS

BASICS

OVERVIEW

A variety of different motivations exist, including fear, territoriality, conflict and possessiveness. Aggression is directed toward a person or dog that does not live in the household. Regular visitors may also be targets. May be within the range of normal behavior, but may be compounded by fearfulness.

SYSTEMS AFFECTED

- Behavioral. • Sympathetic stimulation (e.g., tachypnea, tachycardia).

INCIDENCE/PREVALENCE

Stranger-directed aggression represents 32.5% of canine behavioral referral caseload.

SIGNALMENT

- Can occur at any age. Signs may begin to emerge as primary socialization wanes (approximately 12–16 weeks of age) or may arise or intensify at social maturity (approximately 18–36 months). Genetic concerns and poor prognosis if signs arise before 12 weeks.
- Territorial aggression more common in intact males—initial signs usually present by 1 year.
- Aggression toward unfamiliar people and dogs overrepresented in males.
- Breed predilection for inter-dog aggression in “fighting breeds” (e.g., pit bull terriers) and terriers.

SIGNS

- Aggression (barking, growling, lip-lifting, snarling, snapping, lunging, biting) toward unfamiliar people and dogs. May be accompanied by fearful or submissive body postures/facial expressions (head down, crouching, backing away, ears back, tail tucked, looking away, lip licking) or confident body postures (standing straight up, approach with tail up, ears forward).
- Territorial aggression arises in familiar locations or spaces (e.g., home, yard, car).
- May be confident, fearful or conflict.
- Fear aggression more likely when dog is cornered or cannot escape.
- May be more frequent or severe on- than off-leash.

CAUSES & RISK FACTORS

- May be a normal canine behavior.
- Strongly influenced by previous experience (e.g., early socialization, painful conditions, rough handling, inappropriate punishment, previous fear-evoking experience with unfamiliar people or dogs).
- Underlying medical conditions, especially pain.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fear aggression • Territorial aggression
- Possessive aggression • Conflict aggression
- Generalized anxiety disorder

CBC/BIOCHEMISTRY/URINALYSIS

Usually unremarkable. Abnormalities suggest an underlying medical condition.

OTHER LABORATORY TESTS

Usually unremarkable

IMAGING

MRI if CNS disease suspected. Other imaging as needed to rule out underlying medical conditions.

TREATMENT

CLIENT EDUCATION

Treatment is aimed at controlling the problem, not at achieving a “cure.” Successful treatment, resulting in a decrease in aggressive incidents, depends on owner understanding of basic canine social behavior, risks involved, how to follow safety and management recommendations, correct identification of the aggression-eliciting stimuli, and effective implantation of reward-based behavior modification.

Safety Recommendations

- Owners’ main responsibility is safety by avoiding situations that may evoke a fearful or aggressive reaction. Avoidance is also necessary to insure the pet’s welfare and prevent further learning of aggressive behaviors.
- Owners should be advised that dog owners may be liable for bites and could face civil/criminal prosecutions should a person be injured.
- Successful treatment is more likely if a period of preventing exposure to aggression-provoking stimuli is instituted prior to behavior modification.
- Confining dog away from potential victims, avoid walks or parks where stimulus exposure might occur, or have dog under direct physical control of a responsible adult whenever an aggression-provoking situation could arise (e.g., public location, when visitors are at the house).
- Confining territorial dogs to where they cannot see/hear visitors approaching territory before they become aggressively aroused.
- Introduce a head halter (e.g., Gentle Leader) and basket muzzle for easier and safer control.
- Owners should be advised that punishment/dominance-based training can lead to

increased aggression, fear, agitation, and/or injuries and should be avoided. If safety cannot be insured, dogs should be removed from the household.

Behavior Therapy

- Structured interactions (also known as learn to earn or say please by sitting) where the dog is consistently taught to sit for anything it values (before feeding, petting, play, going for a walk) gives the dog control of its resources by sitting calmly, provides structure and predictability in all interactions, teaches impulse control and trains the dog that good things happen by sitting calmly.
- Commands: teach the dog to focus on the owner for guidance using eye contact and hand target (e.g., dog touch nose to owner’s hand).
- Teach the dog to sit and relax on verbal cue in neutral situations using food rewards; teach to go to mat, bed or crate to settle; teach to walk on loose leash. Train with head halter or muzzle if needed to insure safety. Private session with a force-free trainer should be considered to achieve basics before any exposure.

Behavior Modification: Systematic Desensitization and Counter-conditioning (DS/CC)

- When owner can effectively control and calm in the absence of stimuli, begin exposure by determining the limit (distance, location, person, dog) at which the dog will orient but not yet react. Have the dog focus on the owner or continue walking calmly (heel) and give favored (highest value) rewards to make positive associations with each stimulus exposure.
- Gradually (baby steps) increase stimulus intensity, staying below the threshold that would result in fear and/or aggression by decreasing distance, increasing distractions, or moving to more challenging environments.
- Progress is slow (typically months). Carefully monitor body language to avoid setbacks.
- If the dog is not calm, shows aggression or precursors to aggression (e.g., fixating on the stimulus) reduce the level of stimulation by moving farther away or taking the dog out of the situation. Future sessions should be at greater distances, or in locations or with stimuli where success can be achieved. For example, if the dog is calm when unfamiliar people pass on a walk, but when strangers pass the house the dog barks, revert to practicing DS/CC with the dog on walks and work up more slowly to practicing around the house.
- Owners must always be vigilant for the approach of stimuli that might incite fear or aggression.

SURGICAL CONSIDERATIONS

- Castration reduced aggression by at least 50% toward unfamiliar dogs in < 20% of

AGGRESSION TO UNFAMILIAR PEOPLE AND UNFAMILIAR DOGS (CONTINUED)

dogs studied and toward human territorial intruders in < 10% of dogs studied. Castration reduced inter-male aggression in 62% of dogs. • Military working German shepherds spayed at 5–10 months of age were more reactive 4–5 months post-surgery to approach by an unfamiliar person walking with an unfamiliar dog than intact dogs.

MEDICATIONS

SUPPLEMENTS

- Consider for mild fear or as an adjunct to drug therapy.
- Supplements are not a substitute for and should only be used to facilitate behavior modification.

L-theanine (Anxitane®)

- 2.5–5 mg/kg q12h.
- Active ingredient in green tea purported to increase serotonin, dopamine and GABA.
- Side effects: none reported.

Alpha-casozepine (Zylkene®)

- 15 mg/kg PO q24h (canine). Discontinue if no effect after 10 days.
- Purported to increase GABA.
- Side effects: none reported.
- Alpha-casozepine also in Royal Canin Calm Canine.

DRUG(S)

- There are no medications licensed for treatment of canine aggression. Owners must be aware that the use of medications is off-label. Note in the patient's record that owners were informed of potential risks and side effects. A signed informed consent form is advisable. NEVER use medications without concurrent behavior modification. Before prescribing medication, be sure that owners understand the risks and liability in owning an aggressive dog, will follow safety procedures, and do not expect medications to insure safety. In fact, medication may not be appropriate in all situations (e.g., households with small children, or individuals that have disabilities).
- There is a strong placebo effect when using drugs for behavior therapy in dogs. Studies have not shown a robust effect of drug treatment on aggression.

Selective Serotonin Reuptake Inhibitors

- Fluoxetine 0.5–2 mg/kg PO q24h.
- Paroxetine 0.5–1 mg/kg PO q24h.
- Sertraline 1–3 mg/kg PO q24h.
- Side effects: sedation, irritability, GIT effects, increased aggression; anorexia is common and usually transient.

Tricyclic Antidepressants

- Clomipramine 1–3 mg/kg q12h (label-restricted for aggression).
- Side effects: sedation, GIT effects,

anticholinergic effects, cardiac conduction disturbances if predisposed, and increased aggression.

Alpha-2 agonists

- Clonidine 0.01–0.05 mg/kg PO PRN 1.5–2 hours before eliciting trigger, up to q12h.
- Side effects: transient hyperglycemia, hypotension, collapse, and bradycardia (responsive to atropine), and increased aggression.

Serotonin 2 α antagonist/reuptake inhibitors

- Trazodone 2–5 mg/kg PRN prior to eliciting trigger up to q8h. Titrate to 8–10 mg/kg if no adverse effects.
- Side effects: sedation, anorexia, ataxia, GIT effects, cardiac conduction disturbances, and increased aggression.

PRECAUTIONS

- Use caution as any psychotropic medication may disinhibit, resulting in an increase rather than decrease in aggression. • Do not combine SSRIs, SARI, TCAs, MAO inhibitors (e.g., amitraz, selegiline), opioids (e.g., tramadol) or other medications that increase serotonin—can result in potentially fatal serotonin syndrome.

FOLLOW-UP

PATIENT MONITORING

- Clients need ongoing assistance and should receive at least one follow-up call within the first 1–4 weeks after consultation. Provisions for further follow-up should be made. Ongoing communication improves client compliance.

PREVENTION/AVOIDANCE

- Treatment recommendations are life-long—aggression may recur with treatment lapses and continued exposure to fear- and aggression-producing stimuli. Owners must always be vigilant and in control of the dog's behavior. • Appropriate early socialization and habituation may help prevent fear-based behaviors later in life. Puppies that are not socialized during the first three months of life are more likely to be fearful, defensive, and possibly aggressive later in life. Socialization may include attending well-structured, positive reinforcement puppy classes starting during the sensitive period for socialization from 7–12 weeks (perhaps up to 14–16 weeks). One study found that vaccinated puppies that attended puppy socialization classes were at no increased risk of parvovirus.

POSSIBLE COMPLICATIONS

Human injuries; euthanasia or relinquishment of patient

EXPECTED COURSE AND PROGNOSIS

There is no cure. Prognosis is more favorable if aggression is motivated by fear, at a low intensity, and occurs only in a few predictable situations. Prognosis is highly dependent on owner compliance.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Other fear- or anxiety-based conditions (e.g., noise phobias, separation anxiety) Aggression to other stimuli

ZOONOTIC POTENTIAL

Human injury from bite wounds

PREGNANCY/FERTILITY/BREEDING

Do not breed dogs with extremely fearful behavior or fear/aggression.

AGGRESSION TOWARD CHILDREN—DOGS

A

BASICS

OVERVIEW

Children are the most frequent victims of reported dog bites and tend to be injured more severely than adults.

SIGNALMENT

Any breed, age, gender, and neuter status.

Breed

- Breed reports vary with demographics. Breed identification may be unreliable.
- Breeds most commonly presenting to a behavior referral service that had bitten a child include English springer spaniel, German shepherd, Labrador retriever, golden retriever, and American cocker spaniel.
- Most fatal attacks (uncommon) are attributed to rottweilers, pit bulls, and their mixes. • Larger breeds and mixed breeds may be more likely to inflict severe injury.
- Smaller breeds can also be dangerous.

Sex

- More frequent in males than females.
- Neutering will not significantly reduce the risk.

Age

- Any age, but more frequent in socially mature dogs (2+ years old). • Risk may increase in geriatric dogs because of pain, sensory impairment, or irritability.

CAUSES & RISK FACTORS

Clinical Categories/Motivation for Aggression

- Fear-related • Pain-related • Play-related
- Conflict-related • Predatory • Territorial
- Resource (food/toy/bed) guarding

Dog-Associated Risk Factors

- Disease and associated irritability. • Pain-related aggression and resource guarding are the most common reasons for bites to familiar children < 6 years old. Generalized anxiety.
- Fearful behavior. • Dog lying down, particularly under or on furniture. • Parent/littermate aggression.

Environmental/Social Risk Factors

- Younger children most likely bitten by the family pet or other familiar dogs. • Presence of infants (risk of predatory attacks).
- Presence of young children. • Presence of food, edible toys. • Punishment-based training. • Inadequate supervision by parents/caregivers. • History of growling, snapping, biting. • Hugging, kissing, bending over anxious, fearful, or conflict-aggressive dog.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

See "Clinical Categories/Motivations for Aggression"

CBC/BIOCHEMISTRY/URINALYSIS

Baseline profile to rule out medical contributing factors.

OTHER LABORATORY TESTS

- Anecdotal evidence (only) correlates canine hypothyroidism with increased aggression; however, no data-based evidence.
- Unnecessary supplementation with thyroid hormone may predispose to agitation or aggression.

DIAGNOSTIC PROCEDURES

Thorough physical examination. A detailed history of the bite event and the behavior of both dog and child to determine motivation.

TREATMENT

SAFETY WITH FAMILIAR DOGS

- Never leave infants or young children unsupervised with dogs. Securely separate infants from dogs when alone, if both asleep.
- If one adult is present, separate dog from young children. • If more than one adult is present, assign responsibility for one adult to dog, and one to child. • Do not allow child to approach or interact with dog when dog is lying down. • Do not allow child to remove any object from dog. • Do not allow child to hug, kiss, bend over, or lie down beside dog.
- Separate dog when eating or chewing valued items.

SAFETY WITH UNFAMILIAR DOGS

- Do not tether unsupervised. • Do not allow young children to interact with unfamiliar dogs. • Securely lock gates in yards. • Avoid underground electric fences, which do not prevent entry of children into yard.

BEHAVIOR MODIFICATION THROUGH LEARNING/TRAINING

- Redirect dog's attention: teach "look" or "touch" cues. • Establish secure, separate "safe haven" for dog. • Restrict fearful or reactive dog on lead and offer food at safe distance from children, to turn a negative situation into a positive one. • Do not rely on training alone; safe practices require prevention.

MEDICATIONS

DRUGS

Anxiolytic drug may be indicated for dogs with generalized or situational anxiety or fearful behavior.

Selective Serotonin Reuptake Inhibitors

- Fluoxetine 0.5–2.0 mg/kg q24 h
- Sertraline 0.5–3 mg/kg q24 h

Tricyclic Antidepressants

Clomipramine 1–3 mg/kg q12 h

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Psychotropic medication can increase agitation and anxiety or disinhibit aggression. Use with safety recommendations to prevent bites. • Avoid the following combinations:
 - SSRI + TCA ◦ SSRI or TCA + tramadol
 - SSRI or TCA + MAOI including amitraz
 - SSRI + NSAID (caution, due to increased risk of GI or other hemorrhage).

FOLLOW-UP

PREVENTION/AVOIDANCE

- Do not rely on training alone to eliminate aggression. • Preventive measures are most important in management of canine aggression to children. • Even well-trained, socialized dogs may bite.

POSSIBLE COMPLICATIONS

- Family may not acknowledge risks.
- Disease may aggravate aggression. • Family may not be compliant. • Psychotropic drug may be unrealistically relied upon or ineffective. • Young children may be impulsive and difficult to control.

EXPECTED COURSE AND PROGNOSIS

- Aggressive behavior can often be reduced and controlled. However, lifetime compliance is needed. • Prognosis is poor if social/physical environment cannot be controlled.
- In some cases it may be necessary to rehome or euthanize dog, while in others the dog's behavior may improve as the child grows older.

MISCELLANEOUS

ABBREVIATIONS

- GI = gastrointestinal • MAOI = monoamine oxidase inhibitor • NSAID = nonsteroidal anti-inflammatory drug
- SSRI = selective serotonin reuptake inhibitor • TCA = tricyclic antidepressant

AGGRESSION TOWARD FAMILIAR PEOPLE—DOGS

BASICS

DEFINITION

Aggression, directed toward household members or people with an established relationship with the dog, often in situations involving access to resources. May be status-related/dominance, conflict, impulsive, competitive or possessive aggression.

PATOPHYSIOLOGY

These dogs may show anxiety or be impulsive and unpredictable. When the aggression is guarding of resources, or in response to fear eliciting stimuli (e.g., threats, punishment, possibly handling) might be normal.

SYSTEMS AFFECTED

Behavioral

GENETICS

Pedigree analyses have shown increased occurrence in related dogs. May be genetic factors associated with impulse dyscontrol in English springer spaniel and English cocker spaniel. May be more common in show than field lines.

INCIDENCE/PREVALENCE

20–44% of behavioral referral caseloads.

GEOGRAPHIC DISTRIBUTION

Regional breed differences exist.

SIGNALMENT

Species

Dog

Breed Predilections

Spaniel (English springer and cocker), terrier, but may be exhibited by any breed.

Mean Age and Range

Usually manifested by social maturity (12–36 months of age). May be seen in younger dogs.

Predominant Sex

Males (castrated and intact).

SIGNS

General Comments

Detailed history-taking is needed to make a diagnosis, assess risks, and devise a safe and realistic treatment plan. Mild signs of aggression (e.g., staring, growling, baring teeth) often precede bites. Details of early aggressive episodes are vital to establish the diagnosis and prognosis. Often anxiety or fear based but may be motivated by desire to control, e.g., personal space, resources.

Historical Findings

- Aggression (barking, growling, lip-lifting, snarling, snapping, lunging, biting) directed toward family members. Aggression may occur around resources such as resting areas, food, or toys, handling (e.g., petting and reaching toward), or favored possessions (including resting with one family member

when another approaches). Aggression may be seen in other contexts, e.g., denied access to items or activities, when resting, when confronted or punished, or during uncomfortable or fear-evoking interactions (e.g., ear cleaning, grooming, bathing).

History-taking should attempt to establish triggers and frequency/severity of aggressive episodes.

- Aggression may not be directed uniformly toward each household member.

- Confident/dominant body postures (stiffening, staring, standing straight up, ears forward, tail up, and/or approaching/direct contact with the person) may be associated with aggressive behavior, or the motivation may be fear (tensing, head down, crouching, backing away, ears back, tail tucked, looking away, lip licking). Owners may report a combination of confident and submissive postures representing uncertainty (conflict).
- Owners may describe dog as “moody” and may be able to predict when aggression is likely to occur. Early on the dog may show fear (e.g., eye aversion, tail tucked, avoidance) that may diminish and the dog may give less warning as it becomes more confident that aggression will be effective (negative reinforcement).
- Anxiety may be noted in pet-owner interactions and other situations.

Physical Examination Findings

- Usually unremarkable.
- Medical conditions, especially pain, may contribute to the expression of aggression.

CAUSES

- May be part of normal canine social behavioral repertoire, but its expression is influenced by environment, learning, and genetics.
- Display of aggression may be influenced by underlying medical conditions (especially pain), early experiences (learning that aggression is effective to control situations), and inconsistent or lack of clear rules and routines in the household and in human-pet interactions.

RISK FACTORS

Inconsistent or inappropriate physical punishment and inconsistent owner interactions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fear-based aggression
- Conflict aggression
- Anxiety conditions
- Disease conditions associated with aggression (e.g., painful conditions, endocrinopathies)

CBC/BIOCHEMISTRY/URINALYSIS

Usually unremarkable. Abnormalities may indicate an underlying or contributing medical condition.

OTHER LABORATORY TESTS

As indicated to rule out underlying diseases. Rule out hypothyroidism.

IMAGING

MRI if CNS disease is suspected; other imaging may be needed to rule out other medical conditions.

TREATMENT

ACTIVITY

Insure behavioral needs are being met.

DIET

Low-protein/tryptophan-supplemented diets may help reduce aggression.

CLIENT EDUCATION

General Comments

- Treatment is aimed at controlling the problem, not achieving a “cure.”
- Successful treatment, resulting in a decrease in aggressive incidents, depends on owner understanding of basic canine social behavior and communication, risks involved in living with an aggressive dog, and how to implement safety and management recommendations.
- Owners must be aware that the only certain way to prevent future injuries is euthanasia.
- Owners must be educated about the risks of using physical punishment and training techniques that rely on “dominating” their dogs. Improper and inappropriate use of physical punishment/dominance techniques such as alpha rolls, corrections with choke chains or prong collars, or even yelling “no” can lead to human injury, increased aggression and anxiety, and disruption of the human-animal bond.

Safety Recommendations

- If owners elect not to euthanize, they must be aware that their main responsibility is preventing human injury by diligently avoiding all situations that might evoke an aggressive response including situations that incite fear even if not aggression.
- Treatment must begin with prevention of exposure to all aggression-provoking stimuli prior to any behavior modification.
- Use patient history to identify each situation or trigger for owners to avoid. This may include not allowing on furniture or beds where aggression might arise, not giving valuable treats or toys (e.g., rawhides) except when confined away from family members, and limiting physical contact with the dog including petting in any place or situation where the dog might resist or bite. Instead provide the dog with opportunities (control) to avoid undesirable interactions (e.g., safe haven, crate). Reward the dog for entering the safe haven and for leaving (coming out).
- Do not physically punish or reprimand the dog.
- Introducing a head halter (e.g., Gentle Leader) with a lightweight 8- to 10-foot leash attached or a basket muzzle whenever in contact with people or in any situation where problems might arise, makes controlling potentially dangerous situations

(CONTINUED)

AGGRESSION TOWARD FAMILIAR PEOPLE—DOGS

A

easier and safer. • Use the long leash to safely remove the dog from situations that may elicit aggression; do not reach for the dog directly.

Behavioral Therapy

- Behavior modification—use non-confrontational methods and reward-based training to achieve desirable outcomes and teach the dog behaviors without experiencing fear or becoming aggressive. • Structured interactions (also known as learn to earn or say please by sitting) where the dog is consistently taught to sit for anything it values (before feeding, petting, play, going for a walk) gives the dog control of its resources by sitting calmly, provides structure and predictability in all interactions, teaches impulse control and trains the dog that good things happen by sitting calmly. Owners must ignore the dog until it sits or train “sit”, whenever soliciting attention. • Use positive reinforcement (e.g., food, toys, play, petting) for response substitution (or counter commanding) to teach behaviors that are incompatible with those that have resulted in aggression.

Desensitization and Counter-Conditioning

- Decreasing reactivity to situations that have resulted in aggression by making positive associations with each interaction. Do not begin until owner can insure success with reward-based training and sit for all interactions. • Teach the dog strategies to relax (sit, down, go to your bed) on verbal cue in neutral situations using food rewards.
- Expose the dog to a sufficiently reduced stimulus where no fearful or aggressive reaction is elicited (e.g., owner passing by resting dog at sufficient distance). • Reward calm, non-fearful/aggressive behavior (e.g., verbal praise, tossing favored treats).
- Gradually increase the level of stimulation, staying below the threshold that would result in fear and/or aggression. • Progress is slow (typically months) and careful monitoring is essential to understand and respect the dog’s limits. • Train on cue those behaviors needed to manage specific problems, e.g., go to your bed (for dogs that are protective of resting areas) or “drop it” (for resource guarding).

SURGICAL CONSIDERATIONS

- Castration reduced aggression by at least 50% toward family members in approximately 30% of dogs studied.
- Females that start to show dominance aggression at less than 6 months of age may be less aggressive if spaying delayed until mature.

**MEDICATIONS****DRUG(S)**

- There are no medications licensed for treatment of canine aggression. Owners must

be aware that the use of medications is off-label. Note in the patient’s record that owners were informed of potential risks and side effects. A signed informed consent form is advisable. NEVER use medications without concurrent behavior modification. Before prescribing medication, be sure that owners understand the risks and liability in owning an aggressive dog, will follow safety procedures, and do not expect medications to insure safety. In fact, medication may not be appropriate in all situations (e.g., households with small children or individuals with disabilities).

- There is a strong placebo effect when using drugs for behavior therapy in dogs. Studies have not shown a robust effect of drug treatment on aggression.

Selective Serotonin Reuptake Inhibitors

- Fluoxetine 0.5–2 mg/kg PO q24 h.
- Paroxetine 0.5–2 mg/kg PO q24 h.
- Sertraline 1–3 mg/kg PO q24 h.
- Side effects: sedation, irritability, GIT effects, increased aggression; anorexia is common and usually transient.

Tricyclic Antidepressants

- Clomipramine 1–3 mg/kg q12 h in dogs (label restriction for aggression)
- Side effects: sedation, GIT effects, anticholinergic effects, cardiac conduction disturbances if predisposed, and increased aggression.

CONTRAINdications

Use caution as any psychotropic medication may reduce fear-based inhibition resulting in an increase rather than decrease in aggression.

PRECAUTIONS

Any psychotropic medication may increase rather than decrease aggression.

Corticosteroids are contraindicated in food-aggressive dogs; polyphagia can lead to increased frequency/intensity of aggression.

POSSIBLE INTERACTIONS

Do not combine SSRIs, TCAs, MAO inhibitors (e.g., amitraz, selegiline), opioids (e.g., tramadol), and other medications that increase serotonin—can result in potentially fatal serotonin syndrome.

**FOLLOW-UP****PATIENT MONITORING**

Clients need ongoing assistance and should receive first follow-up call within the first 1–4 weeks after consultation. Provisions for further follow-up (by phone or in person) should then be made.

PREVENTION/AVOIDANCE

Treatment, including safety recommendations, are life-long—aggression

may recur if preventive strategies not maintained.

POSSIBLE COMPLICATIONS

Human injuries; euthanasia or relinquishment of patient.

EXPECTED COURSE AND PROGNOSIS

There is no cure. Prognosis is more favorable if aggression is at a low intensity and occurs in relatively few predictable situations. Prognosis is highly dependent on owner compliance.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Other forms of aggression, including interdog aggression, resource guarding, and aggression to unfamiliar people or dogs. Aggressive dogs often have underlying anxiety.

ZOONOTIC POTENTIAL

Human injury.

PREGNANCY/FERTILITY/BREEDING

Do not breed aggressive dogs.

SYNONYMS

- Competitive aggression • Conflict aggression • Dominance-related aggression
- Rage syndrome • Status-related aggression

ABBREVIATIONS

- CNS = central nervous system • GIT = gastrointestinal tract • MAO = monoamine oxidase • MRI = magnetic resonance imaging
- SSRI = selective serotonin reuptake inhibitor • TCA = tricyclic antidepressant

AGGRESSION TOWARD HUMANS—CATS

BASICS

DEFINITION

Human-directed aggression in cats

PATHOPHYSIOLOGY

The more common causes for human-directed aggression in cats include play, fear/pain-related, redirected, maternal, and petting intolerance. Context is going to contribute greatly when making the correct diagnosis. For example, play aggression is likely to be seen in a young, solitary cat, while pain-related/fear aggression is a common behavior seen in the clinic setting.

SYSTEMS AFFECTED

- Behavioral
- Gastrointestinal—decreased appetite if fear and/or pain-related
- Hemic/Lymphatic/Immune—chronic stress effects on immune function
- Ophthalmic—dilated pupils in response to autonomic nervous system stimulation
- Skin/Exocrine—may show displacement behaviors such as overgrooming

GENETICS

There is no known genetic basis for human-directed aggression in cats.

INCIDENCE/PREVALENCE

Aggression is second only to inappropriate elimination for feline cases seen by veterinary behavior specialists.

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Cats of any age, gender/ neuter status, breed can be affected. Play-motivated aggression more likely in juvenile, solitary cat.

SIGNS

- Play-motivated: cat approaches its “victim,” crouches in wait, stalks and chases; tail is twitching and ears are forward. Typically will attack moving target.
- Fear/Pain-related: ears back, body and tail lowered, piloerection, pupils dilated; may hiss and growl. Avoidance of person(s) who elicit the aggression. Attacks possible if approached and/or cornered. Extreme cases: expression of anal glands, urination, and/or defecation.
- Hiding behavior.
- Redirected: cat is highly aroused by stimulus and seeks out less appropriate target.
- Aggression can be very severe given the cat's level of arousal.
- Maternal: usually predictable and self-limiting. Queen will act to protect her kittens.
- Petting intolerance: cat signals its “displeasure” by twitching its tail and skin when being petted in an undesired location and/or for too long. Ears are usually back;

mydriasis; may hiss and growl before turning to bite person.

CAUSES & RISK FACTORS

- Play-motivated: lacking in opportunities for normal play—no other cats, insufficient and/or inappropriate toys; history of owner using hands/feet to play with kitten and/or playing roughly with the kitten.
- Fear: poor socialization with humans and/or feral living, an aversive event associated with a person, or people in general.
- Pain-related: obvious medical/physical condition.
- Redirected: occurs during interference in, or interruption of, situations that have caused the cat to become aggressively aroused—such as a cat fight (between familiar household cats), the presence of a cat outside or noise.
- Maternal: recent birth of litter.
- Petting intolerance: exact etiology unknown. Cats tend to groom each other on head/neck so human grooming of cat in other locations may contribute to aggressive reaction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

See causes above

CBC/BIOCHEMISTRY/URINALYSIS

Rule out contributing medical conditions based on presentation.

OTHER LABORATORY TESTS

- Senior cats: a complete thyroid panel.
- Urinalysis if inappropriate elimination and/or urine marking is presented as part of the aggression.

IMAGING

Based on clinical examination and/or suspected pain component

DIAGNOSTIC PROCEDURES

Thorough behavioral history including a description of the cat's postures during aggression and injuries inflicted, context, presence of outside cats, early historical information, litter box use, food consumption, and hiding behaviors.

PATHOLOGIC FINDINGS

N/A

TREATMENT

APPROPRIATE HEALTH CARE

Applicable only if health/medical issue diagnosed.

NURSING CARE

Applicable only if health/medical issue diagnosed.

ACTIVITY

- Play-motivated: cat should be provided with increased opportunity for appropriate play—either in the form of toys, human interaction, or additional housemate.
- Redirected: cat should be denied access to windows where outside cats can be seen.

DIET

- Hill's Science Diet c/d Multicare Feline Urinary Stress
- Royal Canin Feline Calm
- Either may be beneficial in helping to decrease anxiety.

CLIENT EDUCATION

- Play-motivated: normal play behavior and the importance for opportunities for appropriate play.
- Fear: avoidance of fear-inducing situations—ongoing exposure may worsen signs, cause severe stress, and compromise animal welfare.
- Redirected: importance in addressing primary stimuli—such as outside cats.
- Maternal: normal maternal and kitten-protective behavior—same as for fear-motivated aggression.
- Petting intolerance: normal feline grooming patterns; observation of cat's warnings so that behavior does not escalate.

Behavior Modification Exercises

Desensitization and Counter-Conditioning (DS & CC)

- Desensitization: exposing cat to the fear-inducing stimulus (scary person) at a low level so the cat does NOT react fearfully or aggressively. Over time, the intensity of the stimulus is increased (i.e., the distance between the cat and stimulus is decreased) without causing fearful responses.
- Counter-conditioning: rewarding the cat with a special treat, toy, grooming, petting, for relaxation.

Classical Conditioning (CC)

Classical conditioning: pairing the stimulus (person threatening to the cat) with a tasty treat, toy, petting. Example: scary person = tuna fish.

MEDICATIONS

The short-term use of medication may be necessary to decrease overall levels of anxiety and reactivity in more severe cases.

DRUG(S) OF CHOICE

Azapirones

Buspirone 0.5–1.0 mg/kg PO q12h. Most useful for fearful and withdrawn cats. Decreases anxiety and may increase “self-confidence.” Anecdotal reports of “increase in affection”; therefore might be useful in severe cases of petting intolerance. Response noted in 1–2 weeks.

(CONTINUED)

AGGRESSION TOWARD HUMANS—CATS

A

Selective Serotonin Reuptake Inhibitors (SSRIs)

- Fluoxetine, paroxetine, sertraline 0.5–1.5 mg/kg PO q24h.
- SSRIs must be given daily. May take 4–8 weeks to reach peak effects.

Tricyclic Antidepressants (TCAs)

- Amitriptyline 0.5–2.0 mg/kg PO q12–24h.
- Clomipramine 0.25–1.3 mg/kg PO q24h.
- TCAs must be given daily. May take 4–8 weeks to reach peak effects.

Benzodiazepines

- Alprazolam 0.125–0.25 mg/cat PO q8–24h.
- Diazepam 0.1–1.0 mg/kg PO q12–24h (rarely used due to potential hepatopathies).
- Can be given “as needed” for specific encounters with people inducing the fear response and during desensitization, counter-conditioning and classical conditioning sessions.
- Can be used in conjunction with azapirones, SSRIs, and TCAs.

**CONTRAINDICATIONS/
PRECAUTIONS/POSSIBLE
INTERACTIONS**

- None of the drugs listed are approved for use in cats.
- All of the medications are to be administered orally, as they have not been shown to be effective through transdermal dosing.
- Azapirones: side effects are uncommon but occasional excitement is noted. Should not be given in combination with an MAOI. Avoid use in the aggressor cat; may increase any “bully” behavior.
- Neither SSRIs nor TCAs should be given with each other, nor in combination with MAOIs.
- SSRIs: side effects include mild sedation and decreased appetite, constipation, and urinary retention. Competitive inhibition of cytochrome P450 liver enzymes; when administered concurrently with medication utilizing the P450 enzymes, elevated plasma levels of the medications may increase, causing toxic levels.
- TCAs: side effects include sedation, constipation, diarrhea, urinary retention, appetite changes, ataxia, decreased tear production, mydriasis, cardiac arrhythmias, tachycardia, and changes in blood pressure.
- Benzodiazepines: side effects include sedation, ataxia, muscle relaxation, increased appetite, paradoxical excitation, and increased friendliness. Idiopathic hepatic necrosis has been reported in cats.

- Specific recommendations for the use of diazepam: baseline physical exam, CBC, and blood chemistries to confirm good health. Repeat the blood chemistries at 3–5 days. Elevated ALT or AST, discontinue the medication.

ALTERNATIVE DRUGS**Pheromones**

- Used alone or concurrently with drugs
- Feliway—available in diffuser, spray and wipes—facial pheromone
- NurtureCALM 24/7 collar—maternal pheromone

Supplements

- Used alone or concurrently with drugs
- Anxitane—contains L-theanine, a calming compound found in green tea
- Zylkene—contains alpha-casozepine, a GABA agonist

**FOLLOW-UP****PATIENT MONITORING**

Weekly follow-up is recommended in the early stages of treatment, especially when on medication(s). Monthly follow-up once stable. For cats on medication, follow-up blood testing recommended every 6–12 months.

PREVENTION/AVOIDANCE

- Play-motivated: provide opportunities for appropriate play.
- Fear: avoidance of the fear-inciting stimuli if at all possible. Early socialization to people and events may help prevent some occurrences of fear-related responses to people.
- Pain: treat underlying condition(s).
- Redirected: address possible arousing stimuli—indoors and outdoors.
- Maternal: as for fear.
- Petting intolerance: limit amount of time petting the cat; desensitization and counter-conditioning to increase petting time.

POSSIBLE COMPLICATIONS

Potential human injury in all of the above cases, especially if the cat is approached or cornered and/or when highly aroused.

EXPECTED COURSE AND PROGNOSIS

Progress occurs slowly. Relearning is a process and each case is individual. If medications are indicated, begin at a low dose and work up as necessary. To discontinue medication, wait

until the new behavior is stable (8–12 weeks) and wean off slowly, usually over weeks. If aggressive behavior recurs, return to the last dose that controlled the anxiety/reactivity and continue treatment.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

Play-motivated: typically seen in young, solitary cat in household.

ZOONOTIC POTENTIAL

People injured during an aggressive attack should seek prompt medical attention. Infection by *Bartonella henselae* can result from a cat scratch or bite.

PREGNANCY/FERTILITY/BREEDING

Avoid medications in breeding/nursing cats.

AGGRESSION, FOOD AND RESOURCE GUARDING—DOGS

BASICS

OVERVIEW

- Aggressively guarding food (e.g., in food bowl, rawhides, bones, stolen/found items) or objects (e.g., toys, stolen objects).
- Usually within the range of normal behavior; genetics, learning or early experience may contribute to excessive expression of aggression.

SYSTEMS AFFECTED

Behavioral

SIGNALMENT

No breed or sex predilections.

SIGNS

Aggression (barking, growling, lip-lifting, snarling, snapping, lunging, biting) toward people or other animals in the presence of valued food items or objects.

CAUSES & RISK FACTORS

- May be part of normal canine behavior. Strongly influenced by previous experiences of successfully defending food, or objects through aggression and by resource availability/novelty.
- Underlying medical conditions and medications, especially those causing polyphagia, or calorie-restricted diets may increase level of food aggression.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fear aggression
- Social status/dominance or conflict aggression

CBC/BIOCHEMISTRY/URINALYSIS

Usually unremarkable. Abnormalities suggest an underlying or contributing medical condition.

OTHER LABORATORY TESTS

Usually unremarkable.

IMAGING

MRI if CNS disease suspected. Other imaging as needed to rule out underlying medical conditions.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

CLIENT EDUCATION

- Treatment is aimed at control, not achieving a "cure." Successful treatment resulting in a decrease in aggressive incidents, depends on owner understanding of basic canine social behavior, risks involved in living with an aggressive dog, and ability to follow safety and management recommendations.
- If safety cannot be insured, pet should be removed from the home.

Safety Recommendations

- The owner's main focus must be on preventing injury by diligently avoiding situations that may evoke an aggressive reaction.
- Owners may be more compliant with avoidance recommendations if they understand both the risk and the potential liability if the dog causes injury.
- Successful treatment is more likely if a period of preventing exposure to aggression-provoking stimuli is instituted prior to behavior modification.
- Always confine the dog away from potential victims or the dog must be under the direct physical control of a responsible adult whenever an aggression-provoking situation could arise.
- Give food and any other objects that the dog might guard in a confinement/safe haven location away from people and other animals; prevent access to items that may evoke aggression.
- Teach the dog to be comfortable wearing a head halter (e.g., Gentle Leader) and basket muzzle for safer control of potentially dangerous situations.
- Punishment/dominance-based training techniques are contraindicated as they cause further fear, agitation, defensive aggression, and further learning (fear of approach and negative reinforcement if successful).

Behavior Modification

- Command-response-reward program (say please by sitting): to increase owners' control of resources, make the dog more responsive to the owner, and create structure and predictability in the dog's life.

- Use positive reinforcement (e.g., food, toys, play) to teach behaviors that are incompatible to those that lead to aggression including a calm sit and watch before giving any food, chews or toys, and "drop it" to release toys for valuable rewards.
- Prevent access to items that might be stolen or guarded by supervising with leash if necessary, dog proofing or confinement training.
- "Booby trap" items by applying an aversive substance such as hot sauce.
- Systematic desensitization and counter-conditioning to specific aggression-provoking stimuli if safety and owner compliance can be insured.
- Find the threshold (distance, location) at which the dog shows no anxiety or aggression when in possession of food or chews and make positive associations by tossing small food treats each time the owner walks by—the goal is for the dog to associate the owner's presence with positive outcomes. If successful, training can very gradually proceed to closer proximities—level of improvement will be limited by safety and the dog's motivation to retain the resource.

MEDICATIONS

DRUG(S)

Medications are generally not indicated in the treatment of resource guarding.

FOLLOW-UP

PATIENT MONITORING

Clients usually need ongoing assistance with at least one follow-up call within the first 1–3 weeks after the consultation. Provisions for further follow-up should be determined at that time.

PREVENTION/AVOIDANCE

Management recommendations (avoiding triggers) are life-long..

POSSIBLE COMPLICATIONS

Human injuries; euthanasia or relinquishment of patient.

(CONTINUED)

AGGRESSION, FOOD AND RESOURCE GUARDING—DOGS

A

EXPECTED COURSE AND PROGNOSIS

There is no cure. Prognosis for improvement is more favorable if aggression is at a low intensity, occurs in only a few predictable situations, and can be effectively and practically prevented.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Fear and dominance/conflict aggression

ZOONOTIC POTENTIAL

Human injury and bite wounds

PREGNANCY/FERTILITY/BREEDING

Do not breed dogs with extreme aggression.

AGGRESSION, INTERCAT AGGRESSION

BASICS

DEFINITION

Intercat aggression—offensive or defensive aggression between cats consisting of staring, displacing, vocalizing (growling, yowling, shrieking), spitting, hissing, swatting, lunging, chasing/stalking, and/or biting other cats.

PATHOPHYSIOLOGY

- May be normal behavior or abnormal.
- May be caused by underlying medical disease (e.g., CNS) or the indirect result of concurrent medical disease lowering the threshold for irritable responses (e.g., pain, hyperthyroid). • May be multiple motivations including predatory/play, disputes over territory, sexual, fear, anxiety, and redirected.

SYSTEMS AFFECTED

- Behavioral. • Skin/Exocrine—secondary to traumatic injury. • Immune—chronic stress may alter the immune response. • Secondary infection (cat bite abscesses) are not uncommon. • Nervous.

GENETICS

No specific genetic basis, although some evidence to suggest that friendliness is mostly genetic and related to paternal effects.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Breed Predilections

None

Mean Age and Range

- Can occur at any age when due to changes in social environment (e.g., addition of a new cat, return of a cat from the veterinarian) or redirected. • Previously stable cat relationships can deteriorate as cats reach social maturity (2–4 years of age).

Predominant Sex

- Intact males more likely to initiate intercat aggression (related to territory, and/or proximity to females). • Females will defend their young from unfamiliar individuals.
- Male kittens are more likely to initiate intercat aggression related to the predatory components of play.

SIGNS

Historical Findings

- May arise spontaneously and vary in frequency and intensity. • Owners most likely to seek behavioral intervention if there are physical injuries, the welfare of the aggressor and /or victim is compromised, or fighting becomes sufficiently distressing. • Human intervention in an attempt to interrupt fighting may result in human-directed aggression/injury.

Aggressor (usually offensive)

- Covert signs: staring, displacing other cats, stiff body language/movements while approaching the other cat. • Overt signs: Growling, yowling, spitting, hissing, swatting, lunging, chasing/stalking, and/or biting other cats, dilated pupils, may be accompanied by body language of fear (e.g., the classic Halloween cat stance—piloerection, back arched, tail up) or more offensive body language (stiff muscles, tail head elevated but rest of tail down, back straight or slightly slanted toward the head, ears forward or to the side), excessive facial marking, and perhaps urine marking.

Victim (usually defensive)

- Covert: avoidance of aggressor, hiding, change in grooming and eating habits, hypervigilance, dilated pupils. • Overt: hissing, swatting, running, vocalizing (including growling), Halloween cat stance, may escalate to defensive attack if cornered.

Elimination Outside of the Litter Box

- Aggressor may block access to the litter box area, forcing victims to choose alternative elimination locations; secondary substrate and/or location preferences and aversions can develop. • Both victims and aggressors may urine mark. • Extremely fearful cats may urinate or defecate in midst of aggressive events.

Physical Examination Findings

- None except injury from fights or if underlying medical issues. • Stress may affect eating and self-grooming (increased or decreased).

CAUSES

- Lack of appropriate socialization to other cats prior to 7 weeks of age. • May be a component of normal social behavior. • Social and environmental instability such as the addition of a new cat, loss of a resident cat, odor stimuli (return of a cat from the veterinarian or giving one cat a bath), aging or illness of one or both cats, cats reaching social maturity. • Household change, e.g., moving, changing furniture or resting areas.
- Genetically unrelated cats and cats that have recently moved in together are more likely to show aggressive behaviors toward each other.
- Resident cats commonly need prolonged exposure to new cats before accepting them into group. • Resource limitation (not enough vertical and/or horizontal space, lack of appropriate hiding areas, and limited food, water, and litter boxes, etc.) in multi-cat households. • Exposure to arousing stimuli (cats in the yard, visitors, noises, scents, etc.) can cause redirected aggression after which aggression might persist. • Medical problems including CNS disorders, hyperthyroidism, or any disorder that causes pain and/or increased irritability.

RISK FACTORS

- Singleton and/or bottle-raised kittens.
- Lack of social exposure and experience with conspecifics during the socialization period (2–7 weeks) and beyond. • Male intact cats in multi-cat households. • Postpartum females with kittens in multi-cat households.
- Separating and returning housemate (e.g., following veterinary visit, groomer).
- Changes in social group such as the addition of a “new” cat to a home of resident cats. • Scratching and biting during the first introduction risks future intercat aggression.
- Access to the outdoors and/or intrusion of unfamiliar cats onto the territory. • Crowding or lack of adequate social space and access to resources (food, water, litter boxes, and resting stations).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Behavioral Differentials

- Fear-related aggression—cat may hiss, spit, arch the back, display piloerection and attempt to flee unless escape is thwarted; pupil dilation will accompany a fear response.
- Status-related aggression—may occur with change or instability of social hierarchy and the control of access to resources; it is undecided if cats have dominance hierarchies or if conflict is better explained by territorial defense. • Territorial aggression—in response to threat to the territory; boundaries are often delineated by marking with urine, feces, or scent glands. • Redirected aggression—exposure to agitating stimuli (cats in the yard, visitors, noises, scents, etc.) with aggression directed toward a target other than the agitating stimuli. • Failure of recognition—aggression between feline housemates after returning from separation (e.g., veterinary visit, grooming); most likely due to change in odor and visual cues of victim. • Maternal aggression—aggression during the periparturient period; females guard kittens and nesting sites from unfamiliar individuals.
- Intermale aggression—between males in response to territorial disputes, hierarchical status, or mates; aggression may be more pronounced at social maturity. • Sexual aggression—male typical behavior of chasing, pouncing, biting on the nape of the neck, and mounting with or without intromission.
- Predatory/play-related aggression—predatory components of play directed toward another cat; the recipient is often an older cat that is not interested in playing.

Medical Differentials

- Any illness causing malaise, pain, or increased irritability • Endocrine, e.g., hyperthyroidism • Neurologic: space-occupying lesions, e.g., meningioma, lymphoma, encephalitis, seizures, feline

(CONTINUED)

AGGRESSION, INTERCAT AGGRESSION

A

ischemic encephalopathy, trauma, sensory or cognitive decline • Infectious: rabies, toxoplasmosis, aberrant parasitic migrations (e.g., cuterebriasis), FIV, FeLV • Iatrogenic: medications that increase irritability or disinhibit aggression (e.g., mirtazapine, benzodiazepines, buspirone) • Toxins: lead, illicit substances

CBC/BIOCHEMISTRY/URINALYSIS

Baseline CBC, biochemistry, urine to rule out medical causes and as a baseline if drug therapy indicated.

OTHER LABORATORY TESTS

- FeLV/FIV • Cats > 6 years should have total T₄ measured

IMAGING

As indicated based on history and physical signs

DIAGNOSTIC PROCEDURES

- Obtain a detailed behavioral and medical history of the patients. • Identify if there is a clear aggressor and/or victim and if aggression is overt or covert. • If multiple cats determine which cats spend time together, mutually groom each other, and which cats physically avoid each other. • Identify the preferred core areas of each cat for feeding, play, and resting and locations of any house soiling or marking.
- Identify: the number, location, types of litter boxes and their management. • Media in the form of video, photographs, and/or drawn floor plans can provide spatial details and information regarding body language during social interactions. • Note any other changes in demeanor, routine, eating, and grooming.

PATHOLOGIC FINDINGS

None unless concurrent medical diseases

**TREATMENT****APPROPRIATE HEALTH CARE**

- Treat as outpatients with behavior and environmental modification (\pm medication)
- Current on routine vaccinations, including rabies

NURSING CARE

Supportive care if any injuries from fighting.

ACTIVITY

May need to be restricted if confinement required to prevent the perpetuation of aggression and negative emotional responses. Provide sufficient alternate outlets for each cat during confinement area and during release.

DIET

None (except possible therapeutic diet trial discussed below)

CLIENT EDUCATION

For chronic, severe cases or for aggression that does not respond to treatment, may require permanent separation either by rehoming one of the cats or by splitting up the residence.

For Cases that have a Low Frequency of Intense, Injurious Aggressive Outbursts

- Separate the cats when they cannot be supervised (create "safe zones"). • Either keep them separate in the same areas each day in an effort to form separate core territories for each cat, or "time share" the space between cats.
- Confine the newly introduced cat or the aggressor to the smaller, less familiar area.
- For multiple cats, separate by stability of relationship between cats. Any despotic/bully cats should be confined alone. • Consider "artificial allomarking" to form a communal scent between the cats that are fighting; a towel (facecloth) may be rubbed (cephalocaudally) to obtain the scent of one cat and then rubbed onto the other cat and vice versa. • Towels should be left in the environment to allow for habituation to each other's scent especially if the cats are kept separated. • Reward cats with food, play, and/or attention for being in the same room together without having aggressive events. Cats should stay at a distance that allows for calm participation. • Engage cats in daily sessions of pleasurable activities (e.g., play, training, eating delectable food treats) at distances that do not incite aggression. Gradually move the fun sessions closer to each other, making sure to stay at a distance that does not trigger overt/covert aggression.
- Teach the cats a "come and/or go to place" cue using positive reinforcement at times, in situations, and with sufficient rewards that the cats are most able to learn. • Interrupt or redirect the cats by cueing to come or go to its place, or by luring one or both cats to their safe zones with food and treats, wand toys, tossed toys, or laser pointers before aggression starts or as initial signs are seen (e.g., staring, tail twitching, pupil dilation). • Aversives and/or punishers can increase aggressive behavior and increase negative associations with other cats, so must be avoided or used cautiously. • The goal of management and safety is to prevent aggressive events. In an emergency, use of a laundry basket or blanket placed between or over the cats, can stop aggression, and direct the cat to its safe area until calm, but should not be considered as a treatment. • Bell the aggressor (using a quick release or safety collar) so both the owners and victim can quickly identify his/her location.
- Increase the number of resources and locations (e.g., food, water, scratching, perching, bedding, play and feeding toys) throughout the residence including each cat's core area. The efficacy of multimodal environmental enrichment should not be underestimated. • Increase litter boxes to the number of cats plus one divided among multiple locations so that one cat cannot keep another from accessing the boxes; locations with more than one exit/entry are ideal.
- Increase the number of hiding places and resting areas; especially concentrate on

increasing vertical space (e.g., resting areas on shelves, window sills). • No new cats should be added to the house.

For Cases where the Cats Cannot be in the Same Room without Immediately Becoming Agitated

- Separate cats completely when unsupervised. • Meet each cat's needs for play, litter boxes, food, water, perching, resting, and attention. • A large wire dog kennel or vertical orientated wire cat cage (with shelving) may be better tolerated than smaller cat kennels and can be used for controlled exposure.
- Cats may be taught to tolerate harnesses and leashes so that they can be used during training and controlled reintroduction. This is especially valuable for the aggressor. • Set up desensitization and counter-conditioning sessions daily; initially utilize physical and visual barriers. • Introduce the cats (in their kennels or on leash and harness) at a distance from each other that prevents overt/covert aggression. Feed the cats or engage in play for classical counterconditioning. • Over many sessions gradually reduce the distance between the cats, being careful to stay far enough apart during each session that no overt or covert behavioral signs of aggression and/or fear are seen. Start and end all sessions on a successful note. • Teach the cats a "come and/or go to place" cue using operant counterconditioning and positive reinforcement. Practice these cues several times daily so each cat learns to respond reliably. Behavioral cues are best taught when animals are not stressed. • When ready to allow the cats more freedom with each other, follow the instructions for less severe interact aggression (above).

SURGICAL CONSIDERATIONS

Neutering intact males is approximately 90% effective in reducing roaming, intercat aggression, and urine spraying.

Neutering/spaying is effective in reducing mounting/sexual behavior.

**MEDICATIONS****DRUG(S) OF CHOICE**

All medications are extra-label, insure that the client is informed, and review target desirable outcomes and potential adverse effects.

For the Aggressor and/or Victim**Selective Serotonin Reuptake Inhibitors (SSRI)**

- Fluoxetine or paroxetine 0.5–1 mg/kg PO q24 h.
- Drugs of choice for aggression, anxiety, and/or urine marking, may decrease impulsivity.
- Side effects may include gastrointestinal upset, decreased appetite, sedation, urinary

retention (paroxetine), and increased agitation/irritability.

Tricyclic Antidepressant (TCA)

- Clomipramine 0.3–0.5 mg/kg PO q24 h: serotonin selective tricyclic: for anxiety and aggression

• Side effects include gastrointestinal upset, sedation, urinary retention, constipation, and lowered seizure threshold. Do not use in patients with arrhythmias or cardiomyopathies.

Pheromones

Feliway and Feliway Multicat (CEVA) and Felifriend (CEVA, presently available in Europe) are feline facial pheromones that may be helpful in cases of intercat aggression when used with a multimodal plan.

For the Victim

Azapirone

Buspirone 0.5–1 mg/kg PO q8–24 h (feline dose): reserved for victims to increase social confidence.

- Side effects rare; may include decreased sociability and increased agitation/irritability. May increase intercat aggression as victim may be more confident and fight back."

Benzodiazepines

- Lorazepam 0.125–0.25 mg/cat PO up to q12–24 h or oxazepam 0.2–0.5 mg/kg PO q12–24 h for anxious or fearfully aggressive cats and as an appetite stimulant helping to facilitate classical counter conditioning. May be used as needed with peak effects seen within 1 hour.
- Side effects may include increased appetite, ataxia, inhibited learning, and disinhibition of aggression.
- Note: controlled substance; dependence can develop; Medication should be gradually weaned if used consistently for longer than 2 weeks.

CONTRAINDICATIONS

- Benzodiazepines should be used cautiously or avoided in cats with hepatopathies.
- Paroxetine and TCAs may produce anticholinergic side effects. Fluoxetine also occasionally reported to cause urine retention.
- SSRIs and TCAs should be used with caution in patients with histories of cardiac abnormalities, seizures, and liver disease.

PRECAUTIONS

- Any behavioral drug has the potential to produce paradoxical reactions, including fear, anxiety, hyperexcitability and/or aggression.
- Medications that alter serotonin levels have the potential to produce serotonin syndrome.

POSSIBLE INTERACTIONS

- Avoid concurrent use of SSRIs and TCAs or MAO inhibitors such as selegiline and use

cautiously or avoid with buspirone, tramadol, and tryptophan due to possible serotonin syndrome. • Caution with concurrent medications considered substrates of P450.

ALTERNATIVE DRUGS

- Amitriptyline (TCA) 0.5–1 mg/kg PO q12–24 h: for anxious cats especially if comorbid recurrent FIC/FLUTD; not selective for serotonin reuptake inhibition and likely less effective for the aggressor. • Dietary supplementation with alpha-casozepine (Zylkene: Veotquinol), ROYAL CANIN Veterinary Diet CALM (contains alpha-casozepine, L-tryptophan, and nicotinamide) or Hill's Prescription Diet Multicare Feline Urinary Stress (contains L-tryptophan and milk protein hydrolysate).

FOLLOW-UP

PATIENT MONITORING

- Clinicians should monitor patients 2 weeks after treatment initiation and monthly for the first few months by phone or email; a follow-up visit should be scheduled 4–8 weeks into treatment if drugs dispensed to assess response and adjust dose if necessary.
- Benzodiazepines may rarely cause cases of fatal hepatopathies; patients should be rechecked immediately if any adverse events, including anorexia. • Medication should be used for at least 4–6 weeks after resolution of signs, then gradually weaned by reducing the dosage no faster than 25% per day on a weekly basis. • Some patients require long-term medication; recheck laboratory work every 6 months to 1 year depending on health and age..

PREVENTION/AVOIDANCE

- Proper socialization 2–7 weeks and ongoing. Gradual introduction more closely resembles the natural process through which new cats enter an existing group at the periphery and may be accepted over time. Intercat aggression may be more common when unfamiliar cats are suddenly placed together. A negative initial encounter is often associated with future intercat aggression. Related and familiar cats are less likely to have intense intercat aggression. In stable multi-cat households, avoid adding additional cats.

POSSIBLE COMPLICATIONS

Abrupt withdrawal of behavioral medications may result in aggression and rebound anxiety.

EXPECTED COURSE AND PROGNOSIS

- The prognosis for most cases is fair; it is complicated by prolonged duration, high intensity, underlying medical conditions, and

incomplete owner compliance. In one study 62% (30/48) were considered cured and 37% (17/48) not cured (cat given away, euthanized or permanently separated). • Recent and mild (low-intensity, low-frequency) cases may have better long-term outcomes.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Urine marking/spraying • House soiling
- Excessive grooming • Fearful/anxiety-related behavior • Human-directed or interspecies aggression

AGE-RELATED FACTORS

Predatory/Play-related aggression more common in young active and playful cats housed indoors with more sedentary or aged individuals.

ZOONOTIC POTENTIAL

Humans intervening while cats are fighting may be injured and contract infections through cat bites and/or scratches.

PREGNANCY/FERTILITY/BREEDING

Most behavioral medications are contraindicated in breeding animals.

SYNONYM

Feline intraspecies aggression

ABBREVIATIONS

- FeLV = feline leukemia virus
- FIC/FLUTD = feline idiopathic cystitis/feline lower urinary tract disease
- FIV = feline immunodeficiency virus
- MAOI = monoamine oxidase inhibitor
- SSRI = selective serotonin reuptake inhibitor • T₄ = thyroxine • TCA = tricyclic antidepressant

Consulting Editor Gary M. Landsberg

BASICS

DEFINITION

- Aggression is a behavioral strategy used to manage aversive situations.
- May be normal and appropriate in certain contexts.
- May be abnormal with serious deleterious effects on the cat's physical and emotional well-being.
- Aggressivity: describes both mood and temperament traits relating to the propensity to show aggression when environmental circumstances dictate it might be used.

OVERVIEW OF TYPES

Play Aggression (Toward People)

- Typically refers to a cat who scratches and bites the owners during play.
- Not true aggression but overzealous play without proper impulse control due to lack of training or proper intraspecific social feedback.
- The cat's intent is not to harm the person.
- Behavior encouraged and rewarded by owners through rough play with a kitten; when larger and stronger, becomes perceived as aggression rather than overzealous play.

Predatory Aggression (Toward People or Other Animals)

- Cats have an innate drive to "hunt" or show predation behavior, which includes stalk, hide, and pounce.
- Predation is not a direct function of hunger.
- Typically stimulated by fast movements and can progress to the cat hiding and waiting for an animal or person to walk by.
- Play is a common way for young cats to perfect predation skills; play aggression and predatory aggression may overlap.

Redirected Aggression (Toward People or Other Animals)

- Cats who see, hear, or smell a trigger and direct aggressive behavior toward the closest bystander.
- In some cases, one person or animal in the home becomes the designated victim, and the cat may bypass a nearby individual and look for the preferred victim.
- Some cats may stay aroused for 24–72 hours after a triggered event.
- Common triggers inciting redirected aggression are seeing another cat or wildlife outside or loud noises.

Fear/Defensive Aggression (Toward People or Other Animals)

- The cat will show body postures indicative of fear/anxiety and may use aggression as a strategy to manage an aversive situation.
- Typical behaviors shown include a combination of any of the following: hissing, spitting, piloerection, arched back, turning away, running away, cowering, rolling on its back and pawing (defensive position, not submissive position) if cornered.

Territorial Aggression (Toward People or Other Animals)

- Some cats, particularly male cats, show territorial behaviors in domestic home settings due to size and the presence of more resources (e.g., people, food, resting areas, feeding areas, elimination sites, etc.) to defend in a smaller area.
- Territorial behaviors include marking with urine, feces, or bunting (the rubbing of the cheeks on surfaces to deposit pheromones) and scratching (also deposits pheromones and leaves visual marker) and may be associated with aggression.
- In severe cases, the aggressor may seek out the other individuals and attack.
- Body posture with territorial aggression is assertive and confident.

Pain Aggression (Toward People and Animals)

Cats who are in pain may show aggression (hiss, growl, scratch, bite) when they are physically handled or prior to or after movements such as jumping onto or off a piece of furniture.

Maternal Aggression

A female cat may show aggressive behaviors toward individuals approaching her kittens.

Impulse Control Aggression

Cats who show intense aggressive responses to mild stimuli without much or any warning may have an impulse control disorder arising from dysfunctional serotonin neural circuits.

Frustration-Induced Aggression (To People and Other Animals)

Some cats have very outgoing, social personalities and exhibit aggression if the captive life indoors does not meet their behavioral needs.

Contact-Induced/Petting Aggression (Toward People)

- Cats will show early signs of aversion when people stroke their cats, with their ears going back and tail swishing.
- If physical contact continues, they typically bite.
- Owners often miss the early warning signs.
- When cats groom one another, they typically limit the grooming to the head region.
- Some cats appear to be particularly sensitive to being stroked along the dorsum, the common method used by owners.

Intercat Aggression within a Home

- Fifty percent of cat owners report fighting (scratching and biting) after introducing a new cat to the home.
- The number of cats, gender, and age are not significant factors in predicting which cats will show aggression.
- Any of the above categories of aggression are all possibilities for fights between or among cats.
- Fear/anxiety is the most common cause of intraspecific aggression.

CONTRIBUTING FACTORS TO THE PATHOPHYSIOLOGY

Behavior problems are typically multifactorial in cause, and Figure 1 is a diagram illustrating some of the more common components that

need to be evaluated to accurately diagnose and treat aggression cases.

SYSTEMS AFFECTED

- Behavioral—vary with type of aggression, occur alone or in combination: tail swishing/twitching, ears turned sideways or flattened, stiffening of shoulders/legs, crouching, dilation of pupils, hissing, spitting, growling, piloerection, staring, chasing, stalking, pawing, lunging.
- Cardiovascular—signs associated with sympathetic activation and HPA activation.
- Endocrine and Metabolic—long-term aggression associated with fear/stress/anxiety, symptoms associated with long-term activation of the HPA system.
- Gastrointestinal—with chronic HPA stimulation may see a cat more prone to anorexia and GI ulcers. With acute fear aggression: evacuation of the bowel and possible diarrhea. IBD possible in chronic stress.
- Hemic/Lymphatic/Immune—decreased immune response with chronic HPA stimulation; stress leukogram.
- Musculoskeletal—an outcome of the aggression may result in damage to the muscles from damage by the nails and teeth.
- Both the victim and the aggressor may suffer injuries. With chronic activation of the HPA, may see muscle wasting.
- Nervous—increased reactivity for up to 72 hours following an aggressive outburst. May see an increase in aggression with decreased provocation as the synapses in the amygdala become sensitized. Some animals may have decreased serotonin, causing aggressive outbursts. Depending on the type of aggression, may see ritualized motor patterns, shaking, or trembling.
- Ophthalmic—dilated pupils with sympathetic stimulation.
- Renal/Urologic—may see associated spraying or small amounts of urine on horizontal surfaces. May exhibit signs consistent with FLUTD with aggression that is due to stress/anxiety/fear.
- Respiratory—tachypnea in acute cases or when stressed.
- Skin/Exocrine—damage due to fights. Damage due to excessive grooming associated with fear-based aggression/anxiety/distress.

SIGNALMENT

- There is preliminary evidence that behavioral traits in cats vary by breed and gender.
- Males were more likely to show aggression to cats than females.
- Abyssinian, Russian blue, Somali, Siamese, and chinchilla breeds showed more aggression.
- Maine Coon, ragdoll, and Scottish folds showed the least aggressiveness.

SIGNS

- May appear at social maturity (2–4 years of age) except for play-related and should occur in specific social contexts/interactions. If onset occurs in an older cat, medical causes should be ruled out first.
- General comments: most owners are able to detect overt signs of aggression (biting, hissing, growling) but may

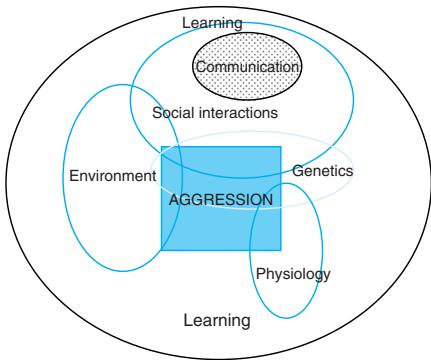

Figure 1.

miss more subtle signs of aggression that typically occur between cats (staring) and the resulting anxious behaviors that can result in aggression (meatloaf position, averting gaze, etc.). Videotapes of intercat interactions allow the clinician to assess the behavior.

CAUSES

- Underlying medical issues can cause aggression.
- Temperament/behavior is influenced by genetics, rearing, socialization, environment in which the cat lives, and types of interactions the cat has with people.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- CNS diseases (e.g., infections, toxins, tumors, partial seizures, focal seizures)
- Hyperthyroid
- Hepatic encephalopathy
- Any condition causing pain (e.g., arthritis, pancreatitis, dental disease, anal sacculitis)
- Lead poisoning
- Rabies
- Diabetic neuropathy (pain-induced aggression when paws touched)

CBC/CHEMISTRY/URINALYSIS

Physical examination, baseline blood and urine screening followed by additional diagnostics as indicated based on history, examination and laboratory results.

OTHER LABORATORY TESTS

- Discuss *Bartonella* testing in any cat that bites or scratches people.
- Thyroid levels.
- Urinalysis ± culture if housesoiling is part of the aggression issue.
- Feline serology (FCV, FeLV, FIV).

TREATMENT

- Never use physical correction/punishment; may escalate the aggression.
- Never try to physically handle or manipulate a cat in an aggressive state.
- Avoid known triggers.
- Identify triggers and desensitize and

counter-condition the cat to the triggers.

- Implement safety measures (nail caps, wearing long pants/long sleeves, keep flattened cardboard boxes around home to place between yourself and your cat, redirect the behavior in early arousal phase).
- Behavior modifications to redirect the cat and reduce arousal (specific plans are dependent upon the specifics of each case).
- Train your cat to commands such as "sit," "go to place," etc.
- Implement environmental enrichment.
- Teach owners to identify early signs of arousal so the cat can be redirected or so they can avoid the cat.
- After a very aggressive outburst, keep aggressor isolated in a room for at least 24 hours (as long as the cat remains aroused after an attack).
- Pheromones.
- Medications.

MEDICATIONS

DRUGS OF CHOICE

- SSRIs: fluoxetine or paroxetine 0.5 mg/kg PO q24h.
- TCAs: clomipramine 0.5 mg/kg PO q24h.
- Buspirone at 0.5–1.0 mg/kg q8–24h or benzodiazepines such as oxazepam at 0.2–0.5 mg/kg q12–24h might reduce fear and build confidence in the fearful cat that does not retaliate or fight back.

CONTRAINDICATIONS

- Cats with renal or hepatic disease
- Caution with TCAs and SSRIs in diabetics
- TCAs in patients with cardiac abnormalities

POSSIBLE INTERACTIONS

- TCAs and SSRIs should not be used together.
- Mirtazapine should not be used in combination with a TCA or SSRI.
- Any other medication the cat is on, the practitioner should look up which liver enzyme system is utilized in metabolism to maximize safety in combining medications.

ALTERNATIVE DRUGS

- Amitriptyline 0.5–1.0 mg/kg PO q12–24h
- SAMe: 100 mg PO q24h • Zylkene 75 mg (15 mg/kg or greater) PO q24h • Feliway Multicat diffuser l-theanine 25 mg PO q24h
- Zylkene 75 mg PO SID

FOLLOW-UP

PATIENT MONITORING

- Call owners once every 1–2 weeks for the first 2 months after a treatment plan has been recommended. Determine implementation of safety recommendations and the behavioral plan.
- If medications are involved, the medication dose should be reevaluated every 3–4 weeks.
- Frequency of follow-up will be dictated by the severity of the case and owner compliance.
- CBC, chemistry, T_4 prior to

medication. Recheck liver and kidney values 2–3 weeks after starting medication. Recheck bloodwork annually in young healthy patients, semiannually in older patients.

- Repeat physical exams in older patients semiannually, as painful conditions may start to contribute to/exacerbate the pain.

EXPECTED COURSE AND PROGNOSIS

- Ultimately depends on the specific kind of aggression and the compliance of clients with the suggested treatment plan.
- Most cases of aggression need a combination of behavioral modification, environmental modification, training, and, when necessary, medication to maximize chances of improvement.
- Some types of aggression can resolve or improve within a few weeks, whereas others may take several months or longer.
- Some forms of aggression have a poor prognosis.

MISCELLANEOUS

AGE-RELATED FACTORS

- Older cats—cognitive decline, CNS disease, arthritis, meningioma, other medical conditions.
- Age 2–4—social maturity, when cats may start to show certain kinds of aggression.

ABBREVIATIONS

- CNS = central nervous system
- FCV = feline calicivirus
- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus
- FLUTD = feline lower urinary tract disease
- GI = gastrointestinal
- HPA = hypothalamic-pituitary-adrenal
- IBD = inflammatory bowel disease
- SAMe = S-adenosyl-L-methionine-tosylate disulfate
- SSRI = selective serotonin reuptake inhibitor
- TCA = tricyclic antidepressant

BASICS

DEFINITION

- Action by one dog directed against another organism with the result of, limiting, depriving, or harming that organism.
- Aggression refers to any behavior along an aggression continuum, from a stare, to immobility (freeze), growl, snarl, lunge, air snap, single bite, multiple bite, multiple attacks, and chase and attack.
- Numerous functional types have been posited. Here, aggression is classified on the basis of (1) affective aggression, (2) predatory aggression, and (3) play-related aggression. Affective (emotional) aggression is the focus of this chapter. Affective states, such as fear and arousal, and motivational factors, such as hunger and sexual drive, influence the probability of overt aggression, such as biting. Affective aggression may be human-directed or dog-directed. Within these contexts, there may be additional specificity, such as human-directed aggression toward unfamiliar persons, or human-directed aggression directed toward familiar persons. Often dogs display aggression in a single context.
- Human-directed aggression toward familiar persons in response to controlling gestures is historically called dominance aggression, although newer terminology, such as conflict aggression, may be used to avoid often-erroneous semantic assumptions inherent in the term “dominance.”
- Human-directed aggression toward unfamiliar persons specific to home location is called territorial aggression.
- Predatory aggression refers to behaviors associated with chasing and hunting prey. It is often considered nonaffective and may be socially facilitated by other dogs. Predatory behaviors may be triggered by movement or high-pitched sounds and may be misdirected to humans or objects.
- Play-related aggression involves aggressive gestures, such as growling and biting, in the context of play and is commonly displayed toward other dogs or humans. It is often initiated by signs of play, such as the play bow.
- In all cases, medical factors that might contribute to aggression (including pain) must be evaluated.

PATHOPHYSIOLOGY

- Affective aggression involves arousal of the sympathetic nervous system. Some pathologic conditions are associated with an increase in aggression because of CNS effects such as pain or irritability.
- Abnormalities in the CNS serotonin neurotransmitter system have been implicated in one type of impulsive human-directed aggression, colloquially called “rage,” directed toward familiar persons over controlling gestures.
- Aggression often has a learned component whereby dogs learn to use aggression to manage distance from fearful stimuli or control resources.

SYSTEMS AFFECTED

- Behavior.
- Other, if there is an underlying medical etiology.

GENETICS

- In some breeding programs, aggressive tendencies and bite styles have been selected for (or against).
- One study in the United States linked English springer spaniels that display human-directed dominance aggression to one breeding sire, implicating a heritable component.
- One study of human-directed dominance aggression among English cocker spaniels reported that males were more aggressive than females, and dogs with solid coat color were more aggressive than those with parti coat color.

INCIDENCE/PREVALENCE

- Canine aggression is the most common diagnostic category seen by board-certified veterinary behaviorists in North America.
- According to the Centers for Disease Control and Prevention (2009), about 4.7 million people are bitten by dogs each year in the US, although this number is considered an underestimation as the majority of dog bites are not reported.
- In the US, it is estimated that one in five of those who are bitten require medical attention for dog bite-related injuries.
- Among children and adults, males are more likely than females to be bitten.
- Based on emergency room data in the US, the rate of dog bite-related injuries is highest for children aged 5–9 years.

- In the majority of cases, people are bitten by dogs that are known to them.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog

Breed Predispositions

- Any breed or breed mix.
- Pit bull, German shepherd dog, and rottweiler are the most common breed types implicated in fatal dog bites in the US.
- In the US, English springer spaniels appear to be at risk for human-directed “dominance” aggression.

Mean Age and Range

Any age

Predominant Sex

- Any sex.
- Males—intact or castrated are most commonly implicated in cases of human-directed “dominance” type aggression. Intact males are overrepresented in dog-bite fatalities.
- Females—spayed are most commonly implicated in aggression to other female dogs in the home. In some studies, spayed females are less likely than males to display human directed aggression.

SIGNS

General Comments

- Any dog can display aggression. Many factors, including individual dog temperament and experience, influence the propensity to bite.
- Dogs may display warning signs—including immobility, growls, snarls, or air snaps that may provide time to avoid overt aggression. These signs should not be punished, as this might decrease the probability of warning signs without affecting the underlying risk, or may further intensify the aggressive (defensive) response. Instead, the animal should be safely removed from the situation and the underlying triggers for the affective state should be addressed.

Historical Findings

- Variable.
- Basis for risk analysis and details of treatment program. Important questions: Who is the target? Who was present to manage the dog? How severe were the resulting injuries? What are the circumstances (including location, time) in which aggression occurred? Are there any reliable triggers for the aggressive behavior? Abnormalities in mentation or awareness might indicate a medical cause

Physical Examination Findings

- Usually unremarkable.
- Use extreme care when handling aggressive dogs.
- A comfortable, well-fitting basket muzzle is recommended prior to examination of any dog with a history of human-directed aggression. Basket-style muzzles allow dogs to pant.
- Abnormalities on the neurologic examination may suggest an organic disease process (e.g., rabies, pain, blindness). Dogs can display aggression preictal, postictal or ictal period.

CAUSES

- Part of the normal range of behavior; strongly influenced by individual temperament, experience, early socialization (before 12 weeks), and other variables.
- Harsh handling and confrontational responses can escalate aggression and should be avoided.
- May be a manifestation of an organic condition, such as hepatic encephalopathy or pain.
- In all cases, evaluate medical causes of aggression.

RISK FACTORS

- Inadequate socialization during the canine critical period (3–12 weeks).
- Traumatic/fearful/negative experience(s).
- Predisposing environmental conditions—lack of training, inadequate restraint, harsh handling.
- Inability of owner to safely confine or manage the dog in order to prevent future incidents. Helpful devices include a barrier fence, a muzzle, a collar or head halter, a leash.
- Previous aggression/bite history (number of incidents, number of bites per incident, target, severity of injury); legal citation for biting.

- Unpredictability of aggressive behaviors, lack of warning signals.
- Presence of children, elderly people, or other humans or animals at high risk living in or visiting household.

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

- A thorough medical evaluation should be conducted on all cases of aggression.
- Identify pathologic conditions associated with aggression before making a purely behavioral diagnosis.
- Rule out developmental abnormalities (hydrocephaly, lissencephaly, hepatic shunts), metabolic disorders (hypoglycemia, hepatic encephalopathy, diabetes), neuroendocrinopathies (hypothyroidism, hyperadrenocorticism), dermatopathy, neurologic conditions (intracranial neoplasm, seizures), toxins, inflammatory diseases (encephalitis, rabies), cognitive dysfunction, acute or chronic pain, and iatrogenic causes, such as glucocorticoid administration.

CBC/BIOCHEMISTRY/URINALYSIS

- May be indicated to evaluate dog as candidate for behavioral medications.
- Abnormalities may suggest underlying metabolic, endocrine causes, or other medical conditions.
- Usually no significant findings outside laboratory range unless an underlying medical etiology is detected.

OTHER LABORATORY TESTS

- Thyroid testing.
- Others as indicated by history and physical exam.

IMAGING

- May be indicated to identify sources of pain or disease.
- MRI or CT—particularly if cerebral disease/neoplasia suspected.

DIAGNOSTIC PROCEDURES

- Collection of thorough behavioral history and evaluation of medical concerns.
- Postmortem fluorescent antibody test is indicated for any aggressive dog for which rabies is a differential diagnosis, including any dog not quarantined for 10 days after a bite injury to a human or other animal.

PATHOLOGIC FINDINGS

None

**TREATMENT****APPROPRIATE HEALTH CARE**

- Manage any underlying medical conditions.
- Management success—combination of multiple modalities: safe environmental control, behavior modification to teach animals appropriate behavior, and pharmacotherapy.
- Consult a veterinarian with experience and training in aggression management.
- Euthanasia should be discussed or recommended when the risk of injury is high. Note recommendation in medical record.
- Rehoming aggressive dogs may put those involved at liability risk.

NURSING CARE

A boarding facility able to safely manage the dog might be used until a safe management plan can be implemented, or until an outcome decision can be made.

ACTIVITY

Since frustration and arousal may increase the incidence of aggression, an appropriate and safe exercise regime should be incorporated into the treatment program.

DIET

There is modest evidence that a low-protein diet may reduce territorial aggression in dogs, an effect that might be enhanced with tryptophan supplementation.

CLIENT EDUCATION

- Safe practices should dictate all decisions. These practices include safe confinement, physical barriers, head halters, leash control, muzzle use, and supervision by a competent adult.
- Situations that have led to aggression in the past should be listed and a specific plan developed to avoid these situations and associated locations in the future, and a long-term management plan developed.
- The dog should calmly be removed from aggression-provoking situations.
- Safe, non-confrontational techniques that manage resources and use positive reinforcement to teach the dog appropriate responses should be employed.

(CONTINUED)

AGGRESSION, OVERVIEW—DOGS

A

- Confrontational management techniques, such as roll-overs, increase the probability of a defensive aggressive response, may lead to human injury, and should be strictly avoided.
- Management (“dominance”) techniques including punishment are associated with defensive fear responses by the dog and an increased risk of human-directed aggression. These should be avoided and replaced with positive management techniques.
- The client should be advised to consider personal and legal liability risks of keeping the dog. Human injury, bite-related lawsuits, and homeowner’s insurance claims can result from canine aggression. Such risk assessment may help the client objectively evaluate the situation.
- Euthanasia should be considered if safe management cannot be employed, or when the risk of injury is high.

SURGICAL CONSIDERATIONS

Castration of males may reduce the incidence of inter-male aggression.

**MEDICATIONS****DRUG(S) OF CHOICE**

- None approved by the FDA for the treatment of aggression.
- No drug will eliminate the probability of aggression.
- Use drugs only when a safe management plan has been implemented.
- Inform the client of the extra-label nature of medication and risk involved; document in the medical record, obtain signed informed consent.
- Drugs that increase serotonin may be helpful to reduce anxiety, arousal, and impulsivity.

- Treatment duration: minimum 4 months, maximum: lifetime.
- See Table 1 for drugs used to facilitate management of aggression in combination with a safe management plan.

CONTRAINdications

- Fluoxetine is generally contraindicated in cases of seizures.
- Clomipramine is contraindicated in cases of cardiac conduction disturbances or seizures; in one open trial, clomipramine was no more effective than control in cases of human-directed aggression.

PRECAUTIONS

Avoid the use of benzodiazepines (e.g., diazepam) in aggressive dogs because of the risk of behavioral disinhibition. Aggression may increase when dogs lose their fear of the repercussions of biting.

POSSIBLE INTERACTIONS

Do not use SSRIs or TCAs with monoamine oxidase inhibitors, including amitraz and selegiline, or with each other because of the risk of serotonin syndrome.

ALTERNATIVE DRUG(S)

- L-Tryptophan (10 mg/kg PO q12 h).
- Trazodone (4–8 mg/kg PO q12 h or PRN) may be used with the agents listed in Table 1 to reduce anxiety and arousal.
- Clonidine (0.01–0.05 mg/kg PO q12 h or PRN), may be used with the agents listed in Table 1 to reduce anxiety and arousal.

**FOLLOW-UP****PATIENT MONITORING**

Weekly to biweekly contact recommended in the initial phases to guide clients with behavior modification plans and medication management.

PREVENTION/AVOIDANCE

- To prevent aggressive incidents, avoid all situations that have led to aggression in the past, using safe confinement, gates, halters, collars, leashes, muzzles.
- Reduce the risk of aggression in young dogs (3–12 weeks) with a positive socialization program; avoid intimidation techniques and negative, fear-inducing situations.

POSSIBLE COMPLICATIONS

- Injury to humans or animals.
- Liability to client, veterinarian.
- In cases of dog-directed aggression, although not the intended target, humans who interfere are often seriously injured either by accident or by redirected aggression; owners should not reach for fighting dogs; pull apart with leashes.
- Aggressive dogs are at risk for relinquishment or euthanasia.

EXPECTED COURSE AND PROGNOSIS

- Aggressive dogs weighing over 18.5 kg are at increased risk for behavioral euthanasia.
- Aggressive dogs may be successfully managed, but should not be considered “cured.”
- Prognosis is case-dependent due to risk factors and management features of each situation.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

Onset of aggression in mature dogs suggests a medical cause; carefully evaluate sensory acuity, sources of pain, endocrinopathy, cognitive function.

Table 1

Drugs and dosages used to manage canine aggression.

<i>Drug</i>	<i>Drug Class</i>	<i>Oral Dosage in Dogs</i>	<i>Frequency</i>	<i>Side Effects-usually transient</i>
Fluoxetine	SSRI	1.0–2.0 mg/kg	q24 h	Decreased appetite, sleepiness
Paroxetine	SSRI	1.0–2.0 mg/kg	q24 h	Constipation
Sertraline	SSRI	2.0–4.0 mg/kg	q24 h	Sleepiness
Clomipramine	TCA	1.0–3.0 mg/kg	q12 h	Sleepiness, vomiting

ZOONOTIC POTENTIAL

- Dog bites are significant public health risk.
- Rabies is a potential cause of aggression.

PREGNANCY/FERTILITY/BREEDING

Tricyclic antidepressants are contraindicated in breeding males and pregnant females.

SYNONYM

Biting

AGGRESSION—BETWEEN DOGS IN THE HOUSEHOLD

BASICS

OVERVIEW

Aggression toward other dog(s) within a household or those dogs that are otherwise familiar and spend time together regularly. Dogs can form stable social relationships quickly, sometimes within minutes of being introduced. Aggression usually revolves around resources (e.g., food, toys, owner attention, resting places), but may be fear-related or can occur at times of excitement/arousal (e.g., visitors or other dogs on the property). Usually within the range of normal behavior, but may be abnormal or excessive due to learning, early environment, or genetics (dogs bred for fighting).

SYSTEMS AFFECTED

Behavioral

SIGNALMENT

Species

Dog

Breed Predilections

- More common in purebreds with 50% being the same breed.
- Breed predilection in “fighting breeds” (e.g., pit bull terrier) and terrier.

Mean Age and Range

Signs usually develop at social maturity (approximately 18–36 months of age).

Predominant Sex

May be more common/intense between females.

SIGNS

- Aggression (barking, growling, lip-lifting, snarling, snapping, lunging, biting) toward other dogs in the home. This may be accompanied by fearful or submissive body postures/facial expressions (crouching, backing away, ears back, tail tucked, looking away, lip licking) or confident/dominant body postures (standing straight up, approaching/direct contact with the other dog, tail up, ears forward).
- History prior to the onset of fights may include subtle signs of social/resource control/dominance (e.g., staring, lying across doorways to block the other dog’s access to a room) and submission (e.g., turning away from the staring dog or not entering the same room as the other dog).
- Dogs fighting in a household may get along well except in specific situations, especially over resources, access to passageways/doorways, times of arousal. Dogs that fight over owner attention often described as “jealous.”
- Aggression typically occurs when the owner is present.

CAUSES & RISK FACTORS

- May be a normal canine behavior; strongly influenced by previous experience (e.g., early socialization, previous aggressive encounters

with other dogs, inappropriate punishment).

- Breed predilections due to selective breeding for interdog aggression.
- Aggression is likely to be more severe toward dogs of the same sex, especially two females.
- Instigators are usually newer to the household and younger than recipients.
- In cases of aggression within a household, there may be history of owners interfering in normal canine communication, especially when one dog appears to be denying another dog access to something that the owners think they should “share.” This shift may actually support one dog in what would be considered inappropriate “canine” behavior and result in escalation of the interdog aggression. For example, an owner calling dog “A” into a room when the other dog “B” has blocked its access even though “A” was willing to remain outside of the room or the owner punishing dog “B” for blocking dog “A’s” access. Both of these situations undermine dog “B” in its hierachal position while it was subtly asserting control to which dog “A” was willing to defer.
- Underlying medical conditions, especially pain, may increase the level of aggression.
- If the aggressor initiates or continues its attack despite deference from the other dogs, or if the deferent dog is overly fearful or defensive, then these may indicate abnormal responses that might have a poor prognosis (unable to socially communicate) or require drug therapy to manage the abnormal behavior.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Play behavior/excited non-aggressive arousal
- Possessive aggression
- Fear aggression
- Others depending on circumstances

CBC/BIOCHEMISTRY/URINALYSIS

Usually unremarkable. Rule out underlying medical contributing conditions with blood, urine and thyroid screening.

OTHER LABORATORY TESTS

As needed to rule out underlying medical conditions.

IMAGING

MRI if CNS disease suspected; as needed to rule out underlying medical conditions.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

CLIENT EDUCATION

General Comments

- Treatment is aimed at controlling the problem, not achieving a “cure.” Successful treatment, as measured by a decrease in aggressive incidents, depends upon owner

understanding of basic canine social behavior and communication, risks involved in living with an aggressive dog(s), and willingness and ability to follow safety and management recommendations.

Safety Recommendations

- The owner’s primary responsibility is to insure safety by identifying and avoiding all situations that may evoke an aggressive response. Dogs within a household may initially need to be kept in separate housing areas to prevent fighting.
- Owners should be advised that they may be liable if their dog bites and could face civil/criminal prosecutions should a person be injured.
- If needed, owners must be instructed in methods of safely breaking up dog fights.
- Treatment is more likely to be successful if aggression-provoking stimuli can be effectively prevented prior to behavior modification.
- The dogs must be confined away from each other or under the direct physical control of a responsible adult whenever an aggression-evoking situation could arise (e.g., around food/valued resources).
- Teaching the dogs to be comfortable wearing a head halter (e.g., Gentle Leader) with a lightweight 8- to 10-foot leash attached or a basket muzzle makes controlling potentially dangerous situations easier and safer. If needed, use the long leash both for prevention and to safely remove the dog from situations that may elicit aggression; do not reach for the dog directly.
- The more dominant dog typically asserts control of resources (e.g., staring, growling) with confident body postures directed toward the more subordinate dog who relinquishes the resource by moving or looking away.
- When there is competition over resources, allow priority access to the more controlling/dominant individual and encourage and reinforce deference in the other dog(s).
- Priority access may vary between resources (individual motivation), and contexts (location, who accesses first)—separate (time out) any dog displaying an inappropriate response.
- For some dogs problems may be resolved if additional resources and sufficient distribution are provided to reduce competition.
- Alternately, dogs may need to be separated when given resources that are a source of repeated conflict.

Behavior Therapy

- Depending on the situation, supporting and reinforcing the hierachal positions of the dogs will result in rapid (e.g., 1–2 weeks) resolution of the problem and a drastic decrease in aggressive incidents between dogs. Fighting is likely to recur if support of the hierarchy by humans is not continued.
- Separately, teach each dog those behaviors that will serve as a foundation for

AGGRESSION—BETWEEN DOGS IN THE HOUSEHOLD

(CONTINUED)

management and control when together including sit and relax, down-settle and teaching to go to mat, bed or crate to settle.

- NEVER allow dogs to “fight it out” as serious injuries may occur.
- During times together, use verbal cues or leave leash attached to train desirable and prevent or interrupt undesirable behavior.
- Structured interactions (also known as learn to earn or say please by sitting) where each dog is consistently taught to sit for anything it values (before feeding, petting, play, going for a walk) provides structure and predictability in all interactions, teaches impulse control and gives the dog control of its resources by sitting calmly.
- Systematic desensitization and counter-conditioning to fear-provoking stimuli.

MEDICATIONS

DRUG(S)

- There are no medications licensed for the treatment of canine aggression. Owners must be aware that the use of medication is off-label.
- A signed informed consent form is advisable listing potential risks and side effects.
- NEVER use medications without concurrent behavior modification.
- Before prescribing medication, be sure that owners understand the risks in owning an aggressive dog, will follow safety procedures, and that they understand that medication will not insure safety.
- Medication may not be appropriate in all situations (e.g., households with small children, individuals that are immunocompromised or have disabilities).
- Studies have not shown a robust effect of drug treatment on aggression. Placebo effect may be strong.
- Medications are most likely to be helpful in situations where there is a strong fear/anxiety component, or where one or both dogs are behaviorally abnormal (e.g., reactivity, impulsivity, intensity) as opposed to situations where closely ranked dogs use aggression to establish resource control.

Selective Serotonin Reuptake Inhibitors

- Fluoxetine 0.5–2 mg/kg PO q24h.
- Paroxetine 0.5–1 mg/kg PO q24h.
- Sertraline 1–3 mg/kg PO q24h.
- Side effects: sedation, irritability, GIT effects, increased aggression; anorexia is common and usually transient.

Tricyclic Antidepressants

- Clomipramine 1–3 mg/kg PO q12h (caution: label restriction for aggression).
- Side effects: sedation, GIT effects, anticholinergic effects, cardiac conduction disturbances if predisposed, and increased aggression.

Alpha-2 agonists

- Clonidine 0.01–0.05 mg/kg PO PRN 1.5–2 hours before eliciting trigger, up to q12h.
- Side effects: transient hyperglycemia, anticholinergic, hypotension, collapse, and bradycardia (responsive to atropine), and increased aggression.

Serotonin 2a antagonist/reuptake inhibitors

- Trazodone 2–5 mg/kg PO PRN prior to eliciting trigger, up to q6h—may titrate up to 8–10 mg/kg if no adverse effects.
- Side effects: sedation, anorexia, ataxia, GIT effects, cardiac conduction disturbances, increased aggression.

CONTRAINdicATIONS

Use caution as any psychotropic medication may reduce fear-based inhibition resulting in an increase rather than decrease in aggression.

PRECAUTIONS

Any psychotropic medication may increase irritability and aggression. Corticosteroids are contraindicated in food-aggressive dogs; polyphagia can lead to increased frequency/intensity of aggression.

POSSIBLE INTERACTIONS

Do not combine SSRIs, TCAs, MAO inhibitors (e.g., amitraz, selegiline), opioids (e.g., tramadol), and other medications that increase serotonin—can result in potentially fatal serotonin syndrome.

FOLLOW-UP

PATIENT MONITORING

Clients usually need ongoing assistance and should receive at least one follow-up call within the first 1–3 weeks after the consultation. Provisions for further follow-up should be made at that time.

PREVENTION/AVOIDANCE

Treatment recommendations are life-long.

POSSIBLE COMPLICATIONS

Injuries to dogs and humans; euthanasia or relinquishment of patient.

EXPECTED COURSE AND PROGNOSIS

There is no cure. Prognosis for improvement is more favorable if aggression is at a fairly low intensity and occurs in only a few predictable situations. Prognosis is highly dependent on owner compliance. Relationship issues may recur with changes in housing, health or age.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Other fear- or anxiety-based conditions; territorial aggression.

ZOONOTIC POTENTIAL

Human injury and bite wounds when separating fighting dogs.

PREGNANCY/FERTILITY/BREEDING

Do not breed dogs with extreme interdog aggression.

ALKALOSIS, METABOLIC (TRADITIONAL APPROACH)

BASICS

DEFINITION

A process in the body that leads to an elevation in pH above the reference interval for that species. An elevation in blood pH is specifically termed Alkalemia. Associated with an increase in plasma bicarbonate concentration (HCO_3^-) (dogs, > 24 mEq/L; cats, > 22 mEq/L) and base excess (BE) (> 4 mmol/L) with a compensatory increase in carbon dioxide tension (PCO_2).

PATHOPHYSIOLOGY

- Metabolic alkalosis may develop from either a gain in bicarbonate or a loss in acid.
- Bicarbonate gain subsequent to:
Contraction alkalosis due to free water deficit; iatrogenic administration of alkalinizing therapy (e.g., Na HCO_3^-); metabolism of organic ions (lactate, citrate, acetate, and ketones); hypokalemia; and renal ammoniogenesis.
- Acid loss subsequent to:
gastric or renal acid loss (loop or thiazide diuretic); mineralocorticoid excess; presence of non-reabsorbable anions; decreased weak acids (hypoalbuminemia and hypophosphatemia).
- Renal HCO_3^- excretion is often very efficient in eliminating an excess HCO_3^- load, but is hindered by decreased effective circulating volume; hypokalemia, hypochloremia, and hyperaldosteronism. Metabolic alkalosis persists only if renal excretion of HCO_3^- is impaired. This primarily occurs from continued high rate of alkali administration, or some stimulus for the kidneys to retain sodium in the presence of a relative chloride deficit.
- Hypochloremic (corrected) metabolic alkalosis results from loss of fluid rich in chloride and H^+ primarily from the alimentary tract or kidneys. Loss of chloride and H^+ is associated with an increase in plasma HCO_3^- concentration. With chloride loss and volume depletion, the kidneys reabsorb sodium with HCO_3^- instead of chloride, perpetuating the metabolic alkalosis. Hypochloremic alkalosis is divided into chloride-responsive and chloride-resistant.
- Chloride-responsive results primarily from the loss of chloride rich fluid and is characterized by decreased extracellular fluid volume, hypochloremia, and low urinary chloride levels. This type of alkalosis responds to administration of chloride salt.
- Chloride-resistant is characterized by excessive mineralocorticoid leading to increased effective circulating volume and is not responsive to chloride salt.
- Hypokalemia may contribute to metabolic alkalosis by shifting H^+ intracellularly; stimulating apical H^+/K^+ ATPase in the collecting duct; stimulating renal ammoniogenesis; impairing chloride ion reabsorption in the distal

nephron; and reducing glomerular filtration rate (GFR) which decreases the filtered load of HCO_3^- and in the presence of volume depletion, impairs renal excretion of the excess HCO_3^- .

• Hypoalbuminemic alkalosis is due to a decrease in the level of plasma albumin. Plasma albumin is a weak acid.

• Compensatory metabolic alkalosis occurs in response to respiratory acidosis. This is associated with a low pH and elevated PCO_2 .

SYSTEMS AFFECTED

- Nervous—muscle twitching and seizures occur rarely in dogs. Metabolic alkalosis and associated hypokalemia may precipitate hepatic encephalopathy in patients with liver failure.
- Urinary—the kidneys rapidly and effectively excrete excessive alkali. In patients with chloride deficiency (and less importantly, volume depletion), the kidneys cannot excrete the excess alkali. Therefore, metabolic alkalosis is maintained. In these patients, chloride administration is required for renal compensation to occur. Volume expansion will hasten compensation. Patients with mineralocorticoid excess have excessive chloride loss. Therefore, chloride administration does not lead to hyperchloremia and correction of metabolic alkalosis (so-called chloride-resistant metabolic alkalosis).
- Respiratory—low $[\text{H}^+]$ (elevated pH) reduces alveolar ventilation. Hypoventilation increases PCO_2 and helps offset the effects of high plasma HCO_3^- on pH. In dogs, for each 1 mEq/L increase in plasma HCO_3^- there is an expected increase of approximately 0.7 mmHg in PCO_2 . Limited data is available for cats, but the degree of respiratory compensation appears to be similar.

SIGNALMENT

Any breed, age, or sex of dog and cat

SIGNS

Historical Findings

- Administration of loop diuretics (e.g., furosemide) or thiazides
- Vomiting

Physical Examination Findings

- Signs related to the underlying disease or accompanying potassium depletion (e.g., weakness, cardiac arrhythmias, ileus, etc.).
- Muscle twitching caused by low ionized calcium concentration.
- Dehydration in volume-depleted patients.
- Muscle twitching and seizures in patients with neurologic involvement (rare).

CAUSES

- Chloride-responsive—gastrointestinal losses (e.g., gastric vomiting, nasogastric tube suctioning); renal losses (diuretic therapy); and rapid correction of chronic hypercapnia (respiratory acidosis).
- Chloride-resistant—hyperadrenocorticism and primary hyperaldosteronism.
- Oral administration of alkalinizing agents—sodium bicarbonate or

other organic anions with sodium (e.g., lactate, acetate, gluconate); administration of cation-exchange resin with non-absorbable alkali (e.g., phosphorus binders).

- Hypoalbuminemia—liver disease, protein losing nephropathy or enteropathy, nephrotic syndrome.
- Free water deficit—diabetes insipidus; water deprivation; post-obstructive diuresis; polyuric renal failure.
- Hypokalemia—see Hypokalemia.

RISK FACTORS

- Administration of loop or thiazide diuretics.
- Vomiting.
- Stomach drainage.
- Diseases associated with hypoalbuminemia (e.g., nephrotic syndrome, liver failure).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

High plasma HCO_3^- and hypochloremia may also occur in animals compensating for chronic respiratory acidosis, in which PCO_2 is high and pH is low despite high HCO_3^- and low chloride concentration; blood gas determination required to differentiate.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results
None

Disorders That May Alter Laboratory Results

- Too much heparin (> 10% of the sample) decreases pH, PCO_2 and HCO_3^- .
- Blood samples stored at room temperature for more than 15 minutes have low pH because of increased PCO_2 .
- Exposure to room air decreases PCO_2 .
- Venous samples may have pH 0.5–1 unit lower and PCO_2 5–10 mmHg higher than an arterial sample.

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- High total CO_2 (total CO_2 in samples handled aerobically closely approximates HCO_3^-).
- Low blood ionized calcium concentration.
- Serum electrolyte abnormalities vary with underlying cause.
- Hypochloremia—consider hypochloremic metabolic alkalosis, the most common reason for metabolic alkalosis in dogs and cats, which usually results from diuretic administration or vomiting of stomach contents.
- High sodium but normal chloride concentration—consider chloride-resistant metabolic alkalosis (e.g., hyperadrenocorticism or primary hyperaldosteronism) or administration of alkali.
- Hypoalbuminemia—consider hypoalbuminemic metabolic alkalosis (e.g., liver failure, protein-losing enteropathy, and protein-losing nephropathy). In vitro, a 1 g/dL decrease in albumin concentration is associated with an increase in pH of 0.093 in cats and 0.047 in dogs.
- Hypokalemia—

hypokalemia likely results from intracellular potassium shifting due to metabolic alkalosis or the underlying problem (e.g., vomiting of stomach contents or loop diuretic administration). • Urinary chloride levels—chloride-responsive metabolic alkalosis has urine chloride levels < 10 mEq/L while chloride-resistant metabolic alkalosis involves urine chloride levels of > 20 mEq/L.

OTHER LABORATORY TESTS

Blood gas analysis reveals high HCO_3^- , PCO_2 , pH and base excess (BE). Unlike HCO_3^- , BE is independent of changes in and is considered a more reliable measure of metabolic acid-base changes.

IMAGING

None

DIAGNOSTIC PROCEDURES

- Blood pressure—the combination of hypertension, hypernatremia, and hypokalemia with metabolic alkalosis may indicate the presence of hyperaldosteronism.
- Diagnostic testing for hyperadrenocorticism or primary hyperaldosteronism (e.g., plasma renin and aldosterone levels).

TREATMENT

• Acid-base disturbances are secondary phenomena. Diagnosis and treatment of the underlying disease process is integral to the successful resolution of acid-base disorders.

• Severe alkalemia is uncommon, but may be life-threatening. Patients with chronic respiratory disease and respiratory alkalosis are at risk of developing severe alkalemia if they start vomiting or receive diuretics.

• Discontinue drugs that may cause metabolic alkalosis. • *Chloride-responsive*—the fluids of choice contain chloride; give patients with volume depletion an intravenous infusion of balanced, buffered isotonic electrolyte replacement fluid supplemented with KCl; patients with hypokalemia may require large doses of KCl (see Hypokalemia).

• *Chloride-resistant* metabolic alkalosis can only be corrected by resolution of the underlying disease; metabolic alkalosis is usually mild in these patients. • If the metabolic alkalosis is associated with hypokalemia and total body potassium deficits, correcting the deficit with KCl is a particularly effective way to reverse the alkalosis.

NURSING CARE

Supportive care to maintain euhydration, euvolemia, adequate nutrition, etc.

MEDICATIONS

DRUG(S) OF CHOICE

Hypochloremic Alkalosis

- If chloride-responsive alkalosis occurs during an edematous state (e.g., congestive heart failure), oral compounds containing chloride without sodium are recommended to correct the alkalosis. If diuresis is needed due to volume overload, a carbonic anhydrase inhibitor (e.g., acetazolamide) or a potassium-sparing diuretic (e.g., spironolactone, amiloride) can be used to correct the alkalosis.
- H2-blocking agents such as famotidine reduce gastric acid secretion and may be considered as adjunctive therapy if gastric losses are ongoing.
- Antiemetics may help prevent further gastric acid loss.

Hypoalbuminemic Alkalosis

- Treatment for hypoalbuminemic alkalosis should be directed at the underlying cause and the decreased colloid oncotic pressure.
- Foster enteral nutrition to increase endogenous albumin production.
- Consider species-specific plasma or albumin (canine albumin) therapy.

CONTRAINDICATIONS

- Avoid chloride-free fluids—they may correct volume depletion but will not correct hypochloremic alkalosis.
- Avoid using salts of potassium without chloride (e.g., potassium phosphate)—potassium will be excreted in the urine and will correct neither the alkalosis nor the potassium deficit.

PRECAUTIONS

Do not use distal blocking agents (e.g., spironolactone) in volume-depleted patients.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

None

FOLLOW-UP

PATIENT MONITORING

Acid-base status—frequency dictated by the underlying disease and patient response to treatment.

POSSIBLE COMPLICATIONS

- Hypokalemia • Neurologic signs

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Hypokalemia • Hypochloremia

AGE-RELATED FACTORS

None

PREGNANCY/FERTILITY/BREEDING

N/A

SYNONYMS

- Non-respiratory alkalosis.
- Chloride-responsive metabolic alkalosis—metabolic alkalosis that responds to chloride administration.
- Chloride-resistant alkalosis—metabolic alkalosis secondary to increased mineralocorticoid activity that does not respond to chloride administration.
- Hypochloremic alkalosis—metabolic alkalosis caused by low chloride concentration.
- Hypoalbuminemic alkalosis—metabolic alkalosis caused by low albumin concentration.
- Concentration alkalosis—metabolic alkalosis resulting from decreased free water in plasma.
- Contraction alkalosis—metabolic alkalosis formerly attributed to volume contraction, but now known to be caused by chloride depletion. Volume depletion is a common but not essential feature.

SEE ALSO

- Hypochloremia • Hypokalemia

BASICS

DEFINITION

- Common problem • Pattern of hair loss—varied or symmetrical • Causes—multifactorial

PATHOPHYSIOLOGY

Specific and unique for each cause

SYSTEMS AFFECTED

- Endocrine/Metabolic • Hemic/Lymphatic/Immune • Skin/Exocrine

SIGNALMENT

- No specific age, breed, or sex predilection.
- Neoplastic and paraneoplastic associated alopecias—generally recognized in older cats.

SIGNS

Depends on specific diagnosis

CAUSES

- Neurologic/behavioral—compulsive disorder.
- Endocrine—sex hormone alopecia, hyperthyroidism, hyperadrenocorticism, diabetes mellitus.
- Immunologic—allergic dermatitis, alopecia areata, alopecia mucinosa, lymphocytic mural folliculitis, pseudopelade.
- Parasitic—demodicosis, cheyletiellosis.
- Infections—dermatophytosis.
- Physiologic/metabolic—sebaceous adenitis.
- Neoplastic—paraneoplastic dermatitis, squamous cell carcinoma in situ, epitheliotrophic lymphoma, thymoma with exfoliative dermatitis.
- Idiopathic/inherited—alopecia universalis, hypotrichosis, spontaneous pinnal alopecia, anagen and telogen defluxion.
- Medication effect—corticosteroids.
- Viral—FeLV- and FIV-associated disease (giant cell dermatosis).

RISK FACTORS

FeLV/FIV—reported risk for demodicosis (not all cases associated with viral infection).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Endocrine Alopecia/Sex Hormone

- Non-inflammatory alopecias are rarely hormonal in etiology; search for other causes before exploring endocrine etiology.
- Hormonal causes—primarily castrated males; alopecia along the caudal aspect of the hind limbs, which may extend along the perineum.
- Excessive corticosteroid administration; may also cause curling of pinnal tips.
- Megestrol acetate—may produce lesions similar to/associated with diabetes mellitus or hyperadrenocorticism.

Compulsive Disorder

- Uncommon as sole source of symptoms.
- Often misdiagnosed in cases of allergic

dermatitis. • Often misdiagnosed as endocrine alopecia. • The pattern of alopecia is frequently symmetrical without associated inflammation.

Allergic Dermatitis

- Varies from mild partial alopecia with little inflammation to severe excoriation and ulceration.
- Barbering of the hair coat often occurs clandestinely leading to a misdiagnosis of endocrine alopecia.
- Distribution—varied; often the head and neck or ventral abdominal regions are most affected.
- Food allergy, atopic dermatitis, contact allergy, and ectoparasite hypersensitivity.

Hyperthyroidism

- Partial to complete alopecia from self-barbering.
- Varied pattern.
- Middle-aged to old cats.
- Often misdiagnosed in cases of allergic dermatoses, compulsive disorder, or other endocrine alopecia.

Diabetes Mellitus

- Partial alopecia with an unkempt or greasy hair coat and excessive scaling.
- Poor wound healing.
- Increased susceptibility to infections.
- Rarely, cutaneous xanthomatosis secondary to hyperlipidemia (nodular to linear, yellow-pink alopecic plaques that tend to ulcerate).

Hyperadrenocorticism

- Rare; characterized by alopecia and extreme fragility of the skin.
- Truncal alopecia, with or without a rattle and curling of the pinnal tips.
- Extreme skin fragility noted in approximately 70% of cases.
- Occurs secondary to pituitary or adrenal tumors.
- Iatrogenic form less common in cats than in dogs; associated with frequent repositol corticosteroid injections.

Paraneoplastic Alopecia

- Most cases associated with pancreatic exocrine adenocarcinomas, bile duct carcinomas, or exfoliative dermatitis with thymoma.
- Middle-aged to old cats (9–16 years).
- Pancreatic carcinoma/bile duct carcinoma: acute onset, progress rapidly, bilaterally symmetrical, ventrally distributed (also located along the bridge of the nose and periocular), hair epilates easily, rare pruritus, erythema with dry fissuring footpads, glistening appearance to alopecic skin, skin is often thin and hypotonic, rapid weight loss.
- Thymoma with exfoliative dermatitis: non-pruritic scaling dermatitis that starts on the head and neck. Brown waxy deposits accumulate around the eyes and nasal region. Surgical removal of the thymoma will cause resolution of the dermatitis within a few months (typically 4–5 months).

Sebaceous Adenitis

- Slowly progressive partial alopecia associated with scaling along the dorsum of the body and the extremities.
- Sebaceous glands are, theoretically, selectively destroyed by toxic intermediate metabolites or

immunologic mechanisms.

- Possible dramatic pigment accumulation along the eyelid margins.
- Questionable association with systemic disease or stressful event (e.g., inflammatory bowel disease, lupus-like syndromes, upper respiratory tract infections).

Squamous Cell Carcinoma In Situ

- Multicentric premalignant dermatosis in old cats.
- Associated with papilloma virus; Bowenoid *in situ* carcinoma.
- Slightly elevated, often pigmented, plaque-like or papillated lesions with scaling and partially alopecic surfaces.
- Often misdiagnosed as seborrhea before distinct lesions develop.
- About 25% may convert to squamous cell carcinoma *in situ* lesions along the borders (histologically).

Epitheliotropic Lymphoma

- Early stages—varying degrees of alopecia associated with scaling and erythema.
- Later stages—plaques and nodules.
- Old cats.

Alopecia Areata/Pseudopelade/Lymphocytic Mural Folliculitis (Lymphocytic Invasion of the Hair Follicle)

- Often associated with an immunologic inciting cause; may occasionally be pre-neoplastic.
- Alopecia areata—rare; complete alopecia in a patchy distribution with no inflammation; head, neck, ears; histologic lymphocytic accumulation around the hair bulb.
- Lymphocytic mucinotic mural folliculitis—diffuse alopecia of the face, eyelids, muzzle; skin has a thick waxy feel; histologic lymphocytic invasion of the follicular outer root sheath and epidermis.
- Pseudopelade—well-circumscribed non-pruritic alopecia that often starts on the face; nails may slough; lymphocytic invasion of the isthmus region of the hair follicle.

Feline Cutaneous Lymphocytosis (Pseudolymphoma)

- Characterized by dermal lymphocytic infiltrate rather than follicular or epidermal.
- Older cats; often solitary lesions of partial alopecia with scaling ± erythema and pruritus.

Alopecia Universalis (Sphynx Cat)

- Hereditary.
- Complete absence of primary hairs; decreased secondary hairs.
- Thickened epidermis; normal dermis.
- Sebaceous and apocrine ducts open directly onto the skin surface; oily feel to skin.
- Wrinkled foreheads; gold eyes; no whiskers; downy fur on paws, tip of tail, and scrotum.
- Comedones with or without secondary folliculitis.

Feline Hypotrichosis

- Siamese and Devon Rex cats (autosomal recessive alopecia).
- Poorly developed primary telogen hair follicles.
- Born with a normal coat; becomes thin and sparse as young adult.

ALOPECIA—CATS

(CONTINUED)

Spontaneous Pinnal Alopecia

- Siamese cats predisposed. • May represent a form of alopecia areata or pattern baldness.

Anagen and Telogen Defluxion

- Acute loss of hair due to interference with the growth cycle. • Causes—stress, infection, endocrine disorder, metabolic disorder, fever, surgery, anesthesia, pregnancy, drug therapy.

Demodocosis

- Rare. • Partial to complete multifocal alopecia of the eyelids, periocular region, head, and neck; can generalize. • Variable pruritus with erythema, scale, and crust, and ceruminous otitis externa. • *Demodex cati* (elongated shape) often associated with metabolic disease (e.g., FIV, systemic lupus erythematosus, diabetes mellitus).
- Short/blunted *D. gatoi* mite is rarely a marker for metabolic disease; this form may be transferable from cat to cat and has been associated with pruritus most often affecting the lateral thorax and abdomen.

Cheyletiellosis

- Variable pruritus with scaling. • Not all animals in the household may be affected.

Dermatophytosis

Numerous clinical manifestations; always associated with alopecia.

CBC/BIOCHEMISTRY/URINALYSIS

Abnormalities may be noted with diabetes mellitus, hyperadrenocorticism, and hyperthyroidism.

OTHER LABORATORY TESTS

- FeLV and FIV—risk factors for demodicosis. • Thyroid hormones—document hyperthyroidism. • ANA titer—look for systemic lupus erythematosus.
- ACTH-response test, LDDST, and HDDST—diagnose hyperadrenocorticism.

IMAGING

- Abdominal ultrasound—assess adrenals in hyperadrenocorticism and look for neoplasia in animals with paraneoplastic syndrome.
- Chest radiographs/ultrasound to rule out thymoma. • CT scan—look for pituitary or other neoplasia tumors in animals with hyperadrenocorticism.

DIAGNOSTIC PROCEDURES

- Skin biopsy • Skin scrapes • Dermatophyte culture • Shirts/collar to prove self-trauma
- Food elimination trials • Intradermal allergy test

**TREATMENT**

- Therapy is specific for many of these disorders. • Behavioral modification or protecting hair coat with a shirt may prevent self-barbering. • Removal of an offending dietary item may alleviate the symptoms of food allergy. • If the pet is compliant,

shampoo and topical therapy may relieve secondary problems, such as hyperkeratosis in sebaceous adenitis, crusting in demodicosis, secondary bacterial infection, and malodor for greasy dermatoses.

**MEDICATIONS****DRUG(S)**

- Compulsive disorder—amitriptyline (10 mg/cat/day) as well as other behavior-modifying medications, such as gabapentin (5–10 mg/kg PO q12h).
- Endocrine alopecia (males)—testosterone supplementation.
- Allergic dermatitis—antihistamines, restricted-ingredient diet, corticosteroids, cyclosporine (7.3 mg/kg/day initially), allergen-specific immunotherapy, ectoparasite control.
- Hyperthyroidism—methimazole (tapazole) or radioactive iodine therapy.
- Diabetes mellitus—regulation of glucose levels (insulin).
- Hyperadrenocorticism—surgery; no known effective medical therapy.
- Paraneoplastic alopecia—no therapy or surgical excision of neoplasia; often fatal.
- Epitheliotropic lymphoma—retinoids (isotretinoin), corticosteroids, interferon, cyclosporine, lomustine.
- Sebaceous adenitis—retinoids, corticosteroids, cyclosporine.
- Squamous cell carcinoma in situ—surgical excision, retinoids (topical and oral), topical imiquimod cream.
- Alopecia areata—no therapy; possibly counterirritants.
- Demodicosis—lime sulfur dips at weekly intervals for four to six dips.
- Cheyletiellosis—topical parasiticides and environmental control.
- Dermatophytosis—griseofulvin (caution: idiosyncratic toxicity), itraconazole (hepatic toxicity, vasculitis), terbinafine.

PRECAUTIONS

Toxicity with griseofulvin and itraconazole (see Dermatophytosis).

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

Determined by specific diagnosis

PREVENTION/AVOIDANCE

Determined by specific diagnosis

POSSIBLE COMPLICATIONS

Determined by specific diagnosis

EXPECTED COURSE AND PROGNOSIS

Determined by specific diagnosis

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

- Dermatophytosis—can cause skin lesions in humans. • Cheyletiellosis—can cause irritation in humans.

PREGNANCY/FERTILITY/BREEDING

Retinoids and griseofulvin should not be administered to pregnant animals.

BASICS

DEFINITION

- Common disorder.
- Characterized by a complete or partial loss of hair in areas where it is normally present.
- May be associated with multiple causes, be the primary problem, or be secondary to an underlying cause.

PATOPHYSIOLOGY

- Multiple causes.
- Represents removal of hair or disruption in the growth of the hair from hypersensitivity, infection, trauma, immunologic attack, mechanical “plugging,” endocrine abnormalities, neoplasia, drug reaction and/or blockage of the receptor sites for stimulation of the hair growth cycle.

SYSTEMS AFFECTED

- Endocrine/Metabolic
- Hemic/Lymphatic/Immune
- Skin/Exocrine

SIGNALMENT

Breed predilection listed below

SIGNS

- May be acute in onset or slowly progressive.
- Multifocal patches of circular alopecia—most frequently associated with folliculitis from bacterial infection and multifocal areas of demodicosis.
- Large, more diffuse areas of alopecia—may indicate a follicular dysplasia or metabolic component.
- The pattern and degree of hair loss are important for establishing a differential diagnosis.

CAUSES

Multifocal

- Localized demodicosis—partial to complete alopecia with erythema comedones, and mild scaling; lesions may become inflamed and crusted.
- Dermatophytosis—partial to complete alopecia with scaling; with or without erythema; not always ring-like.
- Staphylococcal folliculitis—circular patterns of alopecia with epidermal collarettes, erythema, crusting, and hyperpigmented macules.
- Injection reactions—inflammation with alopecia and/or cutaneous atrophy from scarring.
- Rabies vaccine vasculitis—well-demarcated patch of alopecia observed 2–3 months post-vaccination.
- Localized scleroderma—well-demarcated, shiny, smooth, alopecic, thickened plaque; extremely rare; still considered a controversial diagnosis.
- Alopecia areata—non-inflammatory areas of complete alopecia.

- Sebaceous adenitis of short-coated breeds (now termed “idiopathic periadnexal pyogranulomatous dermatitis”)—annular to polycyclic areas of alopecia and scaling.

Symmetrical

- Hyperadrenocorticism—truncal alopecia associated with atrophic skin, comedones, and pyoderma.
- Hypothyroidism—thinning of truncal haircoat; generalized alopecia is an uncommon presentation; alopecic “rat” tail.
- Non-inflammatory alopecia (alopecia X)—symmetrical truncal alopecia associated with hyperpigmentation; alopecia often starts along the collar area of the neck; Pomeranian, chow chow, Akita, Samoyed, Keeshonden, Alaskan malamute, and Siberian husky.
- Hyperestrogenism (females)—symmetrical alopecia of the flanks and perineal and inguinal regions with enlarged vulva and mammary glands; may also be associated with exogenous hormone exposure.
- Hypogonadism in intact females—perineal, flank, and truncal alopecia.
- Testosterone-responsive dermatosis in castrated males—slowly progressive truncal alopecia.
- Male feminization from Sertoli cell tumor—alopecia of the perineum and genital region with gynecomastia.
- Castration-responsive dermatosis—hair loss in the collar area, rump, perineum, and flanks.
- Estrogen-responsive dermatosis in spayed female dogs—alopecia of the perineum and genital regions.
- Seasonal/cyclic/canine flank alopecia—serpiginous flank alopecia with hyperpigmentation; boxer, English bulldog, Airedale terrier.

Patchy to Diffuse

- Demodicosis—often associated with erythema, folliculitis, and hyperpigmentation.
- Bacterial folliculitis—multifocal areas of circular alopecia to coalescing large patches of hair loss; epidermal collarettes.
- Dermatophytosis—often accompanied by scale, erythema, and hyperpigmentation.
- Sebaceous adenitis—alopecia with a thick adherent scale; predominantly on the dorsum of the body, including the head and extremities.
- Color mutant/dilution alopecia—brittle or coarse hair, thinning of the blue or fawn colored hair coat, and secondary folliculitis.
- Follicular dysplasia—slowly progressive alopecia.
- Anagen defluxion and telogen defluxion—acute onset of alopecia.
- Hypothyroidism—diffuse thinning of the hair coat.
- Hyperadrenocorticism—truncal alopecia with thin skin and formation of comedones.
- Epitheliotropic lymphoma—diffuse, generalized truncal alopecia with scaling and intense erythema, later nodule and plaque formation.

- Pemphigus foliaceus—hair loss associated with scale and crust formation.
- Keratinization disorders—alopecia associated with excessive scale and greasy surface texture.

Specific Locations

- Pinnal alopecia/pattern baldness—miniaturization of hairs and progressive alopecia; dachshund, greyhound, American water spaniel, Portuguese water spaniel, Boston terrier, Manchester terrier, whippet, Italian greyhound, Chihuahua.
- Traction alopecia—hair loss on the top and lateral aspect of the cranium secondary to having barrettes or rubber bands applied to the hair.
- Post-clipping alopecia—failure to regrow after clipping; may be associated with hair growth cycle disruption.
- Melanoderma (alopecia of Yorkshire terriers)—symmetrical alopecia of the pinnae, bridge of the nose, tail, and feet.
- Seasonal/cyclic/canine flank alopecia—serpiginous flank alopecia with hyperpigmentation; boxer, English bulldog, Airedale terrier.
- Black hair follicular dysplasia—alopecia of the black-haired areas only.
- Dermatomyositis—alopecia of the face, tip of ears, tail, and digits; associated with scale crusting and scarring.

Breed-Related Alopecia

- Alopecic breeds: Chinese crested, Mexican hairless, Inca hairless, Peruvian Inca Orchid, American hairless terrier (often associated with comedones, folliculitis, and furunculosis).
- Congenital hypotrichosis: cocker spaniel, Belgian shepherd, poodle, whippet, beagle, French bulldog, Yorkshire terrier, Labrador retriever, bichon frise, Lhasa apso, basset hound.
- Color dilution alopecia: blue or fawn Doberman pinscher, silver Labrador, cream chow chow, blond Irish setter, blue pit bull terrier, other breeds with dilute coat colors.
- Melanoderma with alopecia in Yorkshire terrier.
- Seasonal/cyclic/canine flank alopecia—serpiginous flank alopecia with hyperpigmentation; boxer, English bulldog, Airedale terrier.
- Pinnal alopecia/pattern baldness—miniaturization of hairs and progressive alopecia; dachshund, greyhound, American water spaniel, Portuguese water spaniel, Boston terrier, Manchester terrier, whippet, Italian greyhound, Chihuahua.
- Non-inflammatory alopecia (alopecia X)—symmetrical truncal alopecia associated with hyperpigmentation; alopecia often starts along the collar area of the neck; Pomeranian, chow chow, Akita, Samoyed, Keeshonden, Alaskan malamute, and Siberian husky.

ALOPECIA—DOGS

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pattern and degree—important features for formulating a differential diagnosis.
- Inflammation, scale, crust, and epidermal collarettes—important for determining diagnosis.

CBC/BIOCHEMISTRY/URINALYSIS

Rule out metabolic causes such as hyperadrenocorticism

OTHER LABORATORY TESTS

- Thyroid testing—diagnose hypothyroidism.
- ACTH-response test, LDDST, and HDDST—evaluate for hyperadrenocorticism.
- Sex hormone profiles (questionable validity).

IMAGING

Ultrasonography—evaluate adrenal glands for evidence of hyperadrenocorticism.

DIAGNOSTIC PROCEDURES

- Response to therapy as a trial
- Fungal culture
- Skin scraping
- Cytology
- Skin biopsy—very useful to evaluate status of follicle/hair growth as well as epidermal changes associated with specific conditions.

TREATMENT

- Demodicosis—amitraz, ivermectin, milbemycin.
- Dermatophytosis—griseofulvin, ketoconazole, itraconazole, lime sulfur dips, terbinafine.
- Staphylococcal folliculitis—shampoo and antibiotic therapy.
- Sebaceous adenitis—keratolytic shampoo, essential fatty acid supplementation, retinoids, cyclosporine.
- Keratinization disorders—shampoos, retinoids, vitamin D, cyclosporine.
- Endocrine—ovariohysterectomy, castration, Lysodren, trilostane, adrenalectomy.

MEDICATIONS

DRUG(S) OF CHOICE

Varies with specific cause; see "Treatment."

CONTRAINDICATIONS

N/A

PRECAUTIONS

Toxicity with griseofulvin, retinoids, ivermectin, trilostane, lysodren, cyclosporine.

BASICS

DEFINITION

- Uncommon alopecic disorders that are associated with abnormal hair follicle cycling.
- Both endocrine and non-endocrine diseases can be associated with alopecia.
- Definitive diagnosis often requires ruling out the more common endocrine alopcias.
- Alopecia X has also been called growth hormone-responsive alopecia, castration-responsive alopecia, adrenal hyperplasia-like syndrome, among others.

PATOPHYSIOLOGY

- There are many factors that affect the hair cycle, both hormonal and non-hormonal.
- Increased sex hormones can affect the hair cycle. Estrogen is a known inhibitor of anagen, the growth phase of the hair follicle.
- The mechanism by which alopecia X influences the hair cycle is not known.
- Exposure to human exogenous hormone replacement therapy.

SYSTEMS AFFECTED

- Behavioral
- Endocrine/Metabolic
- Hemic/Lymphatic/Immune
- Skin/Exocrine

GENETICS

Breed predispositions exist for alopecia X; however, the mode of inheritance is unknown.

INCIDENCE/PREVALENCE

- Hyperestrogenism and hyperandrogenism are uncommon to rare causes of alopecia.
- Alopecia X is relatively common in predisposed breeds.

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dogs

Breed Predilections

- Hyperestrogenism and hyperandrogenism—no breed predilections.
- Alopecia X—miniature poodle and plush-coated breeds such as Pomeranian, chow chow, Akita, Samoyed, Keeshonden, Alaskan malamute, and Siberian husky.

Mean Age and Range

- Hyperestrogenism and hyperandrogenism—middle-aged to old intact dogs.
- Alopecia X—1–5 years of age; however, older dogs may develop the condition.

Predominant Sex

- Hyperandrogenism, primarily intact males.
- Hyperestrogenism, primarily intact females or males.
- Alopecia X, neutered or intact dogs of either sex.

SIGNS

Historical Findings

- Overall change in the hair coat—dry or bleached because the hairs are not being replaced; lack of normal shed.
- Males with hyperestrogenism may attract other male dogs.

Physical Examination Findings

- Alopecia—usually diffuse and bilaterally symmetrical truncal alopecia sparing the head and distal extremities. Uncommon with hyperandrogenism.
- Hair coat—may be dry or bleached.
- Secondary seborrhea, pruritus, pyoderma, comedones, ceruminous otitis externa, and hyperpigmentation—variable.
- Enlargement of nipples, mammary glands, vulva, prepuce—may be associated with hyperestrogenism.
- Macular melanosis and linear preputial dermatitis—may be associated with hyperestrogenism.
- Abnormal-sized or different-sized testicles—may be associated with hyperestrogenism or hyperandrogenism.
- Testicles may also appear normal in size.
- Tail gland hyperplasia and perianal gland hyperplasia—usually associated with hyperandrogenism.
- Systemic signs (PU/PD/polyphagia) are usually NOT present.

CAUSES

Hyperestrogenism—Females

- Estrogen excess associated with cystic ovaries, ovarian tumors (rare), or exogenous estrogen supplementation.
- Animals with normal serum estrogen concentrations may have increased numbers of estrogen receptors in the skin (undocumented).

Hyperestrogenism—Males

- Estrogen excess due to Sertoli cell tumor (most common), seminoma, or interstitial cell tumor (rare).
- Associated with male pseudohermaphroditism in miniature schnauzers.

Hyperandrogenism—Males

Androgen-producing testicular tumors (especially interstitial cell tumors).

Alopecia X

Hairs fail to cycle but an underlying endocrine cause has not been identified.

RISK FACTORS

- Intact male and female dogs are at increased risk for developing testicular tumors and ovarian cysts/tumors, respectively.
- Cryptorchid males are at increased risk for developing testicular tumors.
- Exogenous estrogen supplementation.
- Exposure to human exogenous hormone replacement therapy.
- There are no known risk factors for alopecia X other than breed predisposition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inflammatory causes of alopecia (pyoderma, demodicosis, and dermatophytosis)—should be ruled out; these diseases usually cause a patchy rather than diffuse pattern of alopecia.
- Sebaceous adenitis—an inflammatory cause of alopecia that may affect specific breeds (Samoyed, Akita).
- Hypothyroidism and hyperadrenocorticism—critical to rule out as these diseases may cause a very similar pattern of diffuse alopecia associated with lack of hair follicle cycling.
- Follicular dysplasias including color-dilution alopecia and black hair follicular dysplasia—alopecia should be color-restricted.
- Patterned alopecia of various breeds (dachshund, Boston terrier, greyhound, water spaniel, and others)—breed-specific alopcias of unknown cause.
- Seasonal/cyclic/canine flank alopecia—alopecia of the flank and dorsum, often serpiginous patterns with hyperpigmentation, more often in short-coated breeds (boxer, English bulldog, Airedale) and may recur seasonally.
- Post-clipping alopecia—hair fails to regrow following clipping; however, hair regrowth occurs within a year.
- Telogen defluxion—alopecia occurs 1–2 months following an illness or severe stressful episode and is usually more sudden in onset with relative ease of epilation.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually unremarkable.
- Anemia and/or bone marrow hypoplasia or aplasia can be associated with hyperestrogenism.

OTHER LABORATORY TESTS

- Serum sex hormone concentrations—often normal, treat according to suspected diagnosis based on clinical signs and ruling out other disorders.
- Serum estradiol concentrations—sometimes elevated in male dogs with testicular tumors or female dogs with cystic ovaries; however, normal fluctuation of estradiol occurs throughout the day, making interpretation of estradiol concentrations difficult.

IMAGING

Radiography, ultrasonography, and laparoscopy—identify cystic ovaries, ovarian tumors, testicular tumors (scrotal or abdominal), adrenal tumors, sublumbar lymphadenopathy, and possible thoracic metastases of malignant tumors.

DIAGNOSTIC PROCEDURES

- Preputial cytology—may demonstrate cornification of cells in males with hyperestrogenism (similar to a bitch in estrus).
- Skin biopsy.

ALOPECIA, NON-INFLAMMATORY—DOGS

(CONTINUED)

PATHOLOGIC FINDINGS

Histologic changes associated with endocrine dermatoses (telogen hairs, follicular keratoses, hyperkeratosis, excess trichilemmal keratinization [flame follicles], thin epidermis and thin dermis) may also be seen with non-inflammatory alopecias including hyperestrogenism and alopecia X. Histopathology will help rule out inflammatory causes of alopecia (pyoderma, demodicosis, dermatophytosis, sebaceous adenitis) and some of the other differentials listed above.

**TREATMENT****APPROPRIATE HEALTH CARE**

N/A

NURSING CARE

N/A

ACTIVITY

None

DIET

None

CLIENT EDUCATION

Alopecia X is a cosmetic condition resulting in coat loss only and there is no definitive cure for the hair loss. The risk of treatment should be emphasized. Hair regrowth will only occur in a portion of dogs regardless of treatment chosen and hair loss may recur months to years later in spite of continued treatment.

SURGICAL CONSIDERATIONS***Hyperestrogenism/Hyperandrogenism***

- Castration—scrotal testicular tumors.
- Exploratory laparotomy—diagnosis and surgical removal (ovariohysterectomy and castration) for ovarian cysts and tumors and abdominal testicular tumors.

Alopecia X

Neuter intact animals—a certain number will regrow hair following neutering. Hair regrowth can take up to 3 months to become evident.

**MEDICATIONS****DRUG(S) OF CHOICE*****General Treatments***

- Topical antiseborrheic shampoos—for comedones and seborrhea associated with alopecia.
- Antibiotics and topical antimicrobial shampoos—for secondary skin infections associated with alopecia.

Alopecia X

• Melatonin—3 mg q12h for small breeds and 6–12 mg q12h for large breeds; hair regrowth can take up to 3 months to become evident.

This treatment works in approximately 40% of cases. Because this treatment is the most benign, it is considered the treatment of choice following neutering. Once hair regrowth has occurred, discontinue treatment.

- Medroxyprogesterone acetate – 5–10 mg/kg SC q4 weeks for 4 treatments. Hair regrowth can take up to 6 months. This treatment works in approximately 40–50% of cases.

CONTRAINDICATIONS

None

PRECAUTIONS

- Melatonin at high doses can cause insulin resistance; therefore, use caution in treating dogs with diabetes mellitus.
- Medroxyprogesterone acetate can cause mammary nodules and cystic endometrial hyperplasia with long term use. Diabetes mellitus has been reported in a few dogs.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

- Mitotane—15–25 mg/kg—once daily as induction for 5–7 days, followed by twice weekly maintenance; hair regrowth occurs in a portion of dogs treated and can take up to 3 months to become evident. Use of this drug can result in an Addisonian crisis and other side effects as for treatment of Cushing's syndrome. Electrolytes and cortisol with ACTH stimulation testing should be monitored regularly.
- Trilostane—dosages as described for treatment of Cushing's syndrome; hair regrowth occurs in a portion of dogs treated and can take up to 3 months to become evident. Use of this drug can result in an Addisonian crisis and other side effects as for treatment of Cushing's syndrome. Electrolytes and cortisol with ACTH stimulation testing should be monitored regularly.
- Growth hormone administration and methyltestosterone may result in hair regrowth. Growth hormone can cause diabetes mellitus. Methyltestosterone can result in increased aggression, cholangiohepatitis, and seborrhea oleosa. Therefore, these drugs are not recommended.

**FOLLOW-UP****PATIENT MONITORING**

- Medroxyprogesterone acetate—complete physical examination and chemistry panel regularly.
- Mitotane—electrolytes and cortisol with ACTH stimulation testing regularly.
- Trilostane—electrolytes and cortisol with ACTH stimulation testing regularly.

PREVENTION/AVOIDANCE

None

POSSIBLE COMPLICATIONS

None

EXPECTED COURSE AND PROGNOSIS

- Female hyperestrogenism—improvement should occur within 3–6 months after ovariectomy.
- Estrogen- and androgen-secreting tumors—resolution of signs should occur within 3–6 months after castration.
- Alopecia X—hair regrowth will only occur in a portion of dogs regardless of treatment chosen and hair loss may recur in spite of continued treatment. Therefore, if hair regrowth occurs, discontinue treatment to preserve treatment for future recurrence of the alopecia. Risk of treatment should be weighed with the fact that this is a cosmetic disease.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Pyoderma, seborrhea, comedones may be associated with the alopecia.
- Behavioral changes associated with hyperestrogenism or hyperandrogenism.

AGE-RELATED FACTORS

None

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

N/A—neutering is usually recommended for managing these conditions.

SYNOMYMS

Alopecia X—growth hormone-responsive alopecia, castration-responsive alopecia, adrenal hyperplasia-like syndrome, among others.

ABBREVIATIONS

- ACTH = adrenocorticotropic hormone
- PU/PD = polyuria/polydipsia

BASICS

OVERVIEW

- Facultative parasitic amoeba that infects people and non-human primates, including dogs and cats.
- Found primarily in tropical areas throughout the world, including North America.

SIGNALMENT

- Dog and cat.
- Mainly young and/or immunosuppressed animals are infected.

SIGNS

Dogs

- *Entamoeba histolytica* infections are usually asymptomatic.
- Severe infections—result in ulcerative colitis to cause dysentery (may be fatal).
- Hematogenous spread—results in failure states of the organs (invariably fatal).
- Granulomatous amoebic meningoencephalitis (caused by *Acanthamoeba* spp.)—causes signs similar to distemper (anorexia, fever, lethargy, oculonasal discharge, respiratory distress, and diffuse neurologic abnormalities).
- Syndrome of inappropriate secretion of antidiuretic hormone has been reported in a young dog with acanthamoebiosis causing granulomatous meningoencephalitis with invasion of the hypothalamus.

Cats

- Colitis—causing chronic intractable diarrhea (as per dogs).
- Systemic amebiasis or *Acanthamoeba*—not reported in cats.

CAUSES & RISK FACTORS

- *Entamoeba histolytica*—infection occurs by ingesting cysts from human feces.
- Encystment of trophozoites seldom occurs in dogs or cats so they are not a source of infection.
- One of the few organisms transmitted from man to pets but rarely from pets to man.
- Trophozoites (the pathogenic stage)—inhabit the colonic lumen as commensals or invade the colonic wall but can disseminate to other organs (rare) including lungs, liver, brain, and skin.
- Trophozoites damage intestinal epithelial cells by secreting enzymes that lyse cells and disrupt intercellular connections.
- Certain bacteria and a diet deficient in protein increase the virulence of the amoeba.
- The host's immune response to invasion exacerbates pathology.
- Colonic ulceration results when trophozoites in the submucosa undermine the mucosa.
- *Acanthamoeba castellani* and *A. culbertsoni*—free-living species found in freshwater, saltwater, soil, and sewage; can infect dogs.
- *Acanthamoeba* spp.—infection thought to be by inhalation of organisms from contaminated water or colonization of the skin or cornea; hematogenous spread or

direct spread from the nasal cavity through the cribiform plate to the central nervous system may occur, resulting in a granulomatous amoebic meningoencephalitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dogs

- Causes of bloody diarrhea or tenesmus, including constipation; food intolerance/allergy; parasitism (whip worms, leishmaniasis, balantidiasis); HGE; foreign body; irritable bowel syndrome; inflammatory bowel disease; diverticula; infectious (parvovirus, clostridial enteritis, bacterial overgrowth and other bacterial causes, fungal such as histoplasmosis or blastomycosis); neoplasia; ulcerative colitis; endocrinopathy (Addison's disease); toxic (lead, fungal, or plant); occasionally major organ disease causing colonic ulceration such as renal failure.
- Other causes of diffuse neurologic disease in young animals, including infectious (distemper, fungal such as *Cryptococcus*, *Blastomyces*, *Histoplasma*, bacteria, protozoa such as *Toxoplasma* and *Neospora*); toxic (lead, organophosphate); trauma; GME; extracranial (hypoglycemia; hepatic encephalopathy); inherited epilepsy; neoplasia.

Cats

- Other causes of diarrhea, including food intolerance/allergy; inflammatory bowel disease; parasitism (giardiasis, parasites such as hookworms, roundworms, trichomonas); infectious (panleukopenia, FIV, FeLV producing panleukopenia-like syndrome, bacterial including *Salmonella*, rarely *Campylobacter*); drug (acetaminophen); neoplasia; pancreatitis; and major organ dysfunction.

CBC/BIOCHEMISTRY/URINALYSIS

Normal; can reflect severe diarrhea.

OTHER LABORATORY TESTS

- Microscopic examination—colonic biopsies (H&E) obtained via endoscopy is the most reliable method.
- Trophozoites in feces—very difficult to detect; methylene blue staining improves chances.
- Trichrome and iron-hematoxyline—the ideal fecal stains but require a reference laboratory to perform.
- Fecal concentration techniques—no help.
- CSF—elevated WBC count (70% mononuclear cells), protein and xanthochromia in dogs with granulomatous amoebic meningoencephalitis due to *Acanthamoeba*.

IMAGING

MRI—shows brain granulomas.

DIAGNOSTIC PROCEDURES

Brain biopsy—required to definitively diagnose neurologic forms antemortem.

TREATMENT

- Colitis (caused by *E. histolytica*)—responds to metronidazole, although dogs continue to shed organisms.
- Systemic forms (particularly neurologic disease)—invariably fatal despite treatment.

MEDICATIONS

DRUG(S)

- Tinidazole (44 mg/kg PO q24h for 6 days) in dogs—found to be more effective than metronidazole in treating amebiasis in humans.
- Metronidazole (20 mg/kg PO q12h for 7 days).

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

High doses of metronidazole (usually > 30 mg/kg) for extended periods may cause neurologic signs in dogs.

FOLLOW-UP

Pets usually acquire infections from the same source as their owners; veterinarians must warn owners of possible risk.

MISCELLANEOUS

ABBREVIATIONS

- CSF = cerebrospinal fluid
- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus
- GME = granulomatous meningoencephalopathy
- H&E = hematoxylin and eosin
- HGE = hemorrhagic gastroenteritis
- MRI = magnetic resonance imaging
- WBC = white blood cell

Consulting Editor Stephen C. Barr

AMELOBLASTOMA

BASICS

OVERVIEW

- Common oral tumor of odontogenic (tooth structure) ectoderm origin.
- Biologically these tumors are benign histologically but possess locally invasive properties.
- Tumors may arise anywhere within the dental arcade.
- Several histologic subtypes exist with similar invasive behavior.

SIGNALMENT

- Middle-aged and old dogs
- Rare in cats

SIGNS

- Dogs may present with a smooth, firm, gingival mass that is usually non-ulcerated.
- It may be incidental finding during dental prophylaxis/procedures. If involving rostral dental arcade, incisor teeth can be displaced and enveloped by proliferative tissue.

CAUSES & RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Epulis
- Gingival hyperplasia
- Squamous cell carcinoma
- Amelanotic melanoma
- Plasma cell tumor
- Other tumors related to the odontogenic apparatus

CBC/BIOCHEMISTRY/URINALYSIS

Unaffected

OTHER LABORATORY TESTS

N/A

IMAGING

- Skull or dental radiographs may show bone lysis deep to the superficial mass. Not particularly useful for diagnostic or treatment planning.
- Regional and distant metastasis has not been described.
- Computed tomography is helpful for planning surgery or radiation therapy, especially in large or caudal tumors.

DIAGNOSTIC PROCEDURES

- Deep tissue biopsies are necessary and recommended for definitive diagnosis.
- Squamous cell carcinoma may be misdiagnosed as ameloblastoma.

TREATMENT

- Surgical excision such as hemi- or total mandibulectomy or maxillectomy with > 1–2 cm margins is recommended as a curative treatment option. Always submit resected tissue for histopathology, in order to confirm the original diagnosis, and evaluate soft tissue and bone margins.
- Radiation therapy may provide long-term control in large tumors, or when the owners decline surgery.
- Intralesional chemotherapy with bleomycin has been reported, but results are generally inferior to those of surgery or radiation.

MEDICATIONS

DRUG(S)

N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

Careful oral examination at 1, 3, 6, 9, and 12 months after definitive treatment is recommended to monitor for local recurrence.

Acknowledgment The author and editors acknowledge the prior contribution of Wallace B. Morrison.

BASICS

OVERVIEW

- Amitraz—formamidine acaricide; applied topically to control ticks, mites, and lice.
- Amitraz-containing products (for dogs)—formulated as a 19.9% emulsifiable concentrate in 10.6-mL bottles for dilution and sponge-on; as a 9% impregnated 25-inch 27.5-g collar and an 18-inch 18.5-g collar; as a 14.34% component of a 0.023 fl. oz., 0.045 fl. oz., 0.113 fl. oz., 0.180 fl. oz., or 0.225 fl. oz. spot-on (discontinued); and as a 7.6% component of a 0.036 fl. oz., 0.072 fl. oz., 0.145 fl. oz., 0.217 fl. oz. spot-on
- Systems affected—nervous; cardiovascular; endocrine/metabolic (β cells of the pancreas); gastrointestinal.
- Clinical signs—most associated with α_2 -adrenoreceptor agonist.
- After high-dose oral administration (dogs)—peak plasma concentration reached at approximately 6 hours; elimination half-life as long as 24 hours; metabolites excreted in the urine.
- Ingestion of sustained-release- impregnated collars—constant release and continued systemic exposure until collar segments have passed in the stool.
- Toxicosis—generally occurs when pieces of impregnated collar are ingested, when concentrated or improperly diluted solutions are applied topically, or when solutions are ingested or applied to the wrong size animal.
- Idiosyncratic reactions may occur.

SIGNALMENT

- Thorough history—usually identifies topical or collar use; topically missing collar or pieces seen in dog's environment or in the stool.
- Dogs—common, owing to more common use.
- Cats—more sensitive than dogs although cats are less likely involved.
- Predilection for old and toy-breed animals.

SIGNS

Historical Findings

Develop acutely after exposure (topical or oral)

Physical Examination Findings

- Minor to severe depression/lethargy
- Weakness
- Ataxia
- Bradycardia
- Vomiting (pieces of collar)
- Hyperthermia/hypothermia
- Hyperglycemia; diabetic patients can show significant hyperglycemia following exposure
- Hypotension
- Polyuria
- Gastrointestinal stasis

- Mydriasis
- Death (prognosis is typically good with treatment)

CAUSES & RISK FACTORS

- Ingestion of impregnated collar or pieces of collar.
- Inappropriate direct dermal application.
- Ingestion of undiluted product.
- After application of properly diluted and applied solutions—less common.
- Elderly, sick, toy-breed, or debilitated animals—may be predisposed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Recreational and prescription drugs—marijuana; opioids; barbiturates; benzodiazepines; phenothiazines; antihypertensive medications; skeletal muscle relaxants; antidepressants (tricyclic, SSRIs), and other depressant drugs or chemicals.
- Ivermectins, avermectins, milbemycins—generally very high dose or exceptionally sensitive breed.
- Macadamia nuts, tea tree oil, and albuterol inhaler toxicosis.
- Alcohols—ethanol; ethylene glycol (antifreeze); methanol (windshield washer fluid); isopropyl alcohol (rubbing alcohol).
- Tick bite paralysis, botulism, cranial trauma, diabetes, hyperadrenocorticism, hypothyroidism, severe anemia, cardiac failure, and anaphylactic shock—marked depression or weakness.
- Depends on clinical signs, history of exposure, or evidence of exposure and elimination of other causes.

CBC/BIOCHEMISTRY/URINALYSIS

- Hyperglycemia—common, related to insulin inhibition
- Elevated liver enzymes—uncommon

IMAGING

Abdominal radiography—may reveal a collar buckle in the gastrointestinal tract; collar itself is not radioopaque..

DIAGNOSTIC PROCEDURES

Identify amitraz on hair or in gastrointestinal contents—analytical methods described; useful only to prove exposure; no data available correlating concentration with clinical signs.

PATHOLOGIC FINDINGS

High-dose, prolonged exposure—increased liver weight; slight enlargement of hepatocytes; thinning of the zonae fasciculata and reticularis; slight hyperplasia of the zona glomerulosa of the adrenal glands.

TREATMENT

- Inpatient—severely affected patients.
- Mild sedation after correctly applied sponge-on solutions—often transient; may require no treatment.
- Mild signs after topical application—wearing gloves, scrub with a hand dishwashing detergent; rinse with copious amounts of warm water; institute non-specific supportive therapy (e.g., intravenous fluids, maintenance of blood pressure and normal body temperature, nutritional support); monitor 1–2 days until improvement is noted.
- Ingestion of collar possible—endoscopic retrieval of the collar—removal of large segments from the stomach may be beneficial; usually numerous small pieces are located throughout the gastrointestinal tract, making removal unrealistic.

MEDICATIONS

DRUG(S)

Collar Ingestion, Asymptomatic Patient

- Emetic—3% USP hydrogen peroxide (2.2 mL/kg PO; maximum 45 mL after feeding a moist meal); apomorphine and especially xylazine not recommended.
- Activated charcoal has not been shown to be effective.
- Bulk diet (whole wheat bread, lactulose, pumpkin, psyllium husk [Metamucil]).
- Warm tap water enema (5–10 mL/kg); will stimulate GI motility and help pass pieces of collar through the GI tract.

Marked Depression

- May require pharmacologic reversal of the α_2 -adrenergic effects.
- Atipamezole (Antisedan) 0.05 mg/kg 1/4th IV 3/4th IM; reverse clinical signs within minutes; repeat as needed; preferred over yohimbine because of its higher alpha-2 activities.
- Yohimbine (Yobine) 0.11–0.2 mg/kg IV, administered slowly; reverses depression and bradycardia within minutes; improves GI motility; objective is to keep the patient in a state of low-level depression with normal heart rate, blood pressure, body temperature, and blood glucose concentrations.
- Collar ingestion—monitor for recurrence of symptoms; may need additional yohimbine until collar segments appear in the stool.
- Yohimbine and atipamezole—may require repeated administration (as needed) possibly every 2–8 hours, because their half-life in dogs is short and amitraz elimination half-life is longer.

AMITRAZ TOXICOSIS

(CONTINUED)

- Atropine contraindicated because of potentiation of GI stasis.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Yohimbine and atipamezole—excessive administration may result in apprehension, CNS stimulation, and rarely seizures.

**FOLLOW-UP**

- Body temperature, blood pressure, serum glucose, and heart rate—important parameters.

- Close observation for recurrence of clinical signs—required for 24–72 hours.
- Yohimbine and atipamezole—requires readministration in severe cases, because reversal effects subside before collar segments have passed or before amitraz has been eliminated from the body.
- No long-term adverse effects expected.

**MISCELLANEOUS****AGE-RELATED FACTORS**

- Elderly, sick, or debilitated animals may take longer to fully recover.

ABBREVIATIONS

- CNS = central nervous system
- GI = gastrointestinal
- SSRI = selective serotonin reuptake inhibitor

AMPHETAMINE AND ADD/ADHD MEDICATION TOXICOSIS

BASICS

DEFINITION

Acute gastrointestinal, neurologic, neuromuscular, and cardiac toxicosis as the result of excessive consumption of amphetamine or a derivative. May be due to ingestion of prescription medications or illegal drugs.

PATOPHYSIOLOGY

- Amphetamine and its derivatives belong to the CNS stimulant class phenylethylamines. Various substitutions of the basic phenylethylamine structure account for many pharmaceutical and illicit compounds found today.
- Amphetamine is a sympathomimetic that is structurally related to norepinephrine.
- Central action—stimulates cortical centers including cerebral cortex, medullary respiratory center, and reticular activating systems.
- Peripheral action—directly stimulates alpha and beta receptors and stimulates the release of norepinephrine from stores in adrenergic nerve terminals.
- Amphetamine may slow catecholamine metabolism by inhibition of monoamine oxidase.
- Several different product formulations including immediate and extended release and topical patch.
- Amphetamines are well absorbed orally; peak plasma levels are generally reached in 1–3 hours; this may be delayed with extended release formulations.
- Metabolism is minimal.
- The half-life, which varies from 7–34 hours, and rate of excretion of unchanged amphetamine in the urine are both dependent upon urine pH, with shorter half-lives associated with more acidic urine.
- Clinical signs may be seen at doses below 1 mg/kg.
- Oral lethal dose in dogs for most amphetamines ranges from 10 mg/kg to 23 mg/kg and for methamphetamine sulfate it is 9–11 mg/kg. Oral lethal dose for amphetamine sulfate is 20–27 mg/kg.
- Amphetamine and its derivatives are used in humans to treat ADD/ADHD, narcolepsy, and obesity.
- Illicit use of amphetamines in humans is also prevalent.

SYSTEMS AFFECTED

- Cardiovascular—stimulation most common: tachycardia and hypertension.
- Nervous—stimulation most common, depression uncommon.
- Neuromuscular—stimulation: muscle tremors and seizures.
- Respiratory—stimulation, tachypnea.
- Ophthalmic—mydriasis.

- Gastrointestinal—anorexia, vomiting, diarrhea.

INCIDENCE/PREVALENCE

N/A

SIGNALMENT

Species

Dogs and cats, although more prevalent in dogs.

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

Historical Findings

- Abnormal behavior—usually hyperactivity, anxiety or pacing, anorexia, fast heart rate, panting; observed or evidence of exposure by owner/caretaker.
- Onset of signs typically begins within 30 minutes to 6 hours post-ingestion; depends on product formulation.

Physical Examination Findings

- Nervous—hyperactivity, agitation, restlessness, head bobbing, pacing, circling, vocalization, disorientation, hyperesthesia, ataxia, lethargy or depression (less common).
- Cardiovascular—tachycardia or bradycardia (less common, may be reflexive), hypertension.
- Neuromuscular—muscle fasciculation or tremors, seizures.
- Gastrointestinal—vomiting, diarrhea, anorexia, excessive salivation.
- Respiratory—tachypnea.
- Ophthalmic—mydriasis with possibly poor to unresponsive pupillary light response.
- Other—hyperthermia.

CAUSES

Accidental ingestion or administration, malicious poisoning.

RISK FACTORS

Households with children or adults currently taking prescription or illicit amphetamine or derivative.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Strychnine
- Organochlorine insecticides
- Methylxanthine
- 4-aminopyridine
- Metaldehyde
- Phenylpropanolamine
- Albuterol
- Nicotine
- Tremorgenic mycotoxins
- Hypernatremia

- Pseudoephedrine, phenylephrine
- 5 fluorouracil
- Ma huang, guarana, or ephedra

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—disseminated intravascular coagulopathy secondary to severe hyperthermia (rare).
- Chemistry—
- Azotemia: prerenal—secondary to dehydration; renal—secondary to rhabdomylosis and myoglobinuria (rare).
- Elevated liver enzymes—secondary to seizures and/or hyperthermia (rare).
- Hypoglycemia.
- Urinalysis—evidence of myoglobinuria, urine specific gravity (high—prerenal azotemia; isosthenuria—renal failure).

OTHER LABORATORY TESTS

- Electrolytes—imbalances secondary to GI effects.
- Acid-base status—acidosis may occur.
- Over-the-counter urine drug screens—watch for false positive or negative. Consult user handbook for further information.
- Amphetamines are present in blood, urine, and saliva; consult with local veterinary diagnostic lab or human hospital for availability and proper sample submission.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- EEG for presence of any tachyarrhythmia or less commonly bradyarrhythmia.
- Blood pressure—identification of hypertension.

PATHOLOGIC FINDINGS

On necropsy presence of amphetamines may be found in the gastric contents, urine, plasma, liver, kidney, or muscle.

TREATMENT

APPROPRIATE HEALTH CARE

Majority of cases require emergency inpatient intensive care management.

NURSING CARE

- Intravenous fluid therapy to correct dehydration and electrolyte imbalances as well as support renal function and promote excretion of amphetamines. Use blood pressure to help guide fluid rate.
- Cool intravenous fluids, fans, cool water baths for hyperthermia.

ACTIVITY

Minimize activity and stimuli.

DIET

Withhold food if moderately to severely affected. Bland diet for a few days post-exposure if significant gastrointestinal signs were noted.

AMPHETAMINE AND ADD/ADHD MEDICATION TOXICOSIS (CONTINUED)

CLIENT EDUCATION

In case of an exposure, owner should contact local veterinarian or veterinary poison center immediately.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

Decontamination

- Induce emesis—if a recent exposure and pet is not already symptomatic.
- Apomorphine—0.04 mg/kg IV, subconjunctival.
- Hydrogen peroxide 3%—2.2 mL/kg, maximum dose 45 mL.
- Gastric lavage if extremely large ingestion or patient is already symptomatic.
- Activated charcoal with a cathartic.

CNS Signs of Stimulation

- Acepromazine 0.05–1.0 mg/kg IV or IM
- Chlorpromazine 0.5 mg/kg IV, titrate up as needed.
- Cyproheptadine (serotonin antagonist): dogs, 1.1 mg/kg orally or rectally, may be repeated q8h as needed for signs consistent with serotonin syndrome; cats, 2–4 mg/cat, may repeat q12h as needed for signs consistent with serotonin syndrome
- Methocarbamol (for muscle tremors): 50–220 mg/kg IV, titrate to effect. Do not exceed 330 mg/kg/day.

Cardiovascular Signs

- Tachyarrhythmia—beta blockers such as propranolol 0.02–0.04 mg/kg IV or esmolol or metoprolol.
- Ventricular premature contractions—lidocaine: dogs at 2–4 mg/kg IV (to maximum of 8 mg/kg over a 10-minute period). Cats—start with 0.1–0.4 mg/kg and increase cautiously to 0.25–0.75 mg/kg IV slowly if no response. Cats are reportedly very sensitive to lidocaine, so monitor carefully if used.

Promote Elimination

Ascorbic acid or ammonium chloride—for urinary acidification to promote elimination; however, only use if can measure acid-base status.

CONTRAINDICATIONS

- While diazepam has been successfully used to treat amphetamine exposures, there is evidence that benzodiazepines may intensify neurologic signs.
- Urinary acidification if unable to monitor acid-base status or if myoglobinuria is present.
- Inducing emesis in a symptomatic patient.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

- Amphetamines inhibit the metabolism of adrenergic blockers (doxazosin, phenoxybenzamine, prazosin, terazosin), phenobarbital, and phenytoin.
- Amphetamines potentiate the metabolism of coumarin anticoagulants, monoamine oxidase inhibitors, opioid analgesics, and tricyclic antidepressants.

ALTERNATIVE DRUG(S)

Phenobarbital, pentobarbital, and propofol for CNS stimulatory signs.

FOLLOW-UP

PATIENT MONITORING

- Monitor in hospital until resolution of clinical signs.
- If severely affected, monitor liver and kidney values every 24 hours for 72 hours or until resolution.

PREVENTION/AVOIDANCE

All medications and illicit drugs should be kept out of pets' reach at all times.

POSSIBLE COMPLICATIONS

Acute renal failure secondary to myoglobinuria or DIC (rare).

EXPECTED COURSE AND PROGNOSIS

- Expected course of clinical signs is 12–72 hours, depending on dose, product formulation, effectiveness of decontamination and treatment, and rate of elimination.
- Prognosis—most patients do well with prompt and appropriate veterinary care. Seizures or severe hyperthermia may be a poor prognostic indicator.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

Pets exposed to human waste products from those taking amphetamines or derivatives could become symptomatic.

PREGNANCY/FERTILITY/BREEDING

Amphetamines are a known teratogen in humans. They have been found to cross the placenta in animals and may also be found in milk.

SYNONYMS

- Common brand names of prescription amphetamine drugs and their active ingredient: Adderall (amphetamine and dextroamphetamine); Ritalin, Metadate, and Concerta (methylphenidate); Daytrana (methylphenidate transdermal patch); Focalin (dexmethylphenidate); Vyvanse (lisdexamfetamine), Cylert (pemoline), Adipex-P (phentermine), Dexedrine (Dextroamphetamine).
- Illicit drug street names: ice, glass, crank, speed, uppers, ecstasy, meth, and many others.

SEE ALSO

- Antidepressant Toxicosis—SSRIs and SNRIs
- Antidepressant Toxicosis—Tricyclics
- Pseudoephedrine/Phenylephrine Toxicosis

ABBREVIATIONS

- ADD = attention deficit disorder
- ADHD = attention deficit hyperactivity disorder

BASICS

DEFINITION

A group of conditions of diverse cause in which extracellular deposition of insoluble fibrillar proteins (amyloid) in various organs and tissues compromises their normal function.

PATHOPHYSIOLOGY

- Patients usually affected by systemic reactive amyloidosis; tissue deposits contain AA, which is a fragment of an acute-phase reactant protein called SAA.
- Phases of amyloid deposition:
 - Predeposition phase: SAA concentration is high but without amyloid deposits; colchicine administration during this phase may prevent development of the disease.
 - Deposition phase (rapid portion): amyloid deposits increase rapidly; colchicine administration delays but does not prevent tissue deposition of amyloid; DMSO may promote resolution of amyloid deposits and a persistent decrease in SAA concentration.
 - Deposition phase (plateau portion): net deposition of amyloid changes little; neither DMSO nor colchicine is beneficial.
- Clinical signs in dogs and cats usually are associated with amyloid deposition in the kidneys.
- Dogs—amyloid deposits usually found in the glomeruli leading to proteinuria and nephrotic syndrome.
- Cats—amyloid deposits usually found in the medullary interstitium but may occur in glomeruli.
- Some Chinese shar-pei dogs with familial amyloidosis have medullary amyloidosis without glomerular involvement.
- Siamese and Oriental shorthair cats with familial amyloidosis have hepatic amyloidosis.
- A different type amyloid, pancreatic islet amyloid polypeptide, or amylin, deposits in the pancreas of old cats. Amylin is a hormone secreted along with insulin by the pancreatic beta cells. Chronic increased stimulus for secretion of amylin by beta cells (e.g., states of insulin resistance) lead to pancreatic islet cell amyloidosis.

SYSTEMS AFFECTED

Renal/Urologic—predisposition for renal AA deposition. Liver, spleen, adrenal glands, pancreas, tracheobronchial tree, and gastrointestinal tract also may be affected.

GENETIC

(See “Breed Predilections.”) No genetic involvement is clearly established; familial amyloidosis occurs in Chinese shar-pei, English foxhound, and beagle dogs, and in Abyssinian, Oriental shorthair, and Siamese cats.

INCIDENCE/PREVALENCE

Uncommon, occurs mostly in dogs; rare in cats, except Abyssinians.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dog—Chinese shar-pei, beagle, collie, pointer, English foxhound, and walker hound; German shepherd dog and mixed breeds are at lower risk.
- Cat—Abyssinian, Oriental shorthair, and Siamese.

Mean Age and Range

- Cats—mean age at diagnosis 7 years; range 1–17 years.
- Dogs—mean age at diagnosis is 9 years; range 1–15 years. Chinese shar-pei dogs—median age at diagnosis is 5 years; range 3.6–17 years.
- Prevalence increases with age.
- Abyssinian cats—range <1–17 years.
- Chinese shar-pei dogs—usually <6 years of age when signs of renal failure develop.
- Siamese cats with familial amyloidosis of the liver and thyroid gland usually develop signs of liver disease when 1–4 years old.

Predominant Sex

Dogs and Abyssinian cats—females at a slightly higher risk (<2:1). Female-to-male ratio is higher in Chinese shar-pei dogs (~2.5:1).

SIGNS

General Comments

- Depend on the organs affected, the amount of amyloid, and the reaction of the affected organs to amyloid deposits.
- Usually caused by kidney involvement; occasionally, hepatic involvement may cause signs in Chinese shar-pei dogs and Oriental shorthair and Siamese cats.

Historical Findings

- No clear history of a predisposing disorder in most (~75%) cases.
- Anorexia, lethargy, polyuria and polydipsia, weight loss, vomiting.
- Ascites and peripheral edema in animals with nephrotic syndrome.
- Chinese shar-pei dogs may have a history of previous episodic joint swelling and high fever that resolves spontaneously within a few days.
- Beagle dogs with juvenile polyarteritis may have a history of fever and neck pain that persist for 3–7 days.
- Oriental shorthair and Siamese cats may present with spontaneous hepatic hemorrhage leading to acute collapse and hemoabdomen.

Physical Examination Findings

- Related to renal failure—oral ulceration, emaciation, vomiting, and dehydration; kidneys usually small, firm, and irregular in affected cats; they may be small, normal-sized, or slightly enlarged in affected dogs.
- Signs of nephrotic syndrome (e.g., ascites, subcutaneous edema).
- Related to the primary inflammatory or neoplastic disease process.
- Thromboembolic phenomena—may occur in up to 40% of affected dogs; signs vary with the location of the thrombus; patients may develop pulmonary

thromboembolism (e.g., dyspnea) or iliac or femoral artery thromboembolism (e.g., caudal paresis).

- Chinese shar-pei dogs and Oriental shorthair and Siamese cats may have signs of hepatic disease (e.g., jaundice, cachexia, and spontaneous hepatic rupture with intraperitoneal bleeding).

CAUSES

- Neoplasia and chronic infectious and non-infectious inflammatory conditions can be found in 30–50% of dogs with reactive amyloidosis.
- Chronic inflammation—systemic mycoses (e.g., blastomycosis, coccidioidomycosis), chronic bacterial infections (e.g., osteomyelitis, bronchopneumonia, pleuritis, steatitis, pyometra, pyelonephritis, chronic suppurative dermatitis, chronic suppurative arthritis, chronic peritonitis, nocardiosis, chronic stomatitis), parasitic infections (e.g., dirofilariasis, leishmaniasis, hepatozoonosis), and immune-mediated diseases (e.g., systemic lupus erythematosus). Amyloid deposits can be found in up to 35% of FIV-positive cats.
- Neoplasia (e.g., lymphoma, plasmacytoma, multiple myeloma, mammary tumors, testicular tumors).
- Familial (e.g., Chinese shar-pei, English foxhound, and beagle dogs; Abyssinian, Siamese, and Oriental shorthair cats).
- Others—cyclic hematopoiesis in gray collies; juvenile polyarteritis in beagles.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dogs—GN; proteinuria tends to be more severe in dogs with glomerular amyloidosis than those with GN but there is great overlap.
- Cats and Chinese shar-pei dogs with medullary amyloidosis—consider other causes of medullary renal disease (e.g., pyelonephritis, chronic interstitial disease).

CBC/BIOCHEMISTRY/URINALYSIS

- Nonregenerative anemia is found in some dogs and cats with amyloid-induced renal failure.
- Dogs—may see hypercholesterolemia (> 85%), azotemia (> 70%), hypoalbuminemia (70%), hyperphosphatemia (> 60%), hypocalcemia (50%), and metabolic acidosis.
- Hypercholesterolemia—common finding in cats with renal disorders (> 70% of cats with renal disease in one study) but does not reliably predict glomerular disease.
- Hypoproteinemia—more common than hyperproteinemia (24 vs. 8.5%) in dogs with amyloidosis; hyperglobulinemia common in cats.
- Proteinuria—with an inactive sediment common in dogs; mild or absent in animals with medullary amyloidosis without glomerular involvement (most mixed-breed cats, at least 25% of Abyssinian cats, and at least 33% of Chinese shar-pei dogs). In a retrospective study with 91 cases of renal

AMYLOIDOSIS

(CONTINUED)

amyloidosis in dogs, hypoalbuminemia was more common in non-Chinese shar-pei dogs (100%) versus shar-pei dogs (65%).

- Isosthenuria, and hyaline, granular, and waxy casts in some patients.

OTHER LABORATORY TESTS

Proteinuria—urinary protein:creatinine ratio to estimate severity.

IMAGING

Abdominal Radiographic Findings

- Kidneys usually small in affected cats.
- Kidneys small, normal-sized, or large in affected dogs.

Abdominal Ultrasonographic Findings

Kidneys usually hyperechoic and small in affected cats; may be small, normal-sized, or large in affected dogs.

DIAGNOSTIC PROCEDURES

Renal biopsy needed to differentiate amyloidosis from GN. In dogs other than Chinese shar-pei, amyloidosis is primarily a glomerular disease; diagnose by renal cortical biopsy. In most domestic cats, some Abyssinian cats, and some Chinese shar-pei dogs, medullary amyloidosis can occur without glomerular involvement; diagnose by renal medullary biopsy.

PATHOLOGIC FINDINGS

• Small kidneys in cats; small, normal, or large kidneys in dogs. • Amyloid deposits appear homogeneous and eosinophilic when stained by hematoxylin and eosin and viewed by conventional light microscopy. They demonstrate green birefringence after Congo red staining when viewed under polarized light. Evaluation of Congo red—stained sections before and after permanganate oxidation permits presumptive diagnosis of AA amyloidosis (vs. other types) because AA amyloidosis loses its Congo red affinity after permanganate oxidation. • The liver is very friable and usually contains extensive amyloid deposits in cats presented with acute hepatic hemorrhage.

TREATMENT

APPROPRIATE HEALTH CARE

- Hospitalize patients with chronic renal failure and dehydration for initial medical management. • Can manage stable patients and those with asymptomatic proteinuria as outpatients.

DIET

- Patients with chronic renal failure—restrict phosphorus and moderately restrict protein.
- Patients with hypertension—restrict sodium.

CLIENT EDUCATION

- Discuss progression of the disease. • Discuss familial predisposition in susceptible breeds.

MEDICATIONS

DRUG(S) OF CHOICE

- Identify underlying inflammatory and neoplastic processes and treat if possible.
- Manage renal failure according to the principles of conservative medical treatment (see Renal Failure, Acute, and Renal Failure, Chronic).
- Normalize blood pressure in patients with hypertension (see Hypertension, Systemic).
- Patients with thromboembolic syndrome and nephrotic syndrome caused by glomerular amyloidosis usually have a low plasma concentration of antithrombin; thus heparin is relatively ineffective. Aspirin (0.5 mg/kg PO q12h) has been suggested for dogs with glomerular disease; this low dosage is as effective in preventing platelet aggregation as is 10 mg/kg PO q24h.
- DMSO—may help patients by solubilizing amyloid fibrils, reducing serum concentration of SAA, and reducing interstitial inflammation and fibrosis in the affected kidneys; may cause lens opacification in dogs. Perivascular inflammation and local thrombosis may occur if undiluted DMSO is administered intravenously. Subcutaneous administration of undiluted DMSO may be painful. The authors have used 90% DMSO diluted 1:4 with sterile water subcutaneously at a dosage of 90 mg/kg 3 times per week in dogs. Whether or not DMSO treatment benefits renal amyloidosis in dogs remains controversial.

- Methylsulfonylmethane is an active metabolite of DMSO that can be given orally and lacks the smell of DMSO. It has been used empirically in dogs with amyloidosis, but there is no evidence that it benefits dogs with renal amyloidosis.
- Colchicine—impairs release of SAA from hepatocytes; prevents development of amyloidosis in humans with familial Mediterranean fever (a familial amyloidosis) and stabilizes renal function in patients with nephrotic syndrome but without overt renal failure; no evidence of benefit once the patient develops renal failure; may cause vomiting, diarrhea, and idiosyncratic neutropenia in dogs. Colchicine (0.01–0.04 mg/kg PO q24h) is used particularly in shar-pei dogs with episodic fever or polyarthritis before development of renal failure.

PRECAUTIONS

- Dosage of drugs excreted by the kidneys may need adjustment in patients with renal failure. • Use nonsteroidal anti-inflammatory drugs cautiously in patients with medullary amyloidosis; they can decrease renal blood flow in dehydrated patients.

FOLLOW-UP

PATIENT MONITORING

- Appetite and activity level daily by the owner; body weight weekly. • Serum albumin, creatinine, and BUN concentrations every 2–6 months in stable patients. • Can assess degree of proteinuria serially by urine protein:creatinine ratios.

PREVENTION/AVOIDANCE

Do not breed affected animals.

POSSIBLE COMPLICATIONS

- Renal failure • Nephrotic syndrome
- Systemic hypertension • Hepatic rupture causing intraperitoneal hemorrhage
- Thromboembolic disease

EXPECTED COURSE AND PROGNOSIS

Disease is progressive and usually advanced at the time of diagnosis. Prognosis improves if an underlying immune, inflammatory, or neoplastic disease is detected and successfully treated. Survival for dogs with glomerular amyloidosis varied from 3 to 20 months in 1 study; some dogs may occasionally live longer. Cats with renal failure because of amyloidosis usually survive < 1 year. Mildly affected cats may not develop renal failure and have an almost normal life expectancy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Urinary tract infection • Polyarthritis in Chinese shar-pei • Polyarteritis in beagle

SEE ALSO

- Glomerulonephritis • Nephrotic Syndrome Proteinuria • Renal Failure, Acute • Renal Failure, Chronic

BASICS

OVERVIEW

- Anaerobic bacteria (i.e., bacteria requiring low oxygen tension) comprise a large portion of the normal flora, especially on mucosal surfaces.
- May be Gram-positive or Gram-negative cocci or rods.
- Most common genera—*Bacteroides*, *Fusobacterium*, *Actinomyces*, *Propionibacterium*, *Pectostreptococcus* (enteric *Streptococcus*), *Porphyromonas*, and *Clostridium*.
- Most anaerobic infections are polymicrobial and contain at least two different anaerobe species admixed with facultative anaerobes or aerobic bacteria (especially *E. coli*).
- Individual organisms vary in potential to withstand oxygen exposure.
- Injurious toxins and enzymes may be elaborated by the organisms, leading to extension of the infection into adjacent, healthy tissue.
- All body systems are at potential risk for anaerobic infection.

SIGNALMENT

Dog and cat

SIGNS

General Comments

- Determined by the body system involved.
- Certain areas more commonly associated with anaerobic infection (mucous membrane proximity).
- It is possible to overlook anaerobes in an infectious process, leading to confusion in interpreting culture results and selection of antimicrobials.

Physical Examination Findings

- A foul odor associated with a wound or exudative discharge.
- Gas in the tissue or associated exudates.
- Discolored tissue, especially when black.
- Peritonitis, pyothorax, or pyometra.
- Severe dental disease.
- Wounds or deep abscesses that do not heal as anticipated.

CAUSES & RISK FACTORS

- Usually caused by normal flora of the body; a break in protective barriers allows bacterial invasion.
- Infection in the proximity of a mucous membrane should raise one's index of suspicion for anaerobe involvement.
- Predisposing factors—immunosuppression, bite wounds, dental disease, open fractures, abdominal surgery, and foreign bodies.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Wounds that fail to respond to appropriate medical therapy—if aerobic cultures are negative, suspect anaerobic organisms.
- Cats

with non-healing wounds—test for FeLV and FIV.

- Middle-aged and old animals—tumor invasion (e.g., in the gastrointestinal tract).

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilic leukocytosis and monocytosis common.
- Biochemical abnormalities depend on specific organ involvement.
- Systemic spread of infection suggested by leukocytosis, hypoglycemia, increased ALP, and hypoalbuminemia.

OTHER LABORATORY TESTS

- Culture of anaerobic bacteria is often unrewarding because of their fastidious nature and errors in sample handling and submission.
- Appropriate media and containers should be on-hand prior to sample collection; diagnostic laboratories can provide guidance.
- Samples should not be refrigerated prior to submission.
- Suitable samples for culture may include fluid (e.g., pleural, peritoneal, etc.) or tissue.

IMAGING

As required for the circumstances of the individual patient (e.g., suspected bone infection, peritonitis, etc.).

DIAGNOSTIC PROCEDURES

- Cytologic inspection reveals abundant degenerate neutrophils with morphologically diverse forms of intracellular and extracellular bacteria; presence of large filamentous bacteria is suggestive.
- If not performed in-house, Gram staining should be requested when the sample is submitted.

MEDICATIONS

- Thoracic drainage—important with pyothorax (see specific chapter).
- Hyperbaric oxygen—some potential use; limited in availability.

SURGERY

- Should not be delayed when anaerobes are suspected.
- Combined with systemic antimicrobial therapy—the best chance of a positive outcome.
- Usually indicated when anaerobic organisms complicate pyometra, osteomyelitis, and peritonitis.
- Cleanse the wound of toxins and devitalized tissue.
- Enhance drainage of pus.
- Improve local blood flow.
- Increase oxygen tension.

DRUG(S)

- Antimicrobial therapy alone—unlikely to be successful; poor drug penetration into exudates.
- Antibiotic selection—largely empiric, owing to the difficulty of isolating anaerobes and the delay in return of culture results.
- Because most anaerobic infections are polymicrobial, therapy targeted against both

anaerobes *and* any aerobic components offers the greatest chance of success.

- Amoxicillin with clavulanate—in many cases, considered the antibiotic of choice; convenient and accessible; clavulanate improves activity against *Bacteroides*.
- Imipenem—beta lactam with significant activity against serious, resistant infections.
- Cefoxitin—a cephalosporin with reliable activity against anaerobes.
- Clindamycin—may be especially useful for respiratory tract infections; concentrated within leukocytes.
- Chloramphenicol—good tissue penetration but bacteriostatic and associated with adverse effects, especially in cats; concern for human exposure also limits use.
- Metronidazole—useful against all clinically significant anaerobes (except *Actinomyces*).
- Aminoglycosides—uniformly ineffective.
- Trimethoprim-sulfa combinations—ineffective; poor penetration into exudates.
- Quinolones—routinely ineffective, although newer expanded-spectrum quinolones do have activity against anaerobes (e.g., pradofloxacin).

FOLLOW-UP

PATIENT MONITORING

Monitoring parameters will vary with the circumstances of each patient.

POSSIBLE COMPLICATIONS

Localized infection may progress to systemic infection if not appropriately identified and treated.

EXPECTED COURSE AND PROGNOSIS

Dependent upon identification and resolution of the underlying cause; long-term antibiotic therapy may be required.

Author Sharon Fooshee Grace

Consulting Editor Stephen C. Barr

ANAL SAC DISORDERS

BASICS

OVERVIEW

- Anal sacs are reservoirs for secretions normally evacuated by compression during defecation.
- Normal gland secretions vary in consistency and color.
- Disorders include impaction, infection (sacculitis), abscess, and neoplasia.
- Treatment options include manual expression, flushing, antibiotics, and surgical excision.

SIGNALMENT

- Dogs and cats (rarely): no age or sex predisposition.
- Breeds predisposed:
 - Impaction—miniature and toy poodle, American cocker and English springer spaniel, Chihuahua.
 - Neoplasia (adenocarcinoma)—German shepherd dog, golden retriever, American cocker and English springer spaniel.

SIGNS

Impaction/Infection

- Anal pruritus—often manifested by “scooting”
- Perianal pruritus
- Hesitancy to defecate
- Tenesmus
- Tail chasing
- Foul-smelling, non-feces anal discharge
- Refusal to sit and/or lift tail
- Cats—excessive licking of the ventral abdomen and tail head
- Abscess—often unilateral; localized pain and discharge

CAUSES & RISK FACTORS

- Predisposing factors—soft feces or diarrhea leading to retention of secretions within anal sacs due to lack of expression; excessive glandular secretions; dermatologic disorders that alter the characteristics (cellularity and organism colonization) of anal sac secretions.
- Retained secretions may lead to infection and abscess formation.
- Other predisposing factors:
 - Obesity
 - Infection – hypersensitivity and/or endocrinopathy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Adverse food reaction or food hypersensitivity
- Flea bite hypersensitivity

- Atopic dermatitis
- Tapeworm infestation
- Tail fold bacterial folliculitis
- Malassezia dermatitis
- Compulsive disorder (anal licking)
- Colitis or other intestinal disorder
- Keratinization disorder
- Anal sac neoplasia (including adenocarcinoma, squamous cell carcinoma)
- Perianal adenoma
- Perianal adenocarcinoma
- Perianal fistulae

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal
- Hypercalcemia—anal sac adenocarcinoma

OTHER LABORATORY TESTS

None unless indicated by an underlying cause

IMAGING

None unless indicated by an underlying cause

DIAGNOSTIC PROCEDURES

- Digital palpation of the anal sacs—normal anal sacs should not be palpable externally.
- Normal anal sac contents vary widely in gross appearance and microscopic characteristics; usually thin or watery, with minimal cellularity and primarily extracellular organisms, but may vary widely in numbers of inflammatory cells and bacteria.
- Impaction—generally more thick, pasty brown secretion; higher numbers of *Malassezia* and intracellular bacteria.
- Anal sacculitis and abscessation—purulent, often blood-tinged, foul-smelling discharge.
- Cytology of anal sac secretions—increased number of neutrophils, erythrocytes, *Malassezia*, and intracellular bacteria indicate infection; reports vary but Gram-positive cocci more common in normal secretions.
- Bacterial culture and sensitivity—normal secretions may contain *Proteus mirabilis*, *Streptococcus spp.*, *Escherichia coli*, *Bacillus spp.*, *Clostridium perfringens*, and *Pseudomonas aeruginosa*.

TREATMENT

- Gentle manual expression of contents for impaction and sacculitis.
- Sedation may be necessary to flush severely impacted or painful anal sacs.
- Infusion of antibiotic and/or corticosteroid medications directly into the anal sacs.
- Drainage of abscesses.
- Use of appropriate oral antibiotics and/or antiyeast medication.
- Anal sac excision with chronic disease.
- Surgical excision and staging of anal sac neoplasia; combine with chemotherapy.

- Identification of underlying causes of predisposing disease.
- Feeding high-fiber diets may help natural expression of anal sacs.

MEDICATIONS

DRUG(S)

- Infection—use of appropriate antibiotics: cephalaxin (22 mg/kg q12h), amoxicillin trihydrate-clavulanate potassium (10–15 mg/kg q12h), clindamycin (11 mg/kg q24h), trimethoprim-sulfamethoxazole (15 mg/kg q12h); metronidazole (10–15 mg/kg q12h); enrofloxacin (dogs, 10–20 mg/kg q24h; cats, 5 mg/kg/day), and orbifloxacin (5 mg/kg q24h).
- Chronic disease associated with perianal fistulae; cyclosporine, modified (name brand preferred: Atopica 5 mg/kg q24h) and/or topical tacrolimus.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Reassess patients weekly initially; then as necessary to monitor healing.
- Manually express anal sac contents and/or flush contents until sacs empty without intervention.
- CBC, serum chemistry profile, and urinalysis with culture—recommended every 3–12 months for patients on chronic corticosteroid or cyclosporine therapy.

MISCELLANEOUS

SEE ALSO

- Adenocarcinoma, Anal Sac
- Perianal Fistula

Consulting Editor Alexander H. Werner

BASICS

DEFINITION

- Acute manifestation of a Type I hypersensitivity reaction mediated through the rapid introduction of an antigen into a host having antigen-specific antibodies of the IgE subclass.
- The binding of antigen to mast cells sensitized with IgE results in the release of preformed and newly synthesized chemical mediators.
- Anaphylactic reactions may be localized (atopy) or systemic (anaphylactic shock).
- Anaphylaxis not mediated by IgE is designated an anaphylactoid reaction and will not be discussed.

PATOPHYSIOLOGY

- First exposure of the patient to a particular antigen (allergen) causes a humoral response and results in production of IgE, which binds to the surface of mast cells; the patient is then considered to be sensitized to that antigen.
- Second exposure to the antigen results in cross-linking of two or more IgE molecules on the cell surface, resulting in mast cell degranulation and activation; release of mast cell granules initiates an anaphylactic reaction.
- Major mast cell-derived mediators include histamine, eosinophilic chemotactic factor, arachidonic acid, metabolites (e.g., prostaglandins, leukotrienes, and thromboxanes), platelet-activating factor, and proteases, which cause an inflammatory response of increased vascular permeability, smooth muscle contraction, inflammatory cell influx, and tissue damage.
- Clinical manifestations depend on the route of antigen exposure, the dose of antigen, and the level of the IgE response.

SYSTEMS AFFECTED

- Gastrointestinal—salivation, vomiting, and diarrhea
- Hepatobiliary (dogs)—because of portal hypertension and vasoconstriction
- Respiratory (cats)—dyspnea and cyanosis
- Skin/Exocrine—pruritus, urticaria, and edema

GENETICS

Familial basis reported for Type I hypersensitivity reaction in dogs.

INCIDENCE/PREVALENCE

- Localized Type I hypersensitivity reactions not uncommon.
- Systemic Type I hypersensitivity reactions rare.

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dogs—numerous breeds documented as having a predilection for developing atopy.
- Cats—no breeds documented as having predilection for atopy.

Mean Age and Range

- Dogs—age of clinical onset ranges from 3 months to several years of age; most affected animals 1–3 years old.
- Cats—age of clinical onset ranges from 6 months to 2 years.

Predominant Sex

- Dogs—atopy more common in females.
- Cats—no reported sex predilection.

SIGNS

General Comments

- Initial clinical signs vary depending on the route of exposure to the inciting antigen (allergen).
- Shock—end result of a severe anaphylactic reaction.
- Shock organ—dogs, liver; cats, respiratory and gastrointestinal systems.
- May be localized to the site of exposure but may progress to a systemic reaction.

Historical Findings

- Onset of signs immediate (usually within minutes).
- Dogs—pruritus, urticaria, vomiting, defecation, and urination.
- Cats—intense pruritus about the head, dyspnea, salivation, and vomiting.

Physical Examination Findings

- Localized cutaneous edema at the site of exposure.
- Hepatomegaly in some dogs.
- Hyperexcitability possible in early stages.
- Depression and collapse terminally.

CAUSES

Virtually any agent; those commonly reported include venoms, blood-based products, vaccines, foods, and drugs.

RISK FACTORS

Previous exposure (sensitization) increases the chance of the animal developing a reaction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other types of shock.
- Trauma.
- Depends on the major organ system involved or if reaction is localized; diagnosis can be made largely on the basis of history and clinical signs.

CBC/BIOCHEMISTRY/URINALYSIS

Because of the acute onset of disease, no tests available that reliably predict individual susceptibility.

OTHER LABORATORY TESTS

- Intradermal skin testing to identify allergens.
- Radioallergosorbent test to quantify the concentration of serum IgE specific for a particular antigen.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Limited because a severely allergic animal can develop an anaphylactic reaction when exposed to even small quantities of antigen.

PATHOLOGIC FINDINGS

- Lesions vary, depending on severity of reaction, from localized cutaneous edema to severe pulmonary edema (in cats) and visceral pooling of blood (in dogs).
- Other non-specific findings vary and are characteristic of shock.
- Non-specific characteristics of localized reactions include edema, vasculitis, and thromboembolism.

TREATMENT

APPROPRIATE HEALTH CARE

In an acutely affected animal, the reaction is considered a medical emergency requiring hospitalization.

NURSING CARE

Elimination of inciting antigen, if possible.

Systemic Anaphylaxis

- Goal—emergency life support through the maintenance of an open airway, preventing circulatory collapse, and reestablishing physiologic parameters.
- Administer fluids intravenously at shock dosages to counteract hypotension.

Localized Anaphylaxis

Goal—limit the reaction and prevent progression to a systemic reaction.

ACTIVITY

N/A

DIET

If a food-based allergen is suspected (uncommon), avoid foods associated with hypersensitivity reaction.

CLIENT EDUCATION

- Discuss the unpredictable nature of the disease.
- Discuss the need to recognize that the animal has an allergic condition that may require immediate medical care.

SURGICAL CONSIDERATIONS

None

MEDICATIONS

DRUG(S) OF CHOICE

Systemic Anaphylaxis

- Epinephrine hydrochloride parenterally (1:1,000; 0.01 mL/kg) for shock.
- Corticosteroids for shock—prednisolone sodium succinate (2 mg/kg IV q8h) or dexamethasone sodium phosphate (0.25 mg/kg IV q12h).
- Atropine sulfate (0.04 mg/kg IM) to counteract bradycardia and hypotension.
- Aminophylline (10 mg/kg IM or slowly IV) in severely dyspneic patients.

Localized Anaphylaxis

- Diphenhydramine hydrochloride (1–2 mg/kg IV or IM).
- Prednisolone (2 mg/kg PO).
- Epinephrine hydrochloride (0.15 mL SC at site of initiation).
- If shock develops, initiate treatment for a systemic anaphylaxis.

CONTRAINDICATIONS

None

PRECAUTIONS

Localized reaction can develop into systemic reaction.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

Closely monitor hospitalized patients for 24–48 hours.

PREVENTION/AVOIDANCE

If inciting antigen (allergen) can be identified, eliminate or reduce exposure.

POSSIBLE COMPLICATIONS

None

EXPECTED COURSE AND PROGNOSIS

- If localized reaction is treated early, prognosis is good.
- If the animal is in shock on examination, prognosis is guarded to poor.

ANEMIA OF CHRONIC KIDNEY DISEASE

A

BASICS

DEFINITION

Progressive decreases in PCV, RBC count, and hemoglobin and hypoplasia of erythroid elements of the bone marrow are predictable features of progressive CKD. Anemia is normocytic, normochromic, nonregenerative, and proportional to the stage of CKD. The underlying cause of the anemia of CKD is multifactorial. Although factors such as gastrointestinal blood loss, reduced red blood cell survival, deficiencies in iron and/or folate, cytokines and inflammatory mediators may be involved, the primary contributing factor to anemia of CKD is an inadequate production of erythropoietin (EPO) by the kidneys. Erythropoietin is a glycoprotein hormone that regulates red blood cell generation at the level of the bone marrow. Erythropoietin is produced in the peritubular interstitial cells of the kidney in response to decrease in tissue oxygen.

SIGNALMENT

Middle-aged to old dogs and cats mostly affected; seen in young animals with heritable, congenital, or acquired CKD.

SIGNS

- Anemia contributes to development of anorexia, weight loss, fatigue, lethargy, depression, weakness, apathy, cold intolerance, and behavior and personality changes characterizing CKD.
- Pallor of the mucous membranes.
- Tachypnea.
- Tachycardia.
- Systolic murmur.
- Syncope and seizures (rare).

CAUSES & RISK FACTORS

- All inherited, congenital, and acquired forms of CKD (e.g., pyelonephritis, glomerulonephritis, amyloidosis, polycystic kidney disease, and lymphoma).
- Exacerbated by iron deficiency, inflammatory or neoplastic disease, gastrointestinal blood loss, hemolysis, and myeloproliferative disorders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anemia of chronic infectious, inflammatory or neoplastic disease; myeloproliferative disease; chronic blood loss; aplastic anemia; endocrine disease; drug reaction; and chronic immune-mediated, toxic, viral, rickettsial, or parasitic anemia; hemodilution.
- Regenerative anemia excludes diagnosis of anemia of CKD.
- Generally masked until advanced CKD.

CBC/BIOCHEMISTRY/URINALYSIS

- Normocytic, normochromic, hypoproliferative anemia (progressive; anemia may be masked by dehydration).
- Reticulocytes—low corrected indices and absolute counts ($\leq 10,000/\mu\text{L}$).
- Moderate to advanced CKD—elevated BUN, creatinine, and phosphorus; variably high calcium; variably low bicarbonate and potassium.
- High BUN:creatinine ratio may predict concurrent” gastrointestinal blood loss.
- Impaired urine-concentrating ability, possible proteinuria, and variably active sediment.

OTHER LABORATORY TESTS

- Serum iron—normal or variably low.
- Transferrin saturation—normal or variably low ($< 20\%$).
- FeLV and FIV and/or haemobartonella testing (cats) or rickettsial titers or PCR (dogs) to exclude agent-induced myelodyscrasia.
- Serum erythropoietin—normal (inappropriately) or low.

IMAGING

- Small, irregular kidneys with loss or disruption of renal architecture detected by radiography or ultrasonography.
- Enlarged, polycystic, hydronephrotic, infiltrative.

DIAGNOSTIC PROCEDURES

Cytologic examination of bone marrow—erythroid hypoplasia; myeloid:erythroid ratio normal or high; stainable iron normal or variably low.

TREATMENT

- Stabilize azotemia in patients in with uremic crisis.
- Ensure adequate and appropriate nutrition.
- Stabilize any metabolic derangement (e.g., acidosis) that could contribute to shortened RBC lifespan and/or anorexia.
- Minimize micronutrient deficiencies that could negatively impact rbc production.
- Identify and manage GI blood loss (gastric acid suppression with H₂ blockers or proton pump inhibitors) (GI protectants such as sucralfate).
- Ensure that patient is iron replete (serum iron panel).
- Correct systemic hypertension.

MEDICATIONS

DRUG(S) AND FLUIDS

Blood Transfusion

- Short-term, rapid correction if hypoxic distress (typically PCV $\leq 15\%$)—give compatible whole blood or packed RBCs.

- Target PCV is 25–30%.

- May be given intermittently for prolonged management, although compatibility issues are likely to occur long term.
- EPO support for progressive or symptomatic anemia (dogs, PCV $\leq 25\%$; cats, PCV $\leq 23\%$).

Erythropoietin Replacement

- Epoetin alfa (r-HuEPO)—original synthetic erythropoiesis stimulating protein, replica of human erythropoietin (Epogen and Procrit); provides consistent, rapid, and long-term correction of anemia in dogs and cats with CKD; potential for anti-r-HuEPO antibody production and pure red cell aplasia.
- Darbepoetin alfa (Aranesp), a new hyperglycylated analogue of r-HuEPO with prolonged half-life and sustained effects; very effective with significantly less tendency for antibody induction; should be used preferentially to epoetin alfa.
- Target PCV—dogs, 30–35%; cats, 30%.
- Initial dosage: darbepoetin alfa—0.5–2.0 $\mu\text{g}/\text{kg}$ SC/IV once weekly until PCV reaches low end of target, then decrease to q2–4 weeks as needed to maintain target. Recommend PCV prior to EVERY injection to avoid overtreatment.
- Epoetin alfa—50–100 U/kg SC thrice weekly until low end of target, then decrease to once to twice weekly.
- If converting from epoetin alfa to darbepoetin—divide weekly units by 400 to establish μg to give once weekly.
- Individualize to each patient; life-long treatment required.
- If PCV exceeds target, discontinue until upper target range is achieved, then increase dosage interval.
- Serum iron and transferrin saturation should be normalized before initiating and during treatment. Injectable iron (10 mg/kg IM) should be administered when indicated on iron panel. Injectable iron is preferable and better tolerated than oral preparations.
- Species-specific erythropoietins for dogs and cats are not currently commercially available.
- Alternative erythropoietin-stimulating treatments are under development.

Anabolic Steroids

Little or no efficacy or indication for use.

FOLLOW-UP

PATIENT MONITORING

- PCV—weekly to semi-monthly for 3 months, then monthly to bimonthly.
- Blood pressure—semi-monthly to monthly.
- Iron and transferrin saturation—at 1, 3, and 6 months, then semiannually.
- Discontinue erythropoietin if patient develops evidence of erythrocythemia, local or systemic sensitivity, anti-r-HuEPO antibody

ANEMIA OF CHRONIC KIDNEY DISEASE

(CONTINUED)

formation, pure red cell aplasia, or refractory hypertension.

POSSIBLE COMPLICATIONS*Erythropoietin-Related*

- Development of erythrocythemia, seizures, hypertension, iron depletion, injection pain, and mucocutaneous reactions.
- Development of a pure red cell aplasia during the course of epoetin alfa treatment suggests formation of anti-r-HuEPO antibodies, which neutralize r-HuEPO and native erythropoietin, causing severe anemia in 20–30% of animals; often reversible with cessation of treatment.
- Development of anti-r-HuEPO antibodies occurs in less than 5% of patients with darbepoetin alfa therapy.
- Signs associated with production of anti-r-HuEPO antibodies while the patient is receiving epoetin alfa include decreasing PCV, erythroid hypoplasia, absolute reticulocyte counts approaching zero, and myeloid:erythroid ratio ≥ 8 .
- Erythropoietin replacements should be used cautiously or withheld if hypertension or iron deficiency develop; treatment can be reinstated once hypertension and iron deficiency are corrected.

Transfusion-Related

- Incompatibility reaction
- Circulatory or iron overload
- Systemic hypertension
- Transmissible infection

EXPECTED COURSE AND PROGNOSIS

- Correction of anemia increases appetite, activity, grooming, affection and playfulness, weight gain, and cold tolerance, and decreases sleeping.
- Use of erythropoietin replacement agents in dogs and cats requires careful assessment of the risks and benefits for individual patients.
- Short-term prognosis depends on the severity of the renal failure.
- Long-term prognosis is guarded to poor because of the underlying chronic renal failure.

**MISCELLANEOUS****ABBREVIATIONS**

- CKD = chronic kidney disease
- FeLV = feline leukemia virus

- FIV = feline immunodeficiency virus
- PCR = polymerase chain reaction
- PCV = packed cell volume
- RBC = red blood cell
- r-HuEPO = recombinant human erythropoietin

BASICS

OVERVIEW

- A disorder of hematopoietic precursor cells characterized by replacement of normal bone marrow with adipose tissue. There is decreased production of granulocytes, erythrocytes, and platelets, resulting in pancytopenia in the peripheral blood. The disease is sometimes also referred to as aplastic pancytopenia.
- In the acute form, neutropenia and thrombocytopenia predominate because of the shorter life spans of these cells; in the chronic form, nonregenerative anemia also occurs. In both forms, the bone marrow exhibits variable degrees of panhypoplasia.
- There are many precipitating causes of deficient hematopoiesis, including infectious diseases, drug administration, starvation and toxin exposure; immune-mediated mechanisms are often suspected.
- Hemic/lymphatic/immune systems affected.

SIGNALMENT

Dogs and cats, no apparent breed or sex predilection. In one study, the mean age of nine affected dogs was 3 years.

SIGNS

- Acute form: fever, petechial hemorrhages, epistaxis, hematuria, melena; i.e., signs due to neutropenia and thrombocytopenia.
- Chronic form: pale mucous membranes, weakness, lethargy; i.e., signs due to anemia, in addition to signs observed in acute forms.

CAUSES & RISK FACTORS

Often not identified

Infectious Agents

- FeLV, FIV
- Canine and feline parvovirus
- Rickettsial organisms (e.g., *Ehrlichia* spp.)

Drugs and Chemicals

- Estrogen (exogenous administration, Sertoli and interstitial cell tumors)
- Methimazole (cats)
- Chemotherapeutic drugs, including azathioprine, cyclophosphamide, cytosine arabinoside, doxorubicin, vinblastine, and hydroxyurea
- Antibiotics, including trimethoprim-sulfadiazine, cephalosporins, and chloramphenicol
- Griseofulvin
- NSAIDs, including phenylbutazone and meclofenamic acid
- Fenbendazole, albendazole
- Captopril
- Quinidine

- Thiacetarsamide
- Ionizing radiation
- Mycotoxins (cats)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Causes of pancytopenia with normal to increased bone marrow cellularity (e.g., myelodysplastic disorders, leukemia, myelofibrosis).

CBC/BIOCHEMISTRY/URINALYSIS

- Leukopenia characterized by neutropenia with or without lymphopenia.
- Normocytic, normochromic, nonregenerative anemia.
- Thrombocytopenia.

OTHER LABORATORY TESTS

- Immunologic tests for infectious diseases (e.g., serologic titers, ELISA, IFA).
- PCR for infectious agents.
- Serologic test for antierythrocyte antibodies (Coombs' test).

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Bone marrow aspiration—frequently an inadequate or fatty sample is obtained because of decreased hematopoietic tissue and replacement by adipocytes.
- Bone marrow core biopsy—permits an evaluation of architecture and reveals hypoplasia of cell lines and replacement by adipose tissue.

TREATMENT

Supportive treatment, antibiotics, blood component therapy, as dictated by clinical condition.

MEDICATIONS

DRUG(S) OF CHOICE

- Cyclosporine A—10–25 mg/kg PO q12h (dogs), 4–5 mg/kg PO q12h (cats).
- Recombinant hematopoietic growth factors (e.g., rhG-CSF: 5 µg/kg/day SC).
- Androgen and corticosteroid administration have been largely unsuccessful.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

OTHER DRUGS

- Antibiotics to treat secondary infections if fever and neutropenia present.
- Whole or component blood transfusion if indicated.

FOLLOW-UP

PATIENT MONITORING

- Daily physical examination.
- CBC every 3–5 days to weekly.
- Repeat bone marrow evaluation if necessary.

PREVENTION/AVOIDANCE

- Castration of cryptorchid males.
- Vaccination for infectious diseases.
- Frequent monitoring of CBC in cancer patients receiving chemotherapy or radiation.

POSSIBLE COMPLICATIONS

- Sepsis
- Hemorrhage

EXPECTED COURSE AND PROGNOSIS

- Guarded to poor.
- Recovery of hematopoiesis may take weeks to months, if it occurs at all.
- Spontaneous recovery occasionally occurs, especially in younger animals.

MISCELLANEOUS

SEE ALSO

Pancytopenia

ABBREVIATIONS

- ELISA = enzyme-linked immunosorbent assay
- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus
- IFA = immunofluorescent antibody (test)

ANEMIA, HEINZ BODY

BASICS

OVERVIEW

- Heinz bodies cause hemolytic anemia and indicate oxidative damage to RBCs.
- Heinz bodies form when oxidants overwhelm protective reductive pathways in RBCs; irreversible denaturation of the globin chains in hemoglobin causes precipitation and attachment of altered hemoglobin to the cell membrane.
- RBCs with Heinz bodies are targeted for removal by macrophages in the spleen, and occasionally undergo intravascular lysis.
- The pitting function of the spleen may remove Heinz bodies, resulting in spherocytes.
- Heinz bodies are usually caused by exposure to chemical or dietary oxidants.
- Cats are particularly susceptible to Heinz body formation because their hemoglobin contains more sulfhydryl groups than that of dogs.
- Healthy cats may have Heinz bodies with no anemia, possibly because cats have a nonsinusoidal spleen with limited pitting function.
- Heinz bodies are reported in hyperthyroidism (cats), lymphoma (cats, dogs), and diabetes mellitus (cats, dogs), possibly due to increased endogenous oxidants (e.g., β -hydroxybutyrate in ketoacidosis). Anemia may or may not be present.
- Heinz bodies may be accompanied by methemoglobinemia (hemoglobin containing Fe^{3+}) and/or eccentrocytes (oxidative damage to RBC membranes causing adhesion of opposing membranes and displacement of hemoglobin to one side of the cell).

SIGNALMENT

- Dogs and cats
- No sex, breed, or age disposition

SIGNS

Historical Findings

- Exposure to oxidant.
- Sudden onset of weakness, lethargy, or anorexia.
- Reddish-brown urine (hemoglobinuria) if severe intravascular hemolysis.
- Signs related to underlying disease in animals with systemic disease and Heinz bodies.

Physical Examination Findings

- Pale and occasionally icteric mucous membranes
- Dark or chocolate-colored blood with methemoglobinemia
- Tachypnea, tachycardia

CAUSES & RISK FACTORS

- Dietary: onions (raw, cooked, dehydrated, and powdered), garlic (dogs), propylene glycol (cats), Chinese chives (dog).
- Drugs: acetaminophen, phenacetin (cats), phenazopyridine (cats), methylene blue, vitamin K1 or K3 (dogs), DL-methionine (cats), benzocaine (topical), phenylhydrazine (dog), propofol (cats).
- Miscellaneous: zinc (nuts, bolts, pennies, dermatologic creams), naphthalene (moth ball ingestion in dogs), skunk musk exposure (dogs).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of regenerative, hemolytic anemia (e.g., immune mediated, hemoparasites).
- Heinz bodies may be found in healthy or ill cats without anemia.

Diagnosis of a Heinz body anemia requires documentation of a regenerative anemia, supporting evidence of a hemolytic process (e.g. hyperbilirubinemia), identification of Heinz bodies on a blood smear, and elimination of other causes of hemolysis or blood loss.

CBC/BIOCHEMISTRY/URINALYSIS

- Regenerative anemia (decreased HCT, polychromasia, nucleated RBCs) is expected if there has been sufficient time for a bone marrow response; the severity of anemia depends on dose of oxidant and duration of exposure.
- Hemoglobin concentration and MCHC may be falsely increased due to Heinz body interference with hemoglobin measurement.
- Heinz bodies are visible on a routinely stained blood smear as small, pale red, round inclusions that may protrude from RBC surface. They may be difficult to identify if there is marked poikilocytosis.
- Single, small ($< 0.5 \mu m$) Heinz bodies may be found in RBCs of cats without anemia.
- Large and/or multiple Heinz bodies in an anemic cat suggest a Heinz body hemolytic anemia.
- Dogs may have concurrent eccentrocytosis on a blood smear.
- Hyperbilirubinemia and bilirubinuria are possible.
- Hemoglobinuria and methemoglobinuria are uncommon but occur with severe intravascular hemolysis.
- Neutrophilia and monocytosis may occur.

OTHER LABORATORY TESTS

- New methylene blue stains Heinz bodies blue, making them easy to identify and quantify on a blood smear, even with marked poikilocytosis.
- Measure methemoglobin if blood is dark or chocolate colored.
- Serum zinc concentration if indicated.

IMAGING

Abdominal radiographs may reveal gastrointestinal metal objects in zinc toxicity.

TREATMENT

- Immediate identification and removal of oxidant may be sufficient, though it often take several days after exposure for the severity of anemia to reach nadir.
- Consider administration of emetics with recent ingestion of an oxidant.
- Supportive care depends on the severity of the hemolytic crisis and includes IV fluids, RBC transfusions, oxygen, and restricted activity.
- Endoscopy

or surgery to remove metallic items in gastrointestinal tract.

MEDICATIONS

DRUG(S) OF CHOICE

Acetaminophen toxicity in cats—N-acetylcysteine (140 mg/kg PO or IV, followed by seven additional treatments of 70 mg/kg q8h).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Administration of methylene blue to treat methemoglobinemia may exacerbate Heinz body formation.

ALTERNATIVE DRUG(S)

The use of dietary antioxidants (e.g., bioflavonoids) is controversial but may help prevent further formation of Heinz bodies.

FOLLOW-UP

PATIENT MONITORING

Serial CBCs and review of blood smears are recommended to assess RBC regeneration and disappearance of Heinz bodies.

PREVENTION/AVOIDANCE

Counsel clients about preventing exposure to oxidants.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Prognosis is good with removal of oxidant and supportive care once the hemolytic crisis is over.

BASICS

DEFINITION

Accelerated destruction or removal of RBCs due to a Type II hypersensitivity reaction.

PATHOPHYSIOLOGY

- Antibodies form against endogenous unaltered RBC surface antigens (primary IMHA) or altered RBC membrane antigens (secondary IMHA).
- Infectious organisms, drugs, exposure of previously unexposed antigens, or adsorption of preformed antigen-antibody complexes to the RBC membrane can alter RBC membrane antigens.
- Immunoglobulin deposits on RBC membrane, causing either direct intravascular hemolysis or accelerated removal by the monocyte/macrophage system.
- Intravascular hemolysis occurs when adsorbed antibodies (usually IgG) activate complement.
- In vivo agglutination of RBCs occurs when IgM or high titers of IgG molecules cause bridging of RBCs.
- Extravascular removal of RBCs occurs primarily in spleen, liver, bone marrow.
- Nonregenerative IMHA is believed to be caused by immune-mediated destruction of RBC precursors in the bone marrow.
- Rarely cold-acting antibodies cause in vivo hemolysis and erythrocyte agglutination in peripheral vasculature.

SYSTEMS AFFECTED

- Cardiovascular—tachycardia; low-grade heart murmur.
- Hemic/Lymphatic/Immune—immune-mediated destruction of RBCs, elaboration of proinflammatory mediators, DIC.
- Hepatobiliary—hyperbilirubinemia and icterus plus bilirubinuria when hepatic function is overwhelmed; centrilobular necrosis.
- Respiratory—tachypnea. PTE may result from hypercoagulable state.
- Skin—rarely cold-type IMHA may cause necrosis of extremities and ear tips.

GENETICS

Cocker spaniels are at increased risk (absence of dog erythrocyte antigen 7).

GEOGRAPHIC DISTRIBUTION

Secondary IMHA may have higher prevalence where associated infectious diseases are endemic.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Cocker spaniel at highest risk. Also, English springer spaniel, Old English sheepdog, Doberman pinscher, collie, bichon frise, miniature pinscher, and Finnish spitz.
- Domestic shorthair cats.

Mean Age and Range

- Dogs, mean age 5–6 years (range 1–13 years)
- Cats, mean age 2 years (range 0.5–9 years)

Predominant Sex

- Female dogs at higher risk
- Male cats overrepresented

SIGNS

Historical Findings

- Lethargy/weakness/collapse
- Anorexia
- Exercise intolerance/dyspnea, tachypnea
- Vomiting and/or diarrhea
- Dark red urine
- Pica (cats)

Physical Examination Findings

- Pale mucous membranes, tachycardia, tachypnea.
- Splenomegaly/hepatomegaly.
- Icterus and pigmenturia (hemoglobin or bilirubin).
- Fever/lymphadenomegaly.
- Systolic murmur.
- Petechiae, ecchymoses, or melena (if concurrent thrombocytopenia or DIC).
- Other findings possible (e.g., joint pain) when IMHA is component of SLE.
- Necrosis of extremities and ear tips in cold-type IMHA (rare).

CAUSES AND RISK FACTORS

Primary IMHA

Poorly characterized immune dysregulation

Secondary IMHA

- Infectious causes: hemotropic *Mycoplasma* spp., *Ehrlichia* spp., *Anaplasma phagocytophilum*, *Anaplasma platys*, *Babesia* spp., *Leishmania*, *Dirofilaria immitis*, FeLV, FIP, chronic bacterial infection.
- Neoplasia: lymphoma, lymphoid leukemia, hemangiosarcoma, hemophagic histiocytic sarcoma.
- Drugs: beta lactam antibiotics, propylthiouracil, methimazole, sulfonamides.
- SLE
- Neonatal isoerythrolysis
- Hemolysis due to DEA incompatible blood transfusion
- Exposure to infectious agents, vaccination, chemicals/drugs, surgery, hormonal change, or other stressful event is hypothesized as potential trigger for IMHA.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dogs

- Pyruvate kinase deficiency
- Phosphofructokinase deficiency
- Toxicity (zinc, onions, garlic, broccoli, copper, naphthalene, skunk musk)
- Snake/spider evenomation (coral snakes, recluse spiders)
- Severe hypophosphatemia
- Anemia due to hemorrhage (immune-mediated thrombocytopenia, rodenticide toxicosis)
- Microangiopathic anemia due to splenic neoplasia, DIC, splenic torsion

Cats

- Toxicity (acetaminophen zinc, onions, garlic)
- Severe hypophosphatemia

- Congenital feline porphyria
- Increased osmotic fragility (Abyssinian, Somali)

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—anemia, high MCV (3–5 days post-hemolytic episode), spherocytes, polychromasia, increased RBC distribution width, leukocytosis with neutrophilia and left shift, monocytosis, lymphocytosis (cats).
- Anemia is nonregenerative in 30% of dogs and 50% of cats.
- Serum biochemistry—hyperbilirubinemia, hemoglobinemia, high ALT.
- Urinalysis—hemoglobinuria, bilirubinuria.

OTHER LABORATORY TESTS

- Spontaneous saline agglutination test—before and after washing RBCs.
- Positive direct antiglobulin test (Coombs' test)—positive in up to 75% of animals with IMHA.
- Flow cytometric detection of membrane-bound immunoglobulin and complement.
- Reticulocytosis—absolute count > 60,000/ μL (dogs) or > 50,000/ μL (cats) in regenerative IMHA.
- Thrombocytopenia 60% of dogs.
- Prolonged APTT and PT, increased fibrin degradation products and d-dimer, decreased antithrombin in animals with DIC.
- Positive ANA titer and LE cell test (animals with SLE).
- Positive serologic titers or PCR in secondary IMHA due to infectious causes.
- Evidence of hematologic parasites in blood smears (secondary IMHA due to infectious causes).

IMAGING

- Radiographic findings—hepatomegaly/splenomegaly; thorax usually normal; may see evidence of PTE (patchy alveolar pattern, interstitial pattern, pleural fluid), but dogs with pulmonary embolism may have normal thoracic radiographs.
- Ultrasonographic findings—hepatomegaly/splenomegaly; liver/spleen can be mottled and hyperechoic or hypoechoic.

DIAGNOSTIC PROCEDURES

- Bone marrow aspirate usually reveals erythroid hyperplasia.
- With nonregenerative IMHA, maturation arrest or erythroid hypoplasia may be evident.
- In chronic IMHA, myelofibrosis may be present.

PATHOLOGIC FINDINGS

- Hepatosplenomegaly, centrilobular hepatic necrosis
- Splenic and hepatic extramedullary hematopoiesis
- Reactive lymphadenomegaly
- PTE and DIC

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient during acute hemolytic crisis; outpatient when PCV stabilized, ongoing hemolysis controlled, and clinical signs of anemia resolved.
- Inpatient if complications such as DIC, PTE, thrombocytopenia, gastrointestinal bleeding, or a need for

ANEMIA, IMMUNE-MEDIATED

(CONTINUED)

multiple transfusions. • Chronic low-grade extravascular hemolysis can be treated on outpatient basis if the patient not exhibiting clinical signs secondary to anemia.

NURSING CARE

- Fluid therapy to maintain vascular volume and correct dehydration. • Packed RBCs typed or cross-matched for naive recipient. Blood should be cross-matched for recipients that have received prior transfusions. Whole blood acceptable if packed RBCs not available. • Transfusion volume = recipient weight (kg) \times 85 (dog) or 50 (cat) \times desired PCV-current PCV/donor PCV. • Transfusion rate 0.25 mL/kg/hr for first 30 minutes then 5–10 mL/kg/h. • Monitoring for complications such as PTE, bleeding (especially GI), DIC, infection. • Cage rest.

CLIENT EDUCATION

- IMHA and complications (e.g., DIC, PTE) can be fatal. • Life-long treatment may be needed; disease may recur. • Side effects of treatment may be severe.

SURGICAL CONSIDERATIONS

- Splenectomy can be considered if medical management fails to control disease.
- Consider blood product administration preoperatively.

MEDICATIONS

DRUG(S) OF CHOICE

- Corticosteroids—prednisone 1–2 mg/kg/day q12h for 2–4 weeks. Use prednisolone in cats due to higher bioavailability. • Once PCV above 30%, decrease dose to 1 mg/kg q12h. Then taper by a maximum rate of 25–50% per month over a 3- to 6-month period, depending upon PCV and severity of side effects. If after 3–6 months disease is in remission on a low q48h dose, try discontinuing the drug. • Add additional immunosuppressive drug such as azathioprine (dogs) cyclosporine (cats) if poor response to prednisone after 5–7 days or if poor prognostic indicators (e.g., intravascular hemolysis, serum bilirubin >8–10 mg/dL, persistent autoagglutination, Evans syndrome). • Azathioprine dose 2 mg/kg/day, can decrease to 0.5–1.0 mg/kg q48h if bone marrow suppression. Monitor for immunosuppression, hepatotoxicosis, pancreatitis.
- For prevention of thromboembolism (dogs) consider unfractionated heparin 300 U/kg SC q6–8h (dose adjusted based on APTT prolongation or measurement of anti-Xa activity) or ultra-low-dose aspirin 0.5–1.0 mg/kg/day or enoxaparin (low-molecular-weight heparin) 0.8 mg/kg SC q6h or 1.5 mg/kg q12h, or clopidogrel 2–3 mg/kg PO q24h (loading dose 10 mg/kg/day).
- Address underlying cause (e.g., infection and drugs) if secondary IMHA.

CONTRAINDICATIONS

- No heparin, enoxaparin, or aspirin in dogs with severe thrombocytopenia (< 80,000/ μ L).
- Do not use multiple cytotoxic drugs concurrently.

PRECAUTIONS

- No azathioprine in cats because of risk of bone marrow toxicity. • Prednisone/prednisolone can cause signs of Cushing's syndrome and may increase risk of PTE, pancreatitis, diabetes mellitus, secondary infection, gastric ulcers (consider gastric protectants). • Cytotoxic drugs can cause bone marrow suppression, secondary infection, pancreatitis (azathioprine), GI upset (cyclosporine, azathioprine, mycophenolate mofetil), gingival hyperplasia, papillomatosis (cyclosporine), infertility.

POSSIBLE INTERACTIONS

Azathioprine and prednisone have been associated with development of pancreatitis.

ALTERNATIVE DRUG(S)

- Dexamethasone (0.25–0.5 mg/kg/day IV)—can be used instead of prednisone/prednisolone in animals that do not tolerate oral drugs, until oral intake is possible.
- Chlorambucil—for cats, 0.1–0.2 mg/kg PO q24h initially, then q48h. • Cyclosporine—microemulsion, e.g., Atopica—dogs, 5–10 mg/kg/day PO divided twice daily; cats, 0.5–3 mg/kg q12h. • Mycophenolate mofetil 10–17 mg/kg q24h.

FOLLOW-UP

PATIENT MONITORING

- Monitor heart rate, respiratory rate, temperature frequently. • Monitor for adverse reactions to treatment (e.g., transfusion reactions/overhydration). • If PTE suspected, monitor thoracic radiographs and arterial blood gases frequently. • During first days of treatment, check PCV daily until stable, then every 1–2 weeks for 2 months; if still stable, recheck PCV monthly for 6 months, then 2–4 times per year; rechecks need to be more frequent if patient is on long-term medication especially cytotoxic drugs. • CBC and reticulocyte count should be rechecked at least monthly during treatment; if the neutrophil count falls < 3,000 cells/ μ L, discontinue cytotoxic drugs until count recovers; reinstitute at lower dosage.
- Coombs' tests and reticulocyte counts to assist in drug tapering.

PREVENTION/AVOIDANCE

Consider need for vaccination on case-by-case basis in dogs that developed IMHA after vaccination.

POSSIBLE COMPLICATIONS

- Pulmonary/multiorgan thromboembolism (up to 80% of all cases at necropsy). • DIC.

- Centrilobular hepatic necrosis and renal tubular necrosis secondary to hypoxia.
- Infection secondary to immunosuppressive therapy. • GI ulceration due to high-dose glucocorticoids. • Iatrogenic hyperadrenocorticism.

EXPECTED COURSE AND PROGNOSIS

- Mortality: 30–80% (dog), 25% (cat).
- Causes of death include thromboembolism, infection due to immunosuppression, DIC, persistent anemia. • Hyperbilirubinemia > 5 mg/dL, autoagglutination, intravascular hemolysis, severe thrombocytopenia, hypoalbuminemia are associated with poorer prognosis. • Response to treatment may take weeks to months; nonregenerative IMHA may have more gradual onset than typical IMHA and may be slower to respond to treatment. • IMHA may recur despite previous/current therapy.

BASICS

OVERVIEW

- Adults—caused by chronic external hemorrhage.
- RBC produced by iron-limited erythropoiesis.
- Importance—prompts clinician to look for chronic external blood loss.

SIGNALMENT

- Fairly common in adult dogs.
- Rare in adult cats.
- Transient neonatal iron-deficiency anemia may occur at 5–10 weeks of age in kittens.

SIGNS

- Signs of anemia (e.g., lethargy, weakness, and tachypnea) and underlying disease.
- Intermittent melena with gastrointestinal blood loss.
- Possible heavy bloodsucking parasite load.

CAUSES & RISK FACTORS

- Chronic external blood loss.
- Common causes—GI lymphoma, hookworms, GI neoplasia.
- Less common—skin (e.g., severe flea infestation) and urinary tract.
- Blood donor overuse.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Any cause of anemia, especially hemorrhage.
- Microcytic anemia in portosystemic shunt disease may or may not be due to iron deficiency.
- Anemia of inflammatory disease iron-limited erythropoiesis.

CBC/BIOCHEMISTRY/URINALYSIS

- PCV usually but not always decreased, generally 10–40% in dogs.
- Anemia either regenerative or non-regenerative.
- Microcytosis—indicated by low normal or low MCV, accompanied by increased heterogeneity, detected by erythrocyte histogram widening or increased RDW.
- RBC changes include microcytosis, hypochromia due to thin cell geometry, and keratocyte and schistocyte formation.
- Newer erythrocyte indices MCVR and CHr, are sensitive for detecting iron-limited erythropoiesis; available on one hematology system.
- Lab tests indicate iron-limited erythropoiesis, but may not differentiate true

from functional iron deficiency. Clinical findings of inflammatory disease versus blood loss are required to differentiate cause of iron limited erythropoiesis. It is also possible that inflammatory disease and true iron deficiency may occur concurrently.

- RBC morphologic changes—hypochromia (increased central pallor), oxidative lesions (e.g., keratocytes), fragmentation.
- Decreased MCHC not sensitive or specific.
- Thrombocytosis may occur.
- Hypoproteinemia—consistent with blood loss.

OTHER LABORATORY TESTS

- Hypoferrremia (serum iron < 70 µg/dL) and transferrin saturation < 15% support the diagnosis.
- Serum iron values may be normal during iron repletion, if blood loss is intermittent.
- Fecal exam for hookworms.
- Fecal examination for occult blood or melena.

IMAGING

Imaging studies—GI disease that may account for blood loss.

DIAGNOSTIC PROCEDURES

As indicated by underlying disease.

TREATMENT

- Identify / correct cause of blood loss.
- Administer iron until hematologic features of iron deficiency resolve.
- If severe (i.e., PCV < 15%), transfusion may be required; whole blood (10–20 mL/kg IV) or packed RBC.

MEDICATIONS

DRUG(S)

Iron Supplementation

Parenteral Iron Supplementation

- Initiate iron therapy with injectable iron.
- Iron dextran—a slowly released form of injectable iron; one injection (10–20 mg/kg IM) followed by oral supplementation.

Oral Iron Supplementation

- Animals with severe iron deficiency may have impaired intestinal iron absorption, making oral therapy of little value until partial iron repletion has occurred.
- Follow injected iron with oral iron supplement for 1–2 months, or until resolved.
- Kittens undergo spontaneous iron repletion beginning at 5–6 weeks of age.

Oral Iron Supplements

- Ferrous sulfate powder—place in food or drinking water (100–300 mg PO q24h).
- Ferrous gluconate—one (325 mg) tablet PO q24h.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Oral iron is associated with unexplained death in kittens and should be avoided.

FOLLOW-UP

- Monitor CBC every 1–4 weeks; if the anemia is severe, more frequently as needed.
- Effective treatment associated with an increase in MCV and reticulocyte volume.
- Erythrocyte histogram—effective treatment associated with microcytic subpopulation reduction over time; it may take a few months to normalize the histogram.

MISCELLANEOUS

ABBREVIATIONS

- CHr = reticulocyte hemoglobin content
- GI = gastrointestinal
- MCHC = mean cell hemoglobin concentration
- MCV = mean cell volume
- MCVR = mean reticulocyte volume
- PCV = packed cell volume
- RBC = red blood cell
- RDW = red cell distribution width

Consulting Editor Alan H. Rebar

ANEMIA, METABOLIC (ANEMIAS WITH SPICULATED RED CELLS)

BASICS

OVERVIEW

- Sometimes occurs concomitantly with diffuse diseases of the liver, kidney, and, rarely, spleen.
- In most animals with liver disease, spiculated cells have 2–10 elongated, blunt, finger-like projections from their surfaces and are classified as acanthocytes.
- Acanthocytic anemias can be associated with renal disease; anemias of renal disease more often have oval red cells with irregular or ruffled membranes (burr cells).
- Rarely, acanthocytic anemias can be seen in association with splenic disease alone.
- Pathogenesis not entirely clear; abnormal lipid metabolism with free cholesterol loading of RBC membranes is most frequently implicated as cause.
- Dogs with disseminated abdominal hemangiosarcoma with liver involvement often have acanthocytes.

SIGNALMENT

Dogs and cats (infrequently)

SIGNS

- None in most animals (usually mild to moderate condition).
- Detection of spiculated RBCs on peripheral blood film can be first marker for liver, kidney, or splenic disease.
- In large-breed dogs with vague signs or large spleen, suggests possibility of splenic or hepatic hemangiosarcoma.

CAUSES & RISK FACTORS

- Any disease of the liver, kidneys, or possibly spleen.
- The likelihood of RBC morphologic abnormalities parallels the severity of organ involvement.
- Hemangiosarcoma involving the liver is a frequent cause.
- Observed in cats with fatty liver syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Determination of renal or hepatic causes based on results of biochemistry profile and urinalysis.

CBC/BIOCHEMISTRY/URINALYSIS

- Mild to moderately low PCV, RBC count, and hemoglobin.

- Normal mean corpuscular volume and mean corpuscular hemoglobin concentration in most animals.
- Normocytic, normochromic, and nonregenerative.
- Polychromasia on blood films only with accompanying blood loss (as with hepatic hemangiosarcoma).
- WBC changes variable, based on underlying cause of hepatic or renal pathology.
- Inflammatory conditions likely to be accompanied by inflammatory leukogram.
- Variable findings in liver and kidney function tests (serum biochemistry and urinalysis).

Hepatic Diseases

- High ALT, ALP, and γ -glutamyl transferase.
- High bile acids, serum ammonia.
- Possibly low albumin and serum urea nitrogen.
- Bilirubinuria, bilirubin crystals in urine.

Renal Diseases

- High serum urea nitrogen, creatinine, and phosphorus.
- Highly variable urinalysis findings, including isosthenuria (urine specific gravity 1.008–1.025 in dogs; 1.008–1.035 in cats).
- Tubular and/or protein casts.
- Pyuria.
- Proteinuria.
- Hematuria.

OTHER LABORATORY TESTS

None

IMAGING

Abdominal radiographs and ultrasound—evaluate hepatic, renal, and splenic structure.

DIAGNOSTIC PROCEDURES

Liver or kidney biopsy if indicated.

TREATMENT

Focus treatment on diagnosis and treatment of underlying hepatic, renal, or splenic disease.

MEDICATIONS

DRUG(S)

Variable according to underlying cause.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Variable according to underlying cause.

FOLLOW-UP

Monitor CBC periodically while treating the underlying condition.

Author Alan H. Rebar

Consulting Editor Alan H. Rebar

BASICS

DEFINITION

Low RBC mass without evidence of increased polychromasia or reticulocytosis in the peripheral blood.

PATHOPHYSIOLOGY

- Low erythroid production or release.
- Onset of anemia and its related signs insidious unless RBC survival is concurrently shortened by hemorrhage or hemolysis.
- May be caused by selective alteration in erythropoiesis or generalized bone marrow injury affecting leukocytes and platelets as well. • Mechanisms for selectively altered erythropoiesis include deficient hormonal stimulation, nutritional deficiency, cytokine-mediated iron sequestration, and disturbed metabolism in or destruction of precursors; generalized bone marrow injury usually caused by toxin, infection, or infiltrative process.

SYSTEMS AFFECTED

- Cardiovascular—heart murmur from low blood viscosity
- Hemic/Lymph/Immune
- Hepatobiliary—centrilobular degeneration from hypoxic injury

SIGNALMENT

- Varies with primary cause.
- Giant schnauzer, Australian shepherd dog, border collie, beagle—congenital cobalamin malabsorption.

SIGNS

General Comments

- Usually secondary.
- Signs associated with primary disease often precede signs of anemia.

Historical Findings

- Lack of energy, exercise intolerance, inappetence, and cold intolerance.
- Other findings reflect primary condition: polyuria and polydipsia (e.g., CRF), paint exposure from remodeling old houses (e.g., lead poisoning), treating female dogs for micturating or urinary incontinence or feminization in male dogs (e.g., hyperestrogenism), failure to thrive observed at 8–12 weeks of age (hereditary cobalamin malabsorption).

Physical Examination Findings

- Pallor, heart murmur (severe anemia), and possibly tachycardia or polypnea.
- Signs reflecting primary condition: oral ulcerations (e.g., CRF), cachexia (e.g., cancer), organomegaly (e.g., lymphoma), gastrointestinal or CNS signs (e.g., lead poisoning), symmetrical alopecia (e.g., hypothyroidism and hyperestrogenism).

CAUSES

Nonregenerative Anemia without Other Cytopenias

- Anemia of inflammatory disease (AID)—most common cause of mild nonregenerative anemia; can be seen within 3–10 days of infection, inflammation, tissue injury, immune-mediated processes, and neoplasia; increased liver production of hepcidin and release of cytokines from T-lymphocytes and macrophages lead to iron sequestration in macrophages, decreased iron absorption; low serum iron and transferrin, increased ferritin, decreased EPO production and function, and shortened RBC lifespan.
- Chronic renal failure—kidneys fail to produce adequate EPO; uremic toxins shorten RBC lifespan and impair response to EPO.
- Chronic liver disease—shortened RBC survival caused by changes in RBC membrane lipids; functional iron deficiency due to decreased transferrin synthesis and impaired mobilization of hepatic iron.
- Endocrine disease—thyroid hormones and cortisol stimulate erythropoiesis and facilitate the effect of erythropoietin.
- Immune-mediated destruction of precursors—pure red cell aplasia.
- Infectious destruction of precursors (although usually > one cell line is involved), e.g., FeLV and ehrlichiosis, *Cytauxzoon felis*.

Nutritional or Mineral Deficiency/Toxicity

- Iron deficiency—usually due to chronic external blood loss; initially regenerative, but as severity increases, anemia becomes nonregenerative.
- Cobalamin (vitamin B₁₂) and/or folate deficiency—rare in dogs and cats; can be caused by dietary insufficiency, malabsorption, or chronic drug administration (e.g., sulfas, methotrexate, anticonvulsants) that inhibits folate; congenital defect in cobalamin absorption in giant schnauzers, border collies, Australian shepherd dogs, and beagles; can occasionally cause normocytic anemia and hypersegmented neutrophils; megaloblastic changes possible in the marrow.
- Disruption of precursor metabolism—chronic lead toxicity and possibly high concentrations of aluminum, arsenic, and cadmium inhibit heme synthesis; cadmium and lead cause renal toxicity and impaired EPO production.

Nonregenerative Anemia with Other Cytopenias

- Toxicities—drugs or chemicals (e.g., cancer chemotherapeutics, chloramphenicol, phenylbutazone, trimethoprim-sulfadiazine, zonisamide, phenobarbital, griseofulvin, methimazole, fenbendazole, albendazole, and benzene), hormones (e.g., estrogen toxicity secondary to abortifacient therapy and Sertoli cell tumor).
- Infections—FeLV, FIV, ehrlichiosis, babesiosis, and parvoviral infection (recovery usually precedes development of anemia).
- Infiltrative processes—myelodysplasia, myeloproliferative

and lymphoproliferative diseases, metastatic neoplasia, myelofibrosis, and osteosclerosis.

RISK FACTORS

- Renal failure • Inflammatory or chronic disease • Liver failure • Sertoli cell tumor
- Cancer • Chronic blood loss • Cats from multicat households (FeLV) • Lead or arsenic exposure—chronic

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Regenerative anemia initially nonregenerative; sudden onset of signs more consistent with regenerative than nonregenerative anemia; exacerbation of a chronic condition may produce the appearance of an acute onset.

LABORATORY FINDINGS

Disorders That May Alter Laboratory Results

- Lipemia can falsely elevate hemoglobin and MCHC values.
- Lead toxicity-increased NRBCs may falsely elevate the WBC count.

Valid If Run in Human Laboratory?

- Dogs—yes.
- Cats—yes, if hematology instrument uses species-specific parameters; instruments designed strictly for human specimens may under-count small feline RBCs.

CBC/BIOCHEMISTRY/URINALYSIS

CBC and Blood Smear

- PCV, RBC count, and hemoglobin low.
- Anemia usually normocytic, normochromic, with normal MCV and MCHC.
- Macrocytosis (high MCV)—without polychromasia suggests nuclear maturation defect (cells skip a division); seen in cats with FeLV; rarely caused by vitamin B₁₂ or folate deficiency.
- Microcytosis (low MCV)—suggests cytoplasmic maturation defect (cells undergo extra division); iron deficiency most common cause; in late stages, concurrent hypochromasia (low MCHC) common in dogs but not in cats; seen in approximately one-third of patients with hepatic insufficiency or vascular shunting.
- Specific RBC morphologies—schistocytes common with iron deficiency ± visibly hypochromic RBCs (dogs); acanthocytes with liver disease; target cells with iron deficiency, liver disease, and hypothyroidism.
- Inflammatory leukogram supports AID.
- Thrombocytosis common in iron deficiency.
- High number of NRBCs without polychromasia or disproportionate to the degree of anemia and polychromasia seen with lead toxicity, EMH, heat stroke, and injury to bone marrow stroma by endotoxemia or hypoxia.
- RBC or WBC precursors in peripheral blood without orderly progression to more mature forms suggest myelodysplasia or myeloproliferative disease.
- Concurrent

ANEMIA, NONREGENERATIVE

(CONTINUED)

cytopenia in other cell lines without evidence of marrow responsiveness (e.g., band neutrophils and macroplatelets) suggests generalized bone marrow injury.

Serum Biochemistry and Urinalysis

- CRF: high BUN and creatinine with inadequate urine concentration (dogs, < 1.030; cats, < 1.035).
- Liver disease: high ALT, total bilirubin, or elevated bile acids suggests liver disease.
- Hypothyroidism: high serum cholesterol (> 500 mg/dL).
- Hypoadrenocorticism: Na/K < 23, lymphocytosis, and eosinophilia.

OTHER LABORATORY TESTS

- Reticulocyte count—value of < 95,000/ μ L (dogs) or < 60,000/ μ L (cats) (automated counts) accompanied by a low PCV confirms nonregenerative anemia.
- Direct antiglobulin test (Coombs')—spherocytosis, autoagglutination, or positive Coombs' test provides support for immune-mediated destruction of erythroid precursors.
- Serum iron profile—may be indicated for patients with microcytic anemia; with iron deficiency both serum iron and ferritin are low, while total iron-binding capacity varies; with AID, serum iron is low but serum ferritin is high (MCV and MCHC usually normal).
- Bile acids measurement—may be indicated for evaluation of microcytic anemia; high values suggest hepatic insufficiency or vascular shunting.
- Serum lead—indicated when NRBCs are present, especially with concurrent gastrointestinal or CNS signs; value > 30 μ L/dL (0.3 ppm) strongly supports lead intoxication.
- Serologic testing—FeLV test in any cat with nonregenerative anemia; *Ehrlichia canis*, *Anaplasma phagocytophilia*, and *Babesia* PCR assays indicated in dogs with unexplained anemia, especially when concurrent with thrombocytopenia.
- Endocrine testing—when clinical signs and laboratory tests suggest hypothyroidism (T_4 , free T_4 , and TSH concentrations) or hypoadrenocorticism (ACTH stimulation test).
- Serum cobalamin \pm urine methylmalonic acid concentrations—puppies at risk for hereditary cobalamin malabsorption.

DIAGNOSTIC PROCEDURES**Cytologic Examination of Bone Marrow and Core Biopsy**

- Cytologic examination of aspirate indicated in all patients unless primary cause is apparent (e.g., AID and CRF).
- Bone marrow core biopsy—useful in evaluation of bone marrow architecture and overall cellularity; important for diagnosis of aplastic marrow or myelofibrosis.
- Erythroid hypoplasia or aplasia confirms the problem, although history and other tests may be needed to determine the underlying etiology.
- Myeloid hyperplasia and high iron stores support AID.

- Classically, iron deficiency has expanded erythron and high numbers of metarubricytes; absence of iron stores supportive in dogs, but not cats.
- Increased erythrophagocytosis suggests injury to cells (e.g., immune-mediated and toxic causes).
- Incomplete maturation sequence suggests injury to specific maturation stage (e.g., immune-mediated and toxic causes) or possibly incomplete recovery from a previous injury (recheck in 3–5 days).
- Disorderly maturation and atypical cellular morphology suggest myelodysplastic syndrome.
- Hypercellular marrow with increased blast cells (> 20% of nucleated cells) indicates hematopoietic neoplasia; immunophenotyping can identify affected cell line(s); circulating neoplastic cells may or may not be seen.
- Non-marrow cells indicate metastatic neoplasia.

Abdominal Ultrasound

Evaluation of microcytic anemia; look for intestinal neoplasia or other source of external blood loss.

**TREATMENT**

- Anemia usually resolves with resolution of underlying disease.
- Conditions associated with severe anemia or pancytopenia often carry guarded-to-poor prognosis and may involve long-term treatment without complete resolution.
- Metabolic compensation occurs with slowly developing nonregenerative anemia; thus mild to moderately severe anemia (PCV > 15%) generally requires no supportive intervention.
- For patients with severe anemia (PCV < 10–15%), the degree of hypoxia may require transfusion (e.g., 6–10 mL/kg for packed RBCs; 10–20 mL/kg for whole blood). Less blood may be needed in animals with chronic anemia.
- Determine blood type prior to transfusion to ensure compatibility. Cross match against donor blood if blood typing reagents are not available, or if patient requires a second transfusion more than 4 days after the first transfusion.
- If blood volume and tissue perfusion are compromised by concurrent blood loss or shock, administer lactated Ringer's solution or colloids.
- With chronic anemia, volume overload is a concern—blood products and fluids should be given slowly.

**MEDICATIONS****DRUG(S)**

- Erythropoietin in patients with anemia of CRF (see Anemia of Chronic Kidney Disease).

- Iron supplementation in patients with iron deficiency anemia (see Anemia, Iron-Deficiency).
- May supplement with folic acid at rate of 4–10 mg/kg/day.
- May supplement with cobalamin (vitamin B₁₂) at rate of 100–200 mg/day PO (dogs) or 50–100 mg/day PO (cats); parenteral cyanocobalamin administration (50 μ g/kg or 0.5–1 mg/dog SC weekly to monthly) needed in dogs with inherited cobalamin malabsorption.

PRECAUTIONS

Monitor for transfusion reactions (see Blood Transfusion Reactions).

**FOLLOW-UP****PATIENT MONITORING**

- With severe anemia: PCV and blood smear examination every 1–2 days.
- Stable animals with chronic or slowly improving disease course: reevaluate every 1–2 weeks.

**MISCELLANEOUS****PREGNANCY/FERTILITY/BREEDING**

Some pregnant animals have mildly low PCV, caused by expanded blood volume.

SYNOMYMS

Non-responsive anemia

ABBREVIATIONS

- ACTH = adrenocorticotrophic hormone

ANEMIA, NUCLEAR MATURATION DEFECTS (ANEMIA, MELOBLASTIC)

BASICS

OVERVIEW

- Nonregenerative anemia characterized by arrested development of the nuclei of RBC precursors (as a result of interference with DNA synthesis) while the cytoplasm develops normally (nuclear-cytoplasmic asynchrony).
- Affected RBC precursors fail to divide normally and thus are larger than corresponding normal precursors with the same degree of cytoplasmic maturity (hemoglobinization); because their nuclei are deficient in chromatin (DNA), they have a distinctive open and stippled appearance; these giant precursors with atypical, immature nuclei are known as megaloblasts.
- Although these asynchronous changes are most prominent in RBC precursors, WBC and platelet precursors are similarly affected.

SIGNALMENT

- Dogs and cats.
- Spontaneous, clinically unimportant occurrence in toy poodles (occasional).
- Breed predilection: giant schnauzers, also border collies, Australian shepherds, and beagles with inherited cobalamin malabsorption.
- Defect usually acquired.

SIGNS

- In dogs, generally mild, usually not clinically important.
- In cats with FeLV-associated nuclear maturation anemia, FeLV-related signs can be anticipated. Anemia may be mild to severe.

CAUSES & RISK FACTORS

- Infectious—FeLV; retroviral infection the most common cause of megaloblastic anemia in cats. FIV has been reported as a cause much less frequently.
- Nutritional—folic acid and vitamin B₁₂ deficiencies (Giant Schnauzers and other with inherited cobalamin malabsorption).
- Toxic—phenytoin, methotrexate (folate antagonist), alkylating agents (cyclophosphamide), plant alkaloids (vincristine), antimetabolites (azathioprine).
- Congenital—toy and miniature poodles.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- In dogs, all other mild to moderate nonregenerative anemias, including anemia of inflammatory disease, renal disease, and lead poisoning.
- Differentiation based on the distinctive CBC and bone marrow findings listed.
- In cats, FeLV infection is the primary differential.

CBC/BIOCHEMISTRY/URINALYSIS

- In dogs, mild to moderate anemia (PCV: 30–40%).
- In cats, anemia can be mild to severe.
- Anemia classically macrocytic (high mean corpuscular volume) and normochromic (normal mean corpuscular hemoglobin concentration). However, mean corpuscular volume and mean corpuscular haemoglobin concentration can be normal.
- Large, fully hemoglobinized RBC; occasional to numerous megaloblasts, particularly at the feather edge; minimal to no polychromasia.
- In cats with FeLV, anemia may occur in association with a myelodysplastic syndrome or in conjunction with leukemia of a different cell line.

OTHER LABORATORY TESTS

FeLV

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

Bone Marrow Biopsy

- In dogs, usually hyperplastic, often in all cell lines.
- In cats, marrow findings are highly variable and may be hyper- to hypocellular.
- Maturation arrest with nuclear and cytoplasmic asynchrony may be seen in all cell lines.
- Many megaloblastic RBC precursors may be observed.
- Macrophagic hyperplasia with active phagocytosis of nucleated RBCs and megaloblasts (common).

TREATMENT

- Treat by targeting the underlying cause if possible.
- Except for that occurring with FeLV in cats, megaloblastic anemia is a relatively mild condition.
- Treat most patients on an outpatient basis.

MEDICATIONS

DRUG(S)

- In animals with drug toxicity, discontinue the offending drug.
- In all animals, consider supplementation with folic acid (4–10 mg/kg/day) or vitamin B₁₂ (dogs, 100–200 mg/day PO; cats, 50–100 mg/day PO).
- Giant schnauzers with inherited cobalamin malabsorption require parenteral treatment with vitamin B₁₂ (0.5–1 mg IM weekly to every few months).

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Drugs known to cause megaloblastic anemia (e.g., methotrexate and phenytoin) should be avoided in patients whose condition results from other causes.

FOLLOW-UP

- Monitor response to treatment by CBC (weekly) and occasional bone marrow collection and evaluation.
- Closely monitor FeLV-positive cats for evidence of onset of other signs of hematopoietic dyscrasias in the peripheral blood and bone marrow.
- Prognosis—depends on underlying cause; in FeLV-positive cats, prognosis guarded; in animals with drug-associated anemia, prognosis good when use of offending drug is interrupted.

ANEMIA, REGENERATIVE

BASICS

DEFINITION

Decreased circulating RBC mass (indicated by low PCV, hemoglobin, and total RBC count) accompanied by appropriate, compensatory increase in RBC production by the bone marrow (e.g., reticulocytosis in the peripheral blood and RBC hyperplasia in the bone marrow).

PATOPHYSIOLOGY

- Caused by blood loss or hemolysis.
- Hemolysis—caused by intrinsic RBC defects (e.g., congenital RBC membrane defects or enzyme deficiencies) or extrinsic factors (e.g., RBC parasites, oxidative injury, hemolysins, osmotic changes, immune-mediated RBC destruction, heat stroke, and severe hypophosphatemia. • Intravascular hemolysis may lead to DIC.

SYSTEMS AFFECTED

- Cardiovascular—murmurs with marked anemia; tachycardia. • Hemic/Lymph/Immune—erythroid hyperplasia in bone marrow; splenic EMH; splenomegaly due to EMH and histiocytic hyperplasia can be feature of extravascular hemolytic anemia.
- Hepatic—anoxia causes centrilobular degeneration of the liver; hemosiderosis ± hemochromatosis possible with chronic hemolytic anemia (e.g., PK-deficient dogs) especially following repeated transfusions.
- Renal—severe intravascular hemolysis rarely leads to renal tubular necrosis and acute renal failure. • Musculoskeletal—progressive osteoclerosis seen in PK-deficient dogs.

SIGNALMENT

- PK deficiency—basenji, beagle, cairn terrier, Chihuahua, dachshund, Labrador retriever, miniature poodle, pug, West Highland white terrier, and American Eskimo; and Somali, Abyssinian, and domestic shorthair cats.
- PFK deficiency—English springer spaniel, American cocker spaniel, whippet, wachtelhund, and mixed breed dogs with spaniel parentage. • Marked RBC osmotic fragility—English springer spaniel and Abyssinian, Somali, Siamese, and domestic shorthair cats. • Feline congenital porphyria—Siamese and domestic shorthair cats. • Some dog breeds have a genetic predisposition for heritable coagulopathies such as factor VIII deficiency and von Willebrand disease. • Middle-aged female dogs, especially American cocker spaniel, English springer spaniel, Irish setter, Old English sheepdog, poodle, and Shetland sheepdog, are predisposed to immune-mediated syndromes, such as SLE and immune-mediated hemolytic anemia.

SIGNS

- Pallor. • Weakness, exercise intolerance.
- Anorexia. • Possible heart murmur, tachycardia, bounding pulses. • Possible jaundice and hemoglobinuria. • Petechiae, epistaxis, melena suggest blood loss due to vasculitis or a platelet problem. • Hematomas or cavity bleeds suggest a coagulation factor deficiency. • Clinical signs depend on degree of anemia and rapidity of onset. • Rapid loss of 15–25% blood volume or acute hemolysis results in shock and possible death. • With chronic anemia, compensatory increases in heart rate, and eventually heart size, lessens RBC circulation time; hemoglobin can drop to as low as 50% of minimum normal value without overt signs of hypoxia.

CAUSES

Immune Mediated

- Antibodies ± complement on membrane shorten RBC lifespan. Antibodies may target RBC membrane components or may be directed against tumor antigens, infectious agents, vaccines, or drugs (e.g., sulfonamides, penicillins, cephalosporins, methimazole, amiodarone) that are either directly adherent to RBC surface or part of immune complexes adherent to RBCs. • Anemia is usually regenerative, but up to 30% of cases will be nonregenerative due to immune-mediated destruction of erythroid precursors in bone marrow. • Hemolysis may be either intravascular, through IgM-mediated activation of complement, or extravascular, through IgG-mediated phagocytosis.
- Hemolytic antibodies are generally reactive at body temperature; rarely cold-reacting antibodies cause *in vivo* hemolysis and/or RBC agglutination in cooler, peripheral vasculature. • Transfusion of a blood type B cat with type A blood can result in rapid, severe, intravascular hemolysis; neonatal isoerythrolysis seen in kittens born to a blood type B queen mated to a blood type A tom.
- Canine blood type DEA 1.1 can cause hemolysis in a DEA 1.1-negative dog, although a single incompatible transfusion can be tolerated. • The newly identified blood types *Mik* (cats) and *Dal* (dogs) can cause significant hemolytic transfusion reactions in animals lacking these common RBC antigens.

Oxidant Injury

- Oxidants can cause Heinz body formation (aggregates of oxidized hemoglobin), eccentrocytes (oxidation of RBC membranes), and methemoglobinemia. • Heinz bodies are removed through extravascular hemolysis, while oxidized membrane components cause intravascular hemolysis. • Oxidants include onions, garlic, acetaminophen (especially in cats), zinc (from pennies minted after 1982, zinc oxide ointment, and zinc bolts), acute copper toxicosis, benzocaine, vitamin K₃ (dogs), propofol, phenolic compounds (moth balls), skunk musk, and phenazopyridine

(cats). • In cats, some systemic diseases (e.g., diabetes mellitus, hyperthyroidism, lymphoma) enhance Heinz body formation but do not necessarily cause anemia.

Erythrocyte Parasites

- Cats: *Mycoplasma haemofelis*, *M. haemominutum*, *M. turicensis*, and *M. haematoparvum*, *Cytauxzoon felis*. • Dogs: *Mycoplasma haemocanis*, *Babesia canis*, and *B. gibsoni*.

Mechanical RBC Fragmentation

- Caused by vasculitis, thromboembolic disease or disease of any vascular organ (e.g., liver, kidney, spleen, heart). • Rare cause of anemia unless accompanied by hemorrhage.

Inherited RBC Abnormalities

- PK deficiency—impaired ATP formation, leading to premature RBC destruction; autosomal recessive trait. • PFK deficiency—marked alkaline fragility caused by impaired synthesis of 2,3-diphosphoglycerate; hemolytic episodes triggered by hyperventilation-induced alkalemia, especially after vigorous exercise; autosomal recessive trait. • Increased RBC osmotic fragility, (unknown RBC defect) leads to recurrent severe anemia and splenomegaly. • Feline congenital porphyria—enzyme deficiency in heme synthetic pathway leads to accumulation of heme precursors, hemolytic anemia and brown-red discoloration of teeth and bones. Siamese tend to have severe hemolytic anemia, while domestic shorthair cats have a less severe autosomal dominant trait that causes mild anemia.

Hypophosphatemia

Severe hypophosphatemia, secondary to treatment with insulin or phosphate binders, impairs ATP production, leading to increased erythrocyte fragility and hemolysis.

Blood Loss

- Trauma • Bleeding neoplasms (e.g., hemangiosarcoma, intestinal adenocarcinoma) • Coagulopathies (e.g., warfarin poisoning, hemophilia, thrombocytopenia) • Bloodsucking parasites (e.g., fleas, ticks, and *Ancylostoma*)
- Gastrointestinal ulcers

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiated from nonregenerative anemia by high reticulocyte count.

LABORATORY FINDINGS

Disorders That May Alter Laboratory Results

- Lipemia can cause mild *in vitro* hemolysis, without appreciable anemia, and may falsely elevate MCHC. • Autoagglutination may falsely decrease the RBC count.
- Intraerythrocytic inclusions (e.g. basophilic

(CONTINUED)

- stippling or intraerythrocyte parasites may falsely increase automated reticulocyte count.
- Exercise and excitement can increase RBC count, PCV, and reticulocyte count through splenic contraction.

Valid If Run in Human Laboratory?

- Dogs—yes.
- Cats—yes, if hematology instrument uses species-specific parameters; instruments designed for analysis of human specimens may under-count small feline RBCs.

CBC/BIOCHEMISTRY/URINALYSIS

- PCV, RBC count, and hemoglobin low.
- Total protein often low with blood loss anemia and may be the only sign with acute blood loss; normal PCV may be maintained through transient splenic contraction.
- Severity of acute blood loss may be underestimated until the plasma volume has been restored by fluid administration and/or internal fluid shifts.
- RBC indices vary depending on the cause of anemia and degree of regenerative response—MCV, normal to high; MCHC, normal to low in most patients; MCHC, artificially high with intravascular hemolysis and hemoglobinemia.
- With iron deficiency, dogs may have a low MCV, MCH, and MCHC; cats have a low MCV but normal MCH and MCHC.
- Specific RBC morphologies may suggest cause of hemolysis: marked spherocytosis suggests immune-mediated disease (not as easily detected in cats whose RBCs generally lack central pallor); Heinz bodies or eccentrocytes suggest oxidant injury; numerous schistocytes suggest microangiopathy.
- Agglutinated RBCs indicate anemia is immune mediated; distinguish autoagglutination from rouleaux by generous sample dilution with saline.
- Hemolysis may cause inflammatory leukogram (neutrophilia with a left shift and monocytosis). Acute blood loss may be associated with stress leukogram (mild neutrophilia and lymphopenia).
- Blood loss may be accompanied by either thrombocytopenia or rebound thrombocytosis; iron deficiency is often accompanied by thrombocytosis.
- Hyperbilirubinemia and bilirubinuria accompany marked hemolysis; hemoglobinemia and hemoglobinuria seen with intravascular hemolysis.

OTHER LABORATORY TESTS

- In anemia automated absolute reticulocyte count (RBC count × reticulocyte %) > 60,000/ μL (cats) or > 95,000/ μL (dogs) suggests regenerative anemia.
- It takes 3–5 days for bone marrow to mount a peak regenerative response, so reticulocytosis may initially be absent with blood loss or hemolysis.
- Direct antiglobulin test (Coombs' test) indicated when immune-mediated hemolytic anemia suspected; a positive test and evidence of spherocytosis

(canine) in the peripheral blood is confirmatory; false negatives and false positives are possible.

- PCR test for PK deficiency: young Basenji, beagle, dachshund, Toy Eskimo, West Highland white terrier, and cairn breeds with persistent anemia, massive reticulocytosis and a negative Coombs' test.
- PCR test for PFK deficiency: spaniels and whippets with recurrent hemolytic crises.

DIAGNOSTIC PROCEDURES

- Bone marrow aspirate—needed only when reticulocytosis is lacking; RBC hyperplasia confirms regenerative response.
- Bone marrow biopsy—useful in evaluation of bone marrow architecture and overall cellularity; important for confirmation of nonregenerative process.

TREATMENT

- Emergency if anemia is severe and develops rapidly.
- Massive hemorrhage leads to hypovolemic shock and anoxia; acute hemolysis leads to anoxia.
- Cage rest and careful observation indicated, depending on severity of signs.

Blood Loss Anemias

- Traumatic blood loss leading to shock-crystallloid fluids can rapidly correct hypovolemia and restore circulation.
- RBC replacement (packed RBCs or whole blood) indicated if PCV < 15–20% and signs of severe hypoxia (i.e., extremely pale mucous membranes, weakness, tachycardia, pounding pulses, tachypnea). Initial dosage depends on product selected; 6–10 mL/kg for packed RBCs; 10–20 mL/kg for whole blood. Less blood may be needed in animals with chronic anemia. Determine blood type prior to transfusion, to ensure compatibility. Cross match against donor blood if blood typing reagents not available, or if patient requires second transfusion more than 4 days after first transfusion.
- Animals with chronic blood loss are normovolemic with increased cardiac output, therefore transfusion volumes and rates should be conservative to avoid cardiac failure.

Hemolytic Anemias

Blood transfusion may be indicated; in patients with immune-mediated process, RBCs probably survive similarly to patient's own RBCs, so transfusion should not be withheld if marked signs of anemia present.

MEDICATIONS

DRUG(S)

- Iron may benefit animals with chronic blood-loss anemia (see Anemia, Iron-Deficiency).

ANEMIA, REGENERATIVE

A

- Hemolytic anemias—varies with cause of hemolysis.

FOLLOW-UP

PATIENT MONITORING

- Initially, monitor of RBC mass (e.g., PCV, RBC count, and hemoglobin) and morphologic features on a blood film (i.e., polychromasia) every 24 hours to evaluate effectiveness of treatment and bone marrow responsiveness.
- As regeneration becomes apparent (rising RBC values and polychromasia), recheck patients every 3–5 days; return to normal values occurs about 14 days after acute hemorrhage but may take longer with immune-mediated process.
- Following transfusion, monitor for complications (see Blood Transfusion Reactions).

ANOREXIA

BASICS

DEFINITION

The lack or loss of appetite for food; appetite is psychological and its existence in animals is assumed. Hunger is physiologically aroused by the body's need for food. Anorexia may be partial (hyporexia) or complete. Anorexia results in decreased food intake, which then leads to weight loss. Pseudoanorexia is associated with the inability to prehend or swallow food rather than actual loss of appetite.

PATHOPHYSIOLOGY

- The control of appetite is a complex interaction between the central nervous system and the periphery. • The hypothalamus and brainstem contain peptidergic feeding-regulatory neurons that act as input stations for sensory and metabolic signals. These cell populations project to several brain regions and interconnect extensively. • Sensory signals that affect appetite include the odor, taste, texture, and temperature of food as well as gastric and duodenal distention. • Metabolic signals for hunger and satiety include a variety of peptides and hormones released during the fasting and fed states as well as plasma concentrations of glucose and fatty acids interacting with nutrient-specific receptors in the liver and gastrointestinal tract. • Leptin is primarily produced by adipocytes and acts on specific hypothalamic receptors to decrease metabolism and decrease appetite.
- Neuropeptide Y release from the gastrointestinal tract induces hunger and hyperphagia, and decreases energy expenditure after food restriction. • Ghrelin produced by the stomach is a prokinetic and decreases leptin and increases neuropeptide Y production. • Cholecystokinin and bombesin released from the gastrointestinal tract decrease appetite. • Serotonin is an important and perhaps final mediator centrally via a serotonergic tract that passes near the ventromedial hypothalamus. • Dopaminergic tracts in the hypothalamus help regulate food intake and are closely associated with the lateral hypothalamus (classical feeding center). • Environmental factors including the location and timing of meals as well as learned behaviors and circadian rhythms modulate appetite and may override other signals for satiety and hunger. • Appetite is stimulated by aldosterone and corticosterone and suppressed by glucagon and somatostatin.
- Inflammatory and neoplastic disease can cause hyporexia by releasing proinflammatory cytokines such as interleukin-1, tumor necrosis factor, and interferon. • The expected upregulation of dietary intake in response to elevated energy expenditure is frequently

absent in cancer patients. • Exogenous and endogenous toxins (e.g., renal and liver failure) cause hyporexia. • Any disorder that decreases cerebral arousal will potentially decrease food intake. • Gastroparesis associated with neoplasia, metabolic disorders, and primary gastrointestinal disease is associated with decreased appetite. • Fear, pain, and stress may decrease appetite.

SIGNS

Historical Findings

- Refusal to eat is a common presenting complaint because pet owners strongly associate poor appetite with illness. • Patients with disorders causing dysfunction or pain of the face, neck, oropharynx, and esophagus may display an interest in food but cannot eat. These patients are referred to as being pseudoanorectic. • Animals lacking a sense of smell (anosmia) often show no sniffing behavior. • Weight loss may be noted.

Physical Examination Findings

- Clinical signs in animals with anorexia/hyporexia vary depending on the underlying cause but may include fever, pallor, icterus, pain, changes in organ size, ocular changes, abdominal distention, dyspnea, muffled heart and lung sounds, adventitious lung sounds, cardiac murmurs, and masses. Weight loss and muscle wasting may be evident depending upon the extent and duration of decreased food intake. • Pseudoanorectic patients commonly display weight loss, halitosis, excessive drooling, difficulty in prehending and masticating food, and odynophagia (painful swallowing).

CAUSES

Anorexia/Hyporexia

- Almost any systemic disease process can cause anorexia/hyporexia. • Psychological—unpalatable diet, food aversion, stress, alterations in routine and environment.
- Pain. • Toxicities and drug side-effects.
- Gastrointestinal disease. • Acid-base disorders. • Cardiac failure. • Endocrine and metabolic disease. • Neoplasia. • Infectious disease. • Immune mediated disease.
- Respiratory disease. • Musculoskeletal disease. • Neurologic disease. • Miscellaneous (e.g., motion sickness, high environmental temperature).

Pseudoanorexia

- Any disease causing painful or dysfunctional prehension, mastication, and swallowing.
- Stomatitis, glossitis, gingivitis, pharyngitis, and esophagitis (e.g., physical agents, caustics, bacterial or viral infections, foreign bodies, immune-mediated diseases, uremia).
- Retropharyngeal disorders (e.g., lymphadenopathy, abscess, hematoma, sialocele). • Dental disease or periodontal disease. • Retrobulbar abscess. • Oral, glossal, pharyngeal, or esophageal neoplasia.
- Neurologic disorders (e.g., rabies; neuropathies of cranial nerves V, VII, IX, X, XII; and central nervous system lesions).
- Musculoskeletal lesions (e.g., masticatory myositis, temporomandibular joint disease, fractures, craniomandibular osteopathy, myasthenia gravis, botulism, and cricopharyngeal achalasia). • Salivary gland neoplasia or inflammation.

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Perform a nutritional assessment. Gather information about the patient's diet (including all foods fed to the patient), food intake (current and normal) and obtain body and muscle condition scores. • Elicit a thorough history regarding the patient's environment, changes in routine, people, or other pets to help identify potential psychological etiologies. • Question owners about the patient's interest in food and ability to prehend, masticate, and swallow food. • A complete physical examination is required to determine the presence of systemic disease.
- Perform a thorough ophthalmic, dental, oropharyngeal, facial, and cervical examination (sedation or anesthesia may be required) in addition to observing the patient eating to rule out pseudoanorexia. • A database including a complete blood count, serum biochemistry panel, urinalysis, heartworm serology, retrovirus serology, abdominal, thoracic and cervical imaging studies, endoscopy, and histologic/cytologic examination of tissue/cell samples are often required to make a definitive diagnosis.
- Only if the history, physical examination, and database strongly suggest psychologic anorexia should further diagnostic work-up be forgone; in such cases, daily contact with the pet owner is essential until the anorexia has resolved.

CBC/BIOCHEMISTRY/URINALYSIS

- Abnormalities vary with different underlying diseases and causes of pseudoanorexia and anorexia. • Can be

(CONTINUED)

normal in patients with medical as well as psychologic causes of anorexia.

OTHER LABORATORY TESTS

Special diagnostic tests may be necessary to rule out specific diseases suggested by history, physical examination, and preliminary tests.

IMAGING

- Thoracic and abdominal imaging (radiographic and ultrasound) studies are often included in the minimum database to detect anatomic or functional abnormalities.
- Videofluoroscopy may be indicated to specifically evaluate pharyngeal and esophageal function.

DIAGNOSTIC PROCEDURES

- Vary with underlying condition suspected.
- Endoscopy may be useful for visualization of the pharyngeal and esophageal structures.

TREATMENT

- The mainstay of treatment is aimed at identifying and correcting the underlying disease. • Symptomatic therapy includes attention to fluid and electrolyte derangements, control of pain and/or nausea, reduction in environmental stressors, and modification of the diet to improve palatability. • Palatability can be improved by adding flavored toppings such as chicken and beef broth, seasoning with condiments such as garlic powder, increasing the moisture, fat or protein content of the food, and warming the food to body temperature. • When learned food aversion is suspected, food should be offered cautiously and removed immediately at the first signs of aversion. A patient showing signs of aversion to its normal diet may accept novel foods.
- Medications the patient is receiving should be reviewed for possible side-effects leading to reduced food intake. • Significantly malnourished dogs and cats are immediate candidates for assisted feeding (enteral or parenteral feeding). Well-nourished patients with debilitating disease should not go without food for longer than 3–5 days before assisted feeding is started. • The decision to institute enteral or parenteral feeding can be influenced by several factors. In animals with inadequate food intake that have $\geq 10\%$ body weight loss, hypoalbuminemia, poor body condition score, evidence of muscle wasting, and/or chronic disease processes, supplemental nutrition should be considered.
- Techniques for providing enteral nutrition include coax feeding and placement of a nasoesophageal, esophagostomy, gastrostomy, or jejunostomy tube. Force feeding should be avoided, particularly in cats in light of the association with conditioned food aversions.

MEDICATIONS

DRUG(S) OF CHOICE

- Diazepam is a short-acting appetite stimulant with sedative properties dosed at 0.1 mg/kg IV q24h or 1 mg PO q24h in cats.
- Oxazepam (2 mg/cat PO q12h) is a short-acting appetite stimulant and sedative.
- Cyproheptadine, an antihistamine with antiserotonergic properties, has been used as an appetite stimulant with mixed success at a dose range of 0.2–0.4 mg/kg PO 10–20 minutes prior to feeding.
- Mirtazapine is a serotonin antagonist that is dosed at 3.75–7.5 mg/dog PO q24h or 1.9 mg/cat PO q24–72h.
- Analgesics may promote appetite in painful conditions but their use must be balanced with the potential to cause gastrointestinal side-effects.
- Metoclopramide (0.2–0.4 mg/kg SC or PO q8–12h), ranitidine (2 mg/kg SC, IV, or PO q12h), or erythromycin (0.5–1 mg/kg PO q12h) are useful if anorexia is associated with gastroparesis or ileus.
- Antiemetics such as prochlorperazine (0.1–0.5 mg/kg PO q12h), maropitant (dogs: 1 mg/kg SC or 2 mg/kg PO q24h; cats: 1 mg/kg SC or PO q24h) or metoclopramide are useful to decrease nausea-associated anorexia.

CONTRAINdicATIONS

- Avoid antiemetics and prokinetics if gastrointestinal obstruction is present or suspected. • Drugs with sedative properties should be used with caution in severely debilitated animals.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Body weight, body and muscle condition score assessment, and hydration determination. • Monitor caloric intake to ensure return of appetite is sufficient to meet nutritional needs.

PREVENTION/AVOIDANCE

- Maximize patient comfort and wellbeing.
- Enhance the palatability of the diet.

POSSIBLE COMPLICATIONS

- Dehydration, malnutrition, and cachexia are most likely; these exacerbate the underlying disease. • A loss of more than 25–30% of body protein compromises the immune system and muscle strength, and death results from infection and/or pulmonary failure. • Feline hepatic lipidosis is a possible complication of anorexia in obese cats. • Breakdown of the intestinal mucosal barrier is a concern in debilitated patients.

EXPECTED COURSE AND PROGNOSIS

Varies with underlying cause

ANTEBRACHIAL GROWTH DEFORMITIES

BASICS

DEFINITION

Abnormally shaped forelimbs and/or malalignments of the elbow or antebrachial carpal joints that result from maldevelopment of the radius or ulna in the growing animal.

PATHOPHYSIOLOGY

- Antebrachium—predisposed to deformities resulting from growth of one bone after premature growth cessation or decreased growth rate of the paired bone.
- Decreased rate of elongation in one bone behaves as a retarding strap; the growing paired bone must twist and curve around the short bone or overgrow at the elbow or carpus; causes joint malalignment.
- Normal growth—bones elongate through the process of endochondral ossification, which occurs in the physis; physis closure occurs when the germinal cell layer stops producing new cartilage and the existing cartilage hypertrophies, ossifies, and is remodeled into bone.
- Hereditary—may be a component of common elbow joint malalignment in many chondrodysplastic breeds (e.g., basset hound and Lhasa apso).
- Osteochondrosis or dietary oversupplementation—possibly associated with retardation of endochondral ossification (retained cartilaginous cores) in giant-breed dogs.
- Hypertrophic osteodystrophy—juvenile growth syndrome with phyeal and periosteal inflammation that may impede growth.
- Trauma—most common cause; if germinal cell layer of the physis is damaged, new cartilage production and bone elongation are stopped. Commonly occurs with fractures involving the distal ulnar or radial growth plates. A crushing-type fracture (Salter-Harris type V) may not be detected on radiographs of the injured antebrachium, and angular deformity only becomes evident over time due to lack of growth of the affected bone.

SYSTEMS AFFECTED

Musculoskeletal

GENETICS

- Skye terriers—reported as a recessive inheritable trait.
- Chondrodysplastic breeds (dogs)—disturbed endochondral ossification results in asynchronous growth of the paired bone system, resulting in altered growth and angular deformity. Affected dogs are predisposed to elbow malalignment.

INCIDENCE/PREVALENCE

- Traumatic—may occur in up to 10% of actively growing dogs that sustain injuries of the antebrachium; uncommon in cats.
- Elbow malalignment syndrome ± angular deformity (chondrodysplastic dog breeds)—fairly common and can be bilateral. Clinical abnormality in affected individuals is variable.
- Nutritionally induced—incidence

decreasing as nutritional standards are improved.

- Congenital agenesis of the radius (cats and rarely dogs)—occurs infrequently; results in severely bowed antebrachium and carpal subluxation.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Skye terrier—recessive inheritable form.
- Chondrodysplastic and toy breeds (especially basset hound, dachshund, Lhasa apso, Pekingese, Jack Russell terrier)—may be predisposed to elbow malalignment and incongruity.
- Giant breeds (e.g., Great Dane, wolfhound)—may be induced by rapid growth owing to excessive or unbalanced nutrition, osteochondrosis, or hypertrophic osteodystrophy.

Mean Age and Range

- Traumatic—any time during the active growth phase.
- Elbow malarticulations—during growth; may not be recognized until secondary arthritic changes become severe, occasionally at several years of age.

Predominant Sex

N/A

SIGNS

General Comments

- Longer-limbed dogs—angular deformities generally more common.
- Shorter-limbed dogs—tend to develop more severe joint malalignments.
- Age at the time of premature closure—affects relative degree of deformity and joint malarticulation; dogs with more growth potential remaining tend to develop more severe deformity.

Historical Findings

- Traumatic—progressive limb angulation or lameness 3–4 weeks after injury; owner may not be aware of causative event.
- Developmental elbow malalignments—insidious onset of lameness in one or both forelimbs; most apparent after exercise.

Physical Examination Findings

Premature Distal Ulnar Closure

- Results in three deformities of the distal radius—lateral deviation (valgus), cranial bowing (recurvatum), and external torsion resulting in supination of the manus.
- Relative shortening of limb length compared to the contralateral normally growing limb.
- Caudolateral subluxation of the radiocarpal joint and malarticulation of the elbow joint—may occur; causes lameness and painful joint restriction.

Premature Radial Phyeal Closure

- Affected limb—significantly shorter than the normal contralateral.
- Severity of lameness—depends on degree of joint malarticulation.
- Complete symmetrical

closure of distal physis—may note straight limb with a widened radiocarpal or radiohumeral joint space; may note caudal bow (recurvatum) to radius and ulna.

- Asymmetrical closure of medial aspect of distal radial physis—varus angular deformity; occasionally internal torsion and pronation.
- Closure of lateral aspect of distal radial physis—valgus angular deformity; external torsion.
- Closure of proximal radial physis with continued ulnar growth—malarticulation of the elbow joint; widened radiohumeral space, and proximal subluxation of the humeroulnar joint (increased humerus to anconeal process space).

CAUSES

- Trauma • Developmental basis
- Nutritional basis

RISK FACTORS

- Forelimb trauma • Excessive dietary supplementation

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Elbow dysplasia • Fragmented medial coronoid process • Ununited anconeal process • Panosteitis • Flexor tendon contracture • Hypertrophic osteodystrophy

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

- Damage to growth potential of the physis—commonly cannot be seen at the time of trauma; usually 2–4 weeks before radiographically apparent.
- Standard craniocaudal and mediolateral radiographic views—include entire elbow joint; from mid-humerus proximally extend to digits distally; take same series for comparison to normal contralateral limb.
- Degree of angular deformities and relative shortening—determined by comparing relative lengths of radius and ulna within the deformed pair to the normal contralateral pair.
- Degree of torsional deformity—determined by comparing position of the elbow and carpus on same view, i.e., lateral projection of elbow and 45° oblique of carpus on same view indicates torsional deformity.
- Cross-sectional imaging and creation of models using stereolithography is useful for full appreciation of the deformity.
- Elbow and carpal joints—evaluate for malalignment and degenerative change.. Presence of degenerative change is associated with less optimal outcome following surgical treatment.
- Elbow joint—evaluate for associated ununited anconeal process and fragmented medial coronoid process.

(CONTINUED)

ANTEBRACHIAL GROWTH DEFORMITIES

A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Cartilage of abnormal growth plate often replaced with bone. Angular deformity can occur due to retained cartilage core (osteochondrosis) of the ulna.

TREATMENT

APPROPRIATE HEALTH CARE

- Genetic predisposition—do not breed.
- Traumatic physeal damage—not seen at time of injury; revealed 2–4 weeks later.
- In young (<6 months) animals, surgical treatment is generally recommended as soon as possible following diagnosis. Treatment may require multiple surgical procedures.

NURSING CARE

N/A

ACTIVITY

Exercise restriction—reduces joint malalignment damage; slows arthritic progression.

DIET

- Decrease nutritional supplementation in giant-breed dogs—slows rapid growth; may reduce incidence.
- Avoid excess weight—helps control arthritic pain resulting from joint malalignment and overuse.

CLIENT EDUCATION

- Discuss heritability in chondrodysplastic breeds.
- Explain that damage to physeal growth potential is not apparent at time of forelimb trauma and that the diagnosis is often made 2–4 weeks following an injury.
- Discuss the importance of joint malalignment and resultant osteoarthritis as primary causes of lameness.
- Emphasize that early surgical treatment leads to a better prognosis.
- Depending on the patient's age, treatment may involve multiple procedures.

SURGICAL CONSIDERATIONS

- Premature distal ulnar physeal closure in a patient <5–6 months of age (significant amount of radial growth potential remaining)—treated with partial ulnar osteotomy, valgus deformities ≤ 25°: may improve and may not require additional surgery; young patients and those with more severe deformities: often require a second definitive correction after maturity.
- Radial or ulnar physeal closure in a mature patient (limited or no growth potential) requires definitive deformity correction, joint realignment, or both.
- Deformity correction—may be accomplished with a variety of osteotomy techniques; may be stabilized with several different internal or external fixation devices; must correct both torsional and angular deformities; performed at the point of greatest curvature.
- Joint malalignment (particularly elbow)—must

correct to minimize arthritis development (primary cause of lameness); obtain optimal joint alignment via dynamic proximal ulnar osteotomy (use triceps brachii muscle traction and joint pressure) or shortening longer bone (radial or ulnar osteotomy as indicated).

- Significant limb length discrepancies—distraction osteogenesis; osteotomy of the shortened bone is progressively distracted at the rate of 1 mm/day with an external fixator system to create new bone length.

MEDICATIONS

DRUG(S) OF CHOICE

Anti-inflammatory drugs—symptomatic treatment of osteoarthritis

CONTRAINDICATIONS

Corticosteroids—do not use owing to potential systemic side effects and cartilage damage seen with long-term use.

PRECAUTIONS

Warn client of possible gastrointestinal upset associated with chronic anti-inflammatory therapy.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Neutraceuticals (e.g., chondroitin sulfate and glucosamine)—may help minimize cartilage damage and osteoarthritis development, but not proven.

FOLLOW-UP

PATIENT MONITORING

- Postoperative—depends on surgical treatment.
- Periodic checkups—evaluate arthritic status and anti-inflammatory therapy.

PREVENTION/AVOIDANCE

- Selective breeding of susceptible breeds.
- Avoid dietary oversupplementation in rapidly growing giant-breed dogs.

POSSIBLE COMPLICATIONS

Routinely seen with various osteotomy fixation techniques (e.g., infection, non-union of osteotomy, fixator pin tract inflammation, undercorrection).

EXPECTED COURSE AND PROGNOSIS

- Generally, best results seen with early diagnosis and surgical treatment—minimizes osteoarthritis.
- Premature ulnar closure—tends to be easier to manage than premature closure of the radial growth plates. Prognosis is dependent on severity of the deformity, joint congruity, and presence of degenerative joint disease. The prognosis worsens with increasing severity.
- Limb lengthening by distraction osteogenesis—requires extensive postoperative management by the veterinarian and owner; high rate of complications.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Osteochondrosis • Hypertrophic osteodystrophy • Un-united anconeal process

AGE-RELATED FACTORS

The younger the patient at the time of traumatically induced physeal closure, the more severe the deformity and malarticulation.

ANTERIOR UVEITIS—CATS

BASICS

DEFINITION

- Inflammation of the anterior uveal tissues, including iris (iritis), ciliary body (cyclitis), or both (iridocyclitis). • May be associated with concurrent posterior uveal and retinal inflammation (choroiditis; chorioretinitis).
- May be unilateral or bilateral.

PATHOPHYSIOLOGY

- Increased permeability of the blood-aqueous barrier related to infectious, immune-mediated, neoplastic, traumatic, or other causes; allows entrance of plasma proteins and blood cellular components into aqueous humor. • Disruption of blood-aqueous barrier is initiated and maintained by numerous chemical mediators, including histamine, prostaglandins, leukotrienes, serotonin, kinins, and complement.

SYSTEMS AFFECTED

- Ophthalmic. • Other systems may also be affected by underlying disease process.

INCIDENCE/PREVALENCE

- Relatively common condition. • True incidence/prevalence unknown.

GEOGRAPHIC DISTRIBUTION

Geographic location may affect incidence of certain infectious causes of uveitis.

SIGNALMENT

Species

Cat

Mean Age and Range

- Mean age 7–9 years. • Any age may be affected.

Predominant Sex

Males/neutered males more commonly affected than females.

SIGNS

Historical Findings

- Cloudy eye—due to corneal edema, aqueous flare, hypopyon, etc. • Painful eye—manifest by blepharospasm, photophobia, or rubbing eye; usually less pronounced than in dogs. • Red eye—due to conjunctival hyperemia and ciliary flush; less pronounced than in dogs in most cases. • Vision loss—variable.

Physical Examination Findings

Importance of a thorough physical examination in cats presenting with uveitis cannot be overstated.

Ophthalmic Findings

- Ocular discomfort—manifest by blepharospasm and photophobia • Ocular discharge—usually serous; sometimes mucoid to mucopurulent. • Conjunctival hyperemia—bulbar and palpebral conjunctiva both usually affected. • Corneal edema—diffuse; mild to severe. • Keratic precipitates—multifocal aggregates of

inflammatory cells adherent to corneal endothelium; most notable ventrally.

- Aqueous flare and cells—cloudiness of aqueous humor due to increased protein content and suspended cellular debris; best visualized with a bright, narrow beam of light shined through anterior chamber.
- Ciliary flush—Injection of deep perilimbal anterior ciliary vessels. • Deep corneal vascularization—circumcorneal distribution (brush border). • Miosis and/or resistance to pharmacologic dilation. • Iridal swelling—may be generalized or nodular. • Reduced IOP is consistent with anterior uveitis but is not a uniform finding. • Posterior synechia—adhesions between posterior iris and anterior lens surface. • Fibrin in anterior chamber.
- Hypopyon or hyphema—accumulations of white blood cells or red blood cells, respectively, in the anterior chamber; usually settles horizontally in ventral aspect of chamber but may be diffuse. • Chronic changes may include rubeosis iridis, iridal hyperpigmentation, secondary cataract, lens luxation, pupillary seclusion, iris bombe, secondary glaucoma, and phthisis bulbi.

CAUSES

- Infectious—mycotic (*Blastomyces* spp., *Cryptococcus neoformans*; *Coccidiodes immitis*; *Histoplasma capsulatum*); protozoal (*Toxoplasma gondii*; *Leishmania infantum*); bacterial (*Bartonella* spp., *Mycobacterium* spp. or any bacterial septicemia); viral (FIV, FeLV, feline coronavirus; FHV-1); parasitic (ophthalmomyiasis; ocular larval migrans).
- Idiopathic—lymphocytic-plasmacytic uveitis. • Immune-mediated—reaction to lens proteins (due to cataract or lens trauma).
- Neoplastic—primary ocular tumors (esp. diffuse iris melanoma, ocular sarcoma); metastasis to uveal tract (esp. lymphoma).
- Metabolic—hyperlipidemia; hyperviscosity; systemic hypertension. • Miscellaneous—trauma (blunt or penetrating); ulcerative keratitis; corneal stromal abscess; toxemia of any cause.

RISK FACTORS

None specific; immune suppression and geographic location may increase incidence of certain infectious causes of uveitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Conjunctivitis—redness limited to conjunctival hyperemia (i.e., no ciliary flush); ocular discharge usually thicker and more copious than in uveitis; discomfort may be alleviated by topical anesthetic. • Glaucoma—elevated IOP is most consistent distinguishing feature of this disease; others may include dilated pupil, Haab's striae, and buphthalmos.
- Ulcerative keratitis—corneal fluorescein staining will detect ulcers; corneal edema

associated with ulcers is either localized to, or most severe at, site of ulcer; ocular discharge often thicker and more copious than with uveitis; discomfort may be alleviated by topical anesthetic. • Horner's syndrome—miosis, enophthalmos, and nictitans protraction are similar in both conditions, but Horner's is non-painful with no ocular discharge; ptosis with Horner's is distinguished from blepharospasm, as the latter is an active process; minor conjunctival hyperemia may be noted with Horner's, but cornea and anterior chamber are clear; clinical signs of Horner's syndrome resolve following topical application of ophthalmic 1–10% phenylephrine.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—often normal; changes may be present related to underlying disease.
- Biochemistry—often normal; most common abnormality in cats with uveitis is elevated serum proteins (usually due to polyclonal gammopathy). • Urinalysis—often normal; changes may be present related to underlying disease.

OTHER LABORATORY TESTS

- FeLV serum titers. • FIV serum titers.
- Coronavirus titers—not specific for FIP but may influence the index of suspicion for this disease. • *Toxoplasma gondii* IgM and IgG titers performed on serum and/or aqueous humor. • *Bartonella* spp. serology, PCR (serum or aqueous humor) and/or blood culture.

IMAGING

- Thoracic radiography—may show evidence of causative disease process (e.g., infiltrates related to infectious disease; evidence of metastatic neoplastic disease). • Ocular ultrasound—indicated if opacity of ocular media precludes direct examination; may reveal intraocular neoplasm or retinal detachment.

DIAGNOSTIC PROCEDURES

- Tonometry—low IOP consistent with uveitis; elevated IOP indicates glaucoma (primary disease or secondary to uveitis).
- Ocular centesis—if retinal detachment is present, cytology of subretinal aspirate may reveal causative agents; anterior chamber centesis may be performed for *Toxoplasma gondii* or *Bartonella* IgM and IgG titers on aqueous humor.

PATHOLOGIC FINDINGS

- Gross—see physical examination findings.
- Histopathologic—corneal edema; peripheral corneal deep stromal vascularization; keratic precipitates; preiridal fibrovascular membrane; peripheral anterior synechia; posterior synechia; entropion or ectropion uveae; leukocyte accumulation in iris, ciliary body, sclera, choroid (lymphocytic-plasmacytic, suppurative, or granulomatous infiltrates, depending on etiology); secondary cataract; with posterior segment involvement

(CONTINUED)

in inflammatory process, cyclitic membrane; vitreal traction bands and retinal detachment may be present. • Lymphoplasmacytic infiltrate of iris and ciliary body (either diffuse or nodular) is most common histopathologic finding.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient medical management generally sufficient.

ACTIVITY

No changes indicated in most cases.

DIET

No changes indicated.

CLIENT EDUCATION

- Inform of potential systemic diseases causing ophthalmic signs and emphasize importance of appropriate diagnostic testing.
- In addition to symptomatic uveitis treatment, treatment of underlying disease (when possible) is paramount to a positive outcome.
- Inform of potential complications and emphasize compliance with treatment and follow-up recommendations that will reduce the likelihood of complications.

SURGICAL CONSIDERATIONS

- None in most cases.
- Specific instances requiring surgical intervention include removal of ruptured lenses and surgical management of secondary glaucoma.
- Chronic uveitis leading to secondary glaucoma commonly necessitates enucleation of affected globes.
- Enucleation is recommended in cats with uveitis related to diffuse iris melanoma or other primary intraocular tumors.

MEDICATIONS

DRUG(S)

Corticosteroids

Topical

- Prednisolone acetate 1%—apply 2–8 times daily, depending on severity of disease; taper medication as condition resolves.
- Dexamethasone 0.1%—apply 2–8 times daily, depending on severity of disease; taper medication as condition resolves.
- Other topical corticosteroids (e.g., betamethasone, hydrocortisone) are considerably less effective in the treatment of intraocular inflammation.
- Taper treatment frequency as condition improves; stopping topical corticosteroids abruptly may result in rebound of ocular inflammation.

Subconjunctival

- Triamcinolone acetonide 4 mg by subconjunctival injection.
- Methylprednisolone 4 mg by subconjunctival injection.
- Often not

required. • Indicated only in severe cases as one-time injection, followed by topical and/or systemic anti-inflammatories.

Systemic

- Prednisone 1–3 mg/kg/day initially; taper dose after 7–10 days.
- Use only if systemic infectious causes of uveitis have been ruled out.

Nonsteroidal Anti-inflammatory Drugs

Topical

- Flurbiprofen—apply 2–4 times daily, depending on severity of disease.
- Diclofenac—apply 2–4 times daily, depending on severity of disease.

Systemic

- Meloxicam 0.2 mg/kg IV, SC, PO once, then 0.05 mg/kg IV, SC, PO q24h for 2 days, then 0.025 mg/kg q24–48h. Due to potential renal effects, limit duration of use to 4 days.
- Robenacoxib 1 mg/kg PO once daily; limit duration of use to 3 days.
- Ketoprofen 1 mg/kg PO q24h; limit duration of use to 5 days.

Topical Mydriatic/Cycloplegic

- Atropine sulfate 1%—apply 1–4 times daily, depending on severity of disease. Use lowest frequency adequate to maintain dilated pupil and ocular comfort; taper medication as condition resolves. Ointment is preferred over solution in cats as it causes less salivation.

CONTRAINDICATIONS

- Avoid the use of miotic medications (e.g., pilocarpine), including topical prostaglandins (e.g., latanoprost), in the presence of uveitis.
- Topical and subconjunctival corticosteroids are absolutely contraindicated in the presence of ulcerative keratitis.
- Corticosteroids (especially systemic) should be avoided in cats with systemic hypertension. Avoid systemic NSAIDs in cats with renal disease.

PRECAUTIONS

Owing to concern for secondary glaucoma, topical atropine should be used judiciously and IOP should be monitored periodically.

POSSIBLE INTERACTIONS

Systemic corticosteroids and nonsteroidal anti-inflammatory drugs should not be used concurrently.

FOLLOW-UP

PATIENT MONITORING

Recheck in 3–7 days, depending on severity of disease. IOP should be monitored at recheck to detect secondary glaucoma. Frequency of subsequent rechecks dictated by severity of disease and response to treatment.

POSSIBLE COMPLICATIONS

Systemic Complications

Occur as a result of the systemic etiology of the uveitis.

Ophthalmic Complications

- Secondary glaucoma—common complication of chronic uveitis in cats.

ANTERIOR UVEITIS—CATS

A

- Secondary cataract.
- Lens luxation.
- Retinal detachment.
- Phthisis bulbi.

EXPECTED COURSE AND PROGNOSIS

- Guarded prognosis for affected eyes.
- Depends on underlying disease and response to treatment.
- Cats with treatable underlying disease (e.g., toxoplasmosis) are more likely to have a favorable ophthalmic outcome than those with idiopathic lymphocytic-plasmacytic uveitis or untreatable underlying condition (e.g., FIP, FIV).

MISCELLANEOUS

AGE-RELATED FACTORS

- Younger cats more likely to be diagnosed with infectious etiology.
- Older cats at higher risk of idiopathic lymphocytic-plasmacytic uveitis and intraocular neoplastic causes.

ZOONOTIC POTENTIAL

- None in most cases.
- Some forms of systemic infection causing uveitis may pose a slight risk to immunocompromised owners.

PREGNANCY/FERTILITY/BREEDING

Avoid systemic corticosteroids. Because of systemic absorption, topical corticosteroids may also pose a risk, especially with frequent application.

SYNONYM

Iridocyclitis

ANTERIOR UVEITIS—DOGS

BASICS

DEFINITION

- Inflammation of the anterior uveal tissues, including iris (iritis), ciliary body (cyclitis), or both (iridocyclitis).
- May be associated with concurrent posterior uveal and retinal inflammation (choroiditis; chorioretinitis).
- May be unilateral or bilateral.

PATHOPHYSIOLOGY

- Increased permeability of the blood-aqueous barrier related to infectious, immune-mediated, traumatic, or other causes allows entrance of plasma proteins and blood cellular components into aqueous humor.
- Disruption of blood-aqueous barrier is initiated and maintained by numerous chemical mediators, including histamine, prostaglandins, leukotrienes, serotonin, kinins, and complement.

SYSTEMS AFFECTED

- Ophthalmic.
- Other systems may also be affected by underlying disease process.

INCIDENCE/PREVALENCE

- Relatively common condition.
- True incidence/prevalence unknown.

GEOGRAPHIC DISTRIBUTION

Geographic location may affect incidence of certain infectious causes of uveitis.

SIGNALMENT

Species

Dog

Breed Predilections

- None for most causes.
- Uveitis associated with iridociliary cysts in golden retriever (a.k.a. golden retriever uveitis, pigmentary uveitis).
- Increased incidence of uveodermatologic syndrome in Siberian husky, Akita, Samoyed, and Shetland sheepdog.

Mean Age and Range

- Any age may be affected.
- Mean age in uveodermatologic syndrome—2.8 years.
- Mean age in golden retriever uveitis—8.6 years.

SIGNS

Historical Findings

- Red eye—due to conjunctival hyperemia and ciliary flush.
- Cloudy eye—due to corneal edema, aqueous flare, hypopyon, etc.
- Painful eye—manifest by blepharospasm, photophobia, or rubbing eye.
- Vision loss—variable.

Physical Examination Findings

The importance of a thorough physical examination in dogs presenting with uveitis cannot be overstated.

Ophthalmic Findings

- Ocular discomfort—manifest by blepharospasm, photophobia, and rubbing

- eye.
- Ocular discharge—usually serous; sometimes mucoid to mucopurulent.
- Conjunctival hyperemia—bulbar and palpebral conjunctiva both usually affected.
- Corneal edema—diffuse; mild to severe.
- Keratic precipitates—multifocal aggregates of inflammatory cells adherent to corneal endothelium; most notable ventrally.
- Aqueous flare and cells—cloudiness of aqueous humor due to increased protein content and suspended cellular debris; best visualized with a bright, narrow beam of light shined through anterior chamber.
- Ciliary flush—Injection of deep perilimbal anterior ciliary vessels.
- Deep corneal vascularization—circumcorneal distribution (brush border).
- Miosis and/or resistance to pharmacologic dilation.
- Iridal swelling.
- Reduced IOP is consistent with uveitis but is not a uniform finding.
- Posterior synechia—adhesions between posterior iris and anterior lens surface.
- Fibrin in anterior chamber.
- Hypopyon or hyphema—accumulations of white blood cells or red blood cells, respectively, in the anterior chamber; usually settles horizontally in ventral aspect of chamber but may be diffuse.
- Chronic changes may include rubeosis iridis, iridal hyperpigmentation, secondary cataract, lens luxation, pupillary seclusion, iris bombe, secondary glaucoma, and phthisis bulbi.

CAUSES

- Infectious—mycotic (*Blastomyces dermatitidis*, *Cryptococcus neoformans*, *Coccidiodes immitis*, *Histoplasma capsulatum*); protozoal (*Toxoplasma gondii*, *Neospora caninum*, *Leishmania donovani*); rickettsial (*Ehrlichia canis*, *Rickettsia rickettsii*); bacterial (*Leptospira* spp., *Bartonella* spp., *Brucella canis*, *Borrelia burgdorferi*, any bacterial septicemia); algal (*Prototheca* spp.); viral (adenovirus, distemper, rabies, herpes); parasitic (ocular filariasis, ocular larval migrans).
- Immune-mediated—reaction to lens proteins (due to cataract or lens trauma); uveodermatologic syndrome; post-vaccinal reaction to canine adenovirus vaccine; vasculitis.
- Neoplastic—primary ocular tumors (especially uveal melanoma, iridociliary adenoma/adenocarcinoma); metastasis to uveal tract (lymphosarcoma most common).
- Metabolic—hyperlipidemia; hyperviscosity; systemic hypertension.
- Miscellaneous—idiopathic; trauma; pigmentary uveitis of golden retrievers; ulcerative keratitis; corneal stromal abscess; scleritis; lens instability/luxation; dental/periodontal disease; toxemia.

RISK FACTORS

None specific; immune suppression and geographic location may increase incidence of certain infectious causes of uveitis; breed predispositions should be considered.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Conjunctivitis—redness limited to conjunctival hyperemia (i.e., no ciliary flush); ocular discharge usually thicker and more copious than in uveitis; discomfort may be alleviated with application of topical anesthetic.
- Glaucoma—elevated IOP is most consistent feature of this disease; others may include dilated pupil, Haab's striae, and buphthalmos.
- Lens luxation—corneal edema may be localized to site of lens contact with endothelium or may be diffuse as a result of associated uveitis and/or glaucoma; lens luxation is highly breed associated.

- Ulcerative keratitis—corneal fluorescein staining will detect ulcers; corneal edema associated with ulcers is either localized to, or most severe at, site of ulcer; ocular discharge often thicker and more copious than with uveitis; discomfort may be partially alleviated by topical anesthetic.
- Corneal endothelial dystrophy or degeneration—diffuse corneal edema is present, but IOP is normal; conjunctival hyperemia and signs of ocular discomfort are generally absent.
- Horner's syndrome—miosis, enophthalmos, and nictitans protraction are similar in both conditions, but Horner's is non-painful with no ocular discharge; ptosis with Horner's is distinguished from blepharospasm as the latter is an active process; minor conjunctival hyperemia may be noted with Horner's, but cornea and anterior chamber are clear; clinical signs of Horner's syndrome resolve following topical application of 1–10% phenylephrine.

CBC/BIOCHEMISTRY/URINALYSIS

Often normal; changes related to underlying disease may be present.

OTHER LABORATORY TESTS

- Serology for infectious diseases listed under "Causes" may be appropriate, depending on index of suspicion for infectious etiology.
- Clinical signs raising the suspicion of systemic disease including lethargy, pyrexia, weight loss, coughing, lymphadenopathy, etc., warrant serology for infectious diseases.

IMAGING

- Thoracic radiography may show evidence of causative disease process (e.g., systemic mycoses; metastatic neoplasia).
- Abdominal ultrasound may be warranted if suspicion for metastatic neoplastic disease is high.
- Ocular ultrasound is indicated if opacity of ocular media precludes direct examination; may reveal intraocular neoplasm or retinal detachment.

DIAGNOSTIC PROCEDURES

- Tonometry—low IOP consistent with uveitis; elevated IOP indicates glaucoma (primary disease or secondary to uveitis).
- Lymph node aspirates—if enlarged nodes

(CONTINUED)

are palpable, aspiration for cytology is indicated. • Ocular centesis—if retinal detachment is present, cytology of subretinal aspirate may reveal causative agents; anterior chamber centesis is generally unrewarding.

PATHOLOGIC FINDINGS

- Gross—see “Physical Examination Findings.”
- Histopathologic—corneal edema; peripheral corneal deep stromal vascularization; keratic precipitates; preiridal fibrovascular membrane; peripheral anterior synechia; posterior synechia; entropion or ectropion uvae; leukocyte accumulation in iris, ciliary body, sclera, choroid (lymphocytic, plasmacytic, suppurative, or granulomatous infiltrates, depending on etiology); secondary cataract; with posterior segment involvement in inflammatory process, cyclitic membrane; vitreal traction bands and retinal detachment may be present.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient medical management is generally sufficient.

NURSING CARE

None

ACTIVITY

- No changes indicated in most cases.
- Reduced exposure to bright light may alleviate discomfort.

DIET

No changes indicated.

CLIENT EDUCATION

- Inform of potential systemic diseases causing ophthalmic signs and emphasize importance of appropriate diagnostic testing.
- In addition to symptomatic uveitis treatment, treatment of underlying disease (when possible) is paramount to a positive outcome.
- Inform of potential complications and emphasize compliance with treatment and follow-up recommendations that will reduce the likelihood of complications.

SURGICAL CONSIDERATIONS

None in most cases. Specific instances requiring surgical intervention include removal of ruptured lenses, removal of cataracts causing uveitis (if prognosis for successful surgery is otherwise favorable), and surgical management of secondary glaucoma.

MEDICATIONS

DRUG(S) OF CHOICE

Corticosteroids

Topical

- Prednisolone acetate 1% apply 2–8 times daily, depending on severity of disease; taper medication as condition resolves.

- Dexamethasone 0.1%—apply 2–8 times daily, depending on severity of disease; taper medication as condition resolves.

- Other topical corticosteroids (e.g., betamethasone, hydrocortisone) are considerably less effective in the treatment of intraocular inflammation.

- Taper treatment frequency over several weeks as condition improves; stopping topical corticosteroids abruptly may result in rebound of ocular inflammation.

Subconjunctival

- Triamcinolone acetonide 4–6 mg by subconjunctival injection.
- Methylprednisolone 3–10 mg by subconjunctival injection.
- Often not required.
- Indicated only in severe cases as one-time injection followed by topical and/or systemic anti-inflammatories.

Systemic

- Prednisone 0.5–2.2 mg/kg/day initially; taper dose after 7–10 days.
- Use only if systemic infectious causes of uveitis have been ruled out.

Nonsteroidal Anti-inflammatory Drugs

Topical

- Less effective than topical corticosteroids.
- Flurbiprofen—apply 2–4 times daily, depending on severity of disease.
- Diclofenac—apply 2–4 times daily, depending on severity of disease.

Systemic

- Do not use concurrently with systemic corticosteroids; avoid in the presence of hyphema.
- Carprofen 2.2 mg/kg PO q12h or 4.4 mg/kg PO q24h.
- Tepoxalin 10 mg/kg PO q24h.
- Meloxicam 0.2 mg/kg PO q24h.
- Firocoxib 5 mg/kg PO q24h.

Topical Mydriatic/Cycloplegic

- Atropine sulfate 1%—apply 1–4 times daily, depending on severity of disease. Use lowest frequency adequate to maintain dilated pupil and ocular comfort; taper medication as condition resolves.

CONTRAINDICATIONS

- Avoid the use of miotic medications (e.g., pilocarpine, demecarium bromide), including topical prostaglandins (e.g., latanoprost), in the presence of uveitis.
- Topical and subconjunctival corticosteroids are contraindicated in ulcerative keratitis.
- Avoid systemic corticosteroids in dogs with systemic hypertension or systemic infections.

PRECAUTIONS

Out of concern for secondary glaucoma, topical atropine should be used judiciously and IOP should be monitored periodically.

POSSIBLE INTERACTIONS

Systemic corticosteroids and NSAIDS should not be used concurrently.

ALTERNATIVE DRUG(S)

N/A

ANTERIOR UVEITIS—DOGS

A

FOLLOW-UP

PATIENT MONITORING

Recheck in 3–7 days, depending on severity of disease. IOP should be monitored at recheck to detect secondary glaucoma. Frequency of subsequent rechecks dictated by severity of disease and response to treatment.

POSSIBLE COMPLICATIONS

- Many systemic complications, including death, may occur due to systemic etiology of uveitis.
- Ophthalmic complications include secondary cataract, secondary glaucoma, lens luxation, retinal detachment, phthisis bulbi.

EXPECTED COURSE AND PROGNOSIS

Extremely variable; depends on underlying disease and response to treatment.

MISCELLANEOUS

ZOONOTIC POTENTIAL

None in most cases. Some forms of systemic infection causing uveitis may pose a slight risk to immune-compromised owners.

PREGNANCY/FERTILITY/BREEDING

Avoid systemic corticosteroids. Because of possibility of systemic absorption, topical corticosteroids may also pose risk, especially with frequent application in small dogs.

SYNOMYS

Iridocyclitis

SEE ALSO

ANTIDEPRESSANT TOXICOSIS—SSRIS AND SNRIS

BASICS

DEFINITION

- Toxicity secondary to the overdose of a selective serotonin reuptake inhibitor (SSRI), serotonin and norepinephrine reuptake inhibitor (SNRI) or co-ingestion of two types of serotonergic drugs.
- SSRIs include citalopram (Celexa), escitalopram (Lexapro), fluoxetine (Prozac), fluvoxamine (Luvox), paroxetine (Paxil), sertraline (Zoloft), vilazodone (Viibryd), vortioxetine (Brintellix). SNRIs include desvenlafaxine (Pristiq), duloxetine (Cymbalta), levomilnacipran (Fetzima), milnacipran (Ixel, Savella), tofenacin (Elamol, Tofacine), and venlafaxine (Effexor).

PATHOPHYSIOLOGY

- SSRIs and SNRIs are antidepressants that inhibit reuptake of serotonin, a neurotransmitter involved in aggression, anxiety, appetite, depression, migraine, pain, and sleep. The SNRIs also inhibit the reuptake of norepinephrine.
- Excessive stimulation of serotonin receptors can occur by enhanced serotonin synthesis, increased presynaptic serotonin release, inhibition of serotonin uptake into the presynaptic neuron, inhibition of serotonin metabolism, or serotonin agonism. Serotonin syndrome is characterized in humans as a combination of symptoms that include at least three of the following: myoclonus, mental aberration, agitation, hyperreflexia, tremors, diarrhea, ataxia, or hyperthermia.
- Toxic dosage varies widely among commonly available SSRIs and SNRIs and are not well defined in veterinary medicine.

SYSTEMS AFFECTED

- Cardiovascular—decreased vascular tone (hypotension), increased heart rate and stroke volume (tachycardia).
- Gastrointestinal—increased smooth muscle contractility (vomiting, diarrhea).
- Nervous—stimulation (agitation, restlessness, seizures) and altered mental status (vocalization, disorientation).
- Neuromuscular—autonomic dysfunction (hyperactivity) and neuromuscular hyperactivity (hyperreflexia, myoclonus, tremors).
- Ophthalmic—increased autonomic function (mydriasis).
- Respiratory—increased bronchial smooth muscle contraction (dyspnea).

INCIDENCE/PREVALENCE

Second most common human prescription medication toxicosis (after cardiac medications).

SIGNALMENT

Species

Dogs and cats

Mean Age and Range

Any age can be affected.

SIGNS

Historical Findings

- Agitation or lethargy
- Dilated pupils
- Vomiting
- Tremors
- Hypersalivation
- Diarrhea
- Seizures
- Nystagmus

Physical Examination Findings

- Agitation
- Ataxia
- Mydriasis
- Tremors
- Vomiting
- Disorientation
- Hyperthermia
- Vocalization
- Depression
- Tachycardia
- Hypotension
- Diarrhea
- Blindness
- Seizures
- Hypersalivation
- Death

CAUSES

- SSRI/SNRI overdose—accidental exposure, inappropriate administration, or therapeutic use.
- Ingestion of an SSRI/SNRI along with another class of medications that increases serotonin (TCAs, MAOIs, novel antidepressants, tramadol, fentanyl, meperidine, amphetamines, cocaine, dextromethorphan, 5-HTP, buspirone, bupropion, triptans, LSD).

RISK FACTORS

- Animals on a serotonergic drug.
- Underlying liver or kidney disease. Cats are attracted to venlafaxine and will eat multiple capsules.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Toxicologic: TCAs, MAOIs, metaldehyde, lead, ethylene glycol, hops, anticholinergics, antihistamines.
- Non-toxicologic: meningitis e.g., (rabies, canine distemper), neoplasia, heat stroke, malignant hyperthermia.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC/biochemistry: no changes are expected.
- Urinalysis: myoglobinuria secondary to rhabdomyolysis may be seen.

OTHER LABORATORY TESTS

- Blood gas: metabolic acidosis may be seen.

- Testing for SSRIs/SNRIs can be performed, but the tests are not clinically useful.
- Note: venlafaxine will give a false positive for PCP on many urine drug screens.

DIAGNOSTIC PROCEDURES

There are no diagnostic tests to confirm serotonin syndrome.

TREATMENT

APPROPRIATE HEALTH CARE

- Emesis (if asymptomatic and recent ingestion) or gastric lavage (if large number of pills ingested).
- Activated charcoal with cathartic (if severe signs are expected, may need to repeat due to long half-life).

NURSING CARE

IV fluids to help maintain blood pressure and body temperature, and to protect kidneys from myoglobinuria.

CLIENT EDUCATION

If animal appears blind, sight should return.

MEDICATIONS

DRUG(S) OF CHOICE

- Agitation:
 - Phenothiazines (acepromazine 0.025–0.05 mg/kg IV, titrate up as needed).
 - Cyproheptadine (dog, 1.1 mg/kg; cat, 2–4 mg PO q4–6h or can be given rectally if vomiting).
 - Benzodiazepines (diazepam 0.5–2 mg/kg IV) (see "Precautions").
- Tremors: methocarbamol (50–150 mg/kg IV, titrate up but do not exceed 330 mg/kg/day).

CONTRAINdicATIONS

- High risk of serotonin syndrome: other SSRIs, SNRIs, MAOIs, TCAs, amphetamines, 5-HTP, clarithromycin, dextromethorphan, lithium, St. John's wort.
- Low risk of serotonin syndrome: tramadol, fentanyl, amantadine, bupropion, carbamazepine, codeine.

PRECAUTIONS

- Benzodiazepines (e.g., diazepam) are reported by some sources to exacerbate serotonin syndrome and their use for SSRI/SNRI toxicosis is not universally recommended.

POSSIBLE INTERACTIONS

- Decreased metabolism of SSRIs/SNRIs: cimetidine, diuretics, quinidine, lithium.
- Increased levels of medications (decreased metabolism): theophylline, coumadin, digoxin.

(CONTINUED)

ANTIDEPRESSANT TOXICOSIS—SSRIS AND SNRIS

A

**FOLLOW-UP****PATIENT MONITORING**

Blood pressure, heart rate, urine color: monitor hourly, then less frequently as the animal remains stable.

PREVENTION/AVOIDANCE

- Keep medications out of the reach of animals.
- Follow label directions when giving serotonergic drugs to animals.

POSSIBLE COMPLICATIONS

Renal failure secondary to myoglobinuria from rhabdomyolysis. DIC secondary to hyperthermia.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is good in most cases, with recovery in 12–24 hours.
- Patients that present in status epilepticus or with severe hyperthermia have a guarded prognosis.

**MISCELLANEOUS****AGE-RELATED FACTORS**

Young and elderly animals are more at risk for developing serious toxicosis.

PREGNANCY/FERTILITY/BREEDING

SSRIs and SNRIs can cause increased litter mortality and possible birth defects.

ABBREVIATIONS

- 5-HTP = 5-hydroxytryptophan
- MAOI = monoamine oxidase inhibitor
- PCP = phencyclidine (angel dust)
- SNRI = serotonin and norepinephrine reuptake inhibitor
- SSRI = selective serotonin reuptake inhibitor
- TCA = tricyclic antidepressant

Suggested Reading

Consulting Editor Lynn R. Hovda

ANTIDEPRESSANT TOXICOSIS—TRICYCLIC

BASICS

DEFINITION

- Toxicity secondary to the acute or chronic ingestion of a tricyclic antidepressant (TCA).
- TCA medications include amitriptyline, amoxapine, clomipramine, desipramine, doxepin, imipramine, maprotiline (tetracyclic antidepressant), nortriptyline, protriptyline, trimipramine, and many others.

PATOPHYSIOLOGY

- TCAs block the reuptake of norepinephrine, dopamine, and serotonin at the neuronal membrane. They also have anticholinergic activity and are thought to have membrane stabilizing effects on the myocardium (particularly inhibiting fast sodium channels in the ventricular myocardium). They can also have slight alpha-adrenergic blocking activity and antihistaminic effects.
- TCAs are rapidly and well absorbed across the digestive tract. They can decrease GI motility and delay gastric emptying, resulting in delayed drug absorption.
- Lipophilic, protein bound, and well distributed across all tissues.
- They are metabolized by the liver and undergo enterohepatic recirculation. The inactive metabolites are eliminated in the urine.

SYSTEMS AFFECTED

- Nervous—increased dopamine, serotonin, and norepinephrine levels in the CNS contribute to CNS signs.
- Cardiovascular—anticholinergic effects and inhibition of norepinephrine reuptake contribute to tachycardia; alpha adrenergic blockade, cardiac membrane stabilization, and decreased cardiac contractility contribute to hypotension and arrhythmias.
- Gastrointestinal—anticholinergic effects may cause ileus and delayed gastric emptying.
- Ophthalmic—anticholinergic effects can cause pupillary dilation.
- Renal/Urologic—anticholinergic effects may cause urinary retention.

GENETICS

Species and individual differences in absorption, metabolism, and elimination can be significant.

INCIDENCE/PREVALENCE

Incidence is unknown.

SIGNALMENT

Species

Dogs and cats

Breed Predilections

None

Mean Age and Range

None

Predominant Sex

None

SIGNS

General Comments

- Signs can occur at therapeutic doses.
- Signs of toxicosis can occur within 30–60 minutes or be delayed by several hours.

Historical Findings

- Evidence of accidental consumption of the owner's or another pet's medication
- CNS depression (lethargy, ataxia)
- Vocalization
- Vomiting or hypersalivation
- Panting
- Agitation or restlessness
- Tachypnea or dyspnea
- Tremors
- Seizures

Physical Examination Findings

- CNS depression or stimulation
- Tachycardia
- Mydriasis
- Hypothermia
- Hypertension
- Pallor
- Cyanosis
- Hyperthermia
- Arrhythmias
- Hypotension
- Urinary retention
- Constipation

CAUSE

Accidental exposure, inappropriate administration, or therapeutic use.

RISK FACTORS

- Concurrent use of other antipsychotic medication
- Pre-existing cardiac disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Toxicity caused by other antipsychotic medication, stimulant substances (e.g., amphetamines, cocaine, methylxanthines, or pseudoephedrine) or substances capable of causing cardiac arrhythmias (e.g., quinidine, propranolol, albuterol, digoxin).
- Non-toxicologic differentials include hyperkalemia, cardiac ischemia, cardiomyopathy, and other diseases of cardiac conduction.

CBC/BIOCHEMISTRY/URINALYSIS

Expected to be normal

OTHER LABORATORY TESTS

- Blood gases—metabolic acidosis may be noted.
- OTC urine drug screen for TCAs—can be used to determine if exposure has occurred; not useful in determining degree of toxicity.

- Serum TCA levels—can be used to determine if exposure has occurred.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- ECG to monitor for arrhythmias
- Blood pressure monitoring

PATHOLOGIC FINDINGS

No specific lesions expected

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—not recommended for symptomatic patients, patients with cardiac disease, or patients ingesting greater than a therapeutic dose of TCAs.
- Inpatient—asymptomatic:
 - Decontamination with emesis (less than 15 minutes of exposure time), gastric lavage in large exposures, and activated charcoal.
 - Monitor at a clinic for a minimum of 6 hours after exposure.
- Inpatient—symptomatic: stabilize the CV and CNS systems and provide supportive care.

NURSING CARE

- Fluid therapy—restore hydration due to vomiting, regulate blood pressure when hypotension is noted.
- Thermoregulation as needed.
- Enema with warm water if not defecating within 6–12 hours.

DIET

NPO if vomiting

CLIENT EDUCATION

- With a prescribed TCA, instruct client to monitor for adverse or idiosyncratic effects, and to stop the medication and contact the clinic if they occur.
- Prevent exposure to non-prescribed medication.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

Decontamination

- Emesis within 15 minutes of ingestion *only if asymptomatic*; induce emesis with either hydrogen peroxide (dog, 1–2 mL/kg PO) or apomorphine (dog/cat, 0.03–0.05 mg/kg IV, IM, or 0.1 mg/kg SC, or 0.25 mg instilled in conjunctiva of eye).
- Gastric lavage under anesthesia may be considered with large exposures.

(CONTINUED)

ANTIDEPRESSANT TOXICOSIS—TRICYCLIC**A**

- After emesis (or if > 15 minutes of exposure), administer activated charcoal (1–2 g/kg PO) with a cathartic such as sorbitol (70% sorbitol at 3 mL/kg) or sodium sulfate (0.25 tsp/5 kg) if no diarrhea.
- Repeat one-half dose of activated charcoal in 4–6 hours if patient is still symptomatic.

Other

- Cyproheptadine: dogs, 1.1 mg/kg q8h PO or rectally; cats, 2–4 mg/cat q12–24h PO or rectally; used for treatment of serotonin syndrome.
- 20% intravenous lipid emulsion—prevents lipophilic TCAs from reaching the site of action by acting as a sequestant in an expanded plasma lipid phase; 1.5 mL/kg IV bolus followed by 0.25 mL/kg/min IV CRI for 1 hour. Can repeat bolus every 3–5 minutes as needed up to 3 mL/kg, not to exceed a total dose of 8 mL/kg.
- Sodium bicarbonate—used to maintain blood pH at 7.55; if not monitoring acid-base status, start with 2–3 mEq/kg IV over 15–30 minutes in a symptomatic patient.
- Diazepam 0.5–1 mg/kg IV, repeat if necessary; for agitation or seizures.
- Acepromazine 0.02 mg/kg IV, repeat if necessary; for agitation or mild hypertension.
- Phenobarbital—as needed for seizure control.

CONTRAINDICATIONS

- Atropine should not be used because TCAs have anticholinergic effects that are exacerbated by atropine.
- Magnesium sulfate should not be used as a cathartic. Ileus or reduced GI motility will enhance absorption of magnesium and may result in magnesium toxicity.
- Beta-blockers (e.g., propranolol, atenolol) should not be used for tachycardia because of their potential to exacerbate hypotension.
- Do not induce emesis in a patient already showing clinical signs.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

- TCAs increase risk of hyperthermia, seizures, and death with use of MAOIs.
- Sympathomimetic and anticholinergic medications increase the risk for arrhythmias or cardiac effects from TCAs.
- Levothyroxine increases the risk for arrhythmias when used with TCAs.

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

- Acid-base status—monitor for acidosis and if implementing sodium bicarbonate therapy.
- Blood pressure—monitor until asymptomatic.
- ECG—monitor until asymptomatic.

PREVENTION/AVOIDANCE

Keep medications out of reach of pets.

POSSIBLE COMPLICATIONS

Pulmonary edema can occur secondary to aggressive fluid therapy.

EXPECTED COURSE AND PROGNOSIS

- Due to the variable half-lives of the different TCAs, signs can last 24 hours or longer.
- The prognosis is generally good in patients exhibiting mild to moderate signs.
- The prognosis is guarded in patients exhibiting severe signs such as seizures, arrhythmias, or hypotension that are poorly responsive to therapy.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Serotonin syndrome may occur as a result of TCA ingestion.

AGE-RELATED FACTORS

None

PREGNANCY/FERTILITY/BREEDING

TCAs cross the placenta and be found in breast milk; the significance of this is not known at this time.

AORTIC STENOSIS

BASICS

DEFINITION

A narrowing of the left ventricular outflow tract (LVOT) that restricts blood flow leaving the ventricle. It is most commonly congenital, often heritable. The lesion is most commonly subvalvular in dogs, but may be valvular or supravalvular (more often in cats). Subvalvular aortic stenosis (SAS) in dogs is caused by fibrous tissue manifested as nodules, a ridge, ring or tunnel-like lesion. SAS may be associated with other defects including mitral valve dysplasia.

PATHOPHYSIOLOGY

Restriction to outflow generates pressure overload of the LV. Degree of obstruction is related to severity of secondary changes. Left ventricular pressure overload causes thickened LV walls, resulting in diminished blood supply relative to muscle demand and myocardial ischemia. This may result in arrhythmogenesis and if severe or infarcted, mechanical dysfunction. The restriction to blood flow causes high velocity, turbulent flow across the valve, which may cause endothelial damage, lead to aortic insufficiency (AI) and predisposing to endocarditis. SAS may lead to chamber enlargement, distortion of the mitral valve annulus and mitral regurgitation with a possible sequela of left-sided congestive heart failure. Sudden death is common with severe SAS and may be secondary to arrhythmias or infarction.

SYSTEMS AFFECTED

- Cardiovascular—LV pressure overload leading to arrhythmias, syncope, sudden death, heart failure, endocarditis
- Respiratory—possible pulmonary edema with CHF
- Multisystemic—possible due to low cardiac output or endocarditis

GENETICS

SAS is inherited in the Newfoundland, golden retriever, rottweiler and Dogue de Bordeaux. A mutation in the phosphatidylinositol-binding clathrin assembly protein gene (PICALM) is reported in Newfoundlands; a screening test is available. Dominant inheritance patterns are proposed with incomplete penetrance responsible for the disease appearing to skip generations. More than one gene or modifying genes may be involved.

INCIDENCE/PREVALENCE

SAS is one of the most common congenital heart defects of dogs. It is reported as second most common, but difficulty in diagnosing mild disease may underestimate true caseload. Aortic stenosis has been reported as a small contributor of feline congenital heart disease, about 6%. Approximately 2 out of 1,000 dogs and 0.2 per 1,000 cats evaluated at veterinary teaching hospitals are diagnosed with SAS.

(dogs), supravalvular aortic stenosis (cats), and dynamic LVOT obstruction (cats).

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog and Cat

Breed Predilections

The Newfoundland, golden retriever, rottweiler, Bouvier des Flanders, Dogue de Bordeaux, German shepherd, and boxer have the highest incidence of SAS and a familial component or heritability is reported. Increased risk is also described for English bulldog, American Staffordshire terrier, bull Terrier, English bulldog, Great Dane, and Samoyed. No breed predilection is reported for cats.

Mean Age and Range

Clinical signs may be seen at any age. Although often inherited, SAS becomes identifiable during the first few weeks to months of life as the subvalvular lesion progresses. Full phenotype is appreciated by 1 year of age.

Predominant Sex

N/A

SIGNS

Historical Findings

Many dogs with SAS show no clinical signs and have no relevant historical findings. Historical findings are related to disease severity and may include syncope, exercise intolerance, sudden death, and signs due to CHF such as respiratory distress and/or coughing when severe.

Physical Examination Findings

- Systolic left basilar ejection murmur; may radiate to the apex, right side of the thorax, include the carotid arteries and if very loud the cranium. A precordial thrill may be palpable. Murmur intensity is loosely correlated to severity of stenosis. As the disease worsens during early life, some may have absence of or a quiet murmur that develops to a more characteristic finding by 1 year.
- Diastolic murmur may be present with significant AI. The combination of this diastolic murmur with the systolic ejection murmur is a to-and-fro murmur.
- Arrhythmias may be auscultated.
- Pulse deficits may be appreciated, often associated with ventricular arrhythmias.
- Weak pulses may be appreciated that are late or slow to rise with severe SAS (pulsus parvus et tardus).
- Tachypnea, respiratory distress and crackles may occur with CHF.

General Comments

- Boxers have a relatively small aorta compared to other breeds, which can be difficult to distinguish from mild SAS.
- Bull terriers are overrepresented for combined mitral valve dysplasia and SAS.

- Newfoundland dogs are overrepresented for combined patent ductus arteriosus and SAS.

- Volume overload of PDA can cause a relative aortic stenosis and be difficult to distinguish from PDA with mild SAS.

CAUSES

- Congenital heart disease.
- Secondary to valvular change as with aortic valve endocarditis or calcification.
- Dynamic or fixed LVOT obstruction in some cats with hypertrophic (obstructive) cardiomyopathy.
- A component of complex congenital heart disease as with some cases of mitral valve dysplasia.

RISK FACTORS

- Familial history of SAS.
- SAS predisposes to aortic valve endocarditis.
- Aortic valve endocarditis predisposes to valvar aortic stenosis.
- HCM predisposes cats to fixed or dynamic LVOT obstruction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The systolic murmur must be differentiated from other causes of similar murmurs. Innocent or physiologic murmurs are commonly auscultated in athletic dogs, or with anemia, fever, stress or excitement. Pulmonic stenosis, tetralogy of Fallot, and atrial septal defects cause a similar murmur. Weak pulses may also occur with conditions that reduce cardiac output such as heart failure, cardiomyopathy, and severe pulmonic stenosis. Other obstruction to flow may cause reduced pulse quality, such as aortic thromboembolism or rarely aortic coarctation/tubular hypoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

Typically within normal limits

OTHER LABORATORY TESTS

Genetic testing for the mutation associated with Newfoundland SAS is a breeding tool to reduce frequency in this breed.

IMAGING

Thoracic Radiography

- Mild disease may be radiographically silent.
- LV hypertrophy may be subtle as pressure overload causes concentric hypertrophy.
- Left heart enlargement.
- Prominent aortic root and/or widened mediastinum.
- Lung fields typically normal unless CHF with pulmonary venous distention and interstitial to alveolar infiltrates.

Echocardiography

- Findings are variably present and associated with disease severity.
- Ridge, ring, nodule, or tunnel-like narrowing below the aortic valve with SAS.
- Thickened LV free wall or interventricular septum.
- Aortic valve thickening and increased echogenicity with valvar stenosis.
- Mitral regurgitation and

(CONTINUED)

thickening of valve leaflet possible.

- Post-stenotic dilatation of the aorta.
- Hyperechoic myocardium associated with ischemia.
- AI with secondary LV chamber enlargement and volume overload if significant.
- Left atrial enlargement may be seen with significant valve regurgitation.
- Elevated LVOT flow velocity ($> 2.4 \text{ m/s}$), with acceleration proximal to the stenosis and turbulent flow distal to the obstruction and valve.
- Transvalvular pressure gradient estimated by the LVOT flow velocity ($4 \times \text{flow velocity squared}$). Estimated gradients of 25–49 mmHg are considered mild; 50–79 mmHg moderate, and $\geq 80 \text{ mmHg}$ severe.
- With myocardial failure the estimated pressure gradient may be falsely low.
- Effective valve orifice, if calculated, is reduced.

DIAGNOSTIC PROCEDURES

- ECG may show changes consistent with LV hypertrophy (tall R waves, widened QRS complexes, left axis deviation); signs of myocardial ischemia (ST segment deviation or slurring). Ventricular arrhythmias may occur and contribute to syncope or sudden death.
- Holter monitoring may be used to quantify arrhythmia severity and therapeutic response.

PATHOLOGIC FINDINGS

Findings vary with severity but typically include LV concentric or mixed (if significant AI) hypertrophy. A subvalvular lesion of dense fibrous tissue is seen with variable. Myocardial ischemia, necrosis and replacement fibrosis may be evident. Post-stenotic dilatation of the aorta and associated valvular endothelial damage and sometimes left atrial enlargement is reported.

TREATMENT

APPROPRIATE HEALTH CARE

Therapy is limited prior to the onset of complications and aimed at preventing clinical signs and avoiding sudden death.

NURSING CARE

Aimed at relieving symptoms and complications such as arrhythmias, syncope and CHF.

ACTIVITY

Restriction is warranted with severe disease; exertion may increase incidence of arrhythmias, syncope and sudden death.

DIET

Modest salt restriction with CHF.

CLIENT EDUCATION

SAS is considered an inherited disease; affected animals should not be bred. Owners should be counseled on the risk of endocarditis and appropriate antibiotics for any wounds, infections or surgical procedures.

Alert owners to the risks of sudden death, CHF and increased anesthetic risk.

SURGICAL CONSIDERATIONS

No surgical or interventional technique has been shown to extend life beyond medical therapy. Balloon valvuloplasty or combined cutting and traditional balloon valvuloplasty may acutely reduce the pressure gradient and temporarily alleviate some clinical signs. However, the effects are not shown to be beneficial beyond those achieved with beta-blockers. Currently, data does not support surgery or intervention.

MEDICATIONS

DRUG(S) OF CHOICE

Beta adrenergic blockers are advocated with moderate to severe SAS, particularly with ventricular arrhythmias, syncope or ECG evidence of ischemia. They may reduce myocardial oxygen demand, eliminate or protect against ventricular arrhythmias, and reduce heart rate. Atenolol is most common (dogs, 0.5–1.5 mg/kg PO q12h; cats 6.25 mg/cat PO q12–24h).

- Therapy for ventricular arrhythmias, CHF, atrial fibrillation or endocarditis may be required.

CONTRAINdicATIONS

Beta blockers are contraindicated in animals with bronchoconstriction such as asthmatic cats. Starting beta-blockers with CHF is contraindicated and continued use in patients that develop CHF is controversial.

PRECAUTIONS

- Beta-blockers are negatively impact cardiac output and starting low doses with gradual up titration is warranted.
- Positive inotropes may worsen a fixed obstruction and are used with caution when treating CHF.
- Anesthetic drugs that cause hypotension, arrhythmias or cardiac depression should be avoided with severe SAS.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

- Carvedilol (dogs, 0.5–1.5 mg/kg PO q12h)
- Metoprolol tartrate (dogs, 0.5–1.5 mg/kg PO q12h)

FOLLOW-UP

PATIENT MONITORING

Monitor by ECG, Holter monitor, thoracic radiography, and echocardiography. Treatment of complications such as CHF and arrhythmias may necessitate additional monitoring for renal/electrolyte, blood pressure, and rhythm disturbances.

PREVENTION /AVOIDANCE

N/A

AORTIC STENOSIS

A

POSSIBLE COMPLICATIONS

Ventricular arrhythmias, syncope, myocardial infarction, sudden death, AI, mitral regurgitation, endocarditis.

EXPECTED COURSE AND PROGNOSIS

Mildly affected dogs may have a normal lifespan and quality without therapy. Severely affected dogs have limited lifespans and typically succumb to sudden death or CHF. In one study the average lifespan for dogs with severe SAS on atenolol was about 4.5 years.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Increased risk of infective endocarditis

AGE-RELATED FACTORS

SAS is not immediately apparent at birth but appears over few weeks to months of life.

PREGNANCY/FERTILITY/BREEDING

Contraindicated

SYNONYMS

Subaortic stenosis, discrete subaortic stenosis.

AORTIC THROMBOEMBOLISM

BASICS

DEFINITION

Aortic thromboembolism results from a thrombus or blood clot that is dislodged within the aorta, causing severe ischemia to the tissues served by that segment of aorta.

PATHOPHYSIOLOGY

- ATE is commonly associated with myocardial disease in cats, most commonly hypertrophic cardiomyopathy. It is theorized that abnormal blood flow (stasis) and a hypercoagulable state contribute to the formation of a thrombus within the left atrium. The blood clot is then embolized distally to the aorta. The most common site of embolization is the caudal aortic trifurcation (hind legs). Other less common sites include the front leg, kidneys, gastrointestinal tract, or cerebrum.
- ATE in dogs typically is associated with neoplasia, sepsis, infectious endocarditis, Cushing's disease, protein-losing nephropathy, or other hypercoagulable states. However, in one recent retrospective study, no concurrent condition was identified in 58% of dogs.

SYSTEMS AFFECTED

- Cardiovascular—the majority of affected cats have advanced heart disease and left heart failure.
- Nervous/Musculoskeletal—severe ischemia to the muscles and nerves served by the segment of occluded aorta causes variable pain and paresis. Gait abnormalities or paralysis results in the leg or legs involved.

GENETICS

Hypertrophic cardiomyopathy, a common associated disease, is likely heritable. Additionally, a family of domestic shorthair cats with remodeled hypertrophic cardiomyopathy who all died of ATE has been reported.

INCIDENCE/PREVALENCE

- Prevalence is not known in the general population of cats. In two large studies of cats with hypertrophic cardiomyopathy, 12–16% presented with signs of ATE. In two retrospective studies of cats with ATE, 11–25% of cats had previous evidence of heart disease.
- Rare in dogs.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Cat, rarely dog

Breed Predilections

Mixed-breed cats are most commonly affected. Abyssinian, Birman, and ragdoll purebred cats were overrepresented in one

study. In dogs, no breed predilection has been identified in the USA. A European study suggested that Cavalier King Charles Spaniels may be overrepresented.

Mean Age and Range

Age distribution is 1–20 years. The median age is approximately 8–9 years in cats. In dogs, the median age is 8–10 years.

Predominant Sex

Males > females (2:1) in cats. In dogs, no sex predilection in dogs in the USA. A European study suggested a male predilection.

SIGNS

The presence of the 5 "P's" is helpful to remember the classic clinical signs associated with ATE: Pain, Paralysis or Paresis, Pulselessness, Pallor, and Poikilothermic (cold).

Historical Findings

- Acute onset paralysis and pain are the most common complaints in cats. Vocalization and anxiety are also common.
- Lameness or a gait abnormality, typically of several week duration, is more common in dogs.
- Tachypnea or respiratory distress is common in cats.
- About 15% of cats may vomit prior to ATE.

Physical Examination Findings

- Usually paraparesis or paralysis of the rear legs with signs of lower motor neuron injury. Less commonly, monoparesis of a front leg. In dogs, the majority are paretic and ambulatory.
- Absent or diminished femoral pulses.
- Pain upon palpation of the legs.
- Gastrocnemius muscle often becomes firm several hours after embolization.
- Cyanotic or pale nail beds and foot pads.
- Tachypnea/dyspnea and hypothermia are common in cats.
- Since commonly associated with heart disease in cats, a cardiac murmur, arrhythmias, or gallop sound may be present.

CAUSES

- Cardiomyopathy (all types)
- Hyperthyroidism
- Neoplasia
- Sepsis (dogs)
- Hyperadrenocorticism (dogs)
- Protein-losing nephropathy (dogs)

RISK FACTORS

- In the cat, cardiomyopathy is a risk factor. Cardiomyopathic cats with a markedly enlarged left atrium, spontaneous echocardiographic contrast (smoke), or an intracardiac thrombus observed on an echocardiogram are at a higher risk for development of ATE.
- In the dog, hypercoagulable conditions, such as neoplasia, sepsis, endocarditis, protein losing nephropathies, or hyperadrenocorticism are risk factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Hind limb paresis secondary to other causes such as spinal neoplasia, trauma, myelitis, fibrocartilaginous infarction, or intervertebral disc protrusion. These conditions resulting in spinal cord injury present with signs of upper motor neuron disease, whereas ATE patients present with signs of lower motor neuron disease.

CBC/BIOCHEMISTRY/URINALYSIS

- High creatine kinase as a result of muscle injury.
- High aspartate aminotransferase and alanine aminotransferase as a result of muscle and liver injury.
- Hyperglycemia secondary to stress.
- Mild increases in blood urea nitrogen and creatinine due to low cardiac output and possible renal emboli.
- Electrolyte derangements, due to low output and muscle damage, such as hypocalcemia, hyponatremia, hyperphosphatemia and hyperkalemia are not uncommon.
- CBC and urinalysis changes are non-specific.

OTHER LABORATORY TESTS

Routinely available coagulation profiles typically do not reveal significant abnormalities because the hypercoagulability results from hyperaggregable platelets. In the dog, thromboelastography may suggest a hypercoagulable state with a clot strength (increased maximum amplitude) or shortened clotting time (decreased R).

IMAGING

Radiographic Findings

- Cardiomegaly is common in cats.
- Pulmonary edema and/or pleural effusion in approximately 50% of cats.
- Rarely, a mass is seen in the lungs, suggestive of neoplasia.

Echocardiographic Findings

- In cats, changes consistent with cardiomyopathy. Hypertrophic cardiomyopathy is most common, followed by restrictive or unclassified cardiomyopathy and then dilated cardiomyopathy.
- Most cases (> 50%) have severe left atrial enlargement (i.e., left atrial to aortic ratio of ≥ 2).
- A left atrial thrombus or spontaneous echocardiographic contrast (smoke) may be seen.

Abdominal Ultrasonographic Findings

- May be able to identify the thrombus in the caudal aorta.
- Typically not necessary to reach a diagnosis in the cat but often needed to reach a diagnosis in the dog.

(CONTINUED)

AORTIC THROMBOEMBOLISM

A

Advanced Diagnostic Imaging

- Nonselective or CT angiography should identify a negative filling defect in the caudal aorta representing the thrombus.
- Typically not necessary to reach a diagnosis.

DIAGNOSTIC PROCEDURES**Electrocardiography**

- Sinus rhythm and sinus tachycardia most common. Less common rhythms include atrial fibrillation, ventricular arrhythmias, supraventricular arrhythmias, and sinus bradycardia.
- Left ventricular enlargement pattern and left ventricular conduction disturbances (left anterior fascicular block) are common.

PATHOLOGIC FINDINGS

- Thrombus typically is identified at the caudal aortic trifurcation.
- Occasionally, a left atrial thrombus is seen.
- Emboli of the kidneys, gastrointestinal tract, cerebrum, and other organs also may be seen.

**TREATMENT****APPROPRIATE HEALTH CARE**

Initially, cats with ATE should be treated as inpatients because many have concurrent congestive heart failure and require injectable drugs, in addition to being in considerable pain and distress.

NURSING CARE

- Fluid therapy is cautiously used as most cats have advanced myocardial disease. If in congestive heart failure, IV fluid therapy may not be necessary.
- Supplemental oxygen therapy or thoracocentesis may be beneficial if in congestive heart failure.
- Initially, minimally handle the affected legs. However, as reperfusion occurs, physical therapy (passive extension and flexion of the legs) may speed full recovery.
- Do not perform venipuncture on the affected legs.
- These animals may have difficulty posturing to urinate and may need to have their bladders expressed to prevent overdistention or urine scald.

ACTIVITY

Restrict activity and stress

DIET

Initially, most cats are anorexic. Tempt these cats with any type of diet to keep them eating and avoid hepatic lipidosis.

CLIENT EDUCATION

- Short- and long-term prognosis is poor in both dogs and cats.
- Most cats will re-embolize. Most cats that survive an initial episode will be on some type of anticoagulant therapy that may require

frequent re-evaluations and an indoor lifestyle.

- Most cats that survive an initial episode will recover complete function to the legs; however, if ischemia was severe and prolonged, sloughing of parts of the distal extremities or persistent neurologic deficits may result. In one study, approximately 15% of cats had permanent neuromuscular abnormalities after surviving the initial embolic event.
- Based on 3 small retrospective studies in dogs, the prognosis is generally poor but may be better in dogs presenting with chronic (vs. acute) lameness and dogs treated appropriately with warfarin.

SURGICAL CONSIDERATIONS

- Surgical embolectomy typically is not recommended because these patients are high risk for surgery because of severe heart disease.
- Rheolytic thrombectomy has been used with limited success in a small number of cats with ATE.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Thrombolytic therapy (e.g., tissue plasminogen activator [TPA]) is used extensively in humans and infrequently in cats and dogs. These drugs are expensive and carry a significant risk for bleeding complications; to date, they have not demonstrated improved treatment efficacy and thus are rarely used in general practice. TPA is theorized to be more beneficial if given early, ideally, within the first 6 hours of the event.
- Clopidogrel is an antiplatelet aggregation drug. One may choose to give a loading dose of clopidogrel for treatment of an acute embolic event. The loading dose in the cat is 75 mg/cat PO once and then maintenance dose starting 24h later is 18.75 mg/cat (one-fourth of 75 mg tablet) PO q24h. The loading dose in the dog is approximately 10 mg/kg once and then a maintenance dose of 1 mg/kg q24h. When compared to aspirin, clopidogrel was superior in preventing re-embolization, resulting improved survival times in cats that had survived an ATE.
- Unfractionated heparin is the preferred anticoagulant drug in general practice for initial management of feline ATE. Heparin has no effect on the established clot; however, it prevents further activation of the coagulation cascade. In either a cat or dog, give an initial dose of 100–200 units/kg IV and then 200–300 units/kg SC q8h. Alternatively, heparin can be administered as a CRI, if there is concern about adequate bioavailability via the SC route, at a dose of 25–35 units/kg/h. Titrate the dose to prolong the activated partial thromboplastin time approximately two-fold.
- Aspirin is theoretically beneficial during and after an episode of thromboembolism because of its antiplatelet effects. The dose in cats is an 81 mg tablet PO q48–72h. Vomiting and diarrhea are not uncommon. Some specialists advocate a mini dose of 5 mg/cat q72h. Antithrombotic dose recommendations for dogs range from 0.5 to 2 mg/kg q24h. Always give aspirin with food.
- Buprenorphine in the cat is useful and widely available drug used for analgesia and sedation at a dose of 5–20 µg/kg IV, SC, or in cheek pouch q6–8h. For stronger analgesia, use fentanyl or hydromorphone.
- Acepromazine may be cautiously used for its sedative and vasodilatory properties at a dose of 0.01–0.02 mg SC q8–12h.
- Warfarin, a vitamin K antagonist, is the anticoagulant most widely used in humans and has been proposed for prevention of re-embolization in cats surviving an initial episode. The initial dose is 0.25–0.5 mg/cat PO q24h or 0.05–0.2 mg/kg PO q 24h in the dog. Overlap with heparin therapy for 3 days. The dose is then adjusted to prolong the prothrombin time approximately two times its baseline value or to attain an international normalized ratio of 2 to 3. Long-term management with warfarin can be challenging because of frequent monitoring and dose adjustments in addition to bleeding complications. In one study, dogs treated appropriately with warfarin had a better clinical outcome.
- Low molecular weight heparin has recently been proposed for the long-term prevention of feline ATE. LMWH has a more predictable relationship between dose and response than warfarin and does not need monitoring or dose adjustments. It also has a lower risk of bleeding complication. The main disadvantage of LMWH is high drug cost and the injectable route of administration. The two LMWHs that have been used in feline ATE are: dalteparin (100–150 units/kg SC q8–24h) and enoxaparin (1 mg/kg SC q12–24h). Best dose unknown. LMWH usually started q24h due to cost. Some studies suggest q6h dosing necessary for stable blood levels, but may increase bleeding risk.

the activated partial thromboplastin time approximately two-fold.

- Aspirin is theoretically beneficial during and after an episode of thromboembolism because of its antiplatelet effects. The dose in cats is an 81 mg tablet PO q48–72h. Vomiting and diarrhea are not uncommon. Some specialists advocate a mini dose of 5 mg/cat q72h. Antithrombotic dose recommendations for dogs range from 0.5 to 2 mg/kg q24h. Always give aspirin with food.

- Buprenorphine in the cat is useful and widely available drug used for analgesia and sedation at a dose of 5–20 µg/kg IV, SC, or in cheek pouch q6–8h. For stronger analgesia, use fentanyl or hydromorphone.

- Acepromazine may be cautiously used for its sedative and vasodilatory properties at a dose of 0.01–0.02 mg SC q8–12h.

- Warfarin, a vitamin K antagonist, is the anticoagulant most widely used in humans and has been proposed for prevention of re-embolization in cats surviving an initial episode. The initial dose is 0.25–0.5 mg/cat PO q24h or 0.05–0.2 mg/kg PO q 24h in the dog. Overlap with heparin therapy for 3 days. The dose is then adjusted to prolong the prothrombin time approximately two times its baseline value or to attain an international normalized ratio of 2 to 3. Long-term management with warfarin can be challenging because of frequent monitoring and dose adjustments in addition to bleeding complications. In one study, dogs treated appropriately with warfarin had a better clinical outcome.

- Low molecular weight heparin has recently been proposed for the long-term prevention of feline ATE. LMWH has a more predictable relationship between dose and response than warfarin and does not need monitoring or dose adjustments. It also has a lower risk of bleeding complication. The main disadvantage of LMWH is high drug cost and the injectable route of administration. The two LMWHs that have been used in feline ATE are: dalteparin (100–150 units/kg SC q8–24h) and enoxaparin (1 mg/kg SC q12–24h). Best dose unknown. LMWH usually started q24h due to cost. Some studies suggest q6h dosing necessary for stable blood levels, but may increase bleeding risk.

CONTRAINdications

N/A

PRECAUTIONS

- Anticoagulant therapy with heparin, warfarin, or the thrombolytic drugs may cause bleeding complications.
- Avoid a nonselective beta-blocker such as propranolol as it may enhance peripheral vasoconstriction.

AORTIC THROMBOEMBOLISM

(CONTINUED)

POSSIBLE INTERACTIONS

Warfarin may interact with other drugs, which may enhance its anticoagulant effects.

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

- ECG monitoring while the cat is in hospital is helpful to detect reperfusion injury and hyperkalemia related ECG changes.
- Monitoring electrolytes and renal parameters periodically may be helpful to optimize management of the cardiac disease.
- Examine the legs frequently to assess clinical response. Initially, APTT should be performed once daily to titrate the heparin dose.
- If warfarin is used, PT or INR is measured approximately 3 days after initiation of therapy and then weekly until the desired anticoagulant effect is reached. Thereafter, measure three to four times yearly or when drug regimen is altered.

PREVENTION/AVOIDANCE

Because of the high rate of re-embolization, prevention with either clopidogrel, aspirin, warfarin, or LMWH is strongly recommended.

POSSIBLE COMPLICATIONS

- Bleeding with the anticoagulant therapy.
- Permanent neurologic deficits or muscular abnormalities in the hind limbs may arise with prolonged ischemia.
- Recurrent congestive heart failure or sudden death.
- Reperfusion injury and death usually associated with hyperkalemic arrhythmias.

EXPECTED COURSE AND PROGNOSIS

- Expected course is days to weeks for full recovery of function to the legs.
- Prognosis, both short term and long term, is poor in cats.

In two large studies, ~ 60% of cats were euthanized or died during the initial thromboembolic episode. Long-term prognosis varies between 2 months to several years; however, the average is a few months with treatment. Predictors of poorer prognosis include hypothermia (< 99°F) and congestive heart failure. One study demonstrated a median survival time of 77 days in cats with congestive heart failure and 223 days in cats without congestive heart failure. Predictors of better prognosis include normothermia, single leg affected, and presence of motor function on initial exam.

- In dogs, the disease is rare and prognosis in general is also poor. One study suggested a better prognosis if the dog had chronic clinical signs and if treated with warfarin.
- Recurrence of ATE is common.

Consulting Editors Larry P. Tilley and Francis W.K. Smith, Jr.

Client Education Handout available online

BASICS

OVERVIEW

- Tumors of endocrine cells that are capable of amine precursor uptake and decarboxylation and secretion of peptide hormones; the tumors are named after the hormone they secrete.
- APUD cells are generally found in the gastrointestinal tract and CNS.
- Gastrin- and pancreatic polypeptide-secreting tumors are discussed here; insulinoma and glucagonoma are discussed separately.
- Hypergastrinemia from gastrin-secreting tumors causes gastritis and duodenal hyperacidity, which can cause gastric ulceration, esophageal dysfunction from chronic reflux, and intestinal villous atrophy.
- High concentration of pancreatic polypeptide also causes gastric hyperacidity and its consequences.

SIGNALMENT

- Gastrinoma—rare in dogs and cats; age range 3–12 years, mean 7.5 years (dogs).
- Pancreatic polypeptide—extremely rare in dogs.

SIGNS

- Vomiting
- Weight loss
- Anorexia
- Diarrhea
- Lethargy, depression
- Polydipsia
- Melena
- Abdominal pain
- Hematemesis
- Hematochezia
- Fever

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other conditions associated with hypergastrinemia, gastric hyperacidity, and gastrointestinal ulceration
- Uremia
- Hepatic failure
- Drug-induced ulceration (e.g., NSAIDs or steroids)
- Inflammatory gastritis
- Stress-induced ulceration
- Mast cell disease

CBC/BIOCHEMISTRY/URINALYSIS

- Normal or reflect the chronic effects of general disease
- Iron-deficiency anemia secondary to gastrointestinal bleeding

- Increased BUN secondary to gastrointestinal bleeding
- Hypoproteinemia
- Electrolyte abnormalities with chronic vomiting

OTHER LABORATORY TESTS

- Serum gastrin concentration normal or high-normal in patients with gastrinoma. Treatment with H₂ antagonists or proton pump inhibitors increases serum concentrations of gastrin and could lead to false-positive diagnosis of gastrinoma, but withdrawal of these drugs results in return of gastrin concentrations to baseline in dogs without gastrinoma.
- Provocative test of gastrin secretion—increased gastrin concentration after intravenous calcium gluconate or secretin administration suggests gastrinoma; see Appendix II for protocol and interpretation.

IMAGING

Abdominal ultrasound sometimes demonstrates a pancreatic mass but is usually normal.

DIAGNOSTIC PROCEDURES

- Endoscopy with gastric and duodenal biopsy.
- Aspirate any detectable masses because of suspicion of mast cell disease.
- If no detectable masses exist, examine a buffy coat smear for mast cells.

PATHOLOGIC FINDINGS

- Endoscopic biopsy reveals gastrointestinal ulceration.
- Histopathologic examination of pancreatic tumors reveals findings consistent with islet cell tumor but not specific for hormone type.
- Immunocytochemical staining can aid in the specific diagnosis.
- Histopathologic examination also can reveal metastasis to liver and regional lymph nodes.

TREATMENT

- Tell owner that most APUDomas are malignant and have metastasized by the time of diagnosis and that long-term control is often difficult.
- Aggressive medical management can sometimes palliate signs for months to years.
- Surgical exploration and excisional biopsy of a pancreatic mass are important both diagnostically and therapeutically.
- Medical management is useful for gastric hyperacidity.

MEDICATIONS

DRUG(S)

- Histamine H₂-receptor antagonists—cimetidine, ranitidine, and famotidine; decrease acid secretion by gastric parietal cells.

- Omeprazole—a proton pump inhibitor; the most potent inhibitor of gastric acid secretion available; highly effective and expensive.
- Sucralfate—adheres to ulcerated gastric mucosa and protects it from acid; promotes healing by binding pepsin and bile acids and stimulating local prostaglandins.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Because sucralfate may be less effective in an alkaline environment, and may reduce the absorption of other drugs, it should be given 1–2 hours prior to antacid drugs.

FOLLOW-UP

PATIENT MONITORING

- Physical examination and clinical signs are the most useful measures of treatment effectiveness and disease progression.
- Gastroscopy can monitor progression of gastritis but is not necessary.
- Abdominal radiography or ultrasound may detect development of abdominal masses.

EXPECTED COURSE AND PROGNOSIS

- Difficult to predict.
- Patients with gastrinoma have been controlled on medical management for months to years.
- No cure available.

MISCELLANEOUS

SEE ALSO

Gastrroduodenal Ulceration/Erosion

ABBREVIATIONS

- APUD = amine precursor uptake and decarboxylation
- CNS = central nervous system
- NSAID = nonsteroidal anti-inflammatory drug

ARTERIOVENOUS FISTULA AND ARTERIOVENOUS MALFORMATION

BASICS

OVERVIEW

Abnormal, low-resistance connections between an artery and vein which bypass a capillary bed; arteriovenous malformations (AVM) are typically congenital and involve a vascular nidus, or complex of communicating vessels, while arteriovenous fistulae (AVF) are often acquired direct connections. Large AVMs and AVFs allow a significant fraction of the total cardiac output to bypass the capillary bed. The resulting increase in cardiac output may lead to circulatory volume overload and congestive heart failure (CHF). The anatomic location of AVMs is variable, most often reported in the liver of dogs. The location of AVFs is also variable, occurring frequently in the limbs or at the site of previous surgery/trauma.

SIGNALMENT

- Dog and cat (rare in both).
- No specific age, breed, or sex predilections known, though AVMs are typically seen in younger animals.

SIGNS

Historical Findings

- Animals with AVF often have a history of trauma to the affected area.
- Owner may notice a warm, non-painful swelling at the site.
- Other findings depend on the lesion location (e.g., ascites with hepatic AVM).
- The shunt may cause local organ dysfunction.

Physical Examination Findings

- Vary and depend on location of the AVM/AVF.
- Signs of CHF (e.g., coughing, dyspnea, tachypnea, exercise intolerance) may develop in animals with long-standing disease and high blood flow.
- Bounding pulses may be present because of high ejection volume and rapid runoff through the AVM/AVF.
- Continuous murmur (bruit) at the site caused by turbulent blood flow through the lesion.
- Cautious compression of the artery proximal to the lesion abolishes the bruit. When blood flow is high, this compression may also elicit an immediate reflex decrease in heart rate (Branham's sign).
- Edema, ischemia, and congestion of organs and tissues caused by high venous pressure in the proximity of the lesion.
- If the lesion is on a limb, pitting edema, lameness, ulceration, scabbing, and gangrene may result.
- Lesions near vital organs may cause signs associated with organ failure such as ascites (liver), seizures (brain), paresis (spinal cord), and dyspnea (lung).

CAUSES & RISK FACTORS

- AVMs are rare; frequently a congenital lesion.
- Acquired AVFs typically result from local damage to vasculature secondary to trauma, surgery, venipuncture, perivascular injection, or tumor.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The lesion may look like a mass if peripherally located (limb, ear).
- Other differentials include an aneurysm or false aneurysm.
- Atypical clinical findings, depending on location, may suggest other disease processes; AVF or AVM may be a late diagnostic consideration.

CBC/BIOCHEMISTRY/URINALYSIS

May reflect damage to systems in the vicinity of the lesion, i.e., biochemical abnormalities suggesting hepatic, renal, or other organ dysfunction are possible.

OTHER LABORATORY TESTS

N/A

IMAGING

Thoracic Radiographic Findings

Cardiac enlargement and pulmonary overcirculation in some animals with hemodynamically significant lesions.

Ultrasonographic Findings

- AVM and AVF appear as cavernous, vascular structures.
- Doppler ultrasound may demonstrate high-velocity, turbulent flow within the lesion.

Cross-sectional Imaging

Computed tomography or magnetic resonance angiography can aid in the diagnosis, particularly when imaged with contrast injection to highlight the vascular anatomy.

Angiography

Selective angiography defines the lesion and may be necessary for definitive diagnosis. This is performed at the time of intervention, if transcatheter therapy is pursued. Placement of the catheter close to the lesion and rapid injection is necessary; high-volume blood flow dilutes the contrast medium quickly.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Surgery can be difficult and labor-intensive and may require blood transfusion, though is the traditional treatment for clinically-significant lesions.
- Transcatheter therapies with coils, devices, or glue represent

newer treatment options. Coils or devices are often sufficient for treatment of AVF; AVMs typically require glue embolization, as closure of the nidus is required for complete cure. Potential advantages include less invasive treatment and intravascular access to remote lesions.

- AVMs and AVFs may recur. In some animals, surgical removal of the affected limb or organ (e.g., amputation, liver lobectomy) may be necessary.

MEDICATIONS

DRUG(S)

- Concurrent medical treatment depends on the site of the lesion and secondary clinical features.
- Medical treatment for CHF or other organ dysfunction may be required before surgery.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Avoid excessive fluid administration; animals with these lesions are often volume overloaded.

FOLLOW-UP

Postoperative reevaluation is needed to determine whether the AVM or AVF has recurred and if organ dysfunction has normalized.

ARTERIOVENOUS MALFORMATION OF THE LIVER

BASIC

OVERVIEW

- Intrahepatic arteriovenous (AV) malformations (also referred to as AV fistulae) are communications between proper hepatic arteries and intrahepatic portal veins; this anatomic union results in hepatofugal (away from the liver) splanchnic circulation.
- Blood flows directly from a hepatic artery into portal vasculature retrograde into the vena cava through multiple acquired portosystemic shunts (APSS).
- Associated with ascites.
- Uncommon, usually congenital, but may be acquired (surgical injury, trauma, neoplasia).

SIGNALMENT

- Dogs, less common in cats
- Age-related presentation (congenital): < 2 years
- No sex or breed predilection

SIGNS

General Comments

Vague or acute illness; present for signs caused by portal hypertension and APSS: ascites and hepatic encephalopathy (HE).

Historical Findings

- Dogs may have a normal transition to growth foods, unlike PSVA that demonstrate HE.
- May have an acute onset of ascites or HE.
- Vague signs include: lethargy, anorexia, vomiting, diarrhea, weight loss, polydipsia, dementia, abdominal distention, and uroliths causing obstructive uropathy.

Physical Examination Findings

- Lethargic, poor body condition, ascites; enlarged liver lobe containing the AV malformation; rarely palpated on initial examination.
- Rarely, bruit auscultated over AV malformation.

CAUSES & RISK FACTORS

- Usually congenital vascular malformations (single or multiple vessels) reflecting failed differentiation of common embryologic anlage.
- Rare: secondary to abdominal trauma, inflammation, neoplasia, surgical interventions, or diagnostic procedures (e.g., liver biopsy).
- Portal hypertension—reflects arterialization of valveless portal system—establishing APSS.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- CNS signs—*infectious disorders* (e.g., distemper); *toxicity* (e.g., lead); hydrocephalus; idiopathic epilepsy; metabolic disorders (e.g., hypoglycemia, hypokalemia or hyperkalemia); HE (e.g., acquired liver disease or PSVA).
- Abdominal effusion:—pure transudate (ascites; protein-losing nephropathy, protein-losing enteropathy, liver disease); modified transudate (congenital cardiac malformations, right-sided heart failure, pericardial tamponade, supradiaphragmatic vena caval obstruction, neoplasia, portal vein thrombosis); hemorrhage.
- Portal hypertension—chronic hepatic disease, ductal plate malformations/congenital hepatic fibrosis, non-cirrhotic or idiopathic portal hypertension, cirrhosis, portal thrombi.

CBC/BIOCHEMISTRY/URINALYSIS

- Erythrocyte microcytosis (APSS), target cells
- Hypoalbuminemia with normal or low serum globulins; ALP and ALT activity normal or moderately increased; variable low BUN and hypcholesterolemia, and anicteric
- Hyposthenuria or isosthenuria
- Ammonium biurate crystalluria

OTHER LABORATORY TESTS

- Coagulation tests—variable, may be normal; low protein C activity reflects APSS.
- Total serum bile acids—preprandial values variable, postprandial values increased; classic shunting pattern.
- Plasma ammonia—usually increased, inferred by ammonium biurate crystalluria.
- Peritoneal fluid—pure transudate (total protein < 2.5 g/dL) or modified transudate.

IMAGING

Radiography

- Abdominal effusion
- Microhepatia or normal sized liver due to enlarged lobe with AV malformation
- Renomegaly
- Normal thorax

Abdominal Ultrasonography

- Abdominal effusion
- Liver lobe with AV malformation—large compared to most other liver lobes that are atrophied due to portal hypoperfusion.
- Tortuous anechoic tubules represent AV structure with unidirectional pulsating or turbulent flow on color-flow Doppler.
- Hepatic artery and/or portal vein branches may appear tortuous.

- Hepatofugal portal flow (away from the liver)—through APSS.
- Renomegaly.
- Urolithiasis: urinary bladder or renal pelvis.
- Rule out portal thrombosis (luminal filling defect, abrupt blood flow termination).

Radiographic Contrast Angiography

- Not indicated in most cases.
- Venous portography—only confirms APSS.
- Hepatic arteriography—required to confirm AV communication (celiac trunk or anterior mesenteric artery contrast injection).

Multi-Sector CT

Non-invasive contrast imaging of hepatic vasculature; arterial and venous phases; 3-dimensional reconstruction illustrates AV malformation, large liver lobe, atrophied liver.

Echocardiography

Rule out right-sided heart disease, pericardial disease, and vena caval occlusion.

DIAGNOSTIC PROCEDURES

- Multi-sector CT and exploratory laparotomy.
- Liver biopsy—collect samples from *affected* and *unaffected* liver lobes; “normal” liver often demonstrates severe vascular arterialization (more severe than associated with PSVA).

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—Treat HE and ascites prior to surgical approach or percutaneous selective acrylamide embolization.

NURSING CARE

- Diet—restrict nitrogen intake to ameliorate HE and hyperammonemia; restrict sodium to attenuate ascites formation.
- HE—resolve endoparasitism, electrolyte and hydration disturbances, treat infections, initiate treatments to alter enteric uptake and formation of HE toxins (see Hepatic Encephalopathy).
- Ascites—mobilize by restricting activity and sodium intake and instituting dual diuretic therapy (furosemide and spironolactone); reserve therapeutic abdominozentesis for tense ascites impairing ventilation, nutrition, sleep, or recumbent posture; (see Portal Hypertension, Portosystemic Shunting, Acquired, and below).

SURGICAL CONSIDERATIONS

- Resection of liver lobe containing AV malformation is complicated by coexistence of additional hepatic vascular malformations; clinical cure possible but unlikely.

- Percutaneous selective acrylamide vascular embolization; complicated by risk of thromboembolism of additional vasculature; temporary improvement; but treatment may be curative.
- Multiple microscopic vascular malformations continue portal hypertension and APSS.
- Do not ligate APSS nor band the vena cava.

MEDICATIONS

DRUG(S)

Hepatic Encephalopathy

See Hepatic Encephalopathy

Ascites

- Restrict sodium intake.
- Furosemide (0.5–2 mg/kg PO IM or IV q12–24h)—combine with spironolactone.
- Spironolactone (0.5–2 mg/kg PO q12h)—double initial dose as loading dose once.
- Chronic diuretic therapy—individualized to response, 4- to 7-day assessment intervals used to titrate dose to response, avoiding hydration, electrolyte, and HE complications.
- Diuretic-resistant ascites—may require therapeutic abdominocentesis; to initiate diuresis.
- Vasopressin V₂ receptor antagonists newly available may control ascites accumulation. (See Portosystemic Shunting, Acquired.)

Bleeding Tendencies

See Coagulopathy of Liver Disease

Gastrointestinal Hemorrhage

- *Histamine type-2 receptor antagonists* (famotidine 0.5–2 mg/kg PO, IV, or SC q12–24h); or *HCl pump inhibitors* (omeprazole 1.0 mg/kg/24h PO or pantoprazole 1 mg/kg/24h IV [omeprazole may induce p450 cytochrome-associated drug interactions and may have a 24–48h delay onset of action]; some clinicians recommend chronic treatment to minimize gastrointestinal bleeding and ulceration that may be chronic problems).
- *Gastroprotectant*—sucralfate: 0.25–1.0 g/10 kg PO q8–12h; titrate to effect, beware of drug interactions as sucralfate may bind other medications, reducing bioavailability.
- *Eliminate endoparasitism*.

CONTRAINDICATIONS

Avoid drugs dependent on hepatic biotransformation or first pass hepatic extraction (reduced by APSS) or that react with GABA-benzodiazepine receptors because of propensity for HE.

FOLLOW-UP

PATIENT MONITORING

Biochemistry—initially monthly until stabilized after surgery or AV malformation embolization, thereafter quarterly; monitor for hypoalbuminemia, infection, optimization of HE management and control of ammonium biurate crystalluria.

EXPECTED COURSE AND PROGNOSIS

- Prognosis fair if patient survives surgical resection of AV malformation or embolization.
- Most patients require indefinite nutritional and medical management (HE, ascites) because of coexisting microscopic vascular malformations across the liver; APSS persists requiring continued management of HE.

MISCELLANEOUS

- HE = hepatic encephalopathy
- PSVA = portosystemic vascular anomalies

Author Sharon A. Center

Consulting Editor Sharon A. Center

BASICS

DEFINITION

Osteoarthritis or degenerative joint disease is the progressive and permanent deterioration of the articular cartilage of diarthrodial (synovial) joints due to primary (idiopathic) and secondary causes.

PATOPHYSIOLOGY

- DJD is initiated by mechanical stress—traumatic injury, instability, abnormal conformation, abnormal activity, etc.
- Metalloproteinases, serine proteases, and cysteine protease enzymes are released from damaged chondrocytes, causing collagen degradation and loss of collagen cross-linking in cartilage.
- Collagen synthesis is altered, resulting in decreased collagen/proteoglycan interaction and reduced hydrophylic matrix properties.
- Cartilage matrix is further compromised by increased breakdown of proteoglycans and manufacture of poorer-quality proteoglycans.
- Nitric oxide is released, which mediates cartilage breakdown and supports chronic inflammation.
- Chondrocyte apoptosis is facilitated by cyclooxygenase-2 enzymes.
- Synovial membrane inflammation results in decreased viscosity of the synovial fluid, reducing lubrication.
- Poorer-quality synovial fluid reduces oxygen and nutrient supply to the chondrocytes.
- Subchondral bone becomes sclerotic, worsening loading qualities of the bone and overlying cartilage.
- Pain of DJD results from stimulation of pain receptors in the tendons, ligament, subchondral bone, and joint capsule.
- The result of these processes is progressive cartilage degradation ranging from fibrillation to deep fissuring of cartilage.
- Full-thickness cartilage loss can eventually occur.
- Periarticular fibrosis occurs to reduce joint motion (and pain), leading to poorer vascularity of the synovial membrane.
- Osteophytes and enthesiophytes develop around and within the joint to increase the load-bearing surface area.
- These changes reduce functionality and may eventually lead to ankylosis.

SYSTEMS AFFECTED

Musculoskeletal—diarthrodial joints

GENETICS

- Primary DJD is rare.
- Dogs—causes of secondary DJD are varied, including hip and elbow dysplasias, osteochondrosis dissecans, patellar luxations, congenital shoulder luxation, Legg-Perthes, and cranial cruciate ligament rupture.
- Cats—causes of secondary DJD are patellar luxation, hip dysplasia, and arthropathy.

INCIDENCE/PREVALENCE

- Dog—very common; 20% of dogs older than 1 year have some degree of DJD.

- Cat—90% of cats over 12 years of age had evidence of DJD on radiographs.
- Clinical problems are more prevalent in larger, overweight, and very active animals.
- Primary DJD is rare.

SIGNALMENT

Species

Dog and cat

Mean Age and Range

- Secondary DJD due to congenital disorders (OCD, hip dysplasia) seen in immature animals; some present with DJD signs when older (hip and elbow dysplasia).
- Secondary to trauma—any age.

SIGNS

Historical Findings

- Dogs—decreased activity level, unwilling to perform certain tasks; intermittent lameness or stiff gait that slowly progresses; possible history of joint trauma, OCD, or developmental disorders; may be exacerbated by exercise, long periods of recumbency, and cold weather.
- Cats—overt lameness may not be seen. May have difficulty grooming, jumping onto furniture, or accessing the litter box; increased irritability.

Physical Examination Findings

- Stiff-legged or altered gait (e.g., bunny hopping in hip dysplasia) or non-use of leg.
- Decreased range of motion.
- Crepitus.
- Joint swelling (effusion and/or thickening of the joint capsule).
- Joint pain.
- Joint instability.

CAUSES

- Primary—no known cause.
- Secondary—results from an initiating cause: abnormal wear on normal cartilage (e.g., joint instability, joint incongruity, trauma to cartilage or supporting soft tissues) or normal wear on abnormal cartilage (e.g., osteochondral defects).

RISK FACTORS

- Working, athletic, and obese dogs place more stress on their joints.
- Dogs with disorders that affect collagen or cartilage (Cushing's disease, diabetes mellitus, hypothyroidism, hyperlaxity, prolonged, steroids).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Neoplastic (synovial sarcoma; rarely, chondrosarcoma; osteosarcoma).
- Septic arthritis (caused by bacteria; spirochetes; L forms in cats; *Mycoplasma*; *Rickettsia*; *Ehrlichia*; viruses, such as feline calicivirus; fungi, and protozoa).
- Immune-mediated arthritis (erosive vs. non-erosive).
- Other musculoskeletal conditions that cause

lameness.

- Neurologic conditions causing lameness or decreased activity/weakness.

OTHER LABORATORY TESTS

- Coombs' test, ANA, and rheumatoid factor may help to rule out immune-mediated arthritis.
- Serum titers for *Borrelia*, *Ehrlichia*, and *Rickettsia* to evaluate for infectious arthritis.

IMAGING

- Radiographic changes—include joint capsular distention, osteophytosis, enthesiophytosis, soft-tissue thickening, and narrowed joint spaces; in severely affected patients: subchondral sclerosis, and intra-articular calcified bodies (joint mice).
- Radiographic severity often does not correlate with clinical severity.
- Stress radiography may identify underlying instability and accentuate joint incongruity (e.g., distraction index, passive hip laxity of the coxofemoral joint is predictive of hip DJD).
- Bone nuclear scintigraphy can assist in localizing subtle DJD.

DIAGNOSTIC PROCEDURES

- Arthrocentesis and synovial fluid analysis—cell counts are normal or slightly increased (< 2,000–5,000 cells/mL) predominantly mononuclear (macrophages) and occasional synovial lining cells.
- Bacterial culture of synovial fluid—negative.
- Biopsy of synovial tissue to rule out neoplasia or immune-mediated arthritides (lymphocytic plasmacytic synovitis, SLE).

PATHOLOGIC FINDINGS

- Fibrillation or erosion of articular cartilage.
- Eburnation and sclerosis of subchondral bone.
- Thickening and fibrosis of the joint capsule.
- Synovial fluid can be grossly normal to thin and watery, usually increased volume.
- Synovial villous hypertrophy and hyperplasia.
- Osteophytes and enthesiophytes at joint capsule attachments and adjacent to the joint.
- Neovascularization or pannus in severe cases over joint surfaces.

TREATMENT

APPROPRIATE HEALTH CARE

- Medical—usually tried initially.
- Surgical options—to improve joint geometry or remove bone-on-bone contact areas.

NURSING CARE

- Physical therapy—very beneficial.
- Maintaining or increasing joint motion—passive range of motion exercises, massage, swimming.
- Pain management—cold and heat therapy.
- Muscle tone/strengthening—swimming (aerobic exercise with minimal weight bearing); controlled leash walks up hills or on soft surfaces, such as sand or dry or underwater treadmill.

ARTHRITIS (OSTEOARTHRITIS)

(CONTINUED)

ACTIVITY

Limited to a level that minimizes aggravation of clinical signs.

DIET

- Weight reduction for obese patients—decreases stress placed on arthritic joints.
- Omega n-6 and n-3 fatty acids decrease the production of certain prostaglandins and modulate inflammation.

CLIENT EDUCATION

- Medical therapy is palliative and the condition is likely to progress. • Discuss treatment options, activity level, and diet.

SURGICAL CONSIDERATIONS

• Arthrotomy—used to remove aggravating causes (e.g., fragmented coronoid process, un-united anconeal process, osteochondral flaps). • Arthroscopy—used to diagnose and remove aggravating causes; flushing the joint may be beneficial. • Reconstructive procedures—used to eliminate joint instability and correct anatomic problems (patella luxation, angular deformity). • Joint removal—femoral head and neck ostectomy, temperomandibular joint arthroplasty. • Joint replacement—total hip replacement is widely used, total elbow replacement still experimental. • Joint fusion (arthrodesis)—in selected chronic cases and for joint instability, complete or partial; carpus, hock: generally excellent outcome; shoulder, elbow, stifle; less predictable outcome.

MEDICATIONS

DRUG(S) OF CHOICE

NSAIDs

- Inhibit prostaglandin synthesis through cyclooxygenase enzymes.
- Deracoxib (3–4 mg/kg PO q24h, chewable).
- Carprofen (2.2 mg/kg PO q12h or q24h).
- Meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h: liquid).
- Tepoxalin (load 20 mg/kg, then 10 mg/kg PO q24h).
- Cats—meloxicam (0.1 mg/kg PO q24h: liquid) or robenacoxib (1 mg/kg PO q24h for 3 days).

Chondroprotective/Regenerative Supplements

- Supply PSGAG molecules to repair and regenerate cartilage.
- Host of products, many with little production oversight so effects vary widely.
- Glucosamine and chondroitin sulfate—injectable Adequan, oral Cosequin, oral MSM, mixtures (e.g., Glycoflex II, SynFlex).

- Adequan—clinical study in dogs with hip dysplasiam; 4.4 mg/kg IM every 3–5 days for 8 injections had a positive, temporary effect.
- Cosequin—trials showed positive effects.

CONTRAINDICATIONS

- NSAIDs must not be given with steroids.
- Acetaminophen must not be given to cats.

PRECAUTIONS

- NSAIDs—may cause gastric ulceration.
- COX-2 selective drugs may interfere with liver function. • When switching NSAIDs—wait 3 days for washout before starting new drug.

POSSIBLE INTERACTIONS

Steroids and NSAIDS

ALTERNATIVE DRUG(S)

- Free-radical scavengers. • Glucocorticoids— inhibit inflammatory mediators and cytokines; however, chronic use delays healing and initiates damage to articular cartilage; potential systemic side effects documented; goal is low-dose (dogs, 0.5–2 mg/kg; cats, 2–4 mg/kg) q48h. • Prednisone—initial dose 1–2 mg/kg PO q24h for dogs and 4 mg/kg PO q24h for cats. • Triamcinolone hexacetonide—intra-articular injection of 5 mg in dogs showed a protective and therapeutic effect in one model.

FOLLOW-UP

PATIENT MONITORING

Clinical deterioration—indicates need to change drug selection or dosage; may indicate need for surgical intervention.

PREVENTION/AVOIDANCE

Early identification of predisposing causes and prompt treatment to help reduce progression of secondary conditions, e.g., surgical removal of osteochondral lesions.

EXPECTED COURSE AND PROGNOSIS

- Slow progression of disease likely. • Some form of medical or surgical treatment usually allows a good quality of life.

MISCELLANEOUS

SYNOMYMS

- Degenerative arthritis • Degenerative joint disease • Osteoarthritis • Osteoarthrosis

ABBREVIATIONS

- ANA = antinuclear antibody • COX-2 = cyclooxygenase-2 • DJD = degenerative joint disease • NSAID = nonsteroidal

anti-inflammatory drug • OCD = osteochondrodysplasia • PSGAGs = polysulfated glycosaminoglycans • SLE = systemic lupus erythematosus

BASICS

DEFINITION

Pathogenic microorganisms within the closed space of one or more synovial joints

PATOPHYSIOLOGY

- Usually caused by contamination associated with traumatic injury (e.g., a direct penetrating injury such as bite, gunshot wound, foreign object), a sequela to surgery, arthrocentesis or joint injection, hematogenous spread of microorganisms from a distant septic focus, or less commonly the extension of primary osteomyelitis
- Primary sources of hematogenous infection—urogenital, integumentary (including ears and anal sacs), respiratory, cardiac, and gastrointestinal systems

SYSTEMS AFFECTED

Musculoskeletal—usually affects one joint

GENETICS

N/A

INCIDENCE/PREVALENCE

Relatively uncommon cause of monoarticular arthritis in dogs and cats

GEOGRAPHIC DISTRIBUTION

May be an increased incidence in Lyme disease-endemic areas

SIGNALMENT

Species

- Most common in dogs
- Rare in cats

Breed Predilections

Any. Medium to large breeds—most commonly German shepherds, Dobermanns, and Labrador retrievers.

Mean Age and Range

Any age; usually between 4 and 7 years. Hematogenous: more common in immature animals.

Predominant Sex

Male

SIGNS

General Comments

Always consider the diagnosis in patients with acute, monoarticular lameness associated with soft tissue swelling, heat, and pain.

Historical Findings

- Lameness—acute onset most common, but can present as chronic lameness
- Lethargy
- Anorexia
- May report previous trauma—dog bite, penetrating injury, prior surgery or other invasive procedure of the joint

Physical Examination Findings

- Monoarticular lameness, rarely polyarticular
- Joint pain and swelling—commonly carpus, stifle, hock, shoulder, or cubital joint
- Localized joint heat

- Decreased range of motion
- Local lymphadenopathy
- Fever

CAUSES

- Aerobic bacterial organisms—most common: staphylococci, streptococci, coliforms and *Pasteurella*
- Anaerobic organisms—most common: *Propionibacterium*, *Peptostreptococcus*, *Fusobacterium* and *Bacteroides*
- Spirochete—*Borrelia burgdorferi*
- Mycoplasma*
- Fungal agents—*Blastomyces*, *Cryptococcus*, and *Coccidioides*
- Rickettsial—*Anaplasma*, *Ehrlichia*, *Rickettsia*
- Leishmania*
- Feline calicivirus

RISK FACTORS

- Predisposing factors for hematogenous infection—diabetes mellitus; hypoadrenocorticism (Addison's disease); immunosuppression
- Penetrating trauma to the joint including surgery
- Existing osteoarthritis or other joint damage
- Intra-articular injection, particularly if steroid injected

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Osteoarthritis
- Trauma
- Immune-mediated arthropathy
- Postvaccinal transient polyarthritidis
- Greyhound polyarthritis
- Feline progressive polyarthritis
- Crystal-induced joint disease
- Synovial sarcoma

CBC/BIOCHEMISTRY/URINALYSIS

- Hemogram—inflammatory left shift in some cases
- Other results normal

OTHER LABORATORY TESTS

Serologic testing for specific pathogens

IMAGING

Radiography

- Early disease—may reveal thickened and dense periarticular tissues; may see evidence of synovial effusion. Often difficult to diagnose early disease radiographically.
- Late disease—reveals bone destruction, osteolysis, irregular joint space, discrete erosions, and periarticular osteophytosis.

DIAGNOSTIC PROCEDURES

Synovial Fluid Analysis

- Increased volume
- Turbid fluid
- Decreased viscosity
- Decreased mucin clot reaction
- Make slides immediately; if additional fluid is obtained, place in EDTA tube

- Elevated WBC count—> 80% neutrophils with $> 40,000/\text{mm}^3$ (normal joint fluid < 10% neutrophils and $< 3,000/\text{mm}^3$)
- Neutrophils may show degenerative changes (chromatolysis, vacuolation, nuclear swelling, loss of segmentation)
- Neutrophils with phagocytosed bacteria—definitive diagnosis or bacteria in the synovial fluid

Synovial Fluid Culture

- Positive culture is definitive but not necessary for diagnosis.
- Must be collected aseptically; requires heavy sedation or general anesthesia.
- Place fluid sample in aerobic and anaerobic culturettes and in blood culture medium.
- Use 1:9 dilution of synovial fluid to blood culture media.
- Culturette samples—cultured immediately upon arrival to the laboratory.
- Blood culture medium—re-culturing after 24 hours of incubation increases accuracy by 50% and is the preferred method.
- Mycoplasma*, bacterial L-forms and protozoa require specific culture procedures—contact laboratory prior to sample collection.

Other

- Synovial biopsy—to rule out immune-mediated joint disease; no more effective than incubated blood culture medium for growing bacterial organisms.
- Blood and urine cultures if hematogenous source is suspected.

PATHOLOGIC FINDINGS

- Synovium—thickened; discolored; often very proliferative
- Histology—evidence of hyperplastic synoviocytes
- Increased numbers of neutrophils, macrophages, and fibrinous debris
- Cartilage—loss of proteoglycan, destruction of articular surface, pannus formation

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient—initial stabilization; initiate systemic antibiotic therapy as soon as fluid is obtained for bacterial culture; consider joint drainage/lavage as soon as possible to minimize intra-articular injury.
- Identify and treat source if hematogenous spread is suspected.
- Outpatient—long-term management.

NURSING CARE

Alternating heat and cold packing—beneficial in promoting increased blood flow and decreased swelling.

ACTIVITY

Restricted until resolution of symptoms

DIET

N/A

CLIENT EDUCATION

- Discuss probable cause.
- Warn client about the need for long-term antibiotics and the likelihood of residual degenerative joint disease.

SURGICAL CONSIDERATIONS

- Acute disease with minimal radiographic changes—joint drainage and lavage via needle arthrocentesis, arthroscopic lavage or arthrotomy. An irrigation catheter (ingress/egress) can be placed in larger joints.
- Chronic disease—may require open arthrotomy with debridement of the synovium and copious lavage; if appropriate, an irrigation catheter (ingress/egress) may be placed to lavage the joint postoperatively.
- Lavage—use warmed physiologic saline or lactated Ringer's solution (2–4 mL/kg q8h) until effluent is clear. Do not add povidone/iodine or chlorhexidine to lavage fluid.
- Effluent fluid—cytologically monitored daily for existence and character of bacteria and neutrophils.
- Removal of catheters—when effluent fluid has no bacteria and the neutrophils are cytologically healthy.
- Arthroscopy allows for visual assessment of articular cartilage, lavage and biopsy, and is a less invasive method of thorough joint lavage than arthrotomy.
- Recent reports suggest there may be no difference between combined medical and surgical management and medical management alone.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Pending culture susceptibility data—bactericidal antibiotics, such as first-generation cephalosporin or amoxicillin-clavulanic acid, preferred.
- Choice of antimicrobial drugs—primarily depends on in vitro determination of susceptibility of microorganisms; toxicity, frequency, route of administration and expense also considered; most penetrate the synovium well; need to be given for a minimum of 4–8 weeks.
- NSAIDs—may help decrease pain and inflammation.

CONTRAINDICATIONS

Avoid fluorinated quinolones in pediatric patients; they induce cartilage lesions experimentally.

PRECAUTIONS

Failure to respond to conventional antibiotic therapy—may indicate anaerobic disease or other unusual cause (fungal, spirochete).

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

- If drainage and irrigation catheters have been placed—may be removed after 4–6 days or after reassessment of synovial fluid cytology.
- Duration of antibiotic therapy—2 weeks following resolution of clinical signs. Total treatment may be 4–8 weeks or longer depending on clinical signs and pathogenic organism.
- Persistent synovial inflammation without viable bacterial organisms (dogs)—may be caused by antigenic bacterial fragments or antigen antibody deposition.
- Systemic corticosteroid therapy (after joint sepsis has been resolved) and aggressive physical therapy—may be needed to maximize normal joint dynamics.

PREVENTION/AVOIDANCE

If clinical signs recur, early (within 24–48 hours) treatment provides the greatest benefit.

POSSIBLE COMPLICATIONS

- Chronic disease—severe degenerative joint disease
- Recurrence of infection
- Limited joint range of motion
- Generalized sepsis
- Osteomyelitis

EXPECTED COURSE AND PROGNOSIS

- Acutely diagnosed disease (within 24–48 hours) responds well to antibiotic therapy.
- Delayed diagnosis or resistant or highly virulent organisms—guarded to poor prognosis.

BASICS

DEFINITION

The escape of fluid, either transudate or exudate, into the abdominal cavity between the parietal and visceral peritoneum.

PATHOPHYSIOLOGY

- Ascites can be caused by the following:
 - CHF and associated interference in venous return
 - Depletion of plasma proteins associated with inappropriate loss of protein from renal or gastrointestinal disease—protein-losing nephropathy or enteropathy, respectively
 - Obstruction of the vena cava or portal vein, or lymphatic drainage due to neoplastic occlusion
 - Overt neoplastic effusion
 - Peritonitis—infective or inflammatory
 - Electrolyte imbalance, especially hypernatremia
 - Liver cirrhosis.

SYSTEMS AFFECTED

- Cardiovascular
- Gastrointestinal
- Hemic/Lymph/Immune
- Renal/Urologic

SIGNALMENT

- Dogs and cats
- No species or breed predisposition

SIGNS

- Episodic weakness
- Lethargy
- Abdominal fullness
- Abdominal discomfort when palpated
- Dyspnea from abdominal distension or associated pleural effusion
- Anorexia
- Vomiting
- Weight gain
- Scrotal or penile edema
- Groaning when lying down

CAUSES

- Nephrotic syndrome
- Cirrhosis of liver
- Right-sided CHF
- Hypoproteinemia
- Ruptured bladder
- Peritonitis
- Abdominal neoplasia
- Abdominal hemorrhage

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiating Abdominal Distension without Effusion

- Organomegaly—hepatomegaly, splenomegaly, renomegaly, and hydrometra.
- Abdominal neoplasia.
- Pregnancy.
- Bladder distension.
- Obesity.
- Gastric dilatation.

Differentiating Diseases

- Transudate—nephrotic syndrome, cirrhosis of liver, right-sided CHF, hypoproteinemia, and ruptured bladder.
- Exudate—peritonitis, abdominal neoplasia, and hemorrhage.

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilic leukocytosis occurs in patients with systemic infection.
- Albumin is low in patients with impaired liver synthesis, gastrointestinal loss, or renal loss.
- Cholesterol is low in patients with impaired liver synthesis.

Liver Enzymes

- Low to normal in patients with impaired liver synthesis.
- High in patients with liver inflammation, hyperadrenocorticism, gallbladder obstruction, and chronic passive congestion.

Total and Direct Bilirubin

- Low to normal in patients with impaired liver synthesis.
- High in patients with biliary obstruction caused by tumor, gallbladder distension, or obstruction.

BUN and Creatinine

- High in patients with renal failure.
- BUN low in patients with impaired liver synthesis or hyperadrenocorticism.

Glucose

Low in patients with impaired liver synthesis.

OTHER LABORATORY TESTS

- To detect hypoproteinemia—protein electrophoresis and immune profile.
- To detect proteinuria—urinary protein:creatinine ratio (normal < 0.5:1).
- To detect liver ascites—analysis of serum ascites albumin gradient.

IMAGING

- Thoracic and abdominal radiography is sometimes helpful.
- Ultrasonography of the liver, spleen, pancreas, kidney, bladder, and abdomen can often determine cause.
- Stages of ascites:
 - Stage I: minimal ascites. Detected by ultrasound only.
 - Stage II: moderate ascites. Abdominal distention visible and/or noted on ballottement.
 - Stage III: significant ascites. Marked abdominal distention. Patient uncomfortable, possibly with labored breathing.

DIAGNOSTIC PROCEDURES

Ascitic Fluid Evaluation

Exfoliative cytologic examination and bacterial culture and antibiotic sensitivity—remove approximately 3–5 mL of abdominal fluid via aseptic technique.

Transudate

- Clear and colorless.
- Protein < 2.5 g/dL.
- Specific gravity < 1.018.
- Cells < 1,000/mm³—neutrophils and mesothelial cells.

Modified Transudate

- Red or pink; may be slightly cloudy.
- Protein 2.5–5 g/dL.
- Specific gravity > 1.018.
- Cells < 5,000/mm³—neutrophils, mesothelial cells, erythrocytes, and lymphocytes.

Exudate (Non-septic)

- Pink or white; cloudy.
- Protein 2.5–5 g/dL.
- Specific gravity > 1.018.
- Cells 5,000–50,000/mm³—neutrophils, mesothelial cells, macrophages, erythrocytes, and lymphocytes.

Exudate (Septic)

- Red, white, or yellow; cloudy.
- Protein > 4.0 g/dL.
- Specific gravity > 1.018.
- Cells 5,000–100,000/mm³—neutrophils, mesothelial cells, macrophages, erythrocytes, lymphocytes, and bacteria.

Hemorrhage

- Red; spun supernatant clear and sediment red.
- Protein > 5.5 g/dL.
- Specific gravity 1.007–1.027.
- Cells consistent with peripheral blood.
- Does not clot.

Chyle

- Pink, straw, or white.
- Protein 2.5–7 g/dL.
- Specific gravity 1.007–> 1.040.
- Cells <10,000/mm³—neutrophils, mesothelial cells, and large population of small lymphocytes.
- Other—fluid in tube separates into cream-like layer when refrigerated; fat droplets stain with Sudan III.

Pseudochyle

- White.
- Protein > 2.5 g/dL.
- Specific gravity 1.007–1.040.
- Cells <10,000/mm³—neutrophils, mesothelial cells, and small lymphocytes.
- Other—fluid in tube does not separate into cream-like layer when refrigerated; does not stain with Sudan III.

Urine

- Clear to pale yellow.
- Protein > 2.5 g/dL.
- Specific gravity 1–> 1.040.
- Cells 5,000–50,000/mm³—neutrophils, erythrocytes, lymphocytes, and macrophages.
- Other—if the urinary bladder ruptured < 12 hours before, urinary glucose and protein could be negative; if bladder ruptured > 12 hours before, urine becomes a dialysis medium with ultrafiltrate of plasma, and urine contains glucose and protein.

Bile

- Slightly cloudy and yellow.
- Protein > 2.5 g/dL.
- Specific gravity > 1.018.
- Cells 5,000–750,000/mm³—neutrophils, erythrocytes, macrophages, and lymphocytes.
- Other—bilirubin confirmed by urine dipstick; non-icteric patient may have gallbladder rupture, biliary tree leakage, or rupture in the proximal bowel.

**TREATMENT**

- Can design treatment on an outpatient basis, with follow-up or inpatient care, depending on physical condition and underlying cause.
- If patients are markedly uncomfortable when lying down or become more dyspneic with stress, consider removing enough ascites to reverse these signs.
- Dietary salt restriction may help control transudate fluid accumulation due to CHF, cirrhosis, or hypoproteinemia.
- For exudate ascites control, address the underlying cause; corrective surgery is often indicated, followed by specific therapeutic

management (e.g., patient with splenic tumor: tumor removed, abdominal bleeding controlled, blood transfusion administered).

LARGE-VOLUME PARACENTESIS

- Stage III treatment.
- Pretreat patient with hetastarch (6%) @ 1–2 mL/kg for 2 hours.
- Abdominal tap (paracentesis), until drainage slows.
- Post-treat patient with hetastarch (6%) @ 1–2 mL/kg for 4 hours.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Patients with liver insufficiency or CHF—restrict sodium and give a diuretic combination of hydrochlorothiazide (2–4 mg/kg q12h PO) and spironolactone (1–2 mg/kg q12h PO); if control is inadequate, furosemide (1–2 mg/kg q8h PO) can be substituted for the thiazide with spironolactone continued; must monitor serum potassium concentration to prevent potassium imbalances.
- Patients with hypoproteinemia, nephrotic syndrome, and associated ascitic fluid accumulation—can treat as above with the addition of hetastarch (6% hetastarch in 0.9% NaCl); administer an IV bolus (dogs, 20 mL/kg; cats, 10–15 mL/kg) slowly over ~ 1 hour; hetastarch increases plasma oncotic pressure and pulls fluid into the intravascular space for up to 24–48 hours.
- Systemic antibiotic therapy is dictated by bacterial identification and sensitivity testing in patients with septic exudate ascites.

**FOLLOW-UP****PATIENT MONITORING**

- Varies with the underlying cause.
- Check sodium, potassium, BUN, creatinine, and weight fluctuations periodically if the patient is maintained on a diuretic.

POSSIBLE COMPLICATIONS

Aggressive diuretic administration may cause hypokalemia, which could predispose to metabolic alkalosis and exacerbation of hepatic encephalopathy in patients with underlying liver disease; alkalosis causes a shift from NH₄ to NH₃.

available online**

BASICS

DEFINITION

- Nasal disease caused by *Aspergillus* spp., primarily *A. fumigatus*. • Saprophytic fungus that is ubiquitous in the environment.
- Opportunistic pathogen.

PATOPHYSIOLOGY

- Inhalation of fungus leads to disease in the nasal cavity and frontal sinus with destruction of turbinates, formation of plaque lesions, and overproduction of mucus causing clinical signs of nasal disease.
- Rarely may be associated with underlying foreign body or previous trauma.
- Causes a locally aggressive and invasive disease but does not result in systemic mycosis.
- Confined to nasal cavity and frontal sinus—sinonasal form (most common in dogs).
- Can result in sino-nasal or sino-orbital disease in cats.

SYSTEMS AFFECTED

Respiratory—nasal cavity, sinus, orbit (cats, rare in dogs)

GENETICS

Unknown

INCIDENCE/PREVALENCE

Unknown, but a common diagnosis in dogs with nasal discharge in many locations.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat (less common)

Breed Predilections

- Dogs—dolichocephalic and mesocephalic breeds
- Cats—brachycephalic breeds may be overrepresented

Mean Age and Range

- Dogs—predominantly young to middle-aged
- Cats—no predilection

Predominant Sex

None identified

SIGNS

Historical Findings

- Unilateral or bilateral nasal discharge—typically mucoïd, mucopurulent, or serosanguinous but may be primarily epistaxis.
- Sneezing.
- Typically chronic signs—several months.
- Many patients will have been treated with antibiotics for a possible bacterial infection before presentation with variable response.

Physical Examination Findings

- Unilateral or bilateral nasal discharge.
- Increased nasal airflow on the affected side.
- Depigmentation with ulceration of the nasal planum—~40% of dogs.
- Facial pain.
- Ipsilateral mandibular lymphadenopathy.
- Stertor, exophthalmos, hard palate

ulceration, facial asymmetry, loss of nasal airflow—sino-orbital disease in cats.

CAUSES

- No underlying cause identified, although preexisting foreign body or trauma is occasionally implicated.
- Likely due to inhalation of a large bolus of fungus that is ubiquitous in the environment.
- Species—most commonly *A. fumigatus* in dogs, *A. felis* in cats others—*A. niger*, *A. flavus*.

RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Foreign body
- Oronasal fistula
- Lymphoplasmacytic rhinitis
- Neoplasia
- Nasopharyngeal polyp, nasal tumor, or cryptococcus—cats only

CBC/BIOCHEMISTRY/URINALYSIS

- Often normal
- Possible inflammatory leukogram

OTHER LABORATORY TESTS

Serology

- Detects fungi-specific serum antibodies.
- AGID—commercially available; 98% specificity, 67% sensitivity in dogs; 43% sensitivity in cats. Serial serology does not appear to correlate with clinical status.
- ELISA—88% sensitivity, 97% specificity in dogs, 90% sensitivity in cats.
- Counter-immunoelectrophoresis—85% specificity in dogs.
- Serum galactomannan—unreliable.

Culture

- Tissue fungal culture of affected area; visualized biopsy sample taken from a region of suspected fungal growth showed 100% specificity, 81% sensitivity in dogs.
- Culture of nasal discharge is less specific and insensitive.

IMAGING

Computed Tomography

- Imaging method of choice.
- Cavitated turbinate lysis.
- Thickening of the mucosa along the nasal turbinates.
- Frontal sinus proliferative mass effect.
- Soft tissue mass in the choana or nasopharynx—cats.
- Necessary for evaluation of the cribriform plate before topical antifungal treatment.

Skull Radiography

- Intraoral dorsoventral radiograph of the nasal cavity shows turbinate lysis.
- Rostrocaudal or skyline frontal sinus view may show increased soft tissue density in the frontal sinus.
- Cannot evaluate cribriform plate.

DIAGNOSTIC PROCEDURES

Rhinoscopy

- Flexible rhinoscopy in dogs allows examination of the nasopharynx and possibly

the frontal sinus if the opening of the nasofrontal duct is destroyed by fungal infection.

- Rigid rhinoscopy—examination of the nasal cavity alone; good visualization is possible due to large airspaces caused by turbinate lysis; excessive mucus and bleeding can make full examination difficult.

- Visualization of fungal plaques (white, yellow, black, or light-green) on the mucosa of the nasal cavity and/or frontal sinus confirms fungal infection.
- Sinuscopy—may be required to confirm the diagnosis in dogs that lack nasal plaques.

PATHOLOGIC FINDINGS

- Biopsies obtained of affected area under direct rhinoscopic visualization using cup biopsy instruments.
- Samples immersion-fixed in buffered 10% formalin, routinely processed.
- Evidence supportive of a diagnosis of aspergillosis—identification of septate, branching hyphae and conidia on histopathology. Surrounding inflammation is commonly neutrophilic or lymphoplasmacytic, rarely eosinophilic.
- Blind biopsies in an unaffected area of the nasal cavity can result in a false diagnosis of inflammation.

TREATMENT

APPROPRIATE HEALTH CARE

Overnight hospitalization advised after topical treatment or surgery.

NURSING CARE

Maintain the nares free of nasal discharge.

ACTIVITY

Restriction of activity is not required if no bleeding is documented.

DIET

N/A

CLIENT EDUCATION

- Dogs—inform client that multiple topical treatments are usually necessary to cure the disease; follow-up with rhinoscopy is highly recommended to ensure resolution.
- No established protocols for treatment in cats.

SURGICAL CONSIDERATIONS

Endoscopic Debridement

- Extensive curettage and removal of fungal material from the nose and frontal sinus are essential to allow efficacy of topical medication.

Trehipination of the Frontal Sinus

- Can be required for dogs with frontal sinus involvement.
- Performed using a Jacob's chuck and intramedullary pin.
- Allows direct visualization of the frontal sinus with a rigid rhinoscope and local debridement of fungal plaques.
- Allows for lavage and topical treatment of the area using a red rubber catheter.

ASPERGILLOSIS, NASAL

(CONTINUED)

Surgical Debridement and Exenteration

- Used in some cats with sino-orbital disease.

**MEDICATIONS****DRUG(S) OF CHOICE*****Topical Clotrimazole or Enilconazole Therapy***

- 1-hour infusion into nasal cavity under anesthesia.
- Treatment is usually performed during the same anesthesia as diagnostics.
- Treatment of choice in dogs; reported efficacy 85–89% with multiple treatments.
- Foley catheters are used to occlude the nares and nasopharynx.
- Dose—Clotrimazole: 1 gram in 100 mL of polyethylene glycol 200 (1% solution) evenly divided between two 60 mL syringes slowly infused over 1 hour into each side for large dogs; if trephination is used, divide the amount between the nasal cavity and sinus on the same side; less volume in smaller dogs.
- Enilconazole: 100 mL of 1%, 2%, or 5% solution.
- Dog is placed in dorsal recumbency with head turned to each side every 15 minutes during the infusion.
- Dog is placed in sternal recumbency with head down at the end of the procedure to drain all medication from the nasal cavity.
- Has been used in cats without orbital involvement in combination with oral antifungal therapy with varying success.

Systemic Therapy

- Antifungal triazole drugs should be considered if the cribriform plate is not intact; also used as primary therapy in some cats.
- Can also be used in combination with topical therapy.
- May be cost-prohibitive.
- Itraconazole 5 mg/kg PO q12h in dogs with a reported efficacy of 60–70%; 10 mg/kg PO q24h in cats.
- Voriconazole 5 mg/kg PO q12h; efficacy as sole therapy has not been established, neurotoxicity in cats.
- Posaconazole: dogs, 5–10 mg/kg PO q12–24h, cats, 5 mg/kg PO q24h or divided q12h; efficacy as sole therapy has not been established.
- Fluconazole is not recommended due to resistance.

CONTRAINdications

- Breach in the cribriform plate can allow contact of antifungal medication with brain resulting in neurologic signs and possible death.
- Sino-orbital disease necessitates the use of systemic therapy. Amphotericin B should be considered.

PRECAUTIONS

- Topical clotrimazole and enilconazole are caustic to all mucosal surfaces—protective gear (gloves, goggles) should be worn by all staff that are in close contact.
- Enilconazole can be associated with tissue swelling and upper airway obstruction.

ALTERNATIVE DRUG(S)***Enilconazole***

- Also active in the vapor phase.

Combined Clotrimazole Irrigation and Depot Therapy

- Clotrimazole (1%) is flushed through a trephine hole in the frontal sinus over 5 minutes; 50 mL in each side in dogs > 10 kg; 25 mL in each side in dogs < 10 kg.
- Clotrimazole cream (1%) is then introduced into the front sinuses; 20 g in each side in dogs > 10 kg, 10 g in each side in dogs < 10 kg.
- Reported efficacy similar to topical clotrimazole or enilconazole alone (86%).

**FOLLOW-UP****PATIENT MONITORING*****Dogs***

- Monitor clinical signs, although reduction of clinical signs does not establish resolution of disease.
- Follow-up rhinoscopy is recommended in all cases to establish response to treatment, regardless of clinical signs—histopathology and culture can help establish response.
- Serial serology (AGID) appears not to correlate with clinical status.
- Repeat CT scan should be considered for reassessment of the cribriform plate before repeat topical treatment if a worsening clinical signs are seen.
- Monitor liver enzymes in animals on triazole therapy.
- Monitor renal parameters in animals on Amphotericin B.

Cats

- Monitor clinical signs for improvement or resolution.
- Monitor liver enzymes in animals on triazole therapy.
- Monitor renal parameters in animals on Amphotericin B.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Topical therapy—monitor after treatment for any complications such as swelling of oropharynx, neurologic signs, infection/swelling of trephine site.
- Triazoles can cause anorexia and can be hepatotoxic.
- Amphotericin B can be nephrotoxic.

EXPECTED COURSE AND PROGNOSIS

- Studies have shown an 87% response rate to topical therapy in dogs after one to three treatments.
- A newer study showed that recurrence or reinfection is more common

than previously thought and can occur years after supposedly successful therapy.

- The prognosis for cats with sinonasal aspergillosis is better than with the sino-orbital form.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

BASICS

OVERVIEW

- Opportunistic fungal infection caused by *Aspergillus* spp., common molds that are ubiquitous in the environment, forming numerous spores in dust, straw, grass clippings, and hay.
- Disseminated disease does not appear to be related to the nasal form of the disease, although one report of a dog developing fungal osteomyelitis 6 months after treatment for nasal aspergillosis raises the possibility.
- Disseminated disease—usually *A. terreus* or *A. deflectus*,
- Portal of entry not definitively established but possibly through the respiratory tract or gastrointestinal tract, with subsequent hematogenous spread.
- Most commonly affects intervertebral discs, bones, thoracic lymph nodes, lung and renal pelvis. May affect respiratory (bronchopulmonary) only, or rarely, cornea or ear canal only.

SIGNALMENT

Dogs

- More common in dogs than in cats.
- German shepherds, and less so Rhodesian ridgebacks, overrepresented but reported sporadically in many breeds; average age 3 years (range 2–8 years); females three times more likely to develop disease as males.

Cats

- Persians—marginally increased incidence.
- Disseminated cases mostly affect the lungs and/or gastrointestinal tract.

SIGNS

Dogs

- May develop acutely or slowly over a period of several months, usually terminally ill when first presenting.
- Lameness—fungal osteomyelitis causing pronounced swelling and discharging, fistulous tracts.
- Neurologic—fungal discospondylitis causing paraparesis, paraplegia, spinal pain. Central signs—vestibular signs, seizures, hemiparesis, mental dullness, ataxia, vision impairment, circling.
- Renal involvement—polyuria/polydipsia, hematuria.
- Respiratory—cough, hemoptysis, increased respiratory effort.
- Reproduction—pyometra.
- Cardiac—pericarditis, ascites due to right sided failure, arrhythmias.
- Gastrointestinal—abdominal distension, anorexia.
- Ocular—uveitis, chorioretinitis, hyphema, panophthalmitis.
- Nonspecific—fever, weight loss, weakness, vomiting, and lymphadenopathy.

Cats

- Usually nonspecific signs (e.g., lethargy, depression, vomiting, and diarrhea).
- Ocular—exophthalmos.

CAUSES & RISK FACTORS

- Caused by *Aspergillus* species, most commonly *A. terreus* or *A. deflectus*, *A. fumigatus*, *A. niger*, *A. flavipes*, and *A. alabamensis* also associated. *A. felis* recently reported to cause fungal rhinosinusitis in cats, disseminated disease in dogs, and pulmonary aspergillosis in humans.
- German shepherds and immunosuppressed animals at higher risk.
- Geographic/environmental conditions—may be a factor, as some regions have a higher incidence (e.g., California, Louisiana, Michigan, Georgia, Florida, and Virginia in the United States; Western Australia; Barcelona; and Milan).
- Cats—associated with FIP, FePLV, FeLV, FIV, diabetes mellitus, and immunosuppressant use.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Bacterial osteomyelitis/discospondylitis; spinal neoplasia; intervertebral disc disease; skeletal neoplasia; bacterial pyelonephritis; bacterial pneumonia; other causes of vestibular signs/seizures; other causes of uveitis (see Anterior Uveitis—Cats, Anterior Uveitis—Dogs).

CBC/BIOCHEMISTRY/URINALYSIS

- Nonspecific.
- Dogs—mature neutrophilic leukocytosis with eosinophilia and monocytosis. One third have normocytic, normochromic nonregenerative anemia. Cats—may have nonregenerative anemia and leukopenia.
- Biochemistry—may see high globulins, ALP, ALT, amylase, creatinine, phosphate, BUN, and calcium.
- Urinalysis—may see isosthenuria, hematuria, pyuria, and possible fungal hyphae in the sediment; detection of the fungal hyphae can be improved by allowing the sample to incubate at room temperature for 24–48 hours; sediment samples may be examined unstained as wet preparations or may be air dried and stained with Diff-Quick (the hyphae branch at 45° and stain purple).

OTHER LABORATORY TESTS

- Methods of detection include: cytology, culture and histopathology.
- Definitive diagnosis by fungal culture from normally sterile body fluids and tissues, e.g., urine, bone, CSF, blood, lymph node, pleural effusions, intervertebral disc aspirates, kidney, spleen. Urine culture positive in approximately 50% of dogs.

- Culture on Sabouraud's dextrose agar (requires 5–7 days).

• Antibody serology (agar gel immunodiffusion, and ELISA) support the diagnosis but is insensitive for diagnosis of disseminated aspergillosis.

- Galactomannan antigen ELISA (urine or serum) good sensitivity (89%) and specificity (89%) in one small study. Pulmonary and ocular infections have lower sensitivity. False positive in dogs treated with Plasmalyte or with other mycotic infections (*Penicillium*, *Paecilomyces*, *Cladosporidium*, *Geotrichum*, *Histoplasma*, *Cryptococcus*).
- Cats—test for FeLV and FIV.

IMAGING

Radiographic Findings

- Spinal views may show end-plate lysis, attempted bony intervertebral bridging, and lysis of vertebral bodies consistent with discospondylitis; productive and destructive lesions of the vertebral bodies.
- Bony proliferation, lysis and periosteal reaction typical of osteomyelitis of the diaphyseal region of long bones.
- Pulmonary involvement rare, mixed interstitial/alveolar pattern, enlarged sternal and/or tracheobronchial lymph nodes, pleural effusion; productive and destructive lesions of sternabrae. Pulmonary cavitary lesions in dogs with chronic pulmonary localization.

Ultrasonographic Findings

- Kidneys—most common site to detect changes; changes seen include renal pelvis dilation ± echogenic debris within pelvis; loss of corticomedullary distinction; renal distortion and mottled appearance of the parenchyma; dilation of proximal ureter; renalomegaly; nodules or masses; hydronephrosis.
- Spleen—hypoechoic, lacy, sharply demarcated areas with no doppler signal suggestive of infarct are most significant finding in spleen; other findings include nodules/masses, mottled parenchyma, splenic venous thrombosis.
- Other—abdominal lymphadenomegaly; diffuse hepatic hypoechogenicity, ascites, or evidence of venous thrombosis.

MRI Findings

Useful for further defining brain lesions in animals with CNS signs; changes similar to other infectious and non-infectious inflammatory brain diseases. May help to identify subtle vertebral lesions in dogs with discospondylitis.

DIAGNOSTIC PROCEDURES

Area to collect sample relies on clinical presentation but may include CSF tap, joint aspirates, intervertebral disc space aspirates, abdominocentesis/thoracocentesis, aspirate of various organs (spleen, liver, kidney) or lymph nodes.

PATHOLOGIC FINDINGS

- Hyphae usually visualized; special stains assist organism detection.
- Focal osteomyelitis with multiple pale granulomas in kidneys, spleen, lymph node, myocardium, pancreas, and liver.
- Microscopic granulomas can be found in lungs, eyes, thyroid, uterus, brain, and prostate and contain numbers of septate, branching hyphae that may have characteristic lateral branching aleuriospores.
- Occasionally pulmonary congestion or GI mucosal reddening and erosions.
- Best visualized with periodic acid-Schiff, Gomori's methenamine silver, or Crocott's stain.

**TREATMENT****DOGS**

- Treatment rarely curative; severely ill dogs are recognized to have poor prognosis. May halt progression of clinical signs.
- Fluid therapy—indicated by the degree of renal compromise and azotemia.
- Pulmonary lobectomy followed by systemic antifungals has been successful in dogs with cavitary lesions without evidence of dissemination.

CATS

Disseminated—likely difficult to treat; limited data.

**MEDICATIONS****DRUG(S)**

- Combination itraconazole 5–10 mg/kg PO q24h (can be divided) and amphotericin B (dogs, 2–3 mg/kg IV 3 days per week for a total of 9–12 treatments, to cumulative dose of 24–27 mg/kg)—treatment of choice.
- Itraconazole as monotherapy has achieved long-term remission in a small number of dogs.

- New triazoles: voriconazole, posaconazole and ravuconazole all have activity against *Aspergillus*. Some dogs treated with voriconazole or posaconazole have gone into remission for many months. *Aspergillus* spp. resistant to fluconazole.
- Terbinfine (5–10 mg/kg PO q24h) used alone or in combination with triazoles has been used to treat resistant infections in humans.
- β -glucan synthase inhibitors caspofungin, micafungin, anidulafungin—limited clinical information in dogs but efficacious in invasive aspergillosis in humans.
- Combination therapy with flucytosine (dogs, 25–50 mg/kg PO q6h) and amphotericin B may prove successful, but no published reports.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Amphotericin B—contraindicated in dogs with pre-existing renal compromise or failure; amphotericin B lipid complex significantly reduced nephrotoxicity.
- Oral azoles—nausea, intermittent anorexia, liver enzyme elevation.
- Combination of flucytosine and amphotericin B—cutaneous drug eruptions in dogs.
- Avoid midazolam and cisapride with azoles—fatal drug reactions noted in humans.
- Hepatotoxicity and ulcerative dermatitis more likely to occur at doses of 10 mg/kg/day or higher. Discontinue itraconazole if adverse effects occur. May be able to reinstitute at lower dose once side effects have resolved.

**FOLLOW-UP**

Disseminated—monitor serial radiographs every 1–2 months, renal function, and urine cultures; prognosis poor, especially in German shepherds.

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

None

ABBREVIATIONS

- ALP = alkaline phosphatase
- ALT = alanine transaminase
- BUN = blood urea nitrogen
- CSF = cerebrospinal fluid
- ELISA = enzyme-linked immunosorbent assay

Client Education Handout available online

BASICS

OVERVIEW

- Given for its antipyretic, analgesic, anti-inflammatory, and antiplatelet effects.
- Aspirin inhibits cyclooxygenase, reducing the synthesis of prostaglandins and thromboxanes.
- Gastric irritation and hemorrhage can occur; dogs are especially sensitive.
- Repeated doses can produce gastrointestinal ulceration and perforation.
- Toxic hepatitis, metabolic acidosis, and anemia can occur, especially in cats.

SIGNALMENT

Cats and less commonly dogs

SIGNS

- Depression
- Anorexia
- Vomiting—vomit may be blood-tinged
- Tachypnea
- Hyperthermia
- Muscular weakness and ataxia
- Ataxia, coma, seizures, and death in 1 or more days

CAUSES & RISK FACTORS

- Owners employing human dosage guidelines to medicate cats and dogs.
- Cats have a decreased ability to conjugate salicylate with glycine and glucuronic acid due to a deficiency in glucuronidyl transferase.
- Half-life increases with dosage—cats, 22–27 hours for 5–12 mg/kg and approximately 44 hours for 25 mg/kg; dogs, 7.5 hours; responsible for higher risk in cats. Elimination is slower in neonatal and geriatric patients.
- Patients with hypoalbuminemia may be at higher risk of toxicity because aspirin is highly protein bound to plasma albumin.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ethylene glycol or alcohol
- Anticoagulant rodenticides

- Other causes of liver failure, including acetaminophen, iron, metaldehyde, and blue-green algae

CBC/BIOCHEMISTRY/URINALYSIS

- Cats—prone to Heinz body formation
- Hyponatremia and hypokalemia
- Anemia, hypoproteinemia, elevated liver enzymes, elevated white blood cell count

OTHER LABORATORY TESTS

- Initial respiratory alkalosis followed by metabolic acidosis
- High ketones and pyruvic, lactic, and amino acid levels
- Decreased sulfuric and phosphoric acid renal clearance

DIAGNOSTIC PROCEDURES

Salicylic acid concentrations in serum or urine

TREATMENT

- Inpatient—following general principles of poisoning management
- Induced gastric emptying—gastric lavage or induced emesis
- Correction of acid-base balance—continuous intravenous fluids; assisted ventilation and supplemental oxygen for severely-affected animals
- Whole blood transfusions for severe cases of hemorrhage and hypotension
- Peritoneal dialysis, hemodialysis, or charcoal hemoperfusion—advanced procedures

MEDICATIONS

DRUG(S)

- No specific antidote available.
- Activated charcoal—1–2 g/kg PO.
- Sodium bicarbonate 1 mEq/kg IV alkalinizes urine; must closely monitor acid-base status.
- Gastrointestinal protectants—sucralfate and a H₂ blocker or proton pump inhibitor; misoprostol for patients at higher risk for gastrointestinal hemorrhage.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Maintaining renal function and acid-base balance is vital.
- Severe acid-base disturbances, severe dehydration, toxic hepatitis, bone marrow depression, and coma are poor prognostic indicators.

MISCELLANEOUS

- Be sure that history of “aspirin” medication does not refer to other available pain medications.
- Question owner about any pre-existing painful condition that may have prompted the aspirin administration.

ASTHMA, BRONCHITIS—CATS

BASICS

DEFINITION

- Chronic bronchitis—inflammation in the airways (bronchi and bronchioles) lacking a specific etiology; chronic daily cough of greater than 2 months in duration.
- Asthma—acute or chronic airway inflammation associated with increased airway responsiveness to various stimuli, airway narrowing due to smooth muscle hypertrophy or constriction, reversibility of airway constriction, and presence of eosinophils, lymphocytes, and mast cells within the airways. • Bronchitis is thought to result in airflow obstruction due to airway remodeling while asthma is associated with airway constriction; however, clinically the two disease processes can appear similar. No physical examination findings or biomarkers can distinguish between the two syndromes, although reversal of airflow obstruction following administration of a beta-agonist is suggestive of the asthmatic form of disease.

PATOPHYSIOLOGY

- Lower airway inflammation likely results from inhalation of irritant substances.
- Bronchiolar smooth muscle constriction—reversible spontaneously or with treatment.
- Increase in mucosal goblet cells, mucus production, and edema of bronchial wall associated with inflammation. • Excessive mucus can cause bronchiolar obstruction, atelectasis, or bronchiectasis. • Smooth muscle hypertrophy implies chronicity—usually not reversible. • Chronic inflammation leads to airway remodeling and irreversible airflow obstruction.

SYSTEMS AFFECTED

- Respiratory • Cardiac—pulmonary hypertension rarely

GEOGRAPHIC DISTRIBUTION

Worldwide.

SIGNALMENT

Species

Cat

Breed Predilections

Siamese overrepresented

Mean Age and Range

Any age; more common between 2 and 8 years

Predominant Sex

One study showed females overrepresented

SIGNS

Historical Findings

- Coughing, tachypnea, labored breathing or wheezing. • Signs are typically episodic and can be acute or chronic.

Physical Examination Findings

- Severely affected cats present with open-mouth breathing, tachypnea, and cyanosis. • Increased tracheal sensitivity is common. • Chest auscultation may reveal crackles and/or expiratory wheezes, but can be normal. • Labored breathing with an abdominal push on expiration, increase in expiratory effort.

CAUSES

Triggers of airway inflammation unknown

RISK FACTORS

- Cigarette smoke, poor environmental hygiene, dusty cat litter, hair sprays, and air fresheners can exacerbate disease. • Use of potassium bromide—implicated in causing signs of bronchitis/asthma in some cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rule out infectious pneumonia (*Mycoplasma*, *Toxoplasma*, bacterial or fungal pneumonia). • Consider *Dirofilaria immitis* and primary lung parasites (*Aelurostrongylus abstrusus*, *Capillaria aerophilus*, *Paragonimus kellicotti*). More common in southern and midwest US, and in outdoor and hunting cats in some geographic regions. • Primary or metastatic neoplasia can have similar clinical and radiographic appearance. • Clinical presentation of idiopathic pulmonary fibrosis may appear similar to feline bronchitis.

CBC/BIOCHEMISTRY/URINALYSIS

Frequently normal, ~40% of cats with bronchial disease have peripheral eosinophilia.

OTHER LABORATORY TESTS

- Fecal exams—flotation for *Capillaria*, sedimentation for *Paragonimus*, Baermann for *Aelurostrongylus*. False-negative tests common.
- Heartworm antigen and antibody testing, particularly if coughing occurs in conjunction with vomiting. • Radioallergosorbent testing or intradermal skin testing—no correlation between skin allergies and respiratory disease currently documented.

IMAGING

Radiography

- Classically, diffuse bronchial wall thickening; interstitial or patchy alveolar patterns also possible. • Severity of radiographic changes does not necessarily correlate with clinical severity or duration, and normal radiographs can be found.
- Hyperinflation of lung fields—flattened and caudally displaced diaphragm, increased distance between the heart and diaphragm, extension of lungs to the first lumbar vertebrae thought to reflect bronchoconstriction. • Collapse of right middle lung lobe due to mucus plugging and atelectasis reported in 11% of cases.

- Pulmonary lobar arterial enlargement is suspicious for heartworm disease.

Echocardiography

Useful to document heartworm disease or secondary pulmonary hypertension.

DIAGNOSTIC PROCEDURES

Transoral Tracheal Wash

Use a sterile endotracheal tube and polypropylene catheter to collect airway fluids at the level of the carina.

Bronchoscopy

• Allows visualization of trachea and bronchi. Excessive amounts of thick mucus are common with bronchitis. Mucosa of the airways is typically hyperemic and edematous.

Cytology of TOTW or BAL

- Eosinophils and neutrophils are most prominent cell types. • Up to 20% eosinophils on BAL cytology can be found in normal cats. • A mixed inflammatory cell population occurs in about 21% of cats.

Bacterial Cultures

- Quantitated cultures recommended; positive cultures frequently encountered but bacterial colony counts > 100–300 cfu/mL uncommon with bronchitis. • Specific *Mycoplasma* culture often needed.

Biopsy

Keyhole biopsy—can differentiate between idiopathic pulmonary fibrosis, neoplasia and bronchitis if needed.

PATHOLOGIC FINDINGS

Hyperplasia/hypertrophy of goblet cells, hypertrophy of airway smooth muscle, epithelial erosion, and infiltrates.

TREATMENT

APPROPRIATE HEALTH CARE

- Remove patient from environment that exacerbates disease. • Hospitalize for acute respiratory distress.

NURSING CARE

Oxygen therapy, bronchodilators, and sedatives in an acute crisis. Minimize manipulation in order to lessen stress and oxygen needs of the animal.

ACTIVITY

Usually self-limited by patient.

DIET

Calorie restriction for obese cats.

CLIENT EDUCATION

- Most causes are chronic and progressive.
- Do not discontinue medical therapy when clinical signs have resolved—subclinical inflammation is common and can lead to progression of disease. Lifelong medication and environmental changes usually necessary.
- Some clients can be taught to give

(CONTINUED)

ASTHMA, BRONCHITIS—CATS

A

terbutaline subcutaneously and corticosteroid injections at home for a crisis situation.

**MEDICATIONS****DRUG(S) OF CHOICE*****Emergency Treatment***

- Oxygen and a parenteral bronchodilator. Injectable terbutaline (0.01 mg/kg IV or SC); repeat if no clinical improvement (decrease in respiratory rate or effort) in 20–30 minutes.
- A sedative can aid in decreasing anxiety (butorphanol tartrate at 0.2–0.4 mg/kg IV or IM, buprenorphine at 0.01 mg/kg IV or IM, or acepromazine at 0.01–0.05 mg/kg SC).
- A short-acting parenteral corticosteroid may also be required. Dexamethasone sodium phosphate (0.1–0.25 mg/kg, IV or SC). Can repeat if no improvement noted within 20–30 minutes.

Long-Term Management**Corticosteroids**

- Decrease inflammation.
- Oral treatment is preferred over injectable for closer monitoring of dose and duration.
- Prednisolone: 0.5–1 mg/kg PO q12h. Begin to taper dose (50% each week) after 1–2 weeks if clinical signs have improved. Maintenance therapy = 0.5–1 mg/kg PO q24–48h.
- Longer-acting parenteral steroids (Vetalog or Depomedrol) should be reserved only for situations where owners are unable to administer oral or inhaled medication on a routine basis.

Inhaled Corticosteroids

- Requires a form-fitting facemask, spacer, and metered-dose inhaler (MDI). Veterinary brand: Aerokat (Trudell Medical).
- The most common corticosteroid used as an MDI is fluticasone propionate (Flovent). 110- μ g Flovent MDI is recommended (1–2 actuations, 7–10 breaths q12h). In one study, use of 44- μ g Flovent decreased BAL eosinophil counts in cats with experimentally induced lower airway disease.
- Flovent is used for long-term control of airway inflammation. Takes 10–14 days to reach peak effect; use oral steroids concurrently during this time.
- Results in some suppression of the hypothalamic-pituitary axis but systemic side effects appear to be limited.

Bronchodilators

- Methylxanthines: sustained-release theophylline formulations recommended, and pharmacokinetics can vary greatly. Only generic currently available. Dose at 15–20 mg/kg PO once daily in the evening.
- Beta-2 agonists (terbutaline, albuterol)—reverse smooth muscle constriction. Oral terbutaline dose is 1/4 of a 2.5 mg tablet

q12h. Initial albuterol dose is 20 μ g/kg PO q12h; can increase to 50 μ g/kg PO q8h.

Inhaled Bronchodilators

- Albuterol—preferred inhalant bronchodilator, effect lasts less than 4 hours. Long-term use of traditional racemic form of inhaled albuterol (R and S-enantiomers) has been associated with worsened airway inflammation. Enantiomer specific R-albuterol should be used if the drug is needed in moderately to severely affected cats (q12–24h) or during respiratory distress.

Anthelmintics

- Empirical therapy is indicated for cats with clinical signs of bronchial disease and eosinophilic airway cytology in an appropriate geographic location.
- Consider fenbendazole, ivermectin, or praziquantel.

Antibiotics

Use based on a positive quantitative culture and susceptibility testing or *Mycoplasma* isolation.

CONTRAINDICATIONS

Beta-2 antagonists (e.g., propranolol) are contraindicated because of their ability to block sympathetically mediated bronchodilation.

PRECAUTIONS

- Long-term use of steroids increases risk of development of diabetes mellitus and predisposes to immunosuppression. • Use of corticosteroids in cats may precipitate congestive heart failure. • Beta agonists could cause tachycardia and exacerbate underlying cardiac disease.

ALTERNATIVE DRUG(S)

Leukotriene receptor blockers and inhibitors of generation: no evidence to support use. Anti-serotonin and antihistamine drugs: no evidence to support use. Immunotherapy: no clinical evidence to support use at this time.

**FOLLOW-UP****PATIENT MONITORING**

- Owners should report any increase in coughing, sneezing, wheezing, or respiratory distress. Medications should be increased appropriately or additional therapy initiated if clinical signs worsen. • Follow-up radiographs may be helpful to detect onset of new disease.
- Owner should watch for signs of PU/PD that could indicate diabetes mellitus or renal disease. Monitor blood glucose and urine cultures.

PREVENTION/AVOIDANCE

Eliminate any environmental factors that can trigger a crisis situation (see "Risk Factors").

Change furnace and air-conditioner filters on a regular basis. Consider dust-free litters.

POSSIBLE COMPLICATIONS

- Acute episodes can be life-threatening.
- Right-sided heart disease rarely develops as a result of long-term bronchitis.

EXPECTED COURSE AND PROGNOSIS

- Long-term therapy should be expected.
- Most cats do well if recurrence of clinical signs is carefully monitored and medical therapy appropriately adjusted. • A few cats will be refractory to treatment; these carry a much worse prognosis.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Cat pulmonale can be a sequela to chronic lower airway disease.

PREGNANCY/FERTILITY/BREEDING

Glucocorticoids are contraindicated in the pregnant animal. Bronchodilators should be used with caution.

SYNONYMS

Allergic bronchitis, asthmatic bronchitis, feline lower airway disease, extrinsic asthma, eosinophilic bronchitis.

ASTROCYTOMA

BASICS

OVERVIEW

- Glial cell neoplasm, most commonly affecting the brain and rarely the spinal cord.
- Neoplastic cells are of astrocytic origin. • It is the most common intra-axial (situated inside of the brain parenchyma) intracranial neoplasm of dogs but is rarely diagnosed in cats. • Tumors are often located in the pyriform area of the temporal lobe, the cerebral hemispheres, the thalamus, hypothalamus, or midbrain. • Biologic behavior of this tumor is dictated by the histopathologic grade (I–IV, from best to worst prognosis) and anatomic involvement.
- Tumors typically do not penetrate the ventricular system or metastasize outside of the cranial vault.

SIGNALMENT

- Dog—often brachycephalic breeds > 5 years of age; no sex predilection reported.
- Cat—usually > 9 years; no sex or breed predilection reported.

SIGNS

- Location and growth kinetic dependent
- Seizures • Behavioural changes • Apathy towards normal activities including eating, playing, and societal interactions
- Disorientation • Loss of conscious proprioception • Cranial nerve abnormalities
- Head muscle atrophy • Upper motor neuron tetraparesis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other primary tumors arising from tissues of the central nervous system • Metastatic neoplasia with brain tropism such as hemangiosarcoma • Granulomatous meningoencephalitis • Trauma
- Cerebrovascular infarction • Meningitis

CBC/BIOCHEMISTRY/URINALYSIS

Usually unremarkable

OTHER LABORATORY TESTS

CSF analysis may show albumin-cytologic dissociation (high protein with low number of nucleated cells). The CSF analysis is indicated to exclude infectious etiology, not to diagnose astrocytoma.

IMAGING

- MRI of brain is ideal for mass lesion confirmation, as it is superior to CT scanning for detecting lesions in the middle and caudal fossae. Additionally, MRI is more sensitive than CT for detection infarcts, bleeding, and edema. • Brain MRI may be useful in establishing a tentative differential diagnosis of a glial tumor, based on tumor

characteristics highlighted in specific sequences.

DIAGNOSTIC PROCEDURES

- Neurologic exam. • Ophthalmic exam.
- MRI. • CSF analysis. • Tumor biopsy for definitive diagnosis, when specific antineoplastic treatment is sought (surgery, curative-intent radiation therapy, experimental therapies).

TREATMENT

- Surgery. • Radiation therapy can be very effective in improving neurologic signs.
- Chemotherapy with lomustine, procarbazine, or temozolamide might exert cytoreductive activities. • Anti-inflammatory dosing with corticosteroids to reduce peritumoral edema. • Consultation with a neurosurgeon and a radiation oncologist is essential for the appropriate patient management.

MEDICATIONS

DRUG(S)

Seizure Control

- Status epilepticus—diazepam (0.5–1 mg/kg IV, up to three times to achieve effect); if no response to diazepam, use pentobarbital (5–15 mg/kg IV slowly to effect).
- Long-term management—phenobarbital (1–4 mg/kg PO q12h) with or without adjuvant potassium bromide (20 mg/kg PO q24h).

Tumor Control

- Timely consultation with a neurosurgeon is of paramount importance for the appropriate management of the patient. • Radiation therapy may be effective, and consultation with a radiation oncologist is recommended. Stereotactic radiosurgery or intensity modulated radiation therapy may be considered as first-line treatment options.
- Chemotherapy may be effective for treating dogs. Potential drugs that may exert measurable anticancer effects include CCNU (60–70 mg/m² PO every 3 weeks) or temozolamide (100–120 mg/m² PO q24h for 5 days every 3 weeks). • Prednisone (1 mg/kg q24h), may be effective in reducing peritumoral edema and improving the neurologic signs. Patients may need to be on steroids long term, even after the definitive treatment of the tumor.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Prednisone and phenobarbital may cause polyphagia, polydipsia, and polyuria.
- Phenobarbital may cause sedation for up to 2 weeks after initiation of treatment, and

increase in hepatic enzymes on serum biochemical panel. • CBC and platelet count is recommended 7–10 days after chemotherapy and immediately before each dose of chemotherapy to monitor myelosuppression. • Chemotherapy has the potential to be synergistic with radiation therapy. Timely specialty to a referral center with neurosurgery, radiation therapy, and medical oncology capabilities is important for patients seeking more than palliative care.

FOLLOW-UP

PATIENT MONITORING

- Blood phenobarbital concentration should be assessed after 7–10 days of treatment, with modifications to dosages for achieving target plasma concentrations. • Serial MRIs should be considered for documenting response if multimodality therapy is used. • Serial CBC and platelet counts should be performed to monitor myelotoxicity associated with chemotherapy.

EXPECTED COURSE AND PROGNOSIS

- Long-term prognosis—guarded. • Median survival after chemotherapy plus medical management may be up to 7 months.
- Median survival after radiation therapy has been reported to be as high as 12 months.

BASICS

OVERVIEW

An uncommon intestinal viral infection characterized by enteritis and diarrhea.

SIGNALMENT

- Cats
- No known breed, sex, or age predilection

SIGNS

- Small bowel diarrhea often green and watery.
- Kittens show more severe signs.
- May be severe and acute enough to cause dehydration and anorexia.

CAUSES & RISK FACTORS

- A small, non-enveloped, RNA virus of the genus *Astrovirus*.
- Details of the incidence, prevalence, and predisposing factors unknown.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Many causes of gastroenteritis
- Food allergy
- Toxin ingestion
- Inflammatory bowel disease
- Neoplasia
- Intestinal parasites
- Viral infections—panleukopenia, rotavirus, enteric coronavirus, enteric calicivirus
- Bacterial infections—salmonellosis, coliforms
- Protozoal infections—*Giardia*, cryptosporidiosis

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Electron microscopy of feces—identify astrovirus particles.
- Difficult to isolate in the laboratory.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

None

PATHOLOGIC FINDINGS

None described; similar to mild enteritis, rotavirus, or coronavirus enteritis.

TREATMENT

- Control diarrhea.
- Reestablish fluid and electrolyte balance.

MEDICATIONS

DRUG(S)

No specific antiviral drugs.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None

FOLLOW-UP

PATIENT MONITORING

Monitor fluid and electrolytes.

PREVENTION/AVOIDANCE

Isolate infected cats during acute disease.

POSSIBLE COMPLICATIONS

Secondary intestinal viral and bacterial infections.

EXPECTED COURSE AND PROGNOSIS

- Illness usually < 1 week.
- Mortality—appears low.
- Prognosis—good.
- If diarrhea persists, investigate other causes.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Sequence analysis of human and animal astroviruses suggests human-to-animal transmission does not occur.

Author Fred W. Scott

Consulting Editor Stephen C. Barr

ATAXIA

BASICS

DEFINITION

- A sign of sensory dysfunction that produces incoordination of the limbs, head, and/or trunk.
- Three clinical types—sensory (proprioceptive), vestibular, and cerebellar; all produce changes in limb coordination, but vestibular and cerebellar ataxia also produce changes in head and neck movement.

PATHOPHYSIOLOGY

Sensory (Proprioceptive)

- Proprioceptive pathways in the spinal cord (i.e., fasciculus gracilis, fasciculus cuneatus, and spinocerebellar tracts) relay limb and trunk position to the brain.
- When the spinal cord is slowly compressed, proprioceptive deficits are usually the first signs observed, because these pathways are located more superficially in the white matter and their larger sized axons are more susceptible to compression than are other tracts.
- Generally accompanied by weakness owing to early concomitant upper motor neuron involvement; weakness not always obvious early in the course of the disease.
- Ataxia can occur with spinal cord, brainstem, and cerebral lesions; mild to absent with unilateral brainstem lesions, and subtle to absent with unilateral cerebral lesion.

Vestibular

- Changes in head and neck position are relayed through the vestibulo-cochlear nerve to the brainstem.
- Vestibular receptors or the nerve in the inner ear are considered part of the peripheral nervous system, whereas nuclei in the brainstem are part of the central nervous system.
- Localize the vestibular signs to peripheral or central vestibular nervous system because prognosis and rule-outs differ for these two locations.
- Both locations of vestibular disease cause various degrees of disequilibrium with ensuing vestibular ataxia.
- Affected animal leans, tips, falls, or even rolls toward the side of the lesion; accompanied by head tilt.
- Central vestibular signs usually have changing types of nystagmus or vertical nystagmus; somnolence, stupor, or coma (due to involvement of the nearby ascending reticular activating system); multiple cranial nerve signs; proprioceptive deficits and quadriplegia or hemiparesis.
- Peripheral vestibular signs do not include changes in mental status, vertical nystagmus, proprioceptive deficits, quadriplegia or hemiparesis.

- Bilateral vestibular involvement, peripheral or central in origin, has characteristic exaggerated head motion with often poor to absent physiologic nystagmus.

Cerebellar

- The cerebellum regulates, coordinates, and modulates motor activity.
- Proprioception is normal because the ascending proprioceptive pathways to the cortex are intact; weakness does not occur because the upper motor neurons are intact.
- Inadequacy in the performance of motor activity; strength preservation; no proprioceptive deficits.
- Affected animal shows uncoordinated motor activity of limbs, head, and neck; hypermetria; dysmetria; head tremors; intention tremors; and truncal sway. Menace responses may be absent without visual dysfunction.

SYSTEMS AFFECTED

Nervous—spinal cord (and brainstem and cortex), cerebellum, vestibular system.

SIGNALMENT

Any age, breed, or sex

SIGNS

- Important to define the type of ataxia to localize the problem.
- Only one limb involved—consider a lameness problem.
- Only hind limbs affected—likely a spinal cord disorder affecting the spinocerebellar tracts.
- All or both ipsilateral limbs affected—cervical spinal cord, or cerebellar localization.
- Head tilt and/or nystagmus—vestibular localization.

CAUSES

Neurologic

Cerebellar

- Degenerative—abiotrophy (Kerry blue terrier, Gordon setter, rough-coated collie, Australian kelpie, Airedale, Bernese mountain dog, Finnish harrier, Brittany spaniel, border collie, beagle, Samoyed, wirehaired fox terrier, Labrador retriever, Great Dane, chow chow, Rhodesian ridgeback, domestic shorthair cats); storage diseases often have cerebellomedullary involvement.
- Anomalous—hypoplasia secondary to perinatal infection with panleukopenia virus (cats); malformed cerebellum due to herpesvirus infection (newborn puppies); arachnoid or epidermoid cyst located near fourth ventricle.
- Neoplastic—any CNS tumor (primary or secondary) localized to the cerebellum.
- Infectious—canine distemper virus; FIP; and any other CNS infection affecting the cerebellum.
- Inflammatory, idiopathic, immune-mediated—granulomatous meningoencephalomyelitis.
- Toxic—metronidazole.

Vestibular—Central Nervous System

- Infectious—FIP; canine distemper virus; rickettsial diseases.
- Inflammatory, idiopathic, immune-mediated—granulomatous meningoencephalomyelitis, meningoencephalomyelitis of unknown origin.
- Nutritional—thiamine deficiency.
- Toxic—metronidazole.

Vestibular—Peripheral Nervous System

- Infectious—otitis media interna; *Cryptococcus* granuloma (cats).
- Inflammatory—nasopharyngeal (middle ear) polyps (cats).
- Idiopathic—geriatric vestibular disease (dogs); idiopathic vestibular syndrome (cats).
- Metabolic—hypothyroidism.
- Neoplastic—squamous cell carcinoma, bone tumors.
- Traumatic.

Spinal Cord

- Degenerative—degenerative myelopathy (old German shepherd, Welsh corgi).
- Vascular—fibrocartilaginous embolic myelopathy.
- Anomalous—hemivertebrae; dens hypoplasia with atlantoaxial subluxation-luxation; Chiari-like malformation; cervical spondylomyelopathy; spinal sub-arachnoid diverticulum; other spinal cord and vertebral malformation.
- Neoplastic—primary bone tumors; multiple myeloma and metastatic tumors that infiltrate the vertebral body; meningioma; others.
- Infectious—discospondylitis; myelitis.
- Traumatic—intervertebral disc herniation; fracture or luxation; atlantoaxial subluxation-luxation.

Metabolic

- Anemia
- Polycythemia
- Electrolyte disturbances—especially hypokalemia, hypocalcemia, and hypoglycemia

Miscellaneous

- Drugs—acepromazine; antihistamines; antiepileptic drugs
- Respiratory compromise
- Cardiac compromise—reverse PDA, aortic thromboembolism

RISK FACTORS

- Intervertebral disc disease—dachshund, poodle, cocker spaniel, and beagle.
- Cervical spondylomyelopathy—Doberman pinscher and Great Dane.
- Fibrocartilaginous embolism—young, large-breed dogs and miniature schnauzers.
- Dens hypoplasia and atlantoaxial luxation—small-breed dogs, poodles.
- Chiari-like malformation—Cavalier King Charles spaniel, small-breed dogs.

(CONTINUED)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differentiate the types of ataxia.
- Differentiate from other disease processes that can affect gait—musculoskeletal, metabolic, cardiovascular, respiratory.
- Musculoskeletal disorders—typically produce lameness, pain, and a reluctance to move; degenerative joint disease signs often improve with increased movements.
- Systemic illness and endocrine, cardiovascular, and metabolic disorders—can cause intermittent ataxia, especially of the pelvic limbs; with fever, weight loss, murmurs, arrhythmias, hair loss, or collapse with exercise, suspect a non-neurologic cause; obtain minimum data from hemogram, biochemistry, and urinalysis.
- Head tilt or nystagmus—likely vestibular localization.
- Intention tremors of the head or hypermetria—likely cerebellar localization.
- All four limbs affected—lesion is in the cervical spinal cord, cerebellum or is multifocal to diffuse.
- Only pelvic limbs affected—lesion is anywhere below the second thoracic vertebra.

CBC/BIOCHEMISTRY/URINALYSIS

Normal unless metabolic cause (e.g., hypoglycemia, electrolyte imbalance, anemia, polycythemia).

OTHER LABORATORY TESTS

- Hypoglycemia—determine serum insulin concentration on sample that has low glucose value; low glucose and higher than expected insulin value suggest insulin-secreting tumor.
- Anemia—differentiate as nonregenerative or regenerative on the basis of the reticulocyte count.
- Electrolyte imbalance—correct the problem; see if ataxia resolves.
- Antiepileptic drugs—if being administered, evaluate serum concentration for toxicity.

IMAGING

- Spinal radiography, myelography, CT or MRI—if spinal cord dysfunction suspected.
- Bullae radiography—if peripheral vestibular disease suspected; CT or MRI superior; for inner ear disease, MRI superior to CT.
- Thoracic radiography—for older patients and patients suspected to have neoplasia or systemic fungal infection.

- CT or MRI—if cerebellar disease suspected; MRI superior to CT.
- Abdominal ultrasonography—if hepatic, renal, adrenal, or pancreatic dysfunction suspected.

DIAGNOSTIC PROCEDURES

Cerebrospinal fluid—helps confirm nervous system etiology.

TREATMENT

- Usually outpatient, depending on severity and acuteness of clinical signs.
- Exercise—decrease or restrict if ataxia originates from spinal cord disease.
- Client should monitor gait for increasing dysfunction or weakness; if paresis worsens or paralysis develops, other testing is warranted.
- Avoid drugs that could contribute to the problem; may not be possible in patients on antiepileptic drugs for seizures.

MEDICATIONS

DRUG(S) OF CHOICE

Not recommended until the source or cause of the problem is identified.

FOLLOW-UP

PATIENT MONITORING

Periodic neurologic examinations to assess condition.

POSSIBLE COMPLICATIONS

- Spinal cord—progression to weakness and possibly paralysis
- Hypoglycemia—seizures
- Cerebellar disease—head tremors and bobbing
- Brainstem disease—stupor, coma, death

ATHEROSCLEROSIS

BASICS

OVERVIEW

Thickening of the inner arterial wall in association with lipid deposits. Chronic arterial change characterized by loss of elasticity, luminal narrowing, and proliferating and degenerative lesions of the intima and media.

SIGNALMENT

- Rare in dogs.
- Not described in cats.
- Higher prevalence in miniature schnauzer, Doberman pinscher, poodle, and Labrador retriever.
- Geriatric patients (> 9 years).

SIGNS

Historical Findings

- None in some animals
- Lethargy
- Anorexia
- Weakness
- Dyspnea
- Collapse
- Vomiting
- Diarrhea

Physical Examination Findings

- Dyspnea
- Irregular rhythm
- Heart failure
- Disorientation
- Blindness
- Circling
- Coma
- Episodic lameness

CAUSES & RISK FACTORS

- Severe hypothyroidism
- Increasing age
- Hyperlipidemia in miniature schnauzers
- Male gender (male dogs may have predisposition)
- High total cholesterol
- Diabetes
- Glomerulonephritis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Arteriosclerosis

CBC/BIOCHEMISTRY/URINALYSIS

- Hypercholesterolemia
- Hyperlipidemia
- High BUN and creatinine
- High liver enzymes

OTHER LABORATORY TESTS

- Low T₃ and T₄.
- High values for alpha-2 and beta fractions on protein electrophoresis.

IMAGING

Radiography

Thoracic and abdominal radiographs may reveal cardiomegaly and hepatomegaly.

DIAGNOSTIC PROCEDURES

Electrocardiography

- Conduction abnormalities and notched QRS complexes.
- Atrial fibrillation.
- ST segment elevation or depression with myocardial infarction.

TREATMENT

- Treat the underlying disorder and clinical signs (e.g., dyspnea if congestive heart failure develops).
- Diet—low-fat diet, weight loss program, and high soluble fiber intake to control hyperlipidemia.

MEDICATIONS

DRUG(S)

- Treat conduction disturbances and arrhythmias if clinically indicated.
- Thyroid replacement if hypothyroidism is confirmed.
- Antihypertensive therapy if hypertension is documented.
- Blood cholesterol-reducing medications if hyperlipidemic.
- Treat diabetes.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Monitor T₄ concentration 4–6 hours post-administration after the first 6 weeks of treatment and adjust dosage accordingly.
- Monitor blood triglyceride and cholesterol levels.
- Monitor ECG for conduction disturbances and ST segment changes.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Hypothyroidism
- Diabetes
- Mitral valve disease (myxomatous)
- Glomerulonephritis

AGE-RELATED FACTORS

Geriatric patients (> 9 years)

SEE ALSO

Myocardial Infarction

Author Larry P. Tilley

Consulting Editors Larry P. Tilley and Francis W.K. Smith, Jr.

BASICS

OVERVIEW

- Results from malformation or disruption of the articulation between the first and second cervical vertebrae (atlas and axis, respectively); causes spinal cord compression.
- AA instability can result in spinal cord trauma or compression at the junction between the atlas and axis—may cause neck pain and/or varying degrees of general proprioceptive (GP) ataxia /upper motor neuron (UMN) tetraparesis, tetraplegia (with or without nociception), and death from respiratory arrest.

Etiology

- Congenital: anomaly of the dens (aplasia, hypoplasia, or malformation [dorsal angulation] of the dens) and its ligamentous attachments.
- Acquired: may be a consequence of traumatic injury.

SIGNALMENT

- Congenital—toy-breed dogs (Yorkshire terrier, miniature or toy poodle, Chihuahua, Pekingese, and Pomeranian).
- Age at onset—usually before 12 months of age.
- Uncommon in larger-breed dogs, dogs > 1 year old, and cats.
- No sex predilection.

SIGNS

- Intermittent or progressive ambulatory tetraparesis, usually with neck pain—most common.
- Neurologic signs vary from mild to moderate GP/UMN ambulatory tetraparesis to non-ambulatory GP/UMN tetraparesis, or tetraplegia depending on degree of spinal cord compression and secondary pathology (i.e., edema, hemorrhage, or gliosis).
- Animals may have only neck pain without concurrent neurologic deficits.
- Episodes of collapse secondary to weakness.
- Abnormal postural reactions with spinal reflexes that are normal to exaggerated with normal to increased muscle tone in all four limbs.
- Acute death may occur when accompanied by trauma and respiratory arrest (uncommon).

CAUSES & RISK FACTORS

- Usually caused by abnormal development of the dens and/or ligamentous support structures, resulting in subluxation of the atlantoaxial joint.
- Fracture of the axis.
- Clinical signs often occur as a result of mild or insignificant trauma (e.g., jumping or playing).
- Clinical signs may be exacerbated by activity such as flexion of the neck.

- Toy-breed dogs—at risk for congenital malformation of the dens.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differential diagnoses are consistent with various causes of cervical myelopathies, including:
 - Other congenital malformation.
 - Trauma.
 - Meningitis or meningoencephalitis (i.e., infectious or non-infectious [granulomatous meningoencephalomyelitis]).
 - Fibrocartilaginous embolic myelopathy.
 - Disk herniation.
 - Neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

IMAGING

- Plain radiography of the cervical vertebral column:
 - Lateral view—caudal and dorsal displacement of the axis in relationship to the atlas, resulting in an increased distance between vertebrae.
 - Ventral dorsal or oblique view—may reveal absence, hypoplasia, or malformation (dorsal angulation) of the dens.
- Cross-sectional imaging:
 - MRI.
 - Diagnosis based on observation of caudal and dorsal displacement of the axis in relationship to the atlas as evidenced by the following features of the atlantoaxial articulation: (1) Dorsal: displacement of the spinous process of the axis; (2) Ventral: increased size of the occipito-atlas-axis joint cavity.
 - Allows identification of spinal cord compression.
 - Allows recognition of secondary spinal cord pathology such as edema, hemorrhage, or gliosis, which may impact prognosis.
- Computed tomography:
 - May provide detailed visualization of bony structures, which allows for the creation of three-dimensional reconstructed image to help surgical planning.
- Precautions:
 - Proper positioning will require sedation or general anesthesia.
 - Sedation or general anesthesia carries significant risk for iatrogenic trauma.
 - Care needs to be exercised when positioning animals.
 - AVOID EXCESSIVE FLEXION OF THE NECK!
 - Flexion may exacerbate compression, which may worsen clinical signs or cause death due to spinal cord trauma.
 - To protect against neck flexion during recovery, affected animals should be closely monitored until they are capable of maintaining normal head and neck carriage.

TREATMENT

- Prior to treatment, consultation with a board-certified neurologist or surgeon should be pursued.
- Improper treatment can lead to irreversible deterioration in neurologic function.

MEDICAL

- Neck brace (splint) to stabilize the cervical vertebral column in extension.
 - Fiberglass cast material is positioned ventrally from the rostral aspect of mandible to the xiphoid and incorporated into bandage material, which immobilizes the head and neck.
 - Strict exercise restriction (cage confinement) for a minimum of 8 weeks.
 - Frequent bandage/splint changes are needed.
- Adjunctive medication (see below).

Overall Prognosis

- Successful outcome observed in 62.5% of dogs.
- Improved prognosis was associated with an acute onset and short duration of clinical signs (< 30 days).
- Surgery is recommended to treat animals that fail to improve or experience recurrence of signs following medical treatment.

SURGERY

- Treatment of choice in the majority of cases.
- Surgical approach; **ventral method is preferred.**
 - Ventral approach—variety of methods:
 - Transarticular pinning or lag screw technique; ventral tips of the pins incorporated in polymethylmethacrylate to prevent pin migration.
 - Transarticular pinning and ventral cortical screws or K-wires in the bodies of the atlas and axis ± K-wires applied longitudinally and wired to the screws; screw heads and K-wires are incorporated in polymethylmethacrylate to provide fixation.
 - Dorsal approach—use wire or synthetic suture material to fix the spinous process of the axis to the dorsal arch of the atlas; provides less rigid fixation and may be associated with greater implant failure.
 - Strict exercise restriction is required for the first month postoperatively, followed by a gradual return to activity over an additional month.
 - Adjunctive medication (see below).
- Overall prognosis ranges from 63% to 91% success: improved prognosis was associated with young (< 24 months) dogs, duration of clinical signs < 10 months, and mild neurologic deficits.

ATLANTOAXIAL INSTABILITY

(CONTINUED)

- Complications:
 - Failure to improve/worsening of neurologic deficits.
 - Implant failure/infection.
 - Respiratory—respiratory arrest, dyspnea, cough, and aspiration pneumonia.
 - Death.

MEDICATIONS

DRUG(S)

- Anti-inflammatory medication:
 - Corticosteroids: prednisone 0.5–1.0 mg/kg PO divided twice daily for 2 weeks, followed by a tapering regime. Suggested protocol following initial dose: 0.5 mg/kg PO daily for 5 days, followed by 0.5 mg/kg PO every other day for 5 days.
 - NSAID: 1- to 4-week course.
- Analgesia:
 - Tramadol 2.0–4.0 mg/kg PO q6–8h.
 - Gabapentin 10–20 mg/kg PO q6–8h.
 - Pregabalin 3–4 mg/kg (begin with 2 mg/kg) PO q8–12h.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Corticosteroid—use caution when given in conjunction with medical treatment; may reduce pain, resulting in increased activity and spinal cord trauma.
- Avoid NSAIDs in combination with corticosteroids in all patients—increases risk of life-threatening gastrointestinal hemorrhage.

FOLLOW-UP

- Dogs treated medically require frequent (weekly) bandage changes for associated soft tissue trauma.

- All dogs should be reevaluated at 1 and 3 months (postoperatively or after neck brace removal) and monthly until neurologic deficits resolve or remain static over 2–3 months.
- More frequent rechecks may be needed for dogs experiencing complications or recurrence of signs.
- Untreated animals may experience deterioration in neurologic function, catastrophic acute spinal cord trauma, respiratory arrest, and death.

MISCELLANEOUS

- Rehabilitation may play a significant role in the ultimate neurologic functional level of the patient.
- Rehabilitation should only be considered in dogs > 30 days postoperatively or after neck brace (splint) removal.

ABBREVIATIONS

- GP = general proprioceptive
- MRI = magnetic resonance imaging
- NSAID = nonsteroidal anti-inflammatory drug
- UMN = upper motor neuron

Authors Mathieu M. Glassman and Marc Kent
Consulting Editor Walter C. Renberg

BASICS

DEFINITION

- A genetically predisposed hypersensitivity reaction to normally innocuous substances.
- Manifests as an inflammatory, chronically relapsing, non-contagious and pruritic skin disease.

PATOPHYSIOLOGY

- Atopic dermatitis (AD) has a multifactorial etiology involving genetic, structural, and immunologic factors. • Classical theory describes the pathway through which susceptible animals become sensitized to environmental allergens producing allergen-specific IgE, followed by mast cell degranulation upon re-exposure to allergens via epicutaneous absorption (extrinsic AD).
- A subset of AD patients does not have increased allergen-specific IgE (intrinsic AD).
- Current focus on the pathogenesis of AD includes abnormalities in barrier function and T-cell dysregulation or imbalance. • Barrier function impairment, shown as increased transepidermal water loss and decreased filagrin expression, in affected dogs has been demonstrated. • Acute lesions of AD are characterized by increased $T_{H}2$ lymphocyte activity while $T_{H}1$ cytokines predominate in chronic lesions. Thus a $T_{H}2:T_{H}1$ imbalance in AD has been proposed. • Recently, aberrant regulatory T-cell function has been reported.
- Following repeat epicutaneous absorption of allergens, mast cell degranulation results in the release of histamine, proteolytic enzymes, cytokines, chemokines, and other chemical mediators. • Bacterial superantigens, auto-antigens released via keratinocyte damage, and *Malassezia* may play a role in perpetuating the inflammation.

SYSTEMS AFFECTED

- Ophthalmic • Respiratory • Skin/Exocrine

GENETICS

- Dogs— inherited predisposition; polygenic with environmental influences important for disease development.
- Cats— inherited predisposition less clear.

INCIDENCE/PREVALENCE

- Canine—true prevalence is unknown; estimated at 3–15% of the canine population.
- Feline—unknown; generally believed to be lower than that for dogs.

GEOGRAPHIC DISTRIBUTION

Canine—recognized worldwide; local environmental factors (temperature, humidity, and flora) influence the seasonality, severity, and duration of signs.

SIGNALMENT

Species

Dogs and cats

Breed Predilections

- Canine—any breed, including mongrels; recognized more frequently in certain breeds or families (can vary geographically). • United States—Boston terrier, boxer, cairn terrier, Chinese Shar-Pei, cocker spaniel, Dalmatian, English bulldog, English and Irish setter, French bulldog, American pit bull terrier, Lhasa apso, miniature schnauzer, pug, Sealyham terrier, Scottish terrier, West Highland white terrier, wirehaired fox terrier, Labrador retriever, and golden retriever.
- Feline—none reported.

Mean Age and Range

- Canine—mean age at onset 1–3 years; range 3 months–6 years; signs may be mild the first year but usually progress and become clinically apparent before 3 years of age.
- Feline—6 months to 2 years.

Predominant Sex

None reported

SIGNS

General Comments

- Pruritus—itching, scratching, rubbing, licking. • Most cutaneous changes caused by self-induced trauma; primary lesions usually unrecognized.

Historical Findings

- Facial, pedal, or axillary pruritus • Early age of onset • History in related individuals
- May be initially seasonal • Recurring skin or ear infection • Temporary response to glucocorticosteroids • Symptoms progressively worsen with time • Feline—face and neck pruritus

Physical Examination Findings

- Areas most commonly affected—interdigital spaces, carpal and tarsal areas, muzzle, periocular region, axillae, groin, and pinnae.
- Lesions—vary from none to broken hairs or salivary discoloration to erythema, papules, and, alopecia, to crusts, hyperpigmentation, lichenification. The skin may become excessively oily or dry seborrhea, and hyperhidrotic (apocrine sweating).
- Secondary bacterial and yeast skin infections (common). • Chronic relapsing otitis externa.
- Conjunctivitis, blepharitis, and rhinitis may occur.

CAUSES

- Pollens (grasses, weeds, and trees) • Mold spores (indoor and outdoor) • *Malassezia*
- House dust and storage mites • Animal dander • Insects

RISK FACTORS

- Temperate environments with long allergy seasons and high pollen and mold spore levels. • Concurrent pruritic dermatoses, such as flea bite hypersensitivity and adverse food reaction (summation effect).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Adverse food reaction—may cause identical symptoms; may occur concurrently with atopic dermatitis; differentiation is made by noting response to hypoallergenic diet. • Flea bite different lesion distribution and response to flea control. • Sarcoptic mange—causes severe pruritus of the ventral chest, lateral elbows, lateral hocks, and pinna margins; differentiation by multiple skin scrapings and/or complete response to a trial of miticidal therapy. • Secondary pyoderma—follicular papules, pustules, crusts, and epidermal collarettes. • Secondary yeast infections—erythematous, scaly, crusty, greasy, and malodorous body folds and intertriginous areas; differentiation by demonstration of numerous budding yeast organisms on skin cytology. • Contact dermatitis (allergic or irritant)—severe erythema and pruritus of the feet and thinly haired areas of the flank and axillae.

CBC/BIOCHEMISTRY/URINALYSIS

Eosinophilia—rare in dogs without concurrent flea infestations; common in cats.

DIAGNOSTIC PROCEDURES

- Diagnosis of AD is made by history, physical examination, and ruling out of differential diagnoses; not by either serologic or intradermal allergy testing. • Greatest treatment success noted when immunotherapy is based on results of both serum and intradermal testing.

Serologic Allergy Tests

- Measures the amount of allergen-specific IgE antibody in the patient's serum.
- Advantages over IDT—availability; hair coat does not require clipping; sedation is not required. • Disadvantages—cannot distinguish between allergic and normal patients; frequent false-positive or false-negative reactions; limited number of allergens tested; inconsistent assay validation, quality control, and reliability (may vary with the laboratory used); a subset of AD patients does not have elevated levels of circulating allergen-specific IgE.

Intradermal Test (Preferred)

- Small amounts of test allergen are injected intradermally causing localized reactions; wheal formation is measured and evaluated subjectively. • Advantages—more physiologically-appropriate determination of allergens for immunotherapy; potentially higher success rate of immunotherapy versus allergens chosen based on serum testing.
- Disadvantages—results more difficult to interpret in cats owing to the relatively small wheals produced; requires sedation and clipping a small patch of hair coat; false

ATOPIC DERMATITIS

(CONTINUED)

positive and false negative reactions may occur.

PATHOLOGIC FINDINGS

Skin biopsy—rule out other differential diagnoses; results not pathognomonic; acanthosis, mixed mononuclear superficial perivascular dermatitis, sebaceous gland metaplasia, with secondary superficial bacterial folliculitis.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient

ACTIVITY

Avoid offending allergens when possible

DIET

Diets rich in essential fatty acids may be beneficial

CLIENT EDUCATION

- Explain the inheritable and progressive nature of the condition.
- Rarely goes into remission and cannot be cured.
- Ongoing therapy may be necessary to maintain quality of life.

MEDICATIONS

DRUG(S) OF CHOICE

Immunotherapy (Hyposensitization)

- Subcutaneous or sublingual administration of gradually increasing doses of the causative allergens to reduce sensitivity.
- Allergen selection—based on allergy test results, patient history, and/or knowledge of local exposure.
- Immunotherapy formulation procedures and administration protocols are not standardized and vary widely between clinicians.
- Preferred treatment in most cases; especially indicated when it is desirable to avoid or reduce the amount of corticosteroids required to control signs, when signs last longer than 4–6 months per year, or when non-steroid forms of therapy are ineffective.
- Successfully reduces pruritus in 60–80% of dogs and cats.
- Response is slow, requiring at least 3 months and up to 1 year for full effect.

Cyclosporine

- Cyclosporine, modified (name brand preferred—Atopica 5 mg/kg/day) effective in controlling pruritus associated with chronic atopic dermatitis.
- Response is similar to that of glucocorticosteroids.
- Slow onset of activity (1–4 weeks).
- Many patients can be adequately controlled with less frequent dosing (every 2–4 days).
- Patient monitoring is recommended.
- Drug blood level monitoring recommended in cats.

Corticosteroids

- May be given for short-term relief and to break the itch-scratch cycle.
- Should be

tapered to the lowest dosage that adequately controls pruritus.

- Prednisolone (0.25–0.5 mg/kg PO q48h).
- Cats—oral steroids or very infrequent methylprednisolone acetate by injection (2–4 mg/kg).

Antihistamines

- Less effective than corticosteroids.
- Dogs—hydroxyzine (1–2 mg/kg PO q12h), chlorpheniramine (0.2–0.4 mg/kg PO q12h), diphenhydramine (2.2 mg/kg PO q12h), fexofenadine (2–5 mg/kg PO q12–24h), and clemastine (0.04–0.10 mg/kg PO q12h).
- Cats—chlorpheniramine (0.5 mg/kg PO q12h); efficacy estimated at 10–50%.

Oclacitinib

Oclacitinib Apoquel (0.4–0.6 mg/kg q12h for 14 days then q24h). Dogs—effective in controlling pruritus associated with chronic atopic dermatitis. Onset time and response similar to glucocorticoids. Long-term safety and efficacy undetermined.

PRECAUTIONS

- Cyclosporine—may affect glucose homeostasis; may increase incidence of urinary tract infection.
- Corticosteroids—use judiciously in dogs to avoid iatrogenic hyperglucocorticism and associated problems, aggravation of pyoderma, and induction of demodicosis.
- Antihistamines—can produce drowsiness, and rarely anorexia, vomiting, diarrhea, increased pruritus; use with caution in patients with cardiac arrhythmias.
- Oclacitinib—not for use in dogs under 1 year of age; insufficient long-term experience.

POSSIBLE INTERACTIONS

Concurrent use of cyclosporine and ketoconazole permits a 50% dose reduction of each drug

ALTERNATIVE DRUG(S)

- Frequent bathing (once to twice weekly) in cool water with antipruritic shampoos is very beneficial and should be strongly encouraged.
- Fatty acids: ω -3 (eicosapentaenoic acid 66 mg/kg/day) may be more effective than ω -6 (linoleic acid 130 mg/kg/day) fatty acids.
- Tricyclic antidepressants: dog—doxepin 1–2 mg/kg PO q12h; or amitriptyline 1–2 mg/kg PO q12h; overall effectiveness is unclear; not extensively studied in the cat.
- Gabapentin (dogs, 10–30 mg/kg q6–12h; cats, 3–8 mg/kg q6–8h).
- Pentoxifylline 10 mg/kg q8–12h.
- Topical triamcinolone spray 0.015% can be used over large body surfaces to control pruritus with minimal side effects.

FOLLOW-UP

PATIENT MONITORING

- Examine patient every 2–8 weeks when a new course of therapy is started.
- Monitor

pruritus, self-trauma, development of bacterial folliculitis, and possible adverse drug reactions.

- Once an acceptable level of control is achieved, examine patient every 3–12 months.
- CBC, serum chemistry profile, and urinalysis with culture—recommended every 3–12 months for patients on chronic corticosteroid, cyclosporine or Oclacitinib therapy.

PREVENTION/AVOIDANCE

- If offending allergens have been identified through allergy testing, avoidance may help to reduce the level of pruritus; this is seldom possible.
- Minimizing other sources of pruritus (e.g., flea infestation, adverse food reaction, and secondary skin infection) permits better response to therapy.

POSSIBLE COMPLICATIONS

- Secondary bacterial folliculitis or *Malassezia* dermatitis.
- Concurrent flea bite hypersensitivity and/or adverse food reaction.

EXPECTED COURSE AND PROGNOSIS

- Not life-threatening unless intractable pruritus results in euthanasia.
- Degree of pruritus usually worsens and the duration of signs last longer each year without intervention.
- Some cases spontaneously resolve.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Flea bite hypersensitivity
- Adverse food reaction/food hypersensitivity
- Bacterial folliculitis
- Malassezia* dermatitis
- Otitis externa

AGE-RELATED FACTORS

Severity worsens with age

PREGNANCY/FERTILITY/BREEDING

- Corticosteroids—contraindicated during pregnancy.
- Affected animals should not be used for breeding.

SYNOMYMS

- Atopy
- Canine atopic disease

SEE ALSO

- Flea Bite Hypersensitivity and Flea Control

ATRIAL FIBRILLATION AND ATRIAL FLUTTER

BASICS

DEFINITION

- Atrial fibrillation—rapid, irregularly irregular supraventricular rhythm. Two forms recognized: primary atrial fibrillation, an uncommon disease that occurs mostly in large dogs with no underlying cardiac disease, and secondary atrial fibrillation, which occurs in dogs and cats secondary to underlying cardiac disease.
- Atrial flutter is similar to atrial fibrillation, but the atrial rate is generally slower and is characterized by saw-toothed flutter waves in the baseline of the ECG. The ventricular response is generally rapid but may be regular or irregular.

ECG FEATURES

Atrial Flutter

- Atrial rhythm usually regular; rate approximately 300–400 bpm.
- P waves usually discerned as either discrete P waves or a “saw-toothed” baseline.
- Ventricular rhythm and rate generally depend on the atrial rate and AV nodal conduction, but are generally regular or regularly irregular and rapid.
- Conduction pattern to the ventricles is variable—in some cases every other atrial depolarization produces a ventricular depolarization (2:1 conduction ratio), giving a regular ventricular rhythm; other times the conduction pattern appears random, giving an irregular ventricular rhythm that can mimic atrial fibrillation.

Secondary Atrial Fibrillation

- No P waves present—baseline may be flat or may have small irregular undulations (“f” waves); some undulations may look like P waves.
- Ventricular rate high—usually 180–240 bpm in dogs and > 220 bpm in cats.
- Interval between QRS complexes is irregularly irregular; QRS complexes usually appear normal.

Primary Atrial Fibrillation

Similar to secondary atrial fibrillation except ventricular rate usually in the normal range.

PATHOPHYSIOLOGY

- Atrial fibrillation—caused by numerous small reentrant pathways creating a rapid (> 500 depolarizations/minute) and disorganized depolarization pattern in the atria that results in cessation of atrial contraction. Depolarizations continuously bombard the AV nodal tissue, which acts as a filter and does not allow all depolarizations to conduct to the ventricles. Many atrial depolarizations activate only a part of the atria because the rapid rate renders portions of the atria refractory, and thus they cannot reach the AV junction. Other atrial impulses penetrate into the AV junctional tissue but are not robust enough to penetrate the entire length. Blocked impulses affect the

conduction properties of the AV junctional tissue and alter conduction of subsequent electrical impulses; electrical impulses are conducted through the AV junction irregularly, producing an irregular ventricular rhythm.

- Atrial flutter—probably originates from one site of reentry that moves continuously throughout the atrial myocardium and frequently and regularly stimulates the AV node. When the atrial rate becomes sufficiently fast, the refractory period of the AV node exceeds the cycle length (P to P interval) of the SVT, and some atrial depolarizations are blocked from traversing the AV node (functional second-degree AV block).

SYSTEMS AFFECTED

Cardiovascular

Loss of atrial contraction may result in decreased stroke volume and cardiac output depending on heart rate; high heart rate may result in deterioration in myocardial function (tachycardia-induced myocardial failure).

GENETICS

No breeding studies available

SIGNALMENT

Species

Dog and cat

Breed Predilections

Large- and giant-breed dogs are more prone to primary atrial fibrillation.

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

General Comments

- Generally relate to the underlying disease process and/or CHF rather than the arrhythmia itself, but previously stable animals may decompensate.
- Patients with primary atrial fibrillation are generally asymptomatic but may demonstrate mild exercise intolerance.

Historical Findings

- Coughing/dyspnea/tachypnea.
- Exercise intolerance.
- Rarely syncope.
- Dogs with primary atrial fibrillation are typically asymptomatic.

Physical Examination Findings

- On auscultation, patients with atrial fibrillation have an erratic heart rhythm that sounds like “tennis shoes in a dryer.”
- First heart sound intensity in atrial fibrillation is variable; second heart sound only heard on beats with effective ejection, not on every beat.
- Third heart sounds (gallop sounds) may be present.
- Patients with atrial fibrillation have pulse deficits and variable pulse quality.
- Signs of CHF often present (e.g., cough, dyspnea, cyanosis).

CAUSES

- Chronic valvular disease • Cardiomyopathy
- Congenital heart disease • Digoxin toxicity
- Idiopathic • Ventricular preexcitation (atrial flutter)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Frequent atrial (supraventricular) premature depolarizations
- Supraventricular tachycardia with AV block
- Multifocal atrial tachycardia (irregular)

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

- Echocardiography and radiography may characterize type and severity of the underlying cardiac disease; moderate to severe left atrial enlargement common.
- Typically normal in patients with primary atrial fibrillation, although mild left atrial enlargement may accompany the hemodynamic alterations imposed by the arrhythmia.

DIAGNOSTIC PROCEDURES

A baseline 24-hour Holter is recommended to determine if the arrhythmia is chronic or paroxysmal. If it is chronic, drug therapy is indicated.

TREATMENT

APPROPRIATE HEALTH CARE

- Patients with fast (secondary) atrial fibrillation are treated medically to slow the ventricular rate. Converting the atrial fibrillation to sinus rhythm would be ideal, but such attempts in patients with severe underlying heart disease or left atrial enlargement are generally futile because of a low success rate and high rate of recurrence. Consider electrical cardioversion to sinus rhythm for a dog with primary atrial fibrillation and only mild structural heart disease.
- Patients with primary atrial fibrillation may be converted back to normal sinus rhythm. The success rate depends on chronicity. Patients that have been in atrial fibrillation for > 4 months generally have a lower success rate and a higher rate of recurrence. In these patients, rate control, if necessary, is the recommended treatment.
- Electrical (DC) cardioversion—application of a transthoracic electrical shock at a specific time in the cardiac cycle; requires special equipment, trained personnel, and general anesthesia. Using a monophasic defibrillator: Start with 4 J/kg; if no conversion occurs,

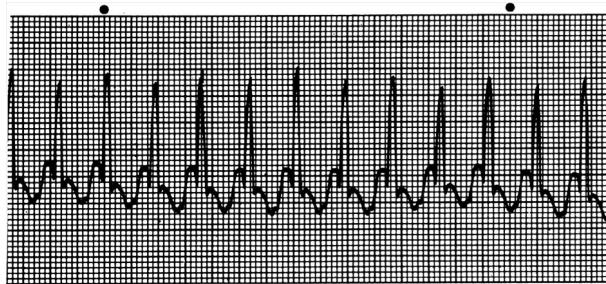

Figure 1.

Atrial flutter with 2:1 conduction at ventricular rate of 330/minute in a dog with an atrial septal defect. This supraventricular tachycardia was associated with a Wolff-Parkinson-White pattern. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

increase dose by 50 J and repeat until a max of 360 J. Using a biphasic defibrillator: Start with 1 to 2 J/kg; if no cardioversion occurs, increase dose by 50 J and repeat until max of 360 J. • For atrial flutter, conversion to sinus rhythm can be done by drug therapy, electrical cardioversion, or rapid atrial pacing (transvenous pacing electrode).

NURSING CARE

As indicated for CHF.

ACTIVITY

Restrict activity until tachycardia is controlled.

DIET

Mild to moderate sodium restriction if CHF.

CLIENT EDUCATION

- Secondary atrial fibrillation and atrial flutter is usually associated with severe underlying heart disease; goal of therapy is to lower heart rate and control clinical signs. • Sustained conversion to sinus rhythm is unlikely with secondary atrial fibrillation.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

- Digoxin, β -adrenergic blockers, esmolol, and calcium channel blockers (diltiazem) are frequently used to slow conduction through the AV node; definition of an adequate heart rate response varies among clinicians, but in dogs is generally 140–160 bpm.
- For atrial flutter, therapy is aimed at suppressing the atrial re-entry circuit using sotalol, amiodarone, or procainamide.

Dogs

- Digoxin—maintenance oral dose 0.005–0.01 mg/kg PO q12h; to achieve a therapeutic serum concentration more rapidly, the maintenance dose can be doubled for the first day. If digoxin is administered alone and

the heart rate remains high, check the digoxin level and adjust the dose to bring the level into the therapeutic range. If the heart rate remains high, consider adding a calcium channel blocker or a β -adrenergic blocker.

- Diltiazem—initially administered at a dose of 0.5 mg/kg PO q8h, then titrated up to a maximum of 1.5 mg/kg PO q8h or until an adequate response is obtained.
- Therapy for atrial fibrillation is aimed at suppressing the atrial reentry circuit using sotalol, amiodarone, or procainamide. The conversion to normal sinus rhythm is usually unsuccessful.

Cats

- Diltiazem (1–2.5 mg/kg PO q8h) or atenolol (6.25–12.5 mg/cat PO q12–24h) are the drugs of choice in most cats.
- If the heart rate is not sufficiently slowed with these drugs or if myocardial failure is present, digoxin (5 μ g/kg PO q24–48h) can be added.

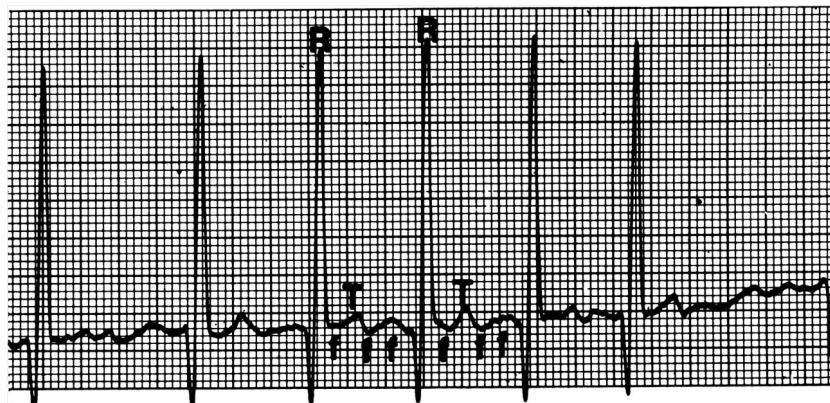

Figure 2.

“Coarse” atrial fibrillation in a dog with patent ductus arteriosus. The f waves are prominent. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

(CONTINUED)

ATRIAL FIBRILLATION AND ATRIAL FLUTTER

A

CONTRAINDICATIONS

- Digoxin, diltiazem, propranolol, and atenolol should not be used in patients with preexisting AV block.
- Use of calcium channel blockers in combination with beta blockers should be avoided because clinically significant bradyarrhythmias and/or AV block can develop.

PRECAUTIONS

- Calcium channel blockers and β -adrenergic blockers, both negative inotropes, should be used cautiously in animals with myocardial failure.
- Using high-dose oral quinidine for conversion into sinus rhythm carries a risk of quinidine toxicity (e.g., hypotension, weakness, ataxia, and seizures)—administration of diazepam intravenously controls seizures; other signs abate within several hours of discontinuing quinidine administration.

POSSIBLE INTERACTIONS

Quinidine raises the digoxin level, generally necessitating a digoxin dose reduction.

**FOLLOW-UP****PATIENT MONITORING**

- Monitor heart rate and ECG closely.
- As heart rates in the hospital and those measured on the surface ECG may be inaccurate (due to patient anxiety and other environmental factors), Holter monitoring provides a more

accurate means for assessing the need for heart rate control and/or the efficacy of medical therapy for heart rate control.

POSSIBLE COMPLICATIONS

Worsening of cardiac function with onset of arrhythmia.

EXPECTED COURSE AND PROGNOSIS

- Secondary atrial fibrillation—associated with severe heart disease, so a guarded-to-poor prognosis.
- Primary atrial fibrillation with normal ultrasound findings—generally a good prognosis.

**MISCELLANEOUS****ABBREVIATIONS**

- AV = atrioventricular
- CHF = congestive heart failure
- ECG = electrocardiogram
- SVT = supraventricular tachycardia

ATRIAL PREMATURE COMPLEXES

BASICS

DEFINITION

Premature atrial beats that originate outside the sinoatrial node and disrupt the normal sinus rhythm for 1 or more beats

ECG FEATURES

- Heart rate usually normal; rhythm irregular due to the premature P wave (called a P' wave) that disrupts the normal P wave rhythm (Figure 1).
- Ectopic P' wave—premature; configuration differs from that of the sinus P waves and may be negative, positive, biphasic, or superimposed on the previous T wave.
- QRS complex—premature; configuration usually normal (same as that of the sinus complexes). If the P' wave occurs during the refractory period of the AV node, ventricular conduction does not occur (non-conducted APCs), so no QRS complex follows the P' wave. If there is partial recovery in the AV node or intraventricular conduction systems, the P' wave is conducted with a long P'-R interval or with an abnormal QRS configuration (aberrant conduction). The more premature the complex, the more marked the aberration.
- In the P–QRS relationship, the P'-R interval is usually as long as, or longer than, the sinus P'-R interval.
- A non-compensatory pause—when the R–R interval of the two normal sinus complexes enclosing an APC is less than the R–R intervals of three consecutive sinus complexes—usually follows an APC (Figure 2). The ectopic atrial impulse discharges the sinus node and resets the cycle.

PATHOPHYSIOLOGY

- Mechanisms—an increase in automaticity of atrial myocardial fibers or a single reentrant circuit.
- May be normal finding in aged dogs; commonly seen in dogs with atrial enlargement secondary to chronic mitral

valvular insufficiency; may also be observed in dogs or cats with any atrial disease.

- May not cause hemodynamic problems; the clinical significance relates to their frequency, timing relative to other complexes, and the underlying clinical problems.
- Can presage more serious rhythm disturbances (e.g., atrial fibrillation, atrial flutter, or atrial tachycardia).

SYSTEMS AFFECTED

Cardiovascular

GENETICS

Geriatric animals, except those with congenital heart disease

SIGNS

Historical Findings

- No signs
- CHF
- Coughing and dyspnea
- Exercise intolerance
- Syncope

Physical Examination Findings

- Irregular heart rhythm
- Cardiac murmur
- Gallop rhythm
- Signs of CHF

CAUSES & RISK FACTORS

- Chronic valvular disease
- Congenital heart disease
- Cardiomyopathy
- Atrial myocarditis
- Electrolyte disorders
- Neoplasia
- Hyperthyroidism

- Toxemias
- Drug toxicity (e.g., digitalis)
- Normal variation in aged animals

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Marked sinus arrhythmia.
- Ventricular premature complexes when aberrant ventricular conduction follows an APC.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

Echocardiography and Doppler ultrasound may reveal the type and severity of the underlying heart disease.

DIAGNOSTIC PROCEDURES

- Electrocardiography
- Holter monitor to quantify APC frequency and event monitor/Holter ECG to correlate symptoms with rhythm.

PATHOLOGIC FINDINGS

Atrial enlargement; other features vary depending on underlying cause.

TREATMENT

APPROPRIATE HEALTH CARE

- Treat animal as inpatient or outpatient.
- Treat the underlying CHF, cardiac disease, or other causes.

NURSING CARE

Usually not necessary; varies with underlying cause.

ACTIVITY

Restrict if symptomatic.

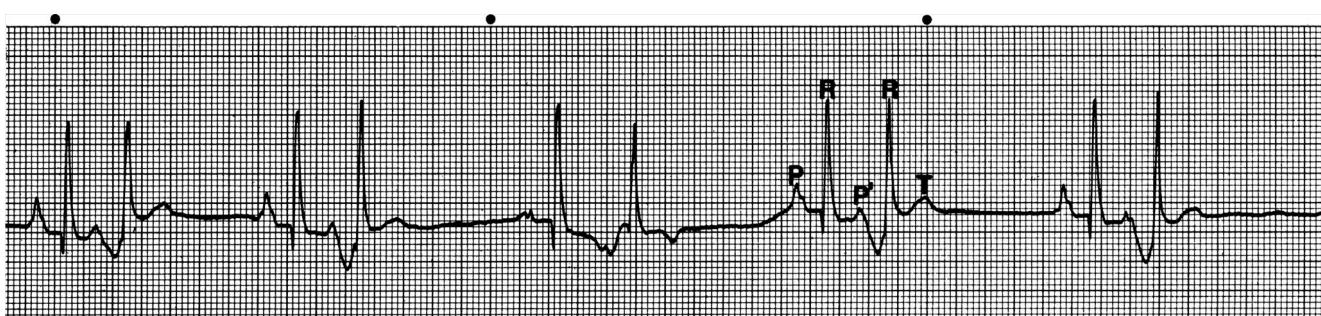

Figure 1.

APCs in a dog. P' represents the premature complex. The premature QRS resembles the basic QRS. The upright P' wave is superimposed on the T wave of the preceding complex. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Blackwell Publishing, 1992, with permission.)

ATRIAL PREMATURE COMPLEXES

A

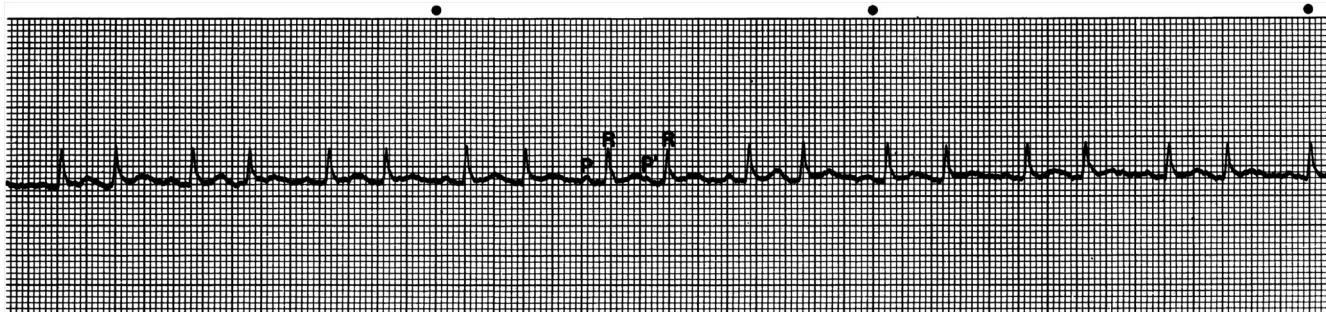

Figure 2.

APCs in bigeminy in a cat under general anesthesia. The second complex of each pair is an APC, where the first is a sinus complex. The abnormality in rhythm disappeared after the anesthetic was stopped. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Blackwell Publishing, 1992, with permission.)

DIET

No modifications unless required for management of underlying condition (i.e., low-salt diet).

CLIENT EDUCATION

APCs may not cause hemodynamic abnormalities; may be precursors of serious arrhythmias.

SURGICAL CONSIDERATIONS

N/A

**MEDICATIONS****DRUG(S) OF CHOICE**

Treat CHF and correct any electrolyte or acid/base imbalances.

Dogs

- Digoxin (0.005–0.01 mg/kg PO q12h, maintenance dosage), diltiazem (0.5–1.5 mg/kg PO q8h), or atenolol (0.25–1 mg/kg PO q12h) are used to treat clinically significant arrhythmias.
- Digoxin—treatment of choice; also indicated to treat the cardiac decompensation that is usually present.
- CHF is treated with appropriate dosage of diuretic, angiotensin converting enzyme inhibitor, and pimobendan; appropriate management of CHF may reduce APC frequency.

Cats

- Cats with hypertrophic cardiomyopathy—diltiazem (1–2.5 mg/kg PO q8h) or atenolol (6.25–12.5 mg PO q12–24h).
- Cats with dilated cardiomyopathy—digoxin (one-fourth of a 0.125 mg digoxin tablet q24h or q48h).

CONTRAINDICATIONS

Negative inotropic agents (e.g., propranolol) should be avoided in animals with CHF.

PRECAUTIONS

Use digoxin, diltiazem, atenolol, or propranolol cautiously in animals with underlying atrioventricular block or hypotension.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

Monitor heart rate and rhythm with serial ECG.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Frequent APCs may further diminish cardiac output in patients with underlying heart disease and worsen clinical symptoms.

EXPECTED COURSE AND PROGNOSIS

Even with optimal antiarrhythmic drug therapy some animals have an increased frequency of APCs or deteriorate to more severe arrhythmia as the underlying disease progresses.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

None

AGE-RELATED FACTORS

Typically occurs in geriatric dogs

ATRIAL SEPTAL DEFECT

BASICS

OVERVIEW

- Congenital defect in which the interatrial septum fails to develop normally, resulting in communication between the atria. Unknown cause; genetic basis suspected. Acquired ASD secondary to atrial rupture reported in dogs with degenerative mitral valve disease.
- Comprises 0.7–3.7% of congenital heart defects in dogs and < 10% of congenital heart defects in cats. Significantly higher incidence (37.7%) noted in a more recent study.
- 3 major types of ASD classified based on the location of the defect within the interatrial septum: ostium primum ASD (most apical portion of septum, adjacent to the atrioventricular valves), ostium secundum ASD (central portion of the septum, region of fossa ovalis), and sinus venosus ASD (upper portion of septum, junction of cranial vena cava).
- Secundum ASD with left-to-right shunting is most common (98.7% in one study of dogs and cats).
- Ostium primum ASDs typically large; may be component of atrioventricular (AV) canal defect.
- Sinus venosus ASDs typically located at the junction of the cranial vena cava (less commonly the caudal vena cava) and right atrium. Right pulmonary veins may be directed at the right atrium through the defect. May be associated with anomalous pulmonary venous connections of some or all pulmonary veins.
- Isolated ASDs typically shunt left-to-right. Magnitude of flow dependent on size (ostium) of defect, relative systemic and pulmonary resistance, and relative compliance of the ventricles. Small defects allowing atria to maintain normal differential pressure are termed restrictive. Large defects more likely to cause significant left-to-right shunting and volume overload to the right heart and pulmonary vessels. Development of secondary pulmonary hypertension can lead to reverse (right-to-left) shunting, termed Eisenmenger's physiology. ASDs may occur with concurrent defects; conditions increasing right atrial pressure (i.e., pulmonic stenosis, tricuspid valve dysplasia, tricuspid valve stenosis) can also cause balanced or reverse shunting.

SIGNALMENT

- Dog and cat
- Various breeds affected; higher prevalence in boxer and standard poodle
- No sex predisposition

SIGNS

General Comments

- Most commonly asymptomatic (73.7% in one study).
- Severe cases may present with signs of CHF.

- Signs related to generalized cyanosis may occur with right-to-left shunting.

Historical Findings

Clinical signs related to concurrent heart disease or cyanosis; exercise intolerance, syncope, cough, and dyspnea.

Physical Examination Findings

- Soft systolic murmur over the pulmonic valve due to relative pulmonic stenosis (increased blood flow across a normal pulmonic valve).
- Rarely a diastolic murmur over the tricuspid valve due to relative tricuspid stenosis.
- Split S2 (fixed) due to delayed closure of the pulmonic valve.
- Cyanosis with right-to-left shunting.
- Ascites and jugular vein distension with right heart failure.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

- Typically normal.
- Polycythemia in some patients with right-to-left shunting.

IMAGING

Radiographic Findings

- None with small defects.
- Right-sided heart enlargement and pulmonary overcirculation with significant shunting.

Echocardiographic Findings

- Right atrial and/or right ventricular dilation
- Septal dropout (not artifactual septal dropout in the region of the fossa ovalis)
- Shunting across ASD by color-flow or spectral Doppler
- Increased pulmonic flow velocity
- Dilation of the pulmonary trunk

OTHER

Electrocardiography

- Usually normal.
- Right atrial and ventricular enlargement (tall P wave, right axis deviation, deep S waves in lead II).
- Arrhythmias and intraventricular conduction disturbances possible.

TREATMENT

GENERAL

- Long-term prognosis for small ASDs is good; treatment is not typically required.
- Large ASDs with hemodynamically significant shunting and right-sided enlargement warrant closure.

MEDICAL THERAPY

- Standard treatment of CHF (furosemide, pimobendan, ACE inhibitor).

- Treatment of polycythemia (right-to-left shunting) if clinically indicated.

SURGICAL THERAPY

- Open heart surgery under cardiopulmonary bypass- direct surgical closure using patch graft.

- Pulmonary artery banding as palliative measure to limit left-to-right shunting.

CATHETER-BASED THERAPY

- Amplatzer® atrial septal occluder (ASO) device delivered percutaneously through the jugular vein for secundum-type defects; requires adequate atrial diameter, ostium diameter, ASD rim tissue, and vessel size for venous access.
- Hybrid procedure involving surgical access to right atrium, transatrial delivery of ASO device, and active device fixation under inflow occlusion reported.

FOLLOW-UP

PATIENT MONITORING

Recheck when decompensation or other clinical signs develop.

EXPECTED COURSE AND PROGNOSIS

- Dependent on defect size and co-existing abnormalities.
- Small, isolated defects unlikely to cause clinical signs.
- Defects > 12 mm more likely to cause heart failure.

MISCELLANEOUS

ABBREVIATIONS

- ASD = atrial septal defect
- CHF = congestive heart failure

Author Sandra P. Tou

Consulting Editors Larry P. Tilley and Francis W.K. Smith, Jr.

BASICS

DEFINITION

ECG rhythm characterized by absence of P waves; condition can be temporary (e.g., associated with hyperkalemia or drug-induced), terminal (e.g., associated with severe hyperkalemia or dying heart), or persistent.

ECG Features

Persistent Atrial Standstill

- P waves absent.
- Heart rate usually slow (< 60 bpm).
- Rhythm regular with supraventricular type QRS complexes.
- Heart rate does not increase with atropine administration.

Hyperkalemic Atrial Standstill

- Heart rate normal or slow.
- Rhythm regular or irregular.
- QRS complexes tend to be wide and become wider as the potassium level rises; with severe hyperkalemia (potassium > 10 mEq/L), the QRS complexes are replaced by a smooth biphasic curve.
- Heart rate may increase slightly with atropine.

PATHOPHYSIOLOGY

Persistent Atrial Standstill

Caused by an atrial muscular dystrophy; skeletal muscle involvement common.

Hyperkalemic Atrial Standstill

Generally occurs with serum potassium levels > 8.5 mEq/L; value influenced by serum sodium and calcium levels and acid-base status. Hyperkalemic patients with atrial standstill have sinus node function, but impulses do not activate atrial myocytes; thus, the associated rhythm is termed a sinoventricular rhythm. Since the sinus node is functional, an irregular rhythm may be due to sinus arrhythmia.

SYSTEMS AFFECTED

Cardiovascular

GENETICS

None

INCIDENCE/PREVALENCE

Rare rhythm disturbance

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dog and cat

Breed Predilections

Persistent atrial standstill—most common in English Springer spaniels; other breeds occasionally affected.

Mean Age and Range

Most animals with persistent atrial standstill are young; animals with hypoadrenocorticism are usually young to middle-aged.

Predominant Sex

Hypoadrenocorticism more common in females (69%).

SIGNS

Historical Findings

- Vary with underlying cause.
- Lethargy common; syncope may occur.
- Patients with persistent atrial standstill may show signs of congestive heart failure.

Physical Examination Findings

- Vary with underlying cause.
- Bradycardia common.
- Patients with persistent atrial standstill may have skeletal muscle wasting of the antebrachium and scapula.

CAUSES

- Hyperkalemia.
- Atrial disease, often associated with atrial distension (e.g., cats with cardiomyopathy).
- Atrial myopathy (persistent atrial standstill).

RISK FACTORS

- Hyperkalemic atrial standstill
- Hypoadrenocorticism
- Conditions leading to obstruction or rupture of the urinary tract
- Oliguric or anuric renal failure

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Slow atrial fibrillation
- Sinus bradycardia with small P waves lost in the baseline

CBC/BIOCHEMISTRY/URINALYSIS

Persistent Atrial Standstill

Normal

Hyperkalemic Atrial Standstill

- Hyperkalemia.
- Hyponatremia and sodium:potassium ratio < 27 if atrial standstill secondary to hypoadrenocorticism.
- Azotemia and hyperphosphatemia with hypoadrenocorticism, renal failure, and rupture or obstruction of the urinary tract.

OTHER LABORATORY TESTS

ACTH stimulation test if hypoadrenocorticism suspected

IMAGING

Echocardiogram and electromyography if persistent atrial standstill suspected—cardiomegaly and depressed contractility may be seen.

DIAGNOSTIC PROCEDURES

Skeletal muscle biopsy in animals with persistent atrial standstill.

PATHOLOGIC FINDINGS

Persistent Atrial Standstill

- Greatly enlarged and paper-thin atria; usually biatrial involvement, although one case of only left atrial involvement was reported.
- Severe scapular and brachial muscle wasting in some dogs.
- Marked fibrosis, fibroelastosis, chronic mononuclear cell inflammation, and steatosis throughout the atria and interatrial septum.

TREATMENT

APPROPRIATE HEALTH CARE

Persistent Atrial Standstill

Not life-threatening condition; animal can be treated as an outpatient.

Hyperkalemic Atrial Standstill

Potentially life-threatening; often requires aggressive treatment.

NURSING CARE

Aggressive fluid therapy with 0.9% saline often required to correct hypovolemia and lower serum potassium levels (see Hyperkalemia) in patients with hyperkalemic atrial standstill.

ACTIVITY

Restrict activity in patients with persistent atrial standstill and signs of CHF or syncope.

DIET

N/A

CLIENT EDUCATION

Persistent Atrial Standstill

Clinical signs generally improve after pacemaker implantation; signs of CHF may develop, and weakness and lethargy may persist even after heart rate and rhythm are corrected with the pacemaker.

SURGICAL CONSIDERATIONS

Persistent Atrial Standstill

Implant permanent ventricular pacemaker to regulate rate and rhythm.

Hyperkalemic Atrial Standstill

Hyperkalemia secondary to urinary tract obstruction or rupture may require surgery.

MEDICATIONS

DRUG(S) OF CHOICE

Persistent Atrial Standstill

Treat with diuretics and ACE inhibitor (e.g., enalapril or benazepril) if CHF develops.

Hyperkalemic Atrial Standstill

- Treat the underlying cause (e.g., oliguric renal failure, hypoadrenocorticism).
- Aggressive fluid therapy with 0.9% saline and possibly sodium bicarbonate or insulin

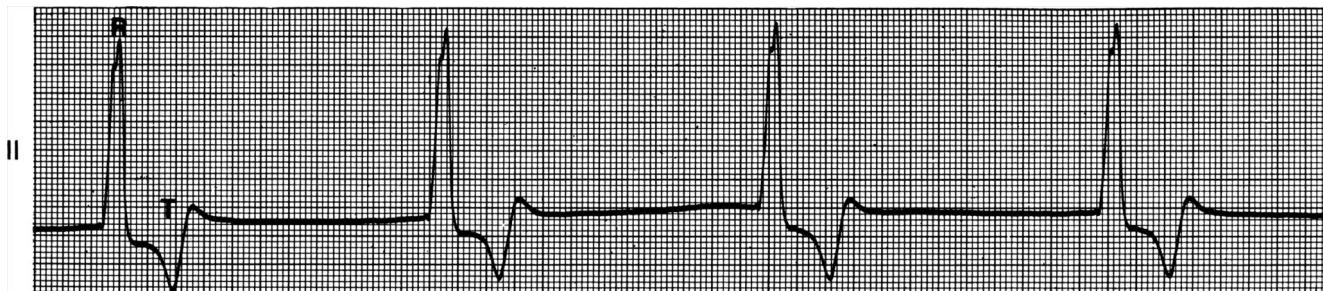

Figure 1.

Atrial stand still in a dog with a potassium of 9 mEq/L. Note the absence of P waves and wide QRS complexes.

with dextrose as discussed under Hyperkalemia.

- Calcium gluconate—counters the cardiac effects of hyperkalemia; can be used in life-threatening situations to reestablish a sinus rhythm while instituting treatment to lower potassium concentration.

CONTRAINDICATIONS

Avoid potassium-containing fluids or medications that increase potassium concentration in hyperkalemic patients.

PRECAUTIONS

Diuretics lower preload and may worsen weakness in dogs with persistent atrial standstill and CHF unless a pacemaker has been implanted.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Monitor ECG during treatment of hyperkalemia and periodically in animals with a permanent ventricular pacemaker.
- Monitor electrolytes in patients with hyperkalemic atrial standstill.
- Monitor patients with persistent atrial standstill for signs of CHF.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

CHF in patients with persistent atrial standstill

EXPECTED COURSE AND PROGNOSIS

Persistent Atrial Standstill

Clinical signs generally improve after pacemaker implantation. Signs of CHF may develop, and weakness and lethargy persist even after heart rate and rhythm are corrected with the pacemaker. There may be persistence of signs related to muscular dystrophy.

Hyperkalemic Atrial Standstill

Long-term prognosis is excellent if underlying cause can be corrected and hyperkalemia reversed.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Diseases causing hyperkalemia (e.g., hypoadrenocorticism, urethral obstruction or urinary tract tear, acidosis, and drugs).

AGE-RELATED FACTORS

Persistent atrial standstill—usually diagnosed in young animals; hypoadrenocorticism—usually diagnosed in young to middle-aged animals.

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

BASICS

DEFINITION

• Endocardial splitting is a linear defect limited to the endocardial layer of the atrium (typically the left atrium) resulting from distension of the atrial wall beyond its elastic limits. • An atrial tear may result if the split extends through the myocardium and epicardium, resulting in a full thickness defect in the atrial wall and hemorrhage into the pericardial space.

PATHOPHYSIOLOGY

• Endocardial splitting typically results from increased left atrial volume and pressure secondary to severe mitral regurgitation and mechanical trauma from the regurgitant jet; primary endocardial degeneration may also play a role. • If the split is incomplete, fibrin may seal the defect temporarily; this either heals as a linear depression in the endocardial surface or subsequently extends through the myocardium resulting in a complete left atrial tear. • A left atrial tear results in peracute bleeding into the pericardial sac and severe, life-threatening hemodynamic compromise secondary to acute cardiac tamponade. • If a tear occurs in the interatrial septum, an acquired atrial septal defect may form. • Tearing of either atrium may also rarely occur secondary to blunt trauma, or iatrogenically during pericardiocentesis.

SYSTEMS AFFECTED

- Cardiovascular • Respiratory

INCIDENCE/PREVALENCE

Atrial tear is a rare cause of hemorrhagic pericardial effusion in the dog encompassing approximately 2% of pericardial effusion cases.

SIGNALMENT

Species

Dog; uncommon in cat

Breed Predilections

- Same as endocardiosis breeds; more common in small- to medium-sized dogs.
- Poodle, dachshund, cocker spaniel, and Shetland sheepdog may be overrepresented.
- If trauma is the cause, any breed may be represented.

Mean Age and Range

Middle-aged to older dogs are predisposed.

SIGNS

Historical Findings

- Acute onset of weakness and collapse that may progress quickly to respiratory or cardiopulmonary arrest; episode may follow a period of increased excitement or activity.
- History of long-standing cardiac disease with signs of CHF described in most patients.
- Acute worsening of cough or dyspnea are

commonly observed. • Possible history of blunt trauma.

Physical Examination Findings

- Collapse. • Tachycardia. • Weak arterial pulses or pulsus paradoxus. • Pale, muddy, or ashen mucous membranes; prolonged CRT.
- Other signs of significant cardiac disease (e.g., murmur, gallop rhythm, arrhythmia, cough, or dyspnea) are typically present.
- Signs of right heart failure (e.g., ascites and jugular venous distension) may also be seen in some patients. • Heart sounds may be muffled, or if a murmur was heard before the atrial wall tear occurred, it may be reduced in intensity.

CAUSES

- Mitral valve endocardiosis • Chordae tendinae rupture • Cardiac neoplasia, most commonly hemangiosarcoma • Chest trauma • Cardiac catheterization

RISK FACTORS

- Severe mitral regurgitation, left atrial enlargement. • May be precipitated by an episode of excitement, stress, or activity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of acute cardiovascular collapse or syncope • Pericardial effusion from other causes (e.g., neoplastic and idiopathic)
- Heart failure • Severe cardiac arrhythmias

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia is uncommon unless pericardiocentesis is performed since volume of blood loss is relatively small.
- Hypoproteinemia is common. • Elevations in serum lactate, metabolic acidosis.
- Increased ALT, AST in some patients.
- Prerenal azotemia; hyponatremia or other electrolyte derangements may be seen.

OTHER LABORATORY TESTS

NT-proBNP and TnI levels may be elevated.

IMAGING

Radiographic Findings

- Moderate to severe left atrial enlargement is expected. • Comparison with previous thoracic radiographs may show rounding and further enlargement of cardiac silhouette; characteristic globoid cardiac silhouette associated with pericardial effusion may be more obvious on the DV view. • Interstitial to alveolar pulmonary infiltrates if concomitant left-sided CHF is present. • Small volume pleural effusion, ascites, hepatomegaly, and large caudal vena cava may be seen due to right-sided CHF.

Echocardiographic Findings

- Pericardial effusion is evidenced by a hypoechoic space between the heart and pericardial sac; the volume of pericardial

effusion identified may be relatively small as the pericardium remains inelastic due to the acute nature of the bleed; a characteristic linear, hyperechoic blood clot may be seen within the pericardial sac. • The actual tear is often not identified though an associated thrombus is occasionally visualized within the left atrium. • Cardiac tamponade is evidenced by diastolic collapse of the right atrium and/or ventricle. • Signs of advanced mitral endocardiosis, including mitral valve thickening and prolapse, moderate to severe mitral regurgitation, moderate to severe left atrial enlargement and often one or more ruptured chordae tendinae.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

- Sinus tachycardia • Atrial or ventricular arrhythmias • Possible dampened QRS complexes • Electrical alternans • ST-segment abnormalities • Possible left ventricular or left atrial enlargement pattern

PATHOLOGIC FINDINGS

- Endocardial splitting is noted grossly as a pale linear depression in the atrial endocardium. • Atrial wall tears appear as full thickness defects extending through the atrial endocardium, myocardium and epicardium; an associated thrombus may or may not be present. The caudolateral aspect of the left atrium is most commonly affected, with many tears occurring at the atrio-auricular junction.
- Hemorrhagic pericardial effusion or pericardial thrombus are seen with acute tears.
- Mitral endocardiosis characterized by thickened mitral valve leaflets with rolled edges; chordae tendinae rupture may be seen; atrial jet lesions are possible. • Cardiomegaly with severe left atrial enlargement expected.

TREATMENT

APPROPRIATE HEALTH CARE

- If a left atrial tear is strongly suspected, perform pericardiocentesis only if the effusion is causing symptomatic, life-threatening cardiac tamponade, since further hemorrhage into the pericardial sac or exsanguination may occur once pericardial fluid is removed. • If pericardiocentesis is performed, remove only enough fluid to improve clinical signs.
- Pericardiocentesis will likely be difficult given the small volume of effusion typically identified, severe cardiac enlargement, and the small size of most dogs with left atrial rupture; ultrasound guidance and continuous ECG monitoring are highly recommended. • Best practices for management of left atrial tears have not been clearly established; however, aggressive medical management to lower left atrial pressure using afterload and preload reducers is recommended based on the author's clinical experience. • If a fibrin clot

ATRIAL WALL TEAR

(CONTINUED)

forms over the defect, the patient may stabilize and recover.

NURSING CARE

- Administer oxygen to dogs with dyspnea or signs of hemodynamic instability.
- Administer IV fluids or blood products only if evidence of hypovolemia is present; most dogs remain in a volume overloaded state and further intravascular volume expansion will increase left atrial pressure and potentially worsen tamponade.

ACTIVITY

Strict cage rest in the acute period should be followed by chronic exercise restriction.

CLIENT EDUCATION

Left atrial tear typically accompanies advanced cardiac disease and chronic medical therapy will be necessary; though the prognosis is guarded for surviving the acute event some dogs with left atrial tear have lived more than a year after the incident.

SURGICAL CONSIDERATIONS

- Exploratory thoracotomy may be considered if hemorrhage persists or recurs but should be undertaken cautiously given the advanced state of cardiac disease typically present.
- Transcatheter septal puncture and balloon tear of the fossa ovalis may also be considered to decompress the left atrium; however, right heart failure or hypoxemia due to right-to-left shunting may result.

MEDICATIONS

DRUG(S) OF CHOICE

- Atrial tears occur secondary to elevated left atrial pressure; thus medical therapy should be focused on lowering of left atrial pressures in order to reduce continued hemorrhage into the pericardial space and permit fibrin clot formation at the site of the tear; this may be accomplished with preload (e.g., diuretics, nitroglycerin paste) and/or afterload reducers (arterial vasodilators).
- Preload and afterload reduction must be undertaken cautiously to avoid worsening of hemodynamic compromise.
- Afterload reduction may be achieved by conservative doses of sodium nitroprusside; a low starting CRI dose of 0.5–1 µg/kg/min is recommended to achieve a decrease in LA pressure without precipitating significant hypotension; blood pressure monitoring is recommended and the dose may be uptitrated as necessary every 15–30 minutes up to a maximum of 10 µg/kg/min to achieve an improvement in clinical signs and/or a reduction in blood pressure of 10–15 mmHg.
- Alternatively, amlodipine may be started at 0.1–0.2 mg/kg PO q24h; chronic amlodipine therapy may be implemented in normotensive

or hypertensive animals to reduce regurgitant fraction and lower left atrial pressure.

- Diuretics should be used cautiously if needed to treat dyspnea associated with concomitant congestive heart failure (e.g., 1–2 mg/kg of furosemide IV as needed); signs of left-sided congestive heart failure may worsen as cardiac tamponade resolves due to augmentation of preload; more aggressive diuretic therapy may then be required.
- Pimobendan (0.2–0.3 mg/kg PO q12h) may result in a further reduction in left atrial pressure though studies have not specifically examined its use in the setting of left atrial rupture and the author typically delays starting inotropes for several days so as not to disrupt stability of the fibrin clot.
- Once the patient is stable, ACE inhibitors (e.g., enalapril 0.5 mg/kg q12–24h) should be implemented for chronic management of accompanying heart failure.

PRECAUTIONS

- Aggressive fluid therapy is not warranted in these patients; further volume expansion may increase left atrial pressure, worsen cardiac tamponade, and contribute to hemodynamic compromise.
- Best practices for management of left atrial tear have not been clearly established; the choice of whether to perform pericardiocentesis, and whether to administer preload and/or afterload reducers should be made based on assessment of the volume status, blood pressure and clinical stability of the patient.

POSSIBLE INTERACTIONS

Sodium nitroprusside should never be administered concurrently with phosphodiesterase-V inhibitors (e.g., sildenafil or tadalafil) due to the potential for life-threatening systemic hypotension.

FOLLOW-UP

PATIENT MONITORING

- Recommend close monitoring of respiratory rate and effort, mucous membrane color and CRT, pulse quality, and heart rate; blood pressure monitoring is recommended if arterial vasodilators are implemented.
- Follow-up examination with echocardiography helps determine resolution of pericardial effusion and resorption of an atrial or pericardial clot.
- Close follow-up every 2–3 months thereafter is recommended for repeat pericardial fluid checks and medication adjustments as deemed appropriate.

PREVENTION/AVOIDANCE

Recommend avoidance of strenuous physical activity and excitement.

POSSIBLE COMPLICATIONS

- Even if the tear seals, the patient is prone to further tears because of underlying cardiac disease.
- Most dogs have or will develop concurrent CHF.

EXPECTED COURSE AND PROGNOSIS

Prognosis for survival is guarded to poor; however, some animals can do well for several months or longer with close monitoring, exercise restriction and optimal medical management of cardiac disease.

atrioventricular block, complete (third degree)

A

BASICS

DEFINITION

- All atrial impulses are blocked at the AV junction; atria and ventricles beat independently. A secondary “escape” pacemaker site (junctional or ventricular) stimulates the ventricles.
- Atrial rate normal.
- Idioventricular escape rhythm slow.

ECG Features

- Ventricular rate slower than the atrial rate (more P waves than QRS complexes)—ventricular escape rhythm (idioventricular) usually < 40 bpm; junctional escape rhythm (idiojunctional) 40–60 bpm in dogs and 60–100 bpm in cats.
- P waves—usually normal configuration (Figure 1).
- QRS complex—wide and bizarre when pacemaker located in the ventricle, or in the lower AV junction in a patient with bundle branch block; normal when escape pacemaker in the lower AV junction (above the bifurcation of the bundle of His) in a patient without bundle branch block.
- No conduction between the atria and the ventricles; P waves have no constant relationship with QRS complexes; P-P and R-R intervals relatively constant (except for a sinus arrhythmia).

PATHOPHYSIOLOGY

Slow ventricular escape rhythms (< 40 bpm) result in low cardiac output and eventual heart failure, often when animal is excited or exercised, since demand for greater cardiac output is not satisfied. As the heart fails, signs increase with mild activity.

SYSTEMS AFFECTED

Cardiovascular

GENETICS

Can be an isolated congenital defect

INCIDENCE/PREVALENCE

Not documented

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT**Species**

Dog and cat

Breed Predilections

- Cocker spaniel—can have idiopathic fibrosis.
- Pug and Doberman pinscher—can have associated sudden death, AV conduction defects, and bundle of His lesions.

Mean Age and Range

Geriatric animals, except congenital heart disease patients. Median age for cats—14 years.

Predominant Sex

Intact female dogs

SIGNS**Historical Findings**

- Exercise intolerance
- Weakness or syncope
- Occasionally, CHF

Physical Examination Findings

- Bradycardia
- Variable third and fourth heart sounds
- Variation in intensity of the first heart sounds
- Signs of CHF
- Intermittent “cannon” A waves in jugular venous pulses

CAUSES & RISK FACTORS

Isolated congenital defect

- Idiopathic fibrosis
- Infiltrative cardiomyopathy (amyloidosis or neoplasia)
- Hypertrophic cardiomyopathy in cats
- Digitalis toxicity
- Hyperthyroidism in cats
- Myocarditis
- Endocarditis
- Electrolyte disorder
- Myocardial infarction

- Other congenital heart defects
- Lyme disease
- Chagas disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Advanced second-degree AV block
- Atrial standstill
- Accelerated idioventricular rhythm

CBC/BIOCHEMISTRY/URINALYSIS

- Abnormal serum electrolytes (e.g., hyperkalemia, hypokalemia) possible.
- High WBC with left shift in animals with bacterial endocarditis.

OTHER LABORATORY TESTS

- High serum digoxin concentration if AV block is due to digoxin toxicity.
- Lyme titer and accompanying clinical signs if AV block due to Lyme disease.

IMAGING

Echocardiography and Doppler ultrasound to assess cardiac structure and function.

DIAGNOSTIC PROCEDURES

- Electrocardiography
- His bundle electrogram to determine the site of the AV block.
- Long-term (Holter) ambulatory recording if AV block is intermittent.

PATHOLOGIC FINDINGS

Degeneration or fibrosis of the AV node and its bundle branches, associated with endocardial and myocardial fibrosis and organized endomyocarditis.

TREATMENT

APPROPRIATE HEALTH CARE

- Temporary or permanent cardiac pacemaker—only effective treatment in symptomatic patients.

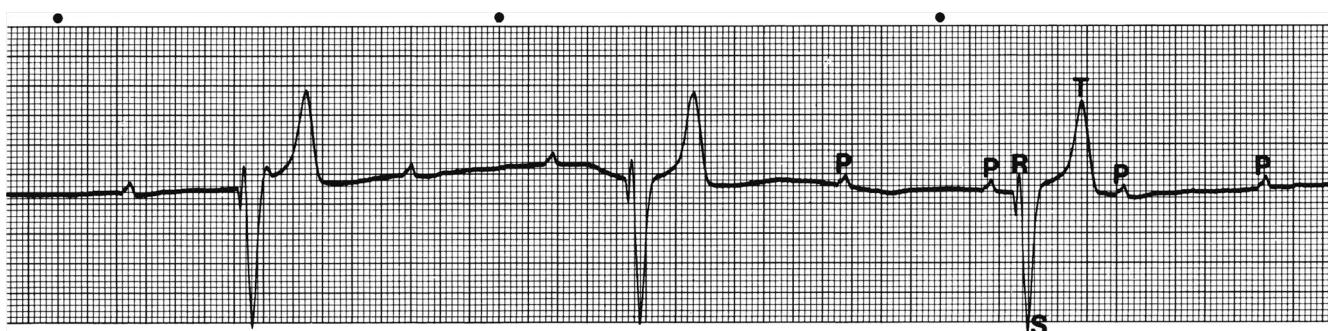

Figure 1.

Complete heart block. The P waves occur at a rate of 120, independent of the ventricular rate of 50. The QRS configuration is a right bundle branch block pattern. The regular rate and stable QRS indicate that the rescuing focus is probably near the AV junction. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Blackwell Publishing, 1992, with permission.)

ATRIOVENTRICULAR BLOCK, COMPLETE (THIRD DEGREE) (CONTINUED)

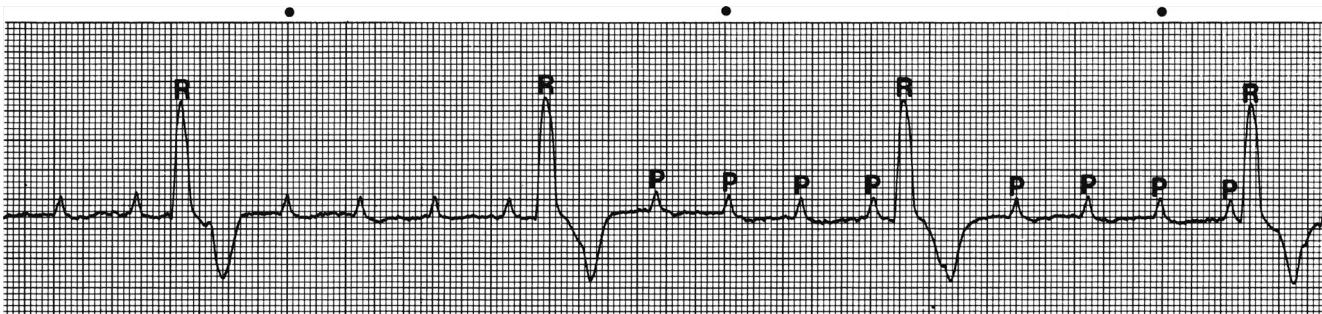

Figure 2.

Complete heart block in a cat. The P waves rate is 240/minute, independent of the ventricular rate of 48/minute. QRS configuration is a left bundle branch block pattern. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Blackwell Publishing, 1992, with permission.)

- Carefully monitor asymptomatic patients without a pacemaker for development of clinical signs.

NURSING CARE

Cage rest prior to pacemaker implantation; when the pulse generator is put into a subcutaneous pocket, a non-constricting bandage is required around the ventral neck or abdomen for 3–5 days to prevent seroma formation or pacemaker movement.

ACTIVITY

Restrict if symptomatic

DIET

No modifications unless required to manage underlying condition (e.g., low-salt diet).

CLIENT EDUCATION

- Temporary or permanent cardiac pacemaker—only effective treatment in symptomatic patients.
- Asymptomatic patients without a pacemaker—must be carefully monitored for development of clinical signs.

SURGICAL CONSIDERATIONS

- Most patients—at high anesthetic cardiopulmonary risk; usually paced preoperatively with a temporary external pacemaker system.
- The small size of cats makes pacemaker implantation more difficult than in dogs.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Treatment with drugs—usually of no value. Traditionally used to treat complete AV block: atropine, isoproterenol, corticosteroids, and dobutamine.
- Intravenous isoproterenol infusion may help increase the rate of the ventricular escape rhythm to stabilize hemodynamics.
- If CHF—diuretic and vasodilator therapy may be needed before pacemaker implantation.

CONTRAINDICATIONS

Avoid digoxin, xylazine, acepromazine, beta blockers (e.g., propranolol and atenolol), and calcium channel blockers (e.g., verapamil and diltiazem); ventricular antiarrhythmic agents are dangerous because they suppress lower escape foci.

PRECAUTIONS

Vasodilators—may cause hypotension in animals with complete AV block; monitor closely if used, especially prior to pacemaker implantation.

**FOLLOW-UP****PATIENT MONITORING**

- Monitor—pacemaker function with serial ECGs.
- Radiographs—following pacemaker implantation, to confirm the position of the lead and generator.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Pulse generators—broad range of clinical life; pacemaker replacement necessary when battery is depleted, pulse generator malfunction occurs, or exit block develops; pacemaker leads can become dislodged and infected.

EXPECTED COURSE AND PROGNOSIS

Poor long-term prognosis if no cardiac pacemaker implanted, especially when the animal has clinical signs. Cats can sometimes survive > 1 year.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

None

ABBREVIATIONS

- AV = atrioventricular
- CHF = congestive heart failure

ATROVENTRICULAR BLOCK, FIRST DEGREE

BASICS

DEFINITION

Refers to a delay in conduction that occurs between atrial and ventricular activation.

ECG Features

- Rate and rhythm—usually normal.
- Usually there are regularly occurring normal P waves and QRS complexes (Figures 1 and 2).
- Prolonged, consistent PR intervals—dogs, > 0.13 sec; cats, > 0.09 sec (Figures 1 and 2).

PATHOPHYSIOLOGY

- Virtually never causes clinical signs.
- May become a more severe AV conduction disturbance in some animals.
- Normally the PR interval tends to shorten with rapid heart rates.
- May be the result of intra-atrial conduction delay (prolongation of the PA interval on surface ECG and simultaneous His bundle electrogram) or delay of conduction within the AV node itself (prolongation of the AH interval on His bundle electrogram).

SYSTEMS AFFECTED

Cardiovascular

GENETICS

N/A

INCIDENCE/PREVALENCE

Common

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dog and cat

Breed Predilections

American cocker spaniel, dachshund, brachycephalic dogs, Persian cats

Mean Age and Range

- May occur in young, otherwise healthy dogs as a manifestation of high vagal tone.
- Intra-atrial conduction delay involving the right atrium may be seen with congenital heart disease, especially atrioventricular septal defects.
- May be noted in aged patients with degenerative conduction system disease, particularly cocker spaniels and dachshunds.
- Persian cats of any age with high vagal tone and in cats of any age with hypertrophic cardiomyopathy.

SIGNS

Historical Findings

- Most animals are asymptomatic.
- If drug-induced, may have a history of clinical signs related to drug toxicity—anorexia, vomiting, and diarrhea with digoxin; weakness with calcium channel blockers or β -adrenergic antagonists.

Physical Examination Findings

- Normal—unless also signs of more generalized myocardial disease, drug toxicity, or non-cardiac disease.

CAUSES

- May occur in normal animals.
- Enhanced vagal stimulation resulting from non-cardiac diseases—usually accompanied by sinus arrhythmia, sinus arrest, and/or Mobitz type I second-degree AV block.
- Pharmacologic agents (e.g., digoxin, β -adrenergic antagonists, calcium channel blocking agents, propafenone, amiodarone, α_2 -adrenergic agonists, parasympathomimetic agents [bethanechol, physostigmine, pilocarpine] and severe procainamide or quinidine toxicity).
- Degenerative disease of the conduction system.
- Hypertrophic cardiomyopathy.

- Myocarditis (especially *Trypanosoma cruzi*, *Borrelia burgdorferi*, *Rickettsia rickettsii*).
- Infiltrative diseases (tumors, amyloid).
- Atropine administered intravenously may briefly prolong the PR interval.

RISK FACTORS

Any condition or intervention that raises vagal tone

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

P waves superimposed upon preceding T waves because of first-degree AV block should be differentiated from bifid T waves.

CBC/BIOCHEMISTRY/URINALYSIS

- Serum electrolytes—hypokalemia and hyperkalemia may predispose to AV conduction disturbances.
- Leukocytosis—may be noted with bacterial endocarditis or myocarditis.

OTHER LABORATORY TESTS

- Serum digoxin concentration—may be high.
- *T. cruzi*, *B. burgdorferi*, *R. rickettsii* titers—may be high.
- T_4 —may be high in cats if associated with thyrotoxic myocardial disease.

IMAGING

Echocardiographic examination—may reveal hypertrophic or infiltrative myocardial disorder.

DIAGNOSTIC PROCEDURES

May be needed to identify causes of high vagal tone—upper airway disease, cervical and thoracic masses, gastrointestinal disorders, and high intraocular pressure.

PATHOLOGIC FINDINGS

Variable—depend on underlying cause

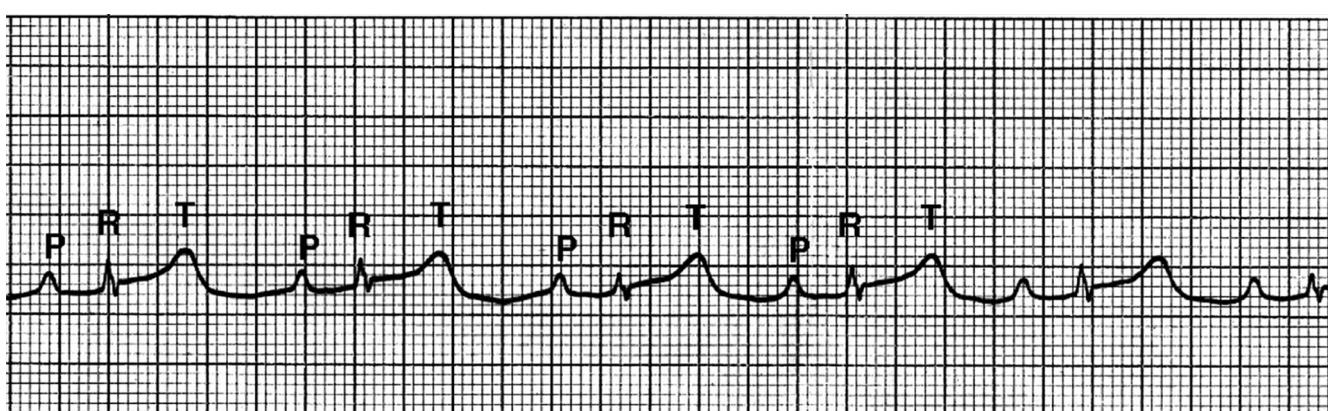

Figure 1.

Lead II ECG rhythm strip recorded from a cat with hypertrophic cardiomyopathy. There is sinus bradycardia (120 bpm) and first-degree atrioventricular conduction block. The PR interval is 0.12 second (paper speed = 50 mm/s).

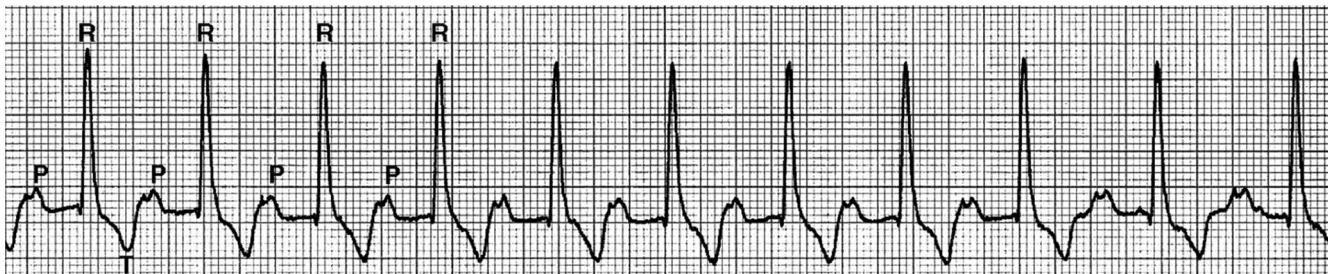

Figure 2.

Lead II ECG rhythm strip recorded from a dog showing sinus tachycardia (175 bpm) and first-degree atrioventricular conduction block. Because the heart rate is rapid, P waves are superimposed on the downslope of the preceding T waves. The PR interval exceeds 0.16 second (paper speed = 50 mm/s).

TREATMENT

APPROPRIATE HEALTH CARE

- Remove or treat underlying cause(s).
- Hospitalization may be necessary to manage the underlying cause (e.g., cardiomyopathy, gastrointestinal disease, airway disease).

NURSING CARE

N/A

ACTIVITY

Unrestricted; unless restriction required for an underlying condition.

DIET

No modifications or restrictions unless required to manage an underlying condition.

CLIENT EDUCATION

Generally unnecessary

SURGICAL CONSIDERATIONS

None unless required to manage an underlying condition.

MEDICATIONS

DRUG(S) OF CHOICE

Medications used only if needed to manage an underlying condition.

CONTRAINDICATIONS

- Avoid hypokalemia—increases sensitivity to vagal tone; may potentiate AV conduction delay.
- Avoid drugs likely to impair impulse conduction further (calcium channel blocking agents, β -adrenergic antagonists, α_2 -adrenergic agonists, amiodarone, propafenone).

PRECAUTIONS

Drugs with vagomimetic action (e.g., digoxin, bethanechol, physostigmine, pilocarpine) may potentiate first-degree block.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

Except in healthy young animals, monitor ECG to detect any progression in conduction disturbance.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Depends on underlying cause.
- Prognosis usually excellent if no significant underlying disease is present.

ATRIOVENTRICULAR BLOCK, SECOND DEGREE—MOBITZ I

A

**BASICS****DEFINITION**

Second-degree AV block refers to failure of one or more P waves but not all P waves to be conducted. Mobitz Type I second-degree AV block occurs when AV transmission is progressively delayed prior to a blocked P wave.

ECG Features

- PR interval—becomes progressively longer prior to the appearance of a P wave that is not followed by a QRS complex (Figure 1).
- Heart rate and QRS morphology—usually normal.
- Often cyclical.

PATHOPHYSIOLOGY

- Frequently associated with high resting vagal tone and sinus arrhythmia in dogs.
- Generally not pathologic or hemodynamically significant.
- This type of AV block usually results from conduction delay within the AV node itself (rather than delay in other segments of the AV conducting system) and is characterized by a progressive increase in AH interval with eventual block between the A and H deflections on a His bundle recording.

SYSTEMS AFFECTED

Cardiovascular

GENETICS

N/A

INCIDENCE/PREVALENCE

Radiotelemetry studies have shown that this arrhythmia occurs in 64% of healthy adult dogs and 100% of healthy puppies 8–12 weeks of age.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT**Species**

Dog; uncommon in cat

Breed Predilections

N/A

Mean Age and Range

- Usually occurs in young, otherwise healthy dogs as a manifestation of high vagal tone.
- Occasionally occurs in older dogs with abnormally strong vagal tone.
- Rarely noted in old dogs with degenerative conduction system disease.

SIGNS**Historical Findings**

- Most animals are asymptomatic.
- If drug-induced, owner may report signs of drug toxicity—anorexia, vomiting, and diarrhea with digoxin; weakness with calcium channel blockers or β -adrenergic antagonists.
- If heart rate is abnormally slow, syncope or weakness may occur.

Physical Examination Findings

- May be normal unless signs of more-generalized myocardial disease or non-cardiac disease are present.
- Intermittent pauses in the cardiac rhythm.
- First heart sound may become progressively softer, followed by a pause.
- An audible S4 may be heard unaccompanied by S1 and S2 when block occurs.

CAUSES

- Occasionally noted in normal animals.
- Enhanced vagal stimulation resulting from non-cardiac diseases—usually accompanied by sinus arrhythmia, sinus arrest.
- Pharmacologic agents—digoxin, β -adrenergic antagonists, calcium channel blocking agents, propafenone, amiodarone, α_2 -adrenergic agonists, opioids.

RISK FACTORS

Any condition or intervention that enhances vagal tone.

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

- Non-conducted P waves from supraventricular premature impulses or supraventricular tachycardias should be distinguished from second-degree AV block.

- Type II second-degree AV block (no variation in PR intervals).

CBC/BIOCHEMISTRY/URINALYSIS

Hypokalemia may predispose to AV conduction disturbances

OTHER LABORATORY TESTS

Serum digoxin concentration—may be high

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- May be necessary to identify specific causes of enhanced vagal tone (e.g., upper airway disease, cervical and thoracic masses, gastrointestinal disorders, and high intraocular pressure).
- Atropine response test—administer 0.04 mg/kg atropine IM and repeat ECG in 20–30 minutes; may be used to determine whether AV block is due to vagal tone; resolution of AV block with atropine supports vagal cause.
- Electrophysiologic studies are generally unnecessary but will confirm this type of second-degree AV block if surface ECG is equivocal.

PATHOLOGIC FINDINGS

Generally, no gross or histopathologic findings

**TREATMENT****APPROPRIATE HEALTH CARE**

- Treatment usually unnecessary
- Treat or remove underlying cause(s)

NURSING CARE

Generally unnecessary

ACTIVITY

Unrestricted

DIET

Modifications or restrictions only to manage an underlying condition.

CLIENT EDUCATION

Explain that any treatment is directed toward reversing or eliminating an underlying cause.

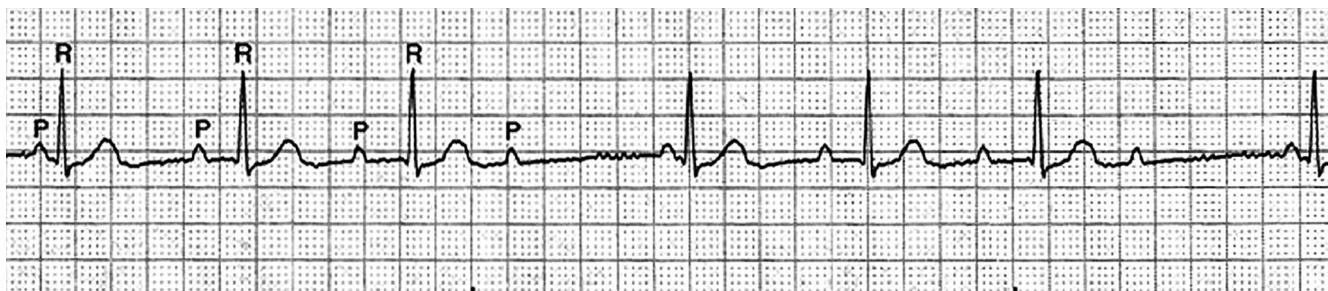

Figure 1.

Lead II ECG strip recorded from a dog with Mobitz type I, second-degree AV block. The PR intervals become progressively longer with the longest PR intervals preceding non-conducted P waves (typical Wenckebach phenomenon) (paper speed = 50 mm/s).

atrioventricular block, second degree—Mobitz I (Continued)

SURGICAL CONSIDERATIONS

N/A except to manage an underlying condition

**MEDICATIONS****DRUG(S)**

Only as needed to manage an underlying condition

CONTRAINDICATIONS

Drugs with vagomimetic action (e.g., digoxin, bethanechol, physostigmine, pilocarpine) may potentiate block.

PRECAUTIONS

Hypokalemia increases the sensitivity to vagal tone and may potentiate AV conduction delay.

POSSIBLE INTERACTIONS

atrioventricular block, second degree—Mobitz II

A

**BASICS****DEFINITION**

Second-degree AV block refers to failure of one or more P waves but not all P waves to be conducted. Mobitz Type II second-degree AV block occurs when one or more P waves are blocked without a preceding progressive delay in AV transmission.

ECG Features

- One or more P waves not followed by a QRS complex; PR interval is constant but may be either normal or consistently prolonged (Figure 1).
- Ventricular rate—usually slow.
- Fixed ratio of P waves to QRS complexes may occur (e.g., 2:1, 3:1, 4:1 AV block).
- High-grade (advanced) second-degree AV block is characterized by two or more consecutive blocked P waves.
- In second-degree AV block with a 2:1 conduction ratio or higher, it is impossible to observe prolongation of the PR interval before the block, so a designation of Mobitz is not appropriate.
- QRS complexes may appear normal but may also be wide or have an abnormal morphology due to aberrant intraventricular conduction or to ventricular enlargement.
- Abnormally wide QRS complexes may indicate serious, extensive cardiac disease.

PATHOPHYSIOLOGY

- Rare in healthy animals.
- May be hemodynamically important when ventricular rate is abnormally slow.
- Frequently progresses to complete AV block, particularly when accompanied by wide QRS complexes.
- Typically this type of AV block results from conduction delay within the AV node itself (rather than delay in another segment of the AV conducting system) that is characterized by normal or prolonged AH intervals with intermittent block between A and H deflections on a His bundle electrogram).

SYSTEMS AFFECTED

- Cardiovascular.
- Central nervous or musculoskeletal systems if inadequate cardiac output.

GENETICS

May be heritable in pugs

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT*Species*

Dog and cat

Breed Predilections

American cocker spaniel, pug, dachshund, Airedale terrier, Doberman pinscher.

Mean Age and Range

Generally occurs in older animals

Predominant Sex

N/A

SIGNS*Historical Findings*

- Presenting complaint may be syncope, collapse, weakness, or lethargy.
- Some animals are asymptomatic.
- Animals may show signs of the underlying disease process.

Physical Examination Findings

- \pm weakness.
- Bradycardia common.
- May be intermittent pauses in the cardiac rhythm.
- An S4 may be audible in lieu of the normally expected heart sounds (i.e., S1, S2) when the block occurs.
- If associated with digoxin intoxication, there may be vomiting, anorexia, and diarrhea.
- May be other abnormalities reflecting the underlying etiology.

CAUSES

- Heritable in pugs.
- Enhanced vagal stimulation from non-cardiac diseases.

- Degenerative change within the cardiac conduction system—replacement of AV nodal cells and/or Purkinje fibers by fibrotic and adipose tissue in old cats and dogs.

- Pharmacologic agents (e.g., digoxin, β -adrenergic antagonists, calcium channel blocking agents, propafenone, α_2 -adrenergic agonists, muscarinic cholinergic agonists, or severe procainamide or quinidine toxicity).
- Infiltrative myocardial disorders (neoplasia, amyloid).

- Endocarditis (particularly involving the aortic valve).
- Myocarditis (viral, bacterial, parasitic, idiopathic).
- Cardiomyopathy (especially in cats).
- Trauma.
- Atropine administered intravenously may cause a brief period of first- or second-degree heart block before increasing the heart rate.

RISK FACTORS

Any condition or intervention that enhances vagal tone

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

- High-grade (advanced) form must be distinguished from complete AV block.
- Non-conducted P waves arising from refractoriness of the conduction system during supraventricular tachycardias must be differentiated from pathologic conduction block.

CBC/BIOCHEMISTRY/URINALYSIS

- Serum electrolytes—hypokalemia and hyperkalemia may predispose to AV.
- Conduction disturbances.
- Leukocytosis—may be noted with bacterial endocarditis or myocarditis.
- Electrolyte abnormalities (e.g., severe hypokalemia, hyperkalemia, or hypercalcemia) may predispose to AV block.

Figure 1.

Lead II ECG rhythm strip recorded from a dog with both first- and second-degree atrioventricular block. The second-degree AV block is high grade with both 2:1 and 3:1 block resulting in variation in the RR intervals. The PR interval for the conducted beats is prolonged but constant (0.28 second) (paper speed = 25 mm/s).

ATRIOVENTRICULAR BLOCK, SECOND DEGREE—MOBITZ II (CONTINUED)

OTHER LABORATORY TESTS

- Serum digoxin concentration—may be high.
- High T₄ in cats—if associated with hyperthyroidism.
- High arterial blood pressure—if associated with hypertensive heart disease.
- Positive *Borrelia*, *Rickettsia*, or *Trypanosoma cruzi* titers—if associated with one of these infectious agents.
- Blood cultures may be positive in patients with vegetative endocarditis.

IMAGING

Echocardiographic examination may reveal structural heart disease (e.g., endocarditis, neoplasia, or cardiomyopathy).

DIAGNOSTIC PROCEDURES

- Atropine response test—administer 0.04 mg/kg atropine IM and repeat ECG in 20–30 minutes; may be used to determine whether AV block is due to high vagal tone.
- Electrophysiologic testing is generally unnecessary but can be done to confirm this type of AV block if surface ECG findings are equivocal.

PATHOLOGIC FINDINGS

- Variable—depend on underlying cause.
- Old animals with degenerative change of the conduction system may have focal mineralization of the interventricular septal crest visible grossly; chondroid metaplasia of the central fibrous body and increased fibrous connective tissue in the AV bundle is noted histopathologically.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Treatment—may be unnecessary if heart rate maintains adequate cardiac output.
- Positive dromotropic interventions are indicated for symptomatic patients.
- Treat or remove underlying cause(s).

NURSING CARE

Generally unnecessary

ACTIVITY

Cage rest advised for symptomatic patients.

DIET

Modifications or restrictions only to manage an underlying condition.

CLIENT EDUCATION

- Need to seek and specifically treat underlying cause.
- Pharmacologic agents may not be effective long term.

SURGICAL CONSIDERATIONS

Permanent pacemaker may be required for long-term management of symptomatic patients.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Atropine (0.02–0.04 mg/kg IV, IM) or glycopyrrolate (5–10 µg/kg IV, IM) may be used short term if positive atropine response.
- Chronic anticholinergic therapy (propantheline 0.5–2 mg/kg PO q8–12h or hyoscyamine 3–6 µg/kg q8h)—indicated for symptomatic patients if improved AV conduction with atropine response test.
- Isoproterenol (0.04–0.09 µg/kg/minute IV to effect) or dopamine (2–5 µg/kg/minute IV to effect) may be administered in acute, life-threatening situations to enhance AV conduction and/or accelerate an escape focus.

CONTRAINdications

- Drugs with vagomimetic action (e.g., digoxin, bethanechol, physostigmine, pilocarpine) may potentiate block.
- Avoid drugs likely to impair impulse conduction further or depress a ventricular escape focus (e.g., procainamide, quinidine, lidocaine, calcium channel blocking agents, β-adrenergic blocking agents).

PRECAUTIONS

Hypokalemia—increases sensitivity to vagal tone and may potentiate AV conduction delay.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

Frequent ECG because often progresses to complete (third-degree) AV block.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Prolonged bradycardia may cause secondary congestive heart failure or inadequate renal perfusion.

EXPECTED COURSE AND PROGNOSIS

Variable—depends on cause. If degenerative disease of the cardiac conduction system, often progresses to complete (third-degree) AV block.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

May be noted in cats with primary or secondary myocardial disease.

AGE-RELATED FACTORS

ATRIOVENTRICULAR VALVE DYSPLASIA

A

BASICS

DEFINITION

A congenital malformation of the mitral or tricuspid valve apparatus.

PATHOPHYSIOLOGY

- Atrioventricular valve dysplasia can result in valvular insufficiency, valvular stenosis, or dynamic outflow tract obstruction, depending on the anatomic abnormality. AVVD may occur alone or in association with abnormalities of the ipsilateral outflow tract (e.g., valvular or subvalvular aortic or pulmonic stenosis). It is not uncommon for mitral and tricuspid valve dysplasia to occur together in the same patient.
- Valvular insufficiency results in dilation of the ipsilateral atrium, eccentric hypertrophy of the associated ventricle, and, if sufficiently severe, signs of CHF. Cardiomyopathy of chronic volume overload and elevated atrial pressures are the end result culminating in pulmonary congestion if the mitral valve is affected and systemic congestion if the tricuspid valve is affected.
- Valvular stenosis results in atrial dilation and hypertrophy and, when severe, hypoplasia of the receiving ventricle. Tricuspid valve stenosis results in elevated right atrial pressure and systemic congestion if pressures exceed 15–20 mmHg. Right-to-left shunting may occur if there is an atrial septal defect or patent foramen ovale. Mitral valve stenosis results in elevated pulmonary capillary pressure and pulmonary edema if pressures exceed 25–30 mmHg. Pulmonary hypertension is a common complicating condition in animals with mitral valve stenosis.
- Outflow tract obstruction may develop from defects that translocate the anterior leaflet to a position closer to the interventricular septum. Concentric left ventricular hypertrophy develops in proportion to the severity of the obstruction.

SYSTEMS AFFECTED

- Cardiovascular—inflow obstruction due to valvular stenosis and chronic volume overload from valvular insufficiency result in elevated pulmonary (left AV valve) or systemic (right AV valve) venous pressures. Signs of low cardiac output develop if the lesion is sufficiently severe. Concentric left ventricular hypertrophy develops secondary to dynamic outflow obstruction.
- Respiratory—pulmonary edema may develop secondary to mitral stenosis or mitral valve insufficiency. Pulmonary hypertension is a common complication in animals with mitral stenosis.
- Neurologic—collapse and loss of consciousness, most often during physical exertion, may occur with severe disease due to low cardiac output and hypotension. Collapse in animals with dynamic outflow obstruction is most often due to ventricular arrhythmia.

GENETICS

Tricuspid valve dysplasia is inherited as an autosomal recessive trait in Labrador retrievers. Heritability and pattern of inheritance not established in other breeds.

INCIDENCE/PREVALENCE

These are common congenital cardiac anomalies in cats (17% of reported congenital cardiac defects in one study). Less frequently diagnosed in dogs.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Tricuspid valve dysplasia—increased risk for Labrador retriever, German shepherd dog, Great Pyrenees, possibly Old English sheepdog. Also common in cat.
- Mitral valve dysplasia—increased risk in bull terrier, Newfoundland, Labrador retriever, Great Dane, golden retriever, Dalmatian, and Siamese cat. Perhaps the most common congenital heart defects of cats. Mitral valve malformations often are noted in cats with hypertrophic cardiomyopathy.

Mean Age and Range

Variable; signs are most often manifest within the first few years after birth.

Predominant Sex

Males are more likely to evidence heart failure.

SIGNS

Historical Findings

- Exercise intolerance is the most common problem in dogs and cats with AV valve dysplasia.
- Abdominal distention, weight loss, and stunting may be observed with severe tricuspid valve dysplasia.
- Labored respiration is common in dogs or cats with mitral valve dysplasia.
- Syncope and collapse if critical mitral or tricuspid valve stenosis, severe outflow tract obstruction, an associated arrhythmia, or heart failure from AV valvular insufficiency.

Physical Examination Findings

Mitral Valve Dysplasia

- A holosystolic murmur is heard over the cardiac apex on the left. With severe disease the murmur is accompanied by a thrill or gallop heart sounds. A soft diastolic murmur may be present in the same location in animals with mitral stenosis but many affected animals have no audible murmur. A systolic ejection murmur that intensifies with exercise or excitement is audible in animals with dynamic outflow tract obstructions.
- Evidence of left heart failure—tachypnea, increased respiratory efforts, pulmonary crackles, and cyanosis in animals with severe defects.

Tricuspid Valve Dysplasia

- A holosystolic murmur is heard over the cardiac apex on the right. With severe disease the murmur is accompanied by a thrill or

gallop heart sounds. Silent tricuspid regurgitation is well documented in cats and is attributable to a large regurgitant orifice and laminar regurgitant flow. Distention and pulsation of the external jugular veins may be evident.

- Evidence of right heart failure—ascites and, more rarely, peripheral edema with severe malformations.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- With the noted exception of the age of onset, congenital AV valvular insufficiency resembles acquired degenerative AV valve insufficiency with respect to historical findings, physical examination abnormalities, and clinical sequelae.
- The right-sided murmur of tricuspid insufficiency is sometimes confused with the right-sided murmur of a ventricular septal defect.
- Ascites caused by silent tricuspid regurgitation or tricuspid valve stenosis is often attributed to pericardial effusion, hepatic disease, or obstruction of the caudal vena cava.
- Dogs and cats with cor triatriatum share many of the clinical features of AV valve stenosis.
- There is no certain way to distinguish mitral valve dysplasia producing outflow tract obstruction and the obstructive form of cardiomyopathy. If the obstruction can be abolished with a beta blocker and left ventricular hypertrophy resolves, it is likely that the primary abnormality was mitral valve dysplasia.

IMAGING

Radiographic Findings

Mitral Valve Dysplasia

- Left atrial and left ventricular enlargement with valvular insufficiency. Isolated left atrial enlargement with valvular stenosis. Mild left atrial enlargement with dynamic outflow obstruction.
- Evidence of left heart failure—distended pulmonary veins, interstitial or alveolar edema in severe cases.

Tricuspid Valve Dysplasia

- Right atrial and right ventricular enlargement with valvular insufficiency. Cardiac silhouette may appear globoid with pronounced enlargement. Isolated right atrial enlargement with valvular stenosis.
- Evidence of right heart failure—dilated caudal vena cava, hepatosplenomegaly, or ascites in severe cases.

Echocardiography

Mitral Valve Dysplasia

- Valvular insufficiency results in left atrial dilation and eccentric hypertrophy of the left ventricle. The papillary muscles are typically flattened and displaced dorsally. Chordae tendineae are often short and thickened. Doppler echocardiography demonstrates a high velocity retrograde systolic transmitral jet

ATRIOVENTRICULAR VALVE DYSPLASIA

(CONTINUED)

and modestly increased transmural inflow velocities. • Mitral stenosis results in left atrial dilation while the left ventricular dimensions are normal or small. The valve leaflets are often thickened, relatively immobile, and often fused. Doppler echocardiography demonstrates a high velocity transmural diastolic jet with a reduced EF slope. There may also be evidence of concurrent mitral insufficiency and/or secondary pulmonary hypertension. Exclude the possibility of cor triatriatum sinister. • Dynamic left ventricular outflow obstruction is characterized by systolic motion of the anterior mitral valve leaflet toward the interventricular septum, increased LV outflow tract velocities, and concentric left ventricular hypertrophy.

Tricuspid Valve Dysplasia

• Valvular insufficiency results in right atrial dilation and eccentric hypertrophy of the right ventricle. The papillary muscles and chordae tendineae may be fused, creating a curtain-like appearance of the tricuspid valve. Doppler echocardiography demonstrates a high velocity retrograde systolic trans-tricuspid jet and modestly increased transtricuspid inflow velocities. • Tricuspid stenosis results in right atrial dilation with normal or small right ventricular dimensions. The valve leaflets do not open completely. Doppler echocardiography demonstrates a high velocity diastolic trans-tricuspid jet with a reduced EF slope. There may be evidence of concurrent tricuspid valve insufficiency and/or right-to-left shunting across a patent foramen ovale or associated atrial septal defect. Exclude the possibility of cor triatriatum dexter.

Cardiac Catheterization

• Indicated only in those cases in which the diagnosis cannot be confirmed by echocardiography or if surgical correction is anticipated. • Mitral dysplasia—hemodynamic measurements should include left ventricular pressures, pulmonary capillary wedge pressure or direct measurement of LA pressure, pulmonary artery pressures, and, in cases of dynamic obstruction, simultaneous recording of aortic and left ventricular pressures with medical provocation. Contrast studies are best accomplished with a left ventricular injection in cases of valvular insufficiency, and direct left atrial injection via trans-septal catheterization in cases of valvular stenosis. • Tricuspid dysplasia—hemodynamic measurements should include right ventricular and right atrial pressures. Contrast studies are best accomplished with a right ventricular injection in cases of valvular insufficiency, and right atrial injection in cases of valvular stenosis.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

- Usually reflect pattern of chamber enlargement. • Severe defects may be

accompanied by a variety of arrhythmias, particularly atrial premature beats, supraventricular tachycardia, or atrial fibrillation.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient treatment required for CHF.

CLIENT EDUCATION

Owners should be informed of heritability and advised against breeding.

DIET

Sodium-restricted if overt or pending CHF.

SURGICAL CONSIDERATIONS

- Valve repair or replacement is available in a few centers. • Balloon valvuloplasty is sometimes effective for valvular stenosis.

MEDICATIONS

DRUG(S) OF CHOICE

- Mitral or tricuspid dysplasia with insufficiency—diuretics, angiotensin converting enzyme inhibitors, and pimobendan (0.3 mg/kg q12h) for patients with imminent or overt congestive heart failure. Furosemide (2–4 mg/kg q12–24h), enalapril (0.5 mg/kg q12h) are used to control congestion. Digoxin (2–4 µg/kg q12h) is used to control supraventricular tachyarrhythmias.
- Mitral or tricuspid stenosis—diuretics to control edema. Furosemide (2–4 mg/kg q12–24h) dose adjusted to resolve congestion. Heart rate should be maintained near 150 bpm using digoxin (2–4 µg/kg q12h), a calcium channel blocker such as diltiazem (1–1.5 mg/kg q8h), or a beta-receptor blocking drug, such as atenolol (0.5–1.5 mg/kg q12–24h).
- Dynamic outflow tract obstruction—titrate a beta-receptor blocking drug, such as atenolol (0.5–1.5 mg/kg q12–24h), to abolish or diminish severity of outflow obstruction.

PRECAUTIONS

Standard patient monitoring for cardiac medication side effects (e.g., digitalis toxicity, azotemia).

FOLLOW-UP

PATIENT MONITORING

- Recheck yearly if no signs of heart failure.
- Recheck at a minimum of every 3 months if signs of CHF (thoracic radiographs, ECG, and echocardiography advisable).

PREVENTION/AVOIDANCE

Do not breed affected animals.

POSSIBLE COMPLICATIONS

- Congestive heart failure—left-sided with mitral valve dysplasia; right-sided with tricuspid valve dysplasia. • Collapse or syncope with exercise. • Paroxysmal supraventricular tachycardia or atrial fibrillation with severe disease.

EXPECTED COURSE AND PROGNOSIS

- Depends on severity of underlying defect
- Guarded to poor with serious defects

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Mitral valve dysplasia commonly accompanies valvular or subvalvular aortic stenosis as well as TVD. • Tricuspid valve dysplasia commonly accompanies pulmonic stenosis as well as MVD.

PREGNANCY/FERTILITY/BREEDING

Should be avoided—heritable defect and possibility of causing decompensated or worsening heart failure.

SEE ALSO

- Congestive Heart Failure, Left-Sided
- Congestive Heart Failure, Right-Sided

ABBREVIATIONS

- AV = atrioventricular • AVVD = atrioventricular valve dysplasia • CHF = congestive heart failure • ECG = electrocardiogram • MVD = mitral valve dysplasia • TVD = tricuspid valve dysplasia

ATRIOVENTRICULAR VALVE (MYXOMATOUS) DISEASE

BASICS

DEFINITION

Myxomatous mitral valve disease is characterized by progressive myxomatous degeneration, which refers to a characteristic pathologic weakening and disturbance in the organization of the connective tissue of the AV valve (mitral and tricuspid) apparatus.

PATHOPHYSIOLOGY

- Lesions characterized by pathologic weakening and disorganization of valvular connective tissue, in which the spongiosa component is unusually prominent with accumulation of mucopolysaccharides and glycosaminoglycans.
- The valve leaflets become thickened and elongated with disease progression.
- Degenerative changes in the chordae tendineae lead to thickening and elongation of these structures; thereby contributing to systolic atrial displacement of the valve leaflets (valve prolapse).
- With progression, the valve lesions cause insufficient coaptation of the leaflets during systole, leading to backward regurgitation of blood from the ventricle into the atrium.
- Severity and progression of AV valve regurgitation depends on severity and progression of valve lesions (leaflets and/or tendinous chords).
- Compensatory mechanisms include cardiac dilatation and eccentric hypertrophy, increased force of contraction, increased heart rate, increased pulmonary lymphatic drainage (left-sided AV valve regurgitation), fluid retention, and neurohormonal modulation of cardiovascular function.
- With progression, the valvular regurgitation can no longer be compensated, leading to reduced cardiac output and increased venous pressures (leading to pulmonary edema if left-sided congestive heart failure [CHF] and to ascites if right-sided). With atrial tear, acute cardiac tamponade may result.

SYSTEMS AFFECTED

- Cardiovascular—both AV valves are commonly affected, but semilunar valves less commonly affected.
- Hepatobiliary—passive congestion.
- Renal/Urologic—prerenal azotemia.
- Respiratory—if edema and/or pulmonary hypertension develops.

GENETICS

Etiology currently unknown, but the current leading scientific hypothesis is that a genetically determined dystrophic process initiates the valve degeneration. The age at which the disease develops is inherited as a polygenic threshold trait (i.e., multiple genes influence the trait and a certain threshold has to be reached before the disease develops).

INCIDENCE/PREVALENCE

The most common cardiac disease in dogs. The prevalence is strongly influenced by age. It is uncommon in young individuals but common in old dogs. The prevalence reaches > 90% in some affected dog breeds > 10 years.

SIGNALMENT

Species

Mainly dogs. Extremely rare in cats.

Breed Predilections

Typically small breeds (< 20 kg but may be encountered in larger dogs), such as Cavalier King Charles spaniels, Chihuahuas, Miniature schnauzers, Maltese, Pomeranians, Cocker spaniels, Pekingese, Poodles, and others.

Mean Age and Range

Murmur may be detected from 2 years of age with a peak incidence at 6–8 years in affected breeds, such as Cavalier King Charles spaniels. Onset of CHF from 8–12 years.

Predominant Sex

Males develop the disease at a younger age than females, which means a higher prevalence at a given age in males.

SIGNS

Signs depend on the stage of disease. The descriptions here align with the grading system described in the ACVIM consensus statement on myxomatous mitral valve disease.

Clinically Healthy Patients but Belonging to a Risk Group (ACVIM Stage A)

No abnormal findings

Patients Without Overt Clinical Signs (ACVIM Stage B)

- Systolic click (early stage).
- Systolic murmur best heard over the mitral or tricuspid areas.
- Murmurs may range from being of soft, low intensity to loud holosystolic. With progression, the murmur typically gets louder and radiates more widely.
- Initially patients have no obvious radiographic or echocardiographic changes in cardiac chamber size (ACVIM stage B1). As the disease progresses, evidence of cardiomegaly will be seen (ACVIM stage B2), often before obvious clinical signs of heart failure are recognized.

Patients with Overt Clinical Signs or Stabilized by CHF Therapy (ACVIM stages C and D)

- Usually loud heart murmur.
- Tachycardia and loss of respiratory sinus arrhythmia.
- Arrhythmia and pulse deficit may be present, most commonly supraventricular premature beats or atrial fibrillation.
- Weak femoral pulse, prolonged capillary refill time and pale mucous membranes in case of low output failure.

- Tachypnea/dyspnea/orthopnea in case of decompensated CHF.
- Respiratory crackles/rales in case of decompensated CHF.
- Pink froth, i.e., pulmonary edema may be evident in the nostrils and oropharynx in cases with severe decompensated CHF.
- Ascites if right-sided CHF.
- Diagnostic imaging invariably shows left atrial (LA) and ventricular (LV) dilatation and eccentric hypertrophy, sometimes bilateral enlargement, and evidence of pulmonary congestion/edema.

CAUSES

Primary (inciting) factor unknown, but the disease is influenced by genetic factors in affected breeds.

RISK FACTORS

- Breed
- Sex (males have an earlier onset)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dilated cardiomyopathy
- Congenital heart disease
- Bacterial endocarditis
- Chronic airway or interstitial lung disease
- Pneumonia
- Pulmonary embolism
- Pulmonary neoplasia
- Heartworm disease

CBC/BIOCHEMISTRY/URINALYSIS

- CBC/Biochemistry usually unremarkable unless severe disease and ongoing CHF therapy
- Prerenal azotemia secondary to impaired renal perfusion; urinary specific gravity is high unless complicated by underlying renal disease or previous diuretic administration.
- High liver enzyme activity in many patients with right-sided CHF.

OTHER LABORATORY TESTS

- Natriuretic peptides—concentrations are often unremarkable unless moderate to severe disease.
- Serum troponin I—concentrations unremarkable unless severe disease.

IMAGING

Radiographic Findings

- Heart size ranges from normal to left-sided or generalized cardiomegaly.
- LA enlargement is usually the earliest finding.
- Left-sided CHF—pulmonary congestion; increased interstitial pattern ± air bronchograms; initially, congestion and edema are perihilar, with all lung fields eventually showing changes.

Echocardiographic Findings

- Thickening and distortion of the AV valve leaflets.

ATRIOVENTRICULAR VALVE (MYXOMATOUS) DISEASE

(CONTINUED)

- Elongation and rupture of the chordae tendineae, causing mitral valve prolapse.
- Atrial dilatation (uni- or bilaterally).
- The LV might be distended and is hyperdynamic if the regurgitant flow is high and myocardial function intact; as the ventricle becomes more grossly distended, it may become normo- or, less commonly, hypodynamic because of myocardial failure.
- Pericardial effusion (usually mild) is rarely seen.
- Doppler studies document a jet of regurgitation into the left atrium.
- Doppler evaluation for the presence of pulmonary hypertension should be routinely performed.

DIAGNOSTIC PROCEDURES

- Systemic blood pressure should be monitored in patients with severe disease or receiving diuretics to check for hypotension. Hypertension is not common.
- Arterial/venous blood gases can be used to quantify hypoxemia and monitor treatment response.
- Abdominocentesis/Pleurocentesis—a modified transudate is characteristic of CHF.

Electrocardiographic Findings

- Sinus tachycardia is common in patients with CHF.
- May show evidence of LA enlargement (P mitrale) or LV enlargement (tall and wide R waves).
- Supraventricular, most commonly atrial fibrillation, or ventricular arrhythmias may develop in severe disease.

PATHOLOGIC FINDINGS

- Gross valvular changes range from only a few discrete nodules at the line of closure to gross distortion of the valve by gray-white nodules and plaques causing contraction of the cusps and rolling of the free edge; the chordae are irregularly thickened, with regions of tapering and rupture.
- Mild disease—normal cardiac size. More progressed cases—LA and LV dilation. Degree of right-sided dilatation variable.
- The degree of LV hypertrophy may be apparent only on weighing the heart.
- Jet lesions—irregular thickening and opacity of the atrial endocardium.
- Recent and healed LA splits or tears in some patients.
- Small thrombi in the LA are rarely seen.

**TREATMENT****APPROPRIATE HEALTH CARE**

Treat patients that need oxygen support as inpatients; if stable, patients may be managed at home.

NURSING CARE

Oxygen therapy as needed for hypoxemia.

ACTIVITY

- Absolute exercise restriction for symptomatic patients.
- Stable patients receiving medical treatment—avoid strenuous exercise.

DIET

- Prevent cardiac cachexia by ensuring adequate calorie intake.
- Avoid food with high sodium content.

CLIENT EDUCATION

- Discuss the progressive nature of the disease.
- Mild disease severity is suggestive of a long period without clinical signs; moderate to severe indicates a shorter period.
- If the client is a breeder, inform him/her about the genetics of the disease and impact of the finding on future breeding.
- Appropriate level of exercise, but at the same time maintain quality of life.
- Common signs of CHF listed above.
- How to medicate (if indicated)—consistent dosing and that doses of diuretics should be adjusted in collaboration with the veterinarian.
- Possible adverse side reactions of medications.
- How to monitor resting/sleeping respiratory rates at home, and at which rate new contact with the clinician should be initiated.
- Diet (if indicated)—emphasize the importance of avoiding cardiac cachexia by paying close attention to appetite and using an appropriate diet.

SURGICAL CONSIDERATIONS

Surgical valve replacement and purse-string suture techniques to reduce the area of the mitral valve orifice have been used; experience with these techniques and access usually limited.

**MEDICATIONS****DRUG(S) OF CHOICE**

Recommended treatment depends on the stage of the disease; these recommendations follow the guidelines set by the consensus statement developed by the ACVIM.

Patients Without Overt Clinical Signs (ACVIM Stage B)

- If no cardiac enlargement, no treatment is currently recommended.
- Administering ACE inhibitors to Stage B2 patients is of unproven efficacy (despite two clinical trials). Administration of pimobendan to Stage B2 patients is of unknown value at this time.

Patients Showing Overt Clinical Signs (ACVIM stage C and D)***Signs of Acute CHF (Often Treated as Inpatient)***

- Furosemide IV, SC, IM, or PO. Dose is dependent on severity of CHF.

- Mild to moderate CHF: 2–4 mg/kg q8–24h.

- Severe or fulminant CHF: 4–8 mg/kg q2–6h, preferably IV, IM, or SC.

- Monitor outcome of treatment by respiratory rate and general clinical status. Dosages can often be reduced when the patient has stabilized.

- Oxygen supplementation and cage rest to patients with significant dyspnea. 40% in O₂ cage (can go as high as 100%) up to 24 hours; nasal O₂ in may be used in large-breed dogs, 50–100 mL/kg/minute through humidifier.

- Pimobendan at 0.25 mg/kg q12h PO.

- Additional options in cases with severe fulminant CHF:

- Nitroglycerin: ointment (one-fourth inch/5 kg up to 2 inches percutaneously) or injectable (1–5 µg/kg/minute CRI).

- Arterial vasodilator to decrease afterload rapidly, such as hydralazine at 0.5 mg/kg q12h titrated up to 2 mg/kg if necessary), or sodium nitroprusside at 1–10 µg/kg/minute. Both drugs require blood pressure monitoring and should be considered only in hospitalized dogs when monitored by a specialist.

- Dobutamine (dogs, 1–10 µg/kg/minute; cats, 1–5 µg/kg/minute).

- Dopamine (1–10 µg/kg/minute).

- Antiarrhythmics—as needed.

- Severe ascites may require abdominal paracentesis.

Chronic CHF (Typically Treated as Outpatient)

- Exact composition of medical therapy depends on disease severity and clinical signs. All dogs with CHF require life-long treatment with a diuretic, such as furosemide.

- Mild to moderate CHF: 1 mg/kg q24h to 3–4 mg/kg q8h PO.

- Moderate to severe CHF: 2–3 mg/kg q12h or higher.

- Pimobendan at 0.25 mg/kg q12h PO.

- ACEI (i.e., enalapril, benazepril, ramipril). Dose and dose interval dependent on ACE inhibitor used (enalapril [0.5 mg/kg q12–24h], benazepril [0.25–0.5 mg/kg q24h]).

- Spironolactone at 2 mg/kg q12–24h PO and/or hydrochlorothiazide at 2–4 mg/kg q12h PO.

- Digoxin at 0.22 mg/m² q12h PO, or lower.

- Adequate antiarrhythmic treatment if significant arrhythmia is present.

- Sildenafil at 0.5–2 mg/kg in case of pulmonary hypertension.

PRECAUTIONS

- Use digoxin, diuretics, and ACE inhibitors with caution in patients with renal disease.

- Nitrate tolerance may develop if appropriate 12-hour nitrate-free intervals are omitted from the dosing schedule.

- Beta-blockers are negative inotropes and may have an acute adverse effect on myocardial function and clinical status.

(CONTINUED)

ATRIOVENTRICULAR VALVE (MYXOMATOUS) DISEASE

A

POSSIBLE INTERACTIONS

- Furosemide potentiates the effects of an ACE-inhibitor, spironolactone, or a thiazide.
- Nonsteroidal anti-inflammatory drugs should be used with caution in patients receiving furosemide and ACEI.

ALTERNATIVE DRUG(S)

- Diuretics—add thiazide and/or potassium sparing diuretic (e.g., spironolactone) in refractory animals.
- Torsemide and bumetanide are alternatives to furosemide.
- Vasodilators—isosorbide dinitrate can be used in place of nitroglycerin ointment in patients requiring long-term nitrate administration.

**FOLLOW-UP****PATIENT MONITORING**

- Frequency of reexaminations depends on severity of myxomatous valve disease and severity of CHF (if present).
- Dogs without signs of CHF:
 - Slight to moderate disease severity: Perform echocardiography when a murmur is first detected and every 6–12 months thereafter to document progressive cardiomegaly. A baseline radiograph may be useful.
 - Moderate to severe disease severity may require more frequent monitoring.
- Dogs with signs of CHF:
 - Once acute CHF has been successfully treated, dogs can be treated at home.
 - Reexamination after 1 to 2 weeks of therapy (check for signs of decompensated CHF, dehydration, electrolyte imbalance, renal dysfunction, and presence of a complication). Moderate to severe disease severity may require more frequent monitoring.

◦ Thereafter once every 3–6 months if the patient is stable on the medication. More severe cases may require more frequent monitoring.

• Monitor BUN and creatinine when diuretics and ACE inhibitors are used in combination. Monitor potassium levels, especially when combinations of spironolactone, ACE inhibitors and digoxin are used.

POSSIBLE COMPLICATIONS

- Asymptomatic patients may develop CHF
- Recurrent CHF in patients stabilized by medical therapy
- Pulmonary hypertension
- Biventricular CHF in patients with initial left-sided CHF
- Mild pleural and/or pericardial effusion
- Arrhythmia, most commonly atrial fibrillation
- Rupture of first-order tendinous chord(s), leading to a flail valve leaflet
- Atrial tear leading to acquired atrial septal defect or cardiac tamponade
- Formation of intracardiac thrombus and/or myocardial infarction.

EXPECTED COURSE AND PROGNOSIS

The lesions on the AV valves are progressive in nature and myocardial function may worsen, necessitating increasing drug dosages; long-term prognosis depends on response to treatment and stage of heart failure.

**MISCELLANEOUS****SYNOMYMS**

- Chronic valvular disease (CVD)
- Chronic mitral valve disease
- Degenerative valvular disease
- Degenerative mitral valve disease (DMVD)
- Myxomatous mitral valve disease (MMVD)
- Endocardiosis

ATRIOVENTRICULAR VALVULAR STENOSIS

BASICS

DEFINITION

Atrioventricular valvular stenosis is a pathologic narrowing of the mitral or tricuspid valve orifice due to valvular dysplasia or an obstructive, supravalvular ring.

PATHOPHYSIOLOGY

- Atrioventricular stenosis increases the resistance to ventricular filling.
- Ventricular filling in clinically significant disease requires a persistent diastolic pressure gradient between atrium and ventricle.
- Concomitant valvular regurgitation is common.
- The increased atrial pressure leads to atrial dilation, venous congestion, and often to CHF. Pulmonary edema occurs with mitral stenosis; whereas ascites, pleural effusion and chylothorax can develop in cases of severe tricuspid stenosis.
- The foramen ovale can remain patent (PFO) in patients with tricuspid stenosis, allowing right-to-left shunting with signs of cyanotic heart disease.
- Partial atrioventricular septal defect (primum ASD and abnormal atrioventricular valve) is observed in some cats with supravalvular mitral (ring) stenosis.
- Cardiac output and therefore exercise capacity are limited with atrioventricular valvular stenosis.
- The atrial pressure increases disproportionately with faster heart rates, thereby creating the risk for "flash" pulmonary edema in dogs or cats with mitral stenosis.
- Development of atrial tachyarrhythmias, especially atrial fibrillation, is associated with cardiac decompensation.
- Pulmonary hypertension can develop consequent to MS, leading to exercise intolerance and right ventricular hypertrophy. This can be severe, especially in cats with mitral stenosis.

SYSTEMS AFFECTED

- Respiratory—with MS—bronchial compression from enlarged left atrium, pulmonary edema from left heart failure; potential for hemoptysis due to rupture of pulmonary venous-bronchial venous connections; pleural effusion with atelectasis in tricuspid stenosis or in long-standing MS complicated by pulmonary hypertension or atrial fibrillation.
- Hepatobiliary—with TS—hepatic congestion, ascites.

GENETICS

- Uncertain in most cases.
- Tricuspid valve dysplasia in Labrador retrievers has been localized to a defect in dog chromosome 9 inherited as an autosomal dominant trait with reduced penetrance.

INCIDENCE/PREVALENCE

Rare

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat

Breed Predilections

- MS is overrepresented in bull terriers and Newfoundlands, and in Siamese cats.
- TS has been reported most often in Old English sheepdogs and Labrador retrievers.

Mean Age and Range

Most patients are presented at a young age, although exceptions occur, especially in cats.

Predominant Sex

N/A

SIGNS

Historical Findings

- Exercise intolerance
- Syncope
- Exertional dyspnea or tachypnea
- Cough—MS
- Cyanosis
- Abdominal distention—TS
- Acute posterior paresis—cats with MS and arterial thromboembolism
- Stunted growth
- Hemoptysis from rupture of intrapulmonary vessels—MS

Physical Examination Findings

- Soft diastolic murmur with point of maximal intensity over the left apex (MS) or right hemithorax (TS).
- Holosystolic murmur of mitral or tricuspid regurgitation is more often detected.
- Tachypnea, dyspnea from pulmonary edema or pleural effusion.
- Crackles from pulmonary edema.
- Jugular distention, jugular pulses, ascites, hepatomegaly with TS or biventricular CHF associated with pulmonary hypertension and atrial fibrillation in chronic MS.
- Cyanosis from right to left shunting with TS or from venous admixture and pulmonary edema with MS.

CAUSES

- Usually due to congenital dysplasia of the mitral or tricuspid valve.
- Supravalvular obstructing rings of tissue have been associated with atrioventricular stenosis; this is especially important in cats.
- Infective endocarditis, intracardiac neoplasia, and hypertrophic cardiomyopathy with scarring are rare causes of acquired AV valve stenosis.
- Acquired tricuspid stenosis has been observed due to fibrous scarring of the tricuspid valve in dogs with transvenous pacing leads.

RISK FACTORS

Breed predispositions (see above); see "Risk Factors" for Endocarditis, Infective; permanent transvenous pacing.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Atrioventricular valvular stenosis must be differentiated from the more common causes of mitral and tricuspid regurgitation in the absence of stenosis. These include both congenital and acquired lesions of the atrioventricular valves and support apparatus. Acquired lesions that obstruct the inflow tracts (see "Causes"). Cor triatriatum dexter and cor triatriatum sinister can mimic some of the clinical findings of pure tricuspid and mitral valve stenosis, respectively.

CBC/BIOCHEMISTRY/URINALYSIS

May be normal or reflect changes related to CHF or drug therapy for CHF.

IMAGING

Thoracic Radiography

- Atrial enlargement is the most consistent and outstanding feature; may see generalized cardiomegaly, especially with atrioventricular valve regurgitation.
- MS—may see pulmonary venous congestion and pulmonary edema; intrapulmonary hemorrhage can be misinterpreted as pneumonia or another parenchymal disease.
- TS—may see hepatomegaly; increased diameter of caudal vena cava.

Echocardiography

- Diagnostic test of choice.
- Two-dimensional echocardiography reveals a markedly dilated atrium and attenuated valve excursion during diastole, often with thickened, irregular AV valve leaflets; valve leaflets may appear to "dome" during diastole. A supravalvular obstructing ring also may be evident as well as other lesions (see "Causes" above).
- M-mode studies show an enlarged atrium and discordant motion of the AV valve leaflets indicating commissural fusion; the E-to-F slope is decreased.
- Color-flow imaging reveals a turbulent diastolic jet that originates proximal to the stenotic valve and projects toward the apex of the ventricle; AV valve regurgitation is often present.
- Spectral Doppler studies show increased diastolic transvalvular flow velocities; prolonged calculated pressure half-time is a hallmark feature; E-wave/A-wave amplitude reversal is often evident in cases still in normal sinus rhythm.
- Right-sided chamber enlargements in MS with pulmonary hypertension or with chronic atrial fibrillation.

(CONTINUED)

ATRIOVENTRICULAR VALVULAR STENOSIS

A

- Concurrent defects such as patent foramen ovale, ASD, or bridging septal leaflet.

Angiography

- Right atrium: injection demonstrates a markedly dilated atrium in TS; with concurrent PFO or ASD, opacification of the left atrium is also observed following right atrial injection.
- Might visualize thickened, irregular valve leaflets or a stenotic valve funnel.
- Ventricular injection often reveal valvular regurgitation.
- There can be delayed opacification of the ventricles and great vessels.

Cardiac Catheterization

- A diastolic pressure gradient is identified between the atrium and ventricle. A large "A" wave is common if atrial function is preserved.
- High left atrial, pulmonary capillary wedge, and pulmonary artery pressures occur in MS.
- High right atrial and central venous pressures are present in TS.
- Ventricular pressure may be normal in the absence of concurrent defects.

DIAGNOSTIC PROCEDURES**Electrocardiography**

- Variable enlargement and ventricular conduction patterns are observed. Widened or tall P-waves are commonly observed.
- Splintered R-waves are present in some dogs with tricuspid dysplasia.
- Axis deviation due to hypertrophy or ventricular conduction disturbances is relatively common in cats with mitral valve malformation.
- Ectopic rhythms, especially of atrial origin, are often observed. Atrial fibrillation is the most important rhythm disturbance as atrial contribution to filling is lost and the R to R intervals vary with short cycles increasing the mean diastolic gradient.

PATHOLOGIC FINDINGS

- The atrioventricular valve is abnormal, with thickened leaflets and fused commissures. Other lesions may be identified such as a supra-mitral ring (see "Causes").
- Many cases also have abnormal chordae tendineae and papillary muscles.
- Atrial dilation and hypertrophy are common.
- Patent foramen ovale with TS or partial atrioventricular septal defect (primum ASD and bridging septal leaflet) with supravalvular mitral (ring) stenosis.

**TREATMENT****APPROPRIATE HEALTH CARE**

Patients in overt CHF should be treated with inpatient medical management. Surgical or catheter-based interventions can be considered once heart failure has been stabilized. Control of heart rhythm

disturbances, especially AF, is also important. These patients are typically complicated and consultation with a cardiologist is highly recommended. Electrocadioversion of atrial fibrillation should be considered but advanced atrial disease can render the procedure less effective or limit the duration of sinus rhythm.

NURSING CARE

Sedation with butorphanol is appropriate for dyspneic patients. Oxygen therapy should be administered to the patient with dyspnea or hypoxemia from left-sided congestive heart failure. Fluid therapy is typically contraindicated in the patient with overt CHF except in cases of moderate to severe azotemia, renal compromise, or severe dehydration. Therapeutic paracentesis may be considered in the patient with pleural effusions or tympanic ascites.

ACTIVITY

Exercise restriction is important recommended for any animal with this condition because tachycardia increases the mean gradient across the stenotic valve predisposing to pulmonary edema or venous congestion. Cage rest for patients with CHF.

DIET

Feed a sodium-restricted diet to patients in CHF.

CLIENT EDUCATION

The client must be advised of symptoms associated with CHF and the urgency of treatment, particularly with left-sided CHF. The likelihood of recurrent bouts of CHF should also be discussed. Development of atrial fibrillation can lead to marked decompensation.

SURGICAL CONSIDERATIONS

- Surgical valve replacement or repair requires cardiopulmonary bypass or hypothermia; cost, availability, and high complication and mortality rates are greatly limiting factors.
- Balloon valvuloplasty is an alternative referral treatment and has been used successfully for managing some cases of AV stenosis.

**MEDICATIONS****DRUG(S) OF CHOICE****CHF**

- Furosemide—dogs, 2–6 mg/kg IV, IM, SC, PO q8–24h; cats, 1–4 mg/kg IV, IM, SC, PO q8–24h.
- ACE inhibitor—enalapril—dogs, 0.25–0.5 mg/kg PO q12h; cats, 0.25–0.5 mg/kg PO q12–24h; see below under "Follow-Up" for patient monitoring.
- Nitroglycerin paste (1/4 to 1 inch topically q12h) to reduce pulmonary venous pressures, but this has not been evaluated critically.

Atrial Tachyarrhythmias

- Digoxin—dogs, 3–5 µg/kg PO q12h; cats, one-fourth of a 0.125-mg tablet PO q24–48h; adjust dosage based on serum concentrations.
- Beta-blockers such as atenolol or the calcium channel blocker diltiazem for suppression of frequent atrial premature complexes and for heart rate control in atrial tachycardia/flutter/fibrillation. Beware: using these drugs in uncontrolled CHF.
- Typical atenolol dosages: dogs, 0.25–1.0 mg/kg q12h; cats, 6.25–12.5 mg/cat q12–24h; start low and titrate to effect.
- Diltiazem dosages: dogs, 2–6 mg/kg daily in two (long-acting diltiazem) or three divided dosages; start low and titrate to effect; cats, 7.5 mg diltiazem HCl PO q8h.. Higher dosages are sometimes needed.
- Sotalol for intractable/recurrent arrhythmias—dogs, 1–2 mg/kg PO q12h; cats, 10–20 mg/cat q12h.
- Dogs can be referred for electrocardioversion to convert AF to sinus rhythm (with follow-up therapy with sotalol or amiodarone); however, reversion back to AF is common owing to marked atrial dilatation.

Pulmonary Hypertension

- Sildenafil—dogs, 0.5–3 mg/kg PO q8–12 hours.

PRECAUTIONS

- As a general rule pimobendan is relatively contraindicated in pure valvular stenosis; however, many dogs and cats with advanced CHF have been treated with this drug with apparent success, especially when there is combined stenosis/regurgitation of the valve.
- Use ACE inhibitors or other vasodilators judiciously in patients with CHF; cardiac output is limited and vasodilation may induce hypotension. Monitor arterial blood pressure and renal function.

POSSIBLE INTERACTIONS

- Furosemide and ACE inhibitors can affect kidney function, alter blood electrolytes, and reduce blood pressure; these parameters should be monitored.
- Sildenafil can also reduce systemic blood pressure and should not be used with nitroglycerin paste or other nitrates.

ALTERNATIVE DRUG(S)

Spironolactone (2 mg/kg PO q12–24h) should be considered as an ancillary diuretic and for its antifibrotic benefit (as an aldosterone antagonist).

**FOLLOW-UP****PATIENT MONITORING**

- Thoracic radiographs for pulmonary edema or pleural effusion.

atrioventricular valvular stenosis

(CONTINUED)

- Echocardiography with Doppler studies—to estimate pulmonary pressures and subjectively assess right heart function if on sildenafil.
- Digoxin level—check 7–10 days following institution of therapy; 8- to 12-hour trough should be 0.8–1.5 ng/mL.
- Renal function, electrolyte status, and arterial blood pressure when on diuretic and/or ACE inhibitor.
- Standard rhythm ECG or Holter (ambulatory ECG) if arrhythmias are present.

POSSIBLE COMPLICATIONS

- CHF
- Atrial fibrillation
- Syncope
- Arterial thromboembolism—cats with MS
- Pulmonary hemorrhage with MS

EXPECTED COURSE AND PROGNOSIS

- Morbidity is high; except for mild cases, prognosis is generally poor once an animal becomes symptomatic. However, some animals will live for many years even with relatively severe stenosis of the mitral or tricuspid valve.
- Surgical intervention or balloon valvuloplasty might alter course of disease, but data are limited.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Concurrent congenital defects are common (e.g., subaortic stenosis in MS, PFO in TS; primum ASD in cats with supravalvular mitral (ring) stenosis).

PREGNANCY/FERTILITY/BREEDING

The possibility that this may be a heritable defect must be considered in assessing suitability of the animal for breeding, particularly in breeds with a predilection for this defect. The additional hemodynamic burden of gestation may be poorly tolerated by an already compromised heart. In general breeding is strongly discouraged.

SYNOMYS

Atrioventricular valve dysplasia with stenosis; supravalvular mitral ring.

BASICS

DEFINITION

- Azotemia is an excess of urea, creatinine, or other non-protein nitrogenous substances in blood, plasma, or serum.
- Uremia is the polysystemic toxic syndrome that results from marked loss in kidney functions. Uremia occurs simultaneously in animals with increased quantities of urine constituents in blood (azotemia), but azotemia may occur in the absence of uremia.

PATHOPHYSIOLOGY

- Azotemia can be caused by (1) increased production of non-protein nitrogenous substances, (2) decreased glomerular filtration rate, or (3) reabsorption of urine that has escaped from the urinary tract into the bloodstream. High production of non-protein nitrogenous waste substances may result from high intake of protein (diet or gastrointestinal bleeding) or accelerated catabolism of endogenous proteins. Glomerular filtration rate may decline because of reduced renal perfusion (prerenal azotemia), acute or chronic kidney disease (renal azotemia), or urinary obstruction (post-renal azotemia). Reabsorption of urine into the systemic circulation may also result from leakage of urine from the excretory pathways (also a form of post-renal azotemia).
- Pathophysiology of uremia—incompletely understood; may be related to (1) metabolic and toxic systemic effects of waste products retained because of renal excretory failure, (2) deranged renal regulation of fluids, electrolytes, and acid-base balance, and (3) impaired renal production and degradation of hormones and other substances (e.g., erythropoietin and 1,25-dihydroxycholecalciferol).

SYSTEMS AFFECTED

- Uremia affects virtually every body system.
- Cardiovascular—arterial hypertension, left ventricular hypertrophy, heart murmur, cardiomegaly, cardiac rhythm disturbances.
- Endocrine/Metabolic—renal secondary hyperparathyroidism, inadequate production of 1,25-dihydroxycholecalciferol (calcitriol) and erythropoietin, hypergastrinemia, weight loss.
- Gastrointestinal—anorexia, nausea, vomiting, diarrhea, uremic stomatitis, xerostomia, uremic breath, constipation.
- Hemic/Lymph/Immune—anemia and immunodeficiency.
- Neuromuscular—dullness, drowsiness, lethargy, fatigue, irritability, tremors, gait imbalance, flaccid muscle weakness, myoclonus, behavioral changes, dementia, isolated cranial nerve deficits, seizures, stupor,

coma, impaired thermoregulation (hypothermia).

- Ophthalmic—scleral and conjunctival injection, retinopathy, acute-onset blindness.
- Respiratory—dyspnea.
- Skin/Exocrine—pallor, bruising, increased shedding, unkempt appearance, loss of normal sheen to coat.

SIGNALMENT

Dog and cat

SIGNS

General Comments

Azotemia may not be associated with historical or physical abnormalities. Unless patient has uremia, clinical findings are limited to the disease responsible for azotemia. Findings described here are those of uremia.

Historical Findings

- Weight loss
- Declining appetite or anorexia
- Reduced activity
- Depression
- Fatigue
- Weakness
- Vomiting
- Diarrhea
- Halitosis
- Constipation
- Polyuria
- Changes in urine volume (increase or decrease)
- Poor haircoat or unkempt appearance

Physical Examination Findings

- Muscle wasting: sarcopenia/cachexia
- Mental depression
- Dehydration
- Weakness
- Pallor
- Petechiae and ecchymoses
- Dull and unkempt haircoat
- Uremic breath
- Uremic stomatitis (including oral ulcers, infarctions of the tongue)
- Scleral and conjunctival injection
- Relative hypothermia

CAUSES

Prerenal Azotemia

- Reduced renal perfusion due to low blood volume or low blood pressure.
- Accelerated production of nitrogenous waste products because of enhanced catabolism of tissues in association with infection, fever, trauma, corticosteroid excess, or burns.
- Increased gastrointestinal digestion and absorption of protein sources (diet or gastrointestinal hemorrhage).

Renal Azotemia

Acute or chronic kidney diseases (primary kidney disease affecting glomeruli, renal tubules, renal interstitium, and/or renal vasculature) that impair at least 75% of kidney function (glomerular filtration rate).

Post-renal Azotemia

Urinary obstruction; rupture of the excretory pathway.

RISK FACTORS

- Medical conditions—kidney disease, hypoadrenocorticism, low cardiac output, hypotension, fever, sepsis, polyuria, liver disease, pyometra, hypoalbuminemia, dehydration, acidosis, exposure to nephrotoxic chemicals, gastrointestinal hemorrhage, urolithiasis, urethral plugs in cats, urethral trauma, and neoplasia.
- Advanced age may be a risk factor.
- Drugs—potentially nephrotoxic drugs, nonsteroidal anti-inflammatory drugs, diuretics, antihypertensive medications; failure to adjust dosage of drugs primarily eliminated by the kidneys to correspond with decline in renal function.
- Toxins—ethylene glycol, grapes (dogs), lilies (cats).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dehydration, poor peripheral perfusion, low cardiac output, history of recent fluid loss, high protein diet, or black, tarry stools—rule out prerenal azotemia.
- Recent onset of altered urine output (high or low), clinical signs consistent with uremia, exposure to possible nephrotoxicants or ischemic renal injury, or kidney size normal or enlarged—rule out acute renal failure.
- Progressive weight loss, polyuria, polydipsia, small kidneys, disparate kidney size (cats—big kidney and little kidney), pallor, and signs of uremia that have developed over several weeks to months—rule out chronic renal failure.
- Abrupt decline in urine output and onset of signs of uremia; disparate kidney size (cats—big kidney and little kidney), occasionally dysuria, stranguria, and hematuria; large urinary bladder or fluid-filled abdomen—rule out post-renal azotemia.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Nonregenerative anemia (normocytic, normochromic)—often present with chronic renal failure.
- Hemoconcentration—often present with prerenal azotemia; can also be seen with acute renal failure and post-renal azotemia.

Biochemistry

- Serial determinations of serum urea nitrogen and creatinine concentrations may help differentiate the cause of azotemia. Appropriate therapy to restore renal perfusion typically yields a dramatic reduction in azotemia in patients with prerenal azotemia (typically within 24–48 hours). Correcting

obstruction to urine flow or a rent in the excretory pathway typically is followed by a rapid reduction in the magnitude of azotemia.

- Concurrent hyperkalemia may be consistent with post-renal azotemia, primary renal azotemia due to oliguric renal failure, or prerenal azotemia associated with hypoadrenocorticism.
- Increased serum albumin and globulin concentration suggest prerenal azotemia or a prerenal component.^s

Urinalysis

- A urine specific gravity value ≥ 1.030 in dogs and ≥ 1.035 in cats supports a diagnosis of prerenal azotemia. Administration of fluid therapy before urine collection may interfere with interpretation of low specific gravity values.
- Azotemic patients that have not been treated with fluids and have urine specific gravity < 1.030 in dogs and < 1.035 in cats typically have primary renal azotemia. A notable exception to this rule is dogs and cats with glomerular disease. Glomerulopathy is sometimes characterized by glomerulotubular imbalance in which adequate urine-concentrating ability may persist despite sufficient renal glomerular damage to cause primary renal azotemia; these patients are recognized by moderate to marked proteinuria in the absence of hematuria and pyuria.
- Urine specific gravity is not useful in identifying post-renal azotemia.

OTHER LABORATORY TESTS

Endogenous or exogenous creatinine, iohexol, or inulin clearance tests or other specific tests of glomerular filtration rate may be used to confirm that azotemia is caused by reduced glomerular filtration rate.

IMAGING

- Abdominal radiographs—used to determine kidney size (small kidneys consistent with chronic kidney disease; mild-to-moderate enlargement of kidneys may be consistent with acute renal failure or urinary obstruction) and to rule out urinary obstruction (marked dilation of the urinary bladder or mineral densities within the excretory pathway).
- Ultrasonography—may detect changes in echogenicity of the renal parenchyma and size and shape of kidneys that support a diagnosis of primary renal azotemia; useful to rule out post-renal azotemia characterized by distension of the excretory pathway and uroliths or masses within or impinging on the excretory pathway and intra-abdominal fluid accumulation (with rupture of the excretory pathway).
- Excretory urography, pyelography, or cystourethrography—may help establish the diagnosis of post-renal azotemia due to

urinary obstruction or rupture of the excretory pathway.

DIAGNOSTIC PROCEDURES

Renal biopsy can be used to confirm the diagnosis of primary kidney disease, to differentiate acute from chronic kidney disease, and to attempt to establish the underlying disease process responsible for primary kidney disease.

TREATMENT

- Prerenal azotemia caused by impaired renal perfusion—correct the underlying cause of renal hypoperfusion; aggressiveness of treatment depends on the severity of the underlying condition and the probability that persistent renal hypoperfusion will lead to primary renal injury or failure.
- Primary renal azotemia and associated uremia—(1) specific therapy directed at halting or reversing the primary disease process affecting the kidneys, and (2) symptomatic, supportive, and palliative therapies that ameliorate clinical signs of uremia; minimize the clinical impact of deficits and excesses in fluid, electrolyte, acid-base balances; minimize the effects of inadequate renal biosynthesis of hormones and other substances, and maintain adequate nutrition.
- Post-renal azotemia—eliminate urinary obstruction or repair rents in the excretory pathway; supplemental fluid administration is often required to prevent dehydration that may develop during the solute diuresis that follows correction of post-renal azotemia.
- Fluid therapy—indicated for most azotemic patients; preferred fluids include 0.9% saline or lactated Ringer's solution. Determine fluid volume to administer on the basis of severity of dehydration or volume depletion. If no clinical dehydration is evident, cautiously assume that the patient is less than 5% dehydrated and administer a corresponding volume of fluid. Generally provide 25% of calculated fluid deficit in the first hour. Thereafter, serially monitor perfusion (capillary refill time, pulse pressure, heart rate, and temperature of feet), blood pressure and urine output to assess adequacy of fluid therapy. If perfusion has not improved, additional fluid should be administered. Provide the remaining fluid deficit over the next 12–24 hours. Fluid therapy should be cautiously administered to patients with overt or suspected cardiac failure and patients that are oliguric or anuric.
- Treat patients in shock appropriately.
- Consider feeding diets formulated for kidney disease to reduce the magnitude of azotemia, hyperphosphatemia, and acidosis.

MEDICATIONS

DRUG(S) OF CHOICE

- Symptomatic therapy may be indicated for uremia in patients with kidney disease.
- Famotidine (0.5–1.0 mg/kg PO, SC, IM, IV q12–24h) or other H₂-receptor antagonists may be used to reduce gastric hyperacidity and nausea (dogs).
- Antiemetics such as maropitant (1 mg/kg q24h PO or SC for 5 days) are indicated for vomiting.

CONTRAINdications

Administration of nephrotoxic drugs

PRECAUTIONS

- Use caution when administering drugs requiring renal excretion. Consult appropriate references concerning dose-reduction schedules or adjustments of maintenance intervals.
- Use caution in administering fluids to patients that are oliguric or anuric. Monitor urine production rates and body weight during fluid therapy to minimize the likelihood of inducing overhydration.
- Stop fluid therapy in overhydrated oliguric/anuric patients. Use caution in administering drugs that may promote hypovolemia or hypotension (e.g., diuretics); carefully monitor the response to such drugs by assessing hydration status, peripheral perfusion, and blood pressure, with serial evaluation of renal function tests.
- Corticosteroids may worsen azotemia by increasing catabolism of endogenous proteins.

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

Serum urea nitrogen and creatinine concentrations 24 hours after initiating fluid administration; also urine production, body weight, and hydration status.

POSSIBLE COMPLICATIONS

- Failure to correct prerenal azotemia caused by renal hypoperfusion rapidly could result in ischemic primary kidney disease.
- Primary renal azotemia can progress to uremia.
- Failure to restore normal urine flow in patients with post-renal azotemia can result in progressive renal damage or death due to hyperkalemia and uremia.

(CONTINUED)

AZOTEMIA AND UREMIA**A****MISCELLANEOUS****ASSOCIATED CONDITIONS**

An association may exist between hypokalemia and azotemia in cats. Preliminary findings suggest that hypokalemia may be associated with functional or structural renal changes leading to azotemia.

AGE-RELATED FACTORS

Primary renal failure may occur in animals of any age, but geriatric dogs and cats appear to be at substantially higher risk for both acute and chronic kidney disease. However, do not assume that azotemia in geriatric dogs and cats indicates primary kidney disease; these

patients are also at higher risk for prerenal and post-renal causes for azotemia.

ZOONOTIC POTENTIAL

Leptospirosis

PREGNANCY/FERTILITY/BREEDING

- Data on azotemia and pregnancy in dogs and cats are very limited. Humans may tolerate minimal renal disease well during pregnancy; however, ability to sustain a viable pregnancy declines as renal function declines.
- Pregnant azotemic animals—pharmacologic agents excreted by non-renal pathways are preferred.

BABESIOSIS

BASICS

OVERVIEW

- Babesiosis is the disease caused by the protozoal parasites of the genus *Babesia*. Merozoites or piroplasms are the stage that infects mammalian red blood cells.
 - *B. canis*—a large (4–7 µm) piroplasm that infects dogs; *B. canis* is distributed worldwide, and there are three subspecies based on genetic, biologic, and geographic data.
 - B. canis vogeli* has been reported in the United States, Africa, Asia, and Australia. *B. canis rossi* is the most virulent and is present in Africa.
 - B. canis canis* has been reported in Europe.
 - Some have proposed that these organisms are indeed three distinct species: *B. vogeli*, *B. rossi*, and *B. canis*.
 - Recent studies have identified at least three genetically distinct small (2–5 µm) piroplasms that can infect dogs:
 - *B. gibsoni* (a.k.a. *B. gibsoni* [Asia])—small piroplasm that infects dogs; worldwide distribution; emerging disease in the United States.
 - *B. conradi* (a.k.a. *B. gibsoni* [United States/California])—small piroplasm that infects dogs; only reported in California.
 - *Babesia (Theileria) annae* (a.k.a. Spanish dog piroplasm and *B. microti*-like parasite)—small piroplasm that infects dogs; reported in Spain, other parts of Europe, and most recently in the United States.
 - *Babesia* sp. (Coco)—large piroplasm identified in splenectomized and immune-suppressed dogs in the United States.
 - Several other single-case reports of novel *Babesia* sp. and other piroplasms (i.e., *T. equi*) have been published.
 - *B. felis*—small (2–5 µm) piroplasm that infects cats; reported in Africa.
 - *Cytauxzoon felis*—small piroplasm that infects cats; reported in the United States.
 - Infection may occur either by tick transmission, direct transmission via blood transfer during dog bites, blood transfusions, or transplacental transmission.
 - Incubation period averages about 2 weeks, but some cases are not clinically diagnosed for months to years.
 - Piroplasms infect and replicate in red blood cells, resulting in both direct and immune-mediated hemolytic anemia.
 - Immune-mediated hemolytic anemia is likely to be more clinically important than parasite-induced RBC destruction, since the severity of signs does not depend on the degree of parasitemia.
- SYSTEMS AFFECTED**
- Hemic/Lymphatic/Immune—anemia, thrombocytopenia (bleeding tendencies appear rare), fever, splenomegaly,

lymphadenomegaly, vasculitis (experimental only).

- Hepatobiliary—increased liver enzymes (mild-moderate, not the sole abnormality detected).
- Nervous—cerebral babesiosis, weakness, disorientation, collapse (most common with *B. canis rossi*).
- Renal/Urologic—renal failure (*B. canis rossi* and *B. annae*).

SIGNALMENT

- Any age or breed of dog can be infected.
- *B. canis* infections are more prevalent in greyhounds.
- *B. gibsoni* (Asia) infections are more prevalent in American pit bull terriers.
- Any age or breed of cat can be infected, but to date, only *C. felis* has been reported in the United States.

SIGNS

- Signs are similar in dogs and cats.
- Signs can be peracute, acute, or chronic.
- Some carrier animals have no detectable clinical signs.
- Dogs—lethargy, anorexia, pale mucous membranes, fever, splenomegaly, lymphadenomegaly, pigmenturia, icterus, weight loss, discolored stool.
- Cats—lethargy, anorexia, pale mucous membranes, icterus.

CAUSES & RISK FACTORS

- History of tick attachment.
- Splenectomized animals develop more severe clinical disease.
- History of splenectomy or chemotherapy appear to be risk factors for *Babesia* sp. (Coco).
- Immune suppression may cause clinical signs and increased parasitemia in chronically infected dogs.
- History of a recent dog-bite wound is a risk for *B. gibsoni* (Asia) infection.
- Recent blood transfusion from a subclinically infected donor.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Any cause of immune-mediated hemolytic anemia or thrombocytopenia, including idiopathic immune-mediated hemolytic anemia or thrombocytopenia, ehrlichiosis, Rocky Mountain spotted fever, systemic lupus erythematosus, neoplasia, endocarditis, hemotrophic mycoplasmosis (haemobartonellosis), and cytauxzoonosis
- A positive Coombs' test does not rule out babesiosis since many animals with babesiosis are also Coombs' positive.
- Non-immune-mediated hemolytic anemia, including microangiopathic anemia, caval syndrome, splenic torsion, DIC, Heinz body

anemia, pyruvate kinase deficiency, phosphofructokinase deficiency.

- Hepatic and post-hepatic jaundice.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia—absent to severe; usually regenerative (reticulocytosis) unless signs are very acute; anemia can be severe in some cases (PCV < 10%), anemia is not present in all cases.
- Thrombocytopenia—usually moderate to severe; some animals have thrombocytopenia without anemia. Thrombocytopenia is the most common hematologic abnormality.
- Leukocyte responses are variable, with both leukocytosis and leukopenia reported.
- Hyperbilirubinemia may be present depending on the rate of hemolysis.
- Hyperglobulinemia is common in chronic infections and may be the only biochemical abnormality in some animals.
- Mildly elevated liver enzymes from anemia/hypoxia.
- Proteinuria and hypoalbuminemia (protein-losing nephropathy) may occur
- Azotemia and metabolic acidosis secondary to renal failure have been reported with *B. canis rossi* and *B. annae*.
- Bilirubinuria is common.
- Hemoglobinuria is detected less commonly in the United States than in Africa.

OTHER LABORATORY TESTS

- Microscopic examination of stained thin or thick blood smears—can provide a definitive diagnosis; sensitivity depends on microscopist experience and staining technique; most success using a quick modified Wright stain; capillary blood may enhance sensitivity; microscopy may not accurately differentiate the species or subspecies.
- IFA—tests for antibodies in serum that react with *Babesia* organisms; cross-reactive antibodies can prevent the differentiation of species and subspecies; some infected animals, particularly young dogs, may have no detectable antibodies.
- PCR—tests for the presence of *Babesia* DNA in a biologic sample (usually EDTA anticoagulated whole blood); can differentiate subspecies and species; more sensitive than microscopy.

TREATMENT

- May require inpatient or outpatient care, depending on the severity of disease.
- Hypovolemic animals should receive aggressive fluid therapy.
- Severely anemic animals may require blood transfusion.

(CONTINUED)

BABESIOSIS**B****MEDICATIONS****DRUG(S) OF CHOICE**

- Imidocarb dipropionate (FDA approved; 6.6 mg/kg SC or IM every 1–2 weeks) and diminazine acetarate (not FDA approved; 3.5–7 mg/kg SC or IM every 1–2 weeks) decrease morbidity and mortality in affected animals. They may completely clear *B. canis* infections but not *B. gibsoni* (Asia).
- Combination therapy of azithromycin (10 mg/kg PO q24h for 10 days) and atovaquone (13.5 mg/kg PO q8h for 10 days) is the treatment of choice and the only treatment that can potentially clear *B. gibsoni* (Asia) infections in dogs. In a controlled study, 85% of dogs cleared the infection after treatment.
- A combination of clindamycin (25 mg/kg PO q12h), metronidazole (15 mg/kg PO q12h), and doxycycline (5 mg/kg PO q12h) had been associated with elimination or reduction of the parasite below the limit of detection of PCR testing. Unfortunately a well-defined treatment course has not been established, with treatment times ranging from 24 to 92 days.
- A combination of doxycycline (7–10 mg/kg PO q24h), enrofloxacin (2–2.5 mg/kg PO q12h) and metronidazole (5–15 mg/kg PO q12h) for 6 weeks was associated with clinical remission in 85% of dogs but PCR was not performed to assess its effect on parasitemia.
- Metronidazole (25–50 mg/kg PO q24h for 7 days), clindamycin (12.5–25 mg/kg PO q12h for 7–10 days), or doxycycline (10 mg/kg PO q12h for 7–10 days) alone each have been reported to decrease clinical signs but not to clear infections.
- Primaquine phosphate (1 mg/kg IM, single injection) is the treatment of choice for *B. felis*.

- Since the anemia and thrombocytopenia are often immune mediated, immunosuppressive agents, such as prednisone (2.2 mg/kg/day PO), may be indicated in some cases that are not responding to anti-protozoal treatments alone. Prolonged immune suppressive therapy BEFORE specific antiprotozoal therapy is contraindicated.
- Antibabesial drugs (imidocarb and diminazene) can cause cholinergic signs that can be minimized by administering atropine (0.02 mg/kg SC, 30 minutes prior to imidocarb or diminazine administration).

CONTRAINdications

High doses of antibabesial drugs (imidocarb and diminazene) have resulted in liver and kidney failure.

**FOLLOW-UP**

- Recheck the CBC and biochemistry as needed to monitor for resolution of anemia, thrombocytopenia, icterus, and other signs.
- Most patients have a clinical response within 1–2 weeks of treatment.
- 2–3 consecutive negative PCR tests beginning 2 months post-treatment should be performed to rule out treatment failure and persistent parasitemia. IFA titers are not recommended for follow-up because titers may persist for years.
- Long-term follow-up of *B. conradae*, *B. annae*, or *B. felis* after treatment has not been reported.
- When a dog housed in a multi-dog kennel is diagnosed with babesiosis, all dogs in that kennel should be screened since there is a high percentage of carrier animals in kennel situations.
- Co-infection with other vector-transmitted pathogens (e.g., *Ehrlichia*, hemotropic *Mycoplasma*, *Leishmania*) should be considered, especially in animals that fail to respond to treatment.

PREVENTION/AVOIDANCE

Vaccines for *B. canis canis* and *B. canis rossi* are available in Europe, but these vaccines may not confer protection against other *Babesia* spp.

Tick control is important for disease prevention. Some recent studies suggest that using acaracides can prevent infection with *Babesia* spp. All attached ticks should be removed as soon as possible.

**MISCELLANEOUS**

All potential blood donors should test negative for the disease (preferably by 2–3 consecutive PCR tests) prior to use as a donor animal.

BACLOFEN TOXICOSIS

B

BASICS

OVERVIEW

• Baclofen is a central acting skeletal muscle relaxant used to prevent spasticity in people with multiple sclerosis, cerebral palsy, and spinal disorders. • It binds to gamma-aminobutyric acid (GABA) receptors and prevents the release of inhibitory neurotransmitters and substance P. • It has been used extra-label in dogs to reduce urethral resistance (1–2 mg/kg, PO, q8h) but is rarely recommended due to its narrow margin of safety. Use in cats is not recommended. • Doses as low as 1.3 mg/kg in dogs have caused vomiting, depression, and vocalization. • Death has been documented in dogs at 8–16 mg/kg.

The following organ systems are predominantly affected:

- Cardiovascular
- Gastrointestinal
- Musculoskeletal
- Nervous
- Respiratory

SIGNALMENT

• Accidental exposure in dogs is more frequently reported than in cats but any animal may be at risk for poisoning. • Cats are extremely sensitive to baclofen.

SIGNS

- Signs begin within 15 minutes of ingestion but, rarely, may be delayed several hours.
- Common signs: vocalization, vomiting, ataxia, disorientation, hypersalivation, depression, weakness, coma, flaccid paralysis, recumbency, seizures, and hypothermia.
- Life-threatening signs: dyspnea, respiratory depression and arrest secondary to diaphragmatic/intercostal muscle paralysis.

CAUSES & RISK FACTORS

Pet owners with medical conditions such as multiple sclerosis, cerebral palsy, and spinal disorders are more likely to have baclofen in the home.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Toxic: benzodiazepines, depressants, ethanol, ethylene glycol, illicit drugs (marijuana, LSD, phencyclidine [PCP], hallucinogenic mushrooms), methanol, opioids, propylene glycol, tranquilizers, xylitol
- Lower motor neuron disease (e.g., botulism, *Neospora*, tick bite paralysis, *Toxoplasma*)
- Metabolic (e.g., hepatic encephalopathy, hypoglycemia, etc.)

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities expected but should be used to rule out other causes.

OTHER LABORATORY TESTS

- Arterial blood gas analysis (hypoxemia, oxygenation, and ventilation)
- Pulse

oximetry (hypoxemia) • End tidal CO₂ (hypercapnia or hypoventilation)

IMAGING

Thoracic radiographs (aspiration pneumonia)

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Many cases quickly become serious and referral to a 24 hour critical care center should be considered. • Treatment is focused on decontamination and supportive care.
- Induce emesis following recent (< 1 hour) ingestion in asymptomatic patients only if they have not already vomited. Consider gastric lavage for very large ingestions. • One dose of activated charcoal. • IV fluid crystalloids at 1.5–2.5 × maintenance to support organ perfusion and enhance elimination. • Monitor for cardiac arrhythmias, hypoventilation, and aspiration pneumonia. • Oxygen if respiratory depression; ventilator support if severe respiratory depression/failure. • Monitor body temperature and provide warming/cooling measures as needed. • Hemodialysis and hemoperfusion have successfully shortened the elimination half-life and lead to full recovery.

MEDICATIONS

DRUG(S)

- Atropine for bradycardia (0.02–0.04 mg/kg IM, IV, or SQ PRN for dogs or cats).
- Antiemetics as needed (e.g., maropitant 1 mg/kg SQ q24h). • Diazepam for seizures (0.25–0.5 mg/kg IV, to effect, PRN for dogs or cats). Use the lowest effective dose as sedation is caused by baclofen. • For refractory seizures use propofol (1–8 mg/kg IV, to effect, PRN, followed by CRI dose of 0.1–0.6 mg/kg IV for dogs or cats) or general anesthesia. • Agitation may be treated with acepromazine (0.05–0.2 mg/kg IV, IM, or SQ PRN for cats or dogs), diazepam, or midazolam. • Cyproheptadine for vocalization/disorientation (dogs, 1.1 mg/kg PO or rectally q4–6h; cats, 2–4 mg total dose q4–6h). • Intravenous lipid emulsion (ILE) is a relatively new treatment for fat-soluble drugs and has successfully treated dogs suffering from baclofen intoxication. It should be reserved for critical cases. Doses vary. Using 20% emulsion, give 1.5 mL/kg IV bolus followed by a CRI of 0.25 mL/kg/min for 30–60 min up to 8 mL/kg daily. If the initial bolus fails to produce the desired effect, consider additional doses of 1.5 mL/kg IV q4–6h for the initial 24 hours. If after 3–5

boluses no clinical response is seen, discontinue use.

CONTRAINDICATIONS / POSSIBLE INTERACTIONS

- Use acepromazine cautiously due to risk of hypotension. • Use all sedatives cautiously as baclofen also causes sedation. • Avoid drugs that cause respiratory depression (e.g., phenobarbital).

FOLLOW-UP

PATIENT MONITORING

- Serious cases require intense, consistent patient monitoring including vital signs, blood pressure, blood gas analysis, pulse oximetry, and end tidal CO₂. • Nursing care should include turning/repositioning q6h, ocular lubrication, keeping patient dry/clean, passive range of motion of limbs, and soft bedding.

PREVENTION/AVOIDANCE

Educate pet owners about the risks of leaving prescription drugs accessible to pets.

POSSIBLE COMPLICATIONS

Aspiration pneumonia due to combination of vomiting, sedation, seizures, and paralysis of diaphragm/intercostal muscles.

EXPECTED COURSE AND PROGNOSIS

- Patients suffering serious intoxications may take 5–7 days to fully recover. • Recovery often occurs with no residual effects.
- Prognosis is good with early and appropriate care but becomes poor if medical care is delayed. Seizures and aspiration pneumonia are associated with a guarded prognosis.

MISCELLANEOUS

ABBREVIATIONS

BARTONELLOSIS

B

BASICS

OVERVIEW

- Emerging infectious agents that are highly adapted to preferential reservoir hosts, where they establish chronic intraerythrocytic bacteremia.
- Agents—small, curved, facultative fastidious intracellular argyrophilic, hemotrophic Gram-negative rod (bacilli) bacteria.
- Vector transmitted (fleas, ticks).
- Human syndrome—wide variety of clinical syndromes, including, most commonly, cat scratch disease, typified by regional lymphadenopathy after a cat scratch or bite distal to the involved lymph node; worldwide occurrence; estimated > 25,000 cases/year in United States; > 2,000 cases require hospitalization; almost no fatalities.
- Cats—usually asymptomatic.
- Dogs—emerging clinical syndrome.
- Seasonal; more cases reported between July and January.

SIGNALMENT

- Dogs and cats.
- Majority of human patients (80%) < 21 years of age; more males than females (1.2:1).

SIGNS

Human

- Erythematous papule at inoculation site (scratch, bite); then unilateral regional lymphadenopathy (painful, often suppurative) in 3–10 days (> 90% of cases).
- Mild fever.
- Chills—infrequent.
- Malaise.
- Anorexia.
- Myalgia.
- Nausea.
- Atypical manifestations (in up to 25% of cases)—encephalopathy (1–7%); palpebral conjunctivitis (3–5%); meningitis; optic neuritis; osteolytic lesions; granulomatous hepatitis; granulomatous splenitis; pneumonia; endocarditis.

Cats

- No signs of illness.
- Between 5 and 60% seropositive, depending on geographical area.
- Lymphoid hyperplasia (sometimes), uveitis, endocarditis (rare), self-limiting fever.

Dogs

Expanding spectrum of disease including endocarditis, myocarditis, granulomatous lymphadenitis, rhinitis, vasculitis, uveitis, choriorretinitis, arthritis, meningoencephalitis, anemia, thrombocytopenia.

CAUSES & RISK FACTORS

- Contact with domestic kittens and cats (> 90%), particularly young cats with fleas.
- Scratched by cat—up to 83%.
- Up to 95% of cats residing in households of affected humans are seropositive.
- Localized infections in immunocompetent; systemic infection in immunocompromised.
- Dogs: risk factors include tick and flea exposure and rural environment.
- Bartonella include: *Bartonella henselae*, *B. claridgeiae*, *B. koehlerae*, *B. bovis*, *B. quintana*.
- Canine

bartonella include: *B. vinsonii* ssp. *berkhoffii*, *B. henselae*, *B. claridgeiae*, *B. washoensis*, *B. quintana*, *B. rochalimae*, *B. elizabethae*.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Benign adenopathy in human children and young adults—most common cause.
- History of contact with a cat.
- Formation of a papule at the site of primary inoculation (scratch or bite).
- Compatible clinical picture—unilateral regional lymphadenitis.
- Exclusion of other identifiable causes.
- Characteristic histopathologic findings.
- Serologic tests—indirect fluorescent antibody for *B. henselae*.
- Positive skin test no longer used.
- Other causes of lymphadenopathy—lymphogranuloma venereum; syphilis; typical or atypical tuberculosis; other forms of bacterial adenitis; sporotrichosis; tularemia; brucellosis; histoplasmosis; sarcoidosis; toxoplasmosis; infectious mononucleosis; and benign or malignant tumors.
- Dogs: co-infections with other tick-borne diseases (*Ehrlichia*, *Babesia*).

CBC/BIOCHEMISTRY/URINALYSIS

Non-contributory

OTHER LABORATORY TESTS

- Indirect fluorescent antibody test.
- Enzyme immunoassay—IgG antibodies to *B. henselae* (Quest Diagnostics Nichols Institute Laboratory, Valencia, CA).
- Culture—on enriched (blood-containing) media in presence of 5% carbon dioxide at 35–37°C; fastidious and slow growing; requires 14–30 days.
- PCR amplification of bacterial DNA from lesions (Galaxy Diagnostics, Research Triangle Park, NC).

PATHOLOGIC FINDINGS

- Histopathology of lymph nodes—non-specific inflammatory reaction, including granuloma, microabscess, and necrosis.
- Warthin-Starry silver stain—bacilli.

TREATMENT

- Supportive treatment—bed rest; heat on swollen lymph nodes; needle aspiration of suppurative nodes.
- Thoroughly cleanse all cat scratches or bites.
- Prevent cats from contacting open wounds.

MEDICATIONS

DRUG(S)

- Specific antimicrobials—not efficacious.
- Most cases spontaneously resolve in a few weeks or months.

- Severe cases—antibiotic therapy (gentamicin, doxycycline, erythromycin, azithromycin) based on the antimicrobial susceptibility of *B. henselae* may be appropriate.

- Dogs—optimal therapy not established but likely long-term (4–6 weeks) antibiotics consisting of macrolides (erythromycin, azithromycin).

FOLLOW-UP

PREVENTION/AVOIDANCE

Immunocompromised people should avoid young cats.

POSSIBLE COMPLICATIONS

Uncommon

MISCELLANEOUS

- One episode appears to confer life-long immunity.
- Bacillary angiomatosis—vascular proliferative disease of the skin; may also be caused by *B. henselae*; responds to antimicrobial drugs (bartonellosis rarely does).
- Natural host of *B. henselae* is unknown but may be the cat; a related species, *B. quintana*, is spread by lice and causes trench fever in humans.

ZOONOTIC POTENTIAL

The risk of transfer of organisms from infected dogs and cats to people is unknown, although infected cats probably serve as a source of organisms for fleas that are thought to transmit the infection to humans by way of contaminating wounds with infected flea feces (i.e., cat scratch disease).

- Dogs may also serve as chronically infected blood reservoirs for *Bartonella* species, which may be spread by arthropod vectors to people.

ABBREVIATIONS

- PCR = polymerase chain reaction

Consulting Editor Stephen C. Barr

BASAL CELL TUMOR

B

BASICS

OVERVIEW

- Originates from the basal epithelium of the skin.
- Includes benign (e.g., basal cell epithelioma and basaloïd tumor) and malignant (e.g., basal cell carcinoma) tumors.
- Metastasis is rare with the benign forms, and uncommon with malignant.

SIGNALMENT

- Most common skin tumor in cats (15–26%) and second to third most common skin tumor in dogs (4–12%).
- Median age—dogs, 6–9 years; cats, 10–11 years.
- Breed predilections includes cocker spaniels, poodles, and Siamese cats.

SIGNS

- Solitary, well-circumscribed, firm, often hairless, intradermal raised mass, typically located on the head, neck, or shoulders.
- Can vary greatly in size from a few millimeters to many centimeters in diameter.
- Feline basal cell tumors are frequently heavily pigmented, and occasionally cystic or ulcerated.

CAUSES & RISK FACTORS

- Breed (see "Signalment").
- Contrary to human basal cell tumors, chronic ultraviolet exposure does not appear to play a role in pets.
- Possible association with canine papillomavirus exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other skin tumors including mast cell tumor, extramedullary plasmacytoma, melanoma, hemangioma, hemangiosarcoma, histiocytoma.
- Melanoma is an especially important differential with the pigmented feline basal cell tumors.
- Intradermal cysts.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Cytologic evaluation of fine-needle aspiration sample reveals round cells with basophilic cytoplasm; mitoses are not uncommon despite benign nature.
- When clinically indicated, fine-needle aspiration of draining lymph nodes to confirm or deny the presence of regional metastases.
- Histopathologic examination required for definitive diagnosis. When highly pigmented, immunohistochemistry occasionally required to differentiate from melanoma.

PATHOLOGIC FINDINGS

- Histologic cellular patterns vary from solid to cystic to ribbon appearance.
- Tumor cells may contain melanin pigmentation; may have a fine eosinophilic stroma.
- Nuclear criteria might help predict risk of local recurrence in feline basal cell carcinomas.

TREATMENT

- Surgical excision treatment of choice and generally curative for fully resectable tumors.
- Cryosurgery or plesiotherapy with strontium-90 can be used for smaller, superficial lesions (< 1 cm).

MEDICATIONS

DRUG(S)

N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Complete surgical excision is usually curative and associated with an excellent prognosis.
- Majority of tumors are locally confined and non-metastatic. Long-term follow-up is generally unnecessary.

Author Louis-Philippe de Lorimier
Consulting Editor Timothy M. Fan

BASICS

OVERVIEW

- Alkaline/Acid-based batteries—ulcers to the gastrointestinal tract from leaking contents, oral injury from chewing on casing and rarely heavy metal toxicity from break down of casing in the GI tract.
- Disc/Button/Lithium Ion batteries—rapid necrosis to the esophagus and stomach due to electric current from the battery. Significant necrosis can occur 15 minutes after contact.

SIGNALMENT

Dogs, cats, birds and small mammals. Young animals are more commonly affected.

SIGNS

- Historical: finding chewed-up electronic equipment without the battery, a chewed or mangled battery, or battery packaging.
- Physical:
 - Oral ulcerations
 - Oral injury from chewing on battery casing
 - Loss of appetite, drooling, regurgitation, vomiting, diarrhea, melena, progressive weakness, dyspnea, coughing, stridor, pleuritis, pyothorax, and pneumo-mediastinum.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

History, complete oral exam and full (esophagus and abdominal gastrointestinal tract) survey radiographs of the digestive tract enable diagnosis. Black debris in the oral cavity is evidence of leaked battery contents from a dry cell battery. Distinguish from exposure to other corrosive compounds (cleaning agents, drain cleaners, pool shocking agents, essential oils, and mechanical injury from chewing).

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia—secondary to bleeding gastrointestinal ulceration.
- Leukocytosis—inflammation and secondary infection.
- Elevated total proteins/prerenal azotemia—secondary to dehydration.
- Elevated liver enzymes secondary to heavy metal toxicity from break down of casing.

IMAGING

- Full survey radiographs—determine if a battery was swallowed, assess location and condition of battery and casing, look for evidence of perforation and/or obstruction.

- Endoscopy—pending severity of signs, evaluate extent of damage to the esophagus. May be able to remove the battery or casing. Use caution and do not damage the esophagus.

TREATMENT

- Lavage the oral cavity for 10–15 minutes for alkaline batteries; for disc batteries give 10–20 mL of water every 15 minutes until battery is out of the esophagus.
- Do NOT induce vomiting as this may expose the esophagus to further injury.
- NPO or slurry feeding for 24–48 hours if oral ulcerations are present.
- Ulceration may not be visible in the oral cavity until 48 hours post exposure.
- Wear gloves when cleaning up any battery debris as leaked acid could cause injury to the hands.
- Small, intact dry cell batteries in the stomach should pass within 48 hours. Evaluate all stools and if the battery has not passed the pylorus in 48 hours it should be surgically removed.
- Punctured dry cell batteries and disc/button/lithium ion batteries should be immediately removed by endoscopy or surgery.

MEDICATIONS

- Analgesics—ulcerations can be very painful.
 - Dogs—tramadol 2–5 mg/kg PO q6–8h.
 - Cats—buprenorphine 0.01–0.03 mg/kg buccal, IV or IM.
- H2 Blocker—to aid in the healing of gastric ulcerations.
 - Famotidine 0.5 mg/kg PO or SQ q12h.
- Sucralfate 0.25–1 gram PO q8h on an empty stomach.
- Antibiotics—to prevent secondary infection when ulcers are present.
 - Metronidazole 10–30 mg/kg PO q12–24h.
 - Enrofloxacin: cats, 5 mg/kg PO q24h; dogs, 5–10 mg/kg PO q12h.

CONTRAINdicATIONS

- Emetics—emesis should not be performed as it may worsen damage to the esophagus.
- Steroids—may reduce risk of esophageal stricture but expected to slow healing time.
- NSAIDs—aid in pain management and swelling reduction but may increase risk of gastric ulceration/perforation.

FOLLOW-UP

PATIENT MONITORING

Consider endoscopy 2 weeks post exposure to assess esophagus.

POSSIBLE COMPLICATIONS

Esophageal perforation, esophageal stricture, gastrointestinal obstruction, heavy metal toxicity.

EXPECTED COURSE AND PROGNOSIS

- Non-ruptured dry cell battery: excellent, most pets pass on own within 48 hours.
- Ruptured dry cell battery: guarded, pending location of corrosive exposure and amount of time before removal. Esophageal injury worsens prognosis.
- Disc/button/lithium ion battery: guarded, rapid removal is needed. Significant injury, including esophageal or gastric perforation, can occur within 15 minutes of the ingestion.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Heavy metal toxicity, esophagitis, esophageal stricture, esophageal perforation, gastrointestinal obstruction.

BAYLISASCARIASIS

B

BASICS

OVERVIEW

- Two forms of baylisascariasis have been reported in dogs: an intestinal infection occurring in adults and visceral disease caused by larval migration to puppies.
- The disease is caused by the raccoon roundworm *Baylisascaris procyonis*. Infection of raccoons occurs by ingestion of eggs or by ingestion of larvae in tissues of mammalian paratenic hosts.
- Dogs are infected by the ingestion of infective eggs or paratenic hosts from which they develop patent infections with adult worms in their small intestine. Puppies, probably infected by the ingestion of eggs, develop visceral disease like most other mammals.
- Dogs with intestinal infection are typically without signs. Puppies with larval baylisascariasis show signs of neurologic disease.

SIGNALMENT

- Dogs.
- Intestinal form—reported from adult animals.
- Larval form—reported in two puppies; suspected that only severe cases have been reported: infection with only a few larvae probably does not cause severe disease in most puppies.

SIGNS

- Intestinal form—none.
- Larval form—weakness, ataxia, dysphagia, circling, recumbency.

CAUSES & RISK FACTORS

Sharing space with areas frequented by raccoons.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Intestinal form—eggs in feces can be distinguished from those of either *Toxocara* or *Toxascaris*.
- Larval form—rabies, canine distemper, congenital neurologic defect.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

IMAGING

Larval form—based on lesions of toxocariasis or baylisascariasis in humans, lesions may appear on abdominal ultrasound or CT scans as small, single or multiple ill-defined, oval or elongated, low-attenuating lesions in the liver parenchyma. In neurologic lesions, MRI reveals diffuse periventricular white matter disease with atrophy.

DIAGNOSTIC PROCEDURES

- Intestinal form—direct fecal smear or fecal flotation.
- Larval form—ophthalmoscopic examination may show migratory tracks in retina, may use imaging methods to visualize lesions in soft tissue or brain.

TREATMENT

- Intestinal form—may want to treat as inpatient to prevent environmental contamination with eggs and to ensure proper disposal (as biohazard) or destruction (incineration) of fecal material and worms after treatment.
- Larval form—no treatment to date.

CLIENT EDUCATION

Alert owner of potential risk to people who may frequent similar habitats as raccoons.

MEDICATIONS

DRUG(S)

Intestinal Form

- Pyrantel pamoate (5 mg/kg).
- Febantel (25–35 mg/kg), pyrantel pamoate (5–7 mg/kg), praziquantel (5–7 mg/kg) (Drontal Plus).
- Ivermectin (5 µg/kg), pyrantel pamoate (5 mg/kg) (Heartgard Plus).
- Milbemycin (0.5 mg/kg), lufenuron (10 mg/kg) (Sentinel).

Larval Form

Corticosteroids and long-term albendazole (25–50 mg/kg/day for 10 days) may prove beneficial.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Intestinal form—check feces 2 weeks after deworming and again 1 month later.
- Larval form—disease has proven fatal.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Intestinal form—eggs are not infectious when passed but can develop in the environment in several days; ingestion of eggs containing infective larvae by humans can cause severe disease, i.e., larval baylisascariasis.
- Larval form—infected puppies pose no zoonotic threat; puppy in one case represented the typical presentation of larval baylisascariasis wherein animals are held in areas that have previously housed a raccoon.
- Alert owner of potential risk to people who may frequent similar habitats as raccoons.

ABBREVIATIONS

- CT = computed tomography
- MRI = magnetic resonance imaging

Author Dwight D. Bowman

Consulting Editor Stephen C. Barr

BENIGN PROSTATIC HYPERPLASIA (BPH)

B

BASICS

OVERVIEW

- Age-related pathologic change in the prostate gland making it non-painfully large.
- Occurs in two phases, glandular and complex.
- Glandular phase characterized by high number of large prostatic cells and a symmetrically large prostate gland.
- Complex phase characterized by glandular hyperplasia, glandular atrophy, small cyst formation, chronic inflammation, and squamous metaplasia of epithelium.

SIGNALMENT

- Observed initially in intact male dogs 1–2 years old.
- Prevalence increases with age; 60% of intact male dogs are affected by 6 years of age and 95% of intact male dogs are affected by 9 years of age.

SIGNS

Historical Findings

- None in most dogs
- Bloody urethral discharge
- Hematuria
- Dysuria
- Blood in ejaculate
- Straining to defecate
- Ribbon-like stools

Physical Examination Findings

- Symmetric, non-painfully enlarged prostate gland.
- Prostatic pain in dogs with complication of bacterial infection or prostatic carcinoma.

CAUSES & RISK FACTORS

- Testosterone and 5- α -dihydrotestosterone
- Estrogens
- Aging
- Risk eliminated by castration

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute bacterial prostatitis—typically associated with fever, depression, pain on rectal palpation, neutrophilia, pyuria, and bacteriuria; may occur concurrently in dogs with benign prostatic hyperplasia.
- Chronic bacterial prostatitis—typically associated with recurrent lower urinary tract infections and subfertility; may occur concurrently in dogs with benign prostatic hyperplasia.
- Prostatic adenocarcinoma—typically associated with poor appetite, weight loss, hind limb weakness, dysuria, hematuria, and

dyschezia; may see carcinoma cells in urine sediment.

- Prostatic and paraprostatic cysts—can cause palpable abdominal cystic mass filled with yellow to orange fluid.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC and biochemistry—normal. If abnormalities detected, see “Differential Diagnosis” above.
- Urinalysis—may be normal or reveal hematuria; pyuria and bacteriuria are absent unless dog has concurrent bacterial infection; see “Differential Diagnosis” above.

OTHER LABORATORY TESTS

- Prostatic fluid obtained by ejaculation or prostatic massage may be clear or hemorrhagic; RBC count high; WBC count normal; culture reveals < 100,000 colony forming units of bacteria/mL unless the dog has concurrent bacterial infection.
- Serum concentration of prostatic esterase is high in some dogs.

IMAGING

Radiography

- Abdominal radiographs reveal prostatomegaly.
- Retrograde urethrocystography may be normal or reveal narrowing of prostatic urethra and/or reflux of contrast media into the prostate gland.

Ultrasonography

- Reveals enlarged prostate gland with uniform prostatic parenchymal echogenicity; small, fluid-filled cysts in some dogs.
- Ultrasound-guided fine-needle aspirate can be used to correctly diagnose prostatic disease in 80% of cases.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Not required if asymptomatic.
- Castration—most effective and prevents recurrence; if benign prostatic hyperplasia is complicated by acute bacterial prostatitis, delay surgery until the infection is resolved.

MEDICATIONS

DRUG(S)

- If castration is not acceptable, the following drugs may temporarily shrink the prostate gland:
 - Finasteride (0.1–0.5 mg/kg/day for up to 4 months)

◦ Megestrol acetate (0.11 mg/kg PO daily for 3 weeks)

- Medroxyprogesterone (3–4 mg/kg SC with subsequent doses administered at no less than 10-week intervals).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Avoid estrogens because of possible hematologic toxicity and development of squamous metaplasia of the prostate.
- Long-term administration of megestrol acetate or medroxyprogesterone may result in development of diabetes mellitus.

FOLLOW-UP

- Castration will result in rapid involution of the enlarged prostate. The prostate decreases in volume by 50% within 3 weeks following castration.
- Treatment with finasteride not associated with decline in libido, decline in semen quality, or induction of birth defects. BPH will recur after withdrawal of finasteride; time until clinical signs recur is variable.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Bacterial prostatitis and prostatic carcinoma.
- Prostatomegaly in a castrated dog strongly suggests prostatic carcinoma.

SEE ALSO

- Prostatic Cysts
- Prostatitis and Prostatic Abscess
- Prostatomegaly

ABBREVIATIONS

- BPH = benign prostatic hyperplasia/hypertrophy
- RBC = red blood cell
- WBC = white blood cell

BENZODIAZEPINE AND OTHER SLEEP AIDS TOXICOSIS

BASICS

DEFINITION

- Toxicosis due to ingestion of sleep aids or antianxiety medications commonly used in human and veterinary medicine.
- Benzodiazepine class—alprazolam (Xanax), clonazepam (Klonopin), diazepam (Valium), lorazepam (Ativan), midazolam (Versed), and many more.
- Imidazopyridine class—eszopiclone (Lunesta), zaleplon (Sonata), and zolpidem (Ambien, Ambien CR, Intermezzo).

PATHOPHYSIOLOGY

- Benzodiazepines and imidazopyridines bind to receptors near the gamma-aminobutyric acid (GABA) receptor/chloride channel on neurons; they potentiate GABA's effect, which increases the opening of the chloride channel, leading to hyperpolarization of the nerve and decreased excitation.
- Imidazopyridines bind near the receptor subset that is responsible for sedation, while benzodiazepines bind to all receptor subsets and so not only mediate sedation but are also anticonvulsant and anxiolytic.
- Paradoxical reactions can occur and are typically described as excitement, irritability, and aberrant demeanor in cats and excitement in dogs, when the expected effect is seizure control or sedation.
- Both classes are well absorbed orally and have rapid onset of actions, often less than 30 minutes.
- Duration of action depends on the drug and may last for hours to days.
- Both classes have wide margins of safety; lethal exposures are rare if a single agent is involved.
- Benzodiazepines—signs can be seen at therapeutic doses; however, the drugs have a wide margin of safety, with the minimal lethal dose being approximately 1,000 times the therapeutic dose. Cats may develop idiosyncratic hepatic failure with chronic oral dosing of diazepam and clonazepam.
- Zaleplon—based on a review of the ASPCA APCC Antox database: In dogs, doses > 0.11 mg/kg have been associated with restlessness and hyperactivity; in cats, doses of > 1.25 mg/kg caused paradoxical reactions.
- Zolpidem—based on a review of the ASPCA APCC Antox database: In dogs, dosages > 0.2 mg/kg can cause mild sedation and ataxia; doses > 0.6 mg/kg can cause paradoxical reactions. In cats, signs of paradoxical reactions were seen at 0.34 mg/kg or greater.

SYSTEMS AFFECTED

- Gastrointestinal—vomiting
- Hepatic—acute necrosis and failure in cats with diazepam and clonazepam
- Nervous—CNS depression and/or paradoxical reactions, ataxia, coma
- Respiratory—depression

GENETICS

N/A

INCIDENCE/PREVALENCE

Commonly prescribed drugs so exposure is common

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dogs and cats—acute toxicity; cats—idiosyncratic hepatic failure with chronic oral dosing of diazepam or clonazepam possible.

Breed Predilections

None

Mean Age and Range

None

Predominant Sex

None

SIGNS

General Comments

- Benzodiazepines can cause sedation with virtually any exposure (even at therapeutic doses).
- Imidazopyridines cause sedation at low doses but likelihood of paradoxical reaction increases with increasing dose, especially in dogs.

Historical Findings

- Evidence of accidental ingestion of medication
- Therapeutic use of drug
- Lethargy
- Ataxia
- Sedation
- Agitation

Physical Examination Findings

- Depression
- Ataxia
- Sedation
- Hypothermia
- Agitation
- Hyperthermia (secondary to agitation)
- Tachycardia
- Icterus (in cats with idiopathic liver failure)

CAUSES

Accidental exposure, inappropriate administration, or therapeutic use

RISK FACTORS

- Younger and older animals
- Animals with preexisting conditions

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- CNS depression—barbiturates, ivermectin, ethylene glycol, alcohols (e.g., ethanol, methanol), marijuana, opioids, and antidepressants (low doses).
- Paradoxical reactions—amphetamines, pseudoephedrine, methylxanthines, cocaine, phenylpropanolamine, and serotonin syndrome (secondary to antidepressants).

CBC/BIOCHEMISTRY/URINALYSIS

- No abnormalities expected in acute overdoses.
- In cats with idiopathic liver failure, elevated liver enzymes and bilirubin.

OTHER LABORATORY TESTS

- Benzodiazepines can be detected in blood, urine, and liver; OTC drug-testing kits may be used to confirm exposure.
- Imidazopyridines can be detected in blood and urine; OTC drug-testing kits are not yet readily available.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

No gross or histologic changes are expected.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—most mildly affected animals can be managed at home with confinement (to avoid injury due to falls) and minimizing stimulation.
- Inpatient—animals who are comatose or showing paradoxical reactions.

NURSING CARE

- Intravenous fluids.
- Monitor and control body temperature.
- Good bedding and frequent turning for recumbent patients.
- Minimize sensory stimulation, especially with paradoxical reactions.

ACTIVITY

Restrict until recovered to avoid injury.

DIET

Cats with liver failure may require forced or tube feeding for support.

CLIENT EDUCATION

- Make all clients aware of proper storage of all medications.

(CONTINUED)

BENZODIAZEPINE AND OTHER SLEEP AIDS TOXICOSIS**B**

- If prescribing diazepam or clonazepam to cats, have owner closely monitor the cat for the first week.

SURGICAL CONSIDERATIONS

N/A

**MEDICATIONS****DRUG(S) OF CHOICE**

- Acpromazine 0.025–0.05 mg/kg IV/IM as needed to control paradoxical reactions.
- Cyproheptadine 1.1 mg/kg PO or rectally for dogs; 2–4 mg/cat for control of paradoxical reactions.
- Flumazenil—a benzodiazepine reversal agent—0.01 mg/kg IV q1–2h as needed.
 - It can be used to reverse both excessive sedation and paradoxical reaction.
 - However, flumazenil can cause seizures so its use is generally restricted to life-threatening situations.

CONTRAINdications

Do not give other benzodiazepines to control paradoxical reactions.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

Care when using other depressant medications (e.g., barbiturates, phenothiazines), as these can potentiate the depressant effects of these drugs.

**FOLLOW-UP****PATIENT MONITORING**

TPR, blood pressure, respiratory effort

PREVENTION/AVOIDANCE

Secure medications out of reach of dogs and cats

POSSIBLE COMPLICATIONS

No long-term complications expected

EXPECTED COURSE AND PROGNOSIS

- Prognosis for acute overdose is excellent with symptomatic care.
- Prognosis for acute hepatic failure in cats with diazepam is poor.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

- Young animals and those with preexisting liver disease may have prolonged signs due to reduced ability to clear the drugs.
- Younger animals may be more prone to paradoxical reactions.

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

Benzodiazepines are considered teratogenic

SEE ALSO

- Amphetamine Toxicosis
- Antidepressant Toxicosis—SSRIs and SNRIs
- Antidepressant Toxicosis—Tricyclic
- Ethanol Toxicosis
- Ethylene Glycol Toxicosis
- Ivermectin and other Macrocytic Lactones Toxicosis

BETA BLOCKER TOXICOSIS

B

BASICS

OVERVIEW

• Beta receptor antagonists are class II antidysrhythmics used to treat hypertrophic or hypertrophic obstructive cardiomyopathy in cats and hypertension and tachydysrhythmias in dogs and cats. • β_1 receptors are primarily located in the heart, eye, and kidney. Blockage may result in significant bradycardia. • β_2 receptors are primarily located in bronchial smooth muscle, gastro-intestinal tract, pancreas, liver, skeletal muscle, vascular smooth muscle, and endothelium. Blockage results in bronchospasm and vasodilation. • Systems affected include: ◦ Cardiovascular—bradycardia, hypotension ◦ Respiratory—bronchospasm ◦ Nervous—decreased mentation, seizures ◦ Endocrine/metabolic—hypoglycemia, metabolic acidosis secondary to hypoperfusion.

SIGNALMENT

Dogs and cats equally affected with no breed, age, or sex predilection.

SIGNS

- Bradycardia • Hypotension • AV block
- Decreased mentation • Respiratory distress/bronchospasm • Seizures • Coma • Death

CAUSES AND RISK FACTORS

Ingestion of medication or inadvertent overdose of beta adrenergic antagonists

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Calcium channel blocker overdose • Cardiac disease with secondary bradycardia
- Cardiovascular drug overdose (e.g. clonidine, digoxin toxicosis) • Sedative overdose (e.g. opioid or baclofen toxicosis)
- Sick sinus syndrome • Hyperkalemia
- Decompensated shock/sepsis

CBC/CHEMISTRY/URINALYSIS

- Hypoglycemia • Hypokalemia • Azotemia and elevated liver enzymes with prolonged hypoperfusion

OTHER LABORATORY TESTS

Blood gas—metabolic acidosis secondary to hypoperfusion

DIAGNOSTIC PROCEDURES

- ECG—1st, 2nd, and 3rd degree AV block; prolonged PR, QRS and QT intervals
- Echocardiogram—negative inotropy, decreased cardiac output

TREATMENT

- Emesis if asymptomatic and recent (< 2 hours) ingestion. • Consider gastric lavage if decreased mental status or large number of pills ingested. • Whole bowel irrigation considered for extended (ER) or sustained release (SR) medications. • Central line placement for CVP monitoring, frequent glucose monitoring and dextrose administration during high dose insulin (HDI) therapy. • Volume resuscitation with IV fluid bolus for hypotension:
 - 10–20 mL/kg for cats over 15–30 minutes
 - 20–30 mL/kg for dogs over 15–30 minutes.

MEDICATIONS

DRUGS

- Activated charcoal (1–2 g/kg) administered within 2 hours post-exposure. • Atropine (0.02–0.04 mg/kg IV) may be used for sinus bradycardia. • Intravenous fat emulsion (IFE): ◦ Used to treat lipid-soluble drug intoxication ◦ Three possible mechanisms:
 - (1) Provide a lipid sink for fat soluble drugs;
 - (2) Supply a fatty acid source for cardiac performance;
 - (3) Increase intracellular calcium (Ca) via activation of voltage gated Ca channels to improve myocyte function.
- IFE dose: 1.5 mL/kg IV bolus of a 20% solution over 1 minute. Follow with a CRI of 0.25 mL/kg/min for 30–60 minutes. Can repeat bolus every 3–5 minutes as needed up to 3 mL/kg, not to exceed a total dose of 8 mL/kg. • HDI/glucose administration:
 - The exact mechanism of HDI is unknown but appears to promote uptake and utilization of carbohydrates as an energy source. May increase myocardial cell cytosolic Ca levels to increase cardiac contractility and cardiac output.
 - HDI increases cardiac output through positive inotropic effects but does not increase systemic vascular resistance. Blood pressure may not improve significantly even though clinical signs and perfusion may improve.
- Recommended treatment:
 - (1) Check blood glucose (BG) concentration and administer dextrose if BG is < 100 mg/dL for dogs and < 200 mg/dL in cats.
 - (2) Administer regular insulin at 1 unit/kg IV. Follow with a CRI IV of regular insulin at 2 units/kg/h. Increase every 10 minutes as needed up to a maximum dose of 10 units/kg/h. When clinical signs resolve, decrease insulin by 1–2 units/kg/h.
 - (3) Monitor BG every 10 minutes while titrating insulin dosing. Once insulin dosing is stabilized, check BG every 30–60 minutes. Dextrose supplementation IV will be needed to maintain BG concentrations. May need to continue dextrose supplementation up to 24 hours after discontinuation of the insulin

therapy. (4) Monitor potassium concentration every hour. Administer potassium chloride to keep potassium concentrations in the low therapeutic range. • 10% calcium chloride or gluconate for hypotension and may increase efficacy of HDI therapy. • 10% Ca chloride 0.2 mL/kg or Ca gluconate 0.6 mL/kg IV bolus to maintain ionized Ca at 1–2 X therapeutic levels. • Glucagon: increases inotropy by increasing myocardial cAMP levels. May not be as effective as HDI or ILE. Dose recommended is 0.05–0.2 mg/kg slow IV bolus followed by a CRI of 0.1–0.15 mg/kg/h.

CONTRAINDICATION/POSSIBLE INTERACTIONS

Vasopressors: Literature suggests that vasopressors are not as effective as other therapies (IFE and HDI) and may make patients less responsive to other therapy.

FOLLOW-UP

PATIENT MONITORING

- Monitor for 8 hours with immediate release preparations and up to 24 hours for ER preparations
- Heart rate/ECG
- Blood pressure
- Potassium levels
- Blood glucose

POSSIBLE COMPLICATIONS

Organ damage (especially kidney and liver damage) can occur secondary to prolonged hypoperfusion.

EXPECTED COURSE AND PROGNOSIS

- Ingestion of immediate release preparations typically result in clinical signs in 6 hours.
- SR or ER preparations may take up to 24 hours for clinical signs to develop.
- Prognosis depends on the dose ingested and response to therapy. • Toxicosis normally results in bradycardia, hypotension and in severe cases decreased mental status, coma and apnea.

MISCELLANEOUS

ABBREVIATIONS

- BG = blood glucose • Ca = calcium
- CRI = continuous rate infusion • ECG = electrocardiogram • ER = extended release
- HDI = high dose insulin • ILE = IV lipid emulsion • IV = intravenous • SR = sustained release

BETA-2 AGONIST INHALER TOXICOSIS

B

BASICS

OVERVIEW

• Beta-2 agonist inhaler toxicosis occurs when dogs chew and puncture pressurized inhalers containing albuterol (salbutamol), levalbuterol, or salmeterol. • Loss of beta-2 adrenergic selectivity with overdose results in beta-1 stimulation (sinus tachycardia). Failure of the myocardium to effectively oxygenate during extreme periods of tachycardia can result in other tachyarrhythmias such as VPCs and ventricular tachycardia. • Generalized adrenergic stimulation releases catecholamines which exacerbate CV stimulation, stimulate the CNS and respiratory systems, and can result in significant intracellular translocation of potassium and phosphorus. • Propellants are now hydrofluoroalkanes (HFAs) and are expected to sensitize the myocardium less to catecholamines than older chlorofluorocarbon propellants.

SYSTEMS AFFECTED

- Behavioral—hyperactivity, apprehension, nervousness, restlessness.
- Cardiovascular—sinus tachycardia, other tachyarrhythmias.
- Endocrine/Metabolic—hypokalemia, hypophosphatemia.
- Gastrointestinal—mild vomiting.
- Musculoskeletal—tremors, weakness with catecholamine depletion.
- Nervous—anxiety, apprehension initially, depression with catecholamine depletion.
- Neuromuscular—tremors.
- Respiratory—tachypnea.

SIGNALMENT

Young dogs are overrepresented due to their predilection for dietary indiscretion.

SIGNS

- Tachycardia, other tachyarrhythmias
- Lethargy, weakness, depression
- Hyperactivity, apprehension, nervousness, restlessness
- Tachypnea
- Vomiting
- Tremors

CAUSES & RISK FACTORS

- Puncture of inhalers containing beta-2 agonists
- Pets prone to dietary indiscretion with access to inhalers

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Amphetamines and related drugs such as those used for attention deficit hyperactivity disorder (ADHD) (e.g., Adderall, Adipex, Concerta, Cylert, Daytrana, Fastin, Focalin, Ionamin, Metadate, Methylin, Obermine, Quillivant, Phentrol, Ritalin, Straterra, Termene, Vyvanse) and street drugs

- Sympathomimetics (e.g., phenylpropanolamine, pseudoephedrine, phenylephrine, ephedrine)
- Methylxanthines (e.g., caffeine, theobromine)
- Metaldehyde
- Thyroxine
- Tremorgenic mycotoxins
- Hops (*Humulus lupulus*)
- Nicotine

CBC/BIOCHEMISTRY/URINALYSIS

- Hypokalemia
- Hypophosphatemia

DIAGNOSTIC PROCEDURES

ECG to confirm, monitor for arrhythmias.

TREATMENT

- Inpatient treatment—initiate medical management and emergency care as soon as possible following exposure.
- Nursing care required—fluid support.
- Altered activity—cage rest, quiet environment.
- NPO if vomiting.
- Discuss with owner the timing of presentation relative to exposure; patients that have a delayed presentation and prolonged, untreated CNS and CV stimulation may be at greater risk for more serious arrhythmias and slower recovery due to catecholamine depletion.
- No surgical or anesthetic considerations.

MEDICATIONS

DRUG(S)

- Benzodiazepines PRN for anxiety, nervousness, tremors:
 - Diazepam: 0.5 mg/kg IV or 1 mg/kg rectally, repeat PRN.
 - Midazolam: 0.25 mg/kg IV, repeat PRN.
- Beta blockers for severe tachycardia (HR > 160 in large dogs; > 200 in miniature breeds), hypokalemia:
 - Propranolol (preferred, nonspecific blocker): dogs, 0.02–0.06 mg/kg IV to effect.
 - Esmolol (blocks beta-1 only; ultra-short acting): dogs, 0.25–0.5 mg/kg IV as a slow bolus then a CRI of 0.01–0.2 mg/kg/min.
- Potassium chloride supplementation:
 - Up to 0.5 mEq potassium/kg/h IV maximum, based on degree of hypokalemia.
 - Potassium phosphate if phosphorus < 1 mg/dL:
 - 0.01–0.03 mM/kg/h IV.
- Lidocaine for ventricular arrhythmias:
 - Dogs, 2–4 mg/kg IV (maximum of 8 mg/kg over 10 minutes) followed by a CRI of 40–80 µg/kg/min.
 - Cats, 0.25–0.5 mg/kg IV slowly (caution in this species due to predilection for CNS and CV toxicity).

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Electrolytes (potassium, phosphorus) q12h or PRN if ECG changes, weakness (potassium), hemolysis (phosphorus). *Note:* Monitor for rebound hyperkalemia upon recovery if aggressively supplemented.
- Electrocardiography.
- Mentation.

POSSIBLE COMPLICATIONS

- Rarely fatal. Persistent, severe tachycardia can result in myocardial hypoxia and more serious arrhythmias or other cardiac sequelae, especially if preexisting cardiac disease is present.
- Catecholamine depletion can result in weakness and depression once the stimulatory effects wane.

EXPECTED COURSE AND PROGNOSIS

Excellent prognosis with prompt and appropriate treatment in an otherwise healthy patient.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- Albuterol crosses the placenta. Overdose effects are expected to be similar for the fetus. Hypoxia with cardiac compromise in the bitch may harm the fetus.
- No adverse effects expected with regard to fertility.

ABBREVIATIONS

- ADHD = attention deficit hyperactivity disorder
- CNS = central nervous system
- CRI = constant rate infusion
- CV = cardiovascular
- ECG = electrocardiogram
- HFA = hydrofluoroalkane
- VPCs = ventricular premature contractions

BILE DUCT CARCINOMA

B

BASICS

OVERVIEW

- Epithelial neoplasia that arises from the cells lining the biliary duct or gallbladder.
- Second most common malignant hepatic tumor in dogs, representing 22–41% of all malignant canine liver tumors. • Most common malignant hepatobiliary tumor in cats, but less common than benign biliary cystadenoma. • Benign biliary cystadenomas may undergo malignant transformation into cystadenocarcinomas. • Common metastatic sites include the lungs, regional lymph nodes, and peritoneum (carcinomatosis). • Other metastatic sites include intestine, pancreas, heart, spleen, kidney, spinal cord, urinary bladder, and bone. • Paraneoplastic alopecia has been associated with feline biliary carcinoma.

SIGNALMENT

- Dog and cat • Possible predilection for Labrador retrievers • Affected animals typically > 10 years of age • Possible predisposition for female dogs

SIGNS

Historical Findings

- Anorexia • Lethargy • Weight loss
- Vomiting • Polydipsia and polyuria
- Icterus • Abdominal distension

Physical Examination Findings

- Hepatomegaly (\pm palpable abdominal mass)
- Ascites • Icterus

CAUSES & RISK FACTORS

- Potential association between canine cholangiocarcinoma and trematode (hookworms, whipworms) infection.
- Carcinoma of the canine biliary tract has been experimentally induced by N-ethyl-N'-nitro-N-nitrosoguanidine.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Imaging and gross pathology—Hepatocellular adenoma (hepatoma), hepatocellular adenocarcinoma, biliary adenoma and cystadenoma, nodular hyperplasia, cirrhosis, chronic active hepatitis, hepatic myelolipoma, carcinoids, hepatic abscess. • Histopathology – Will distinguish from hepatocellular adenocarcinoma based on morphology, however immunohistochemistry (hepatocyte paraffin-1) and Claudin-7 can be used to distinguish between hepatocellular and biliary neoplasms.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia. • Leukocytosis. • Elevated serum enzyme (e.g., ALP, GGT, ALT, AST) activity

is often present but not specific for neoplastic disease. • Hyperbilirubinemia possible.

OTHER LABORATORY TESTS

- α -Fetoprotein (an oncofetal glycoprotein) is elevated in 55% of dogs with bile duct carcinoma and may help differentiate neoplastic from non-neoplastic lesions in dogs. • Coagulation profile (PT, PTT) should be performed before biopsy or surgical procedures.

IMAGING

Abdominal Radiography

May localize a mass to the liver or may demonstrate displacement of the stomach or loss of detail in patients with ascites.

Abdominal Ultrasonography

Can be used to assess location and character of lesion, detect and sample peritoneal effusion, and to guide tumor biopsy.

Thoracic Radiography

Should be used to screen for pulmonary metastasis.

CT and MRI

More sensitive techniques that can discriminate histologic tumor type in humans and are more likely to detect smaller lesions not visible on ultrasound.

DIAGNOSTIC PROCEDURES

- Abdominocentesis and cytologic evaluation of peritoneal fluid, if present. • Cytology or needle core (Tru-Cut) biopsy samples can be obtained via ultrasound guidance.
- Laparoscopy or laparotomy may be needed to obtain larger sample for definitive diagnosis.

PATHOLOGIC FINDINGS

- Gross findings—Morphologic types include massive (37–46%), nodular (0–21%), or diffuse (17–54%). • Can be intrahepatic (most common in dogs), extrahepatic, or within the gall bladder (rare). • Malignant lesions often involve multiple lobes, whereas benign (adenomas/cystadenomas) tend to be solitary. • Histopathology findings—Histologic subtypes include solid (cholangiocarcinoma) and cystic (biliary cystadenocarcinoma) forms. Histologic classification (solid vs. cystic) is not prognostic.

TREATMENT

- Surgical excision is treatment of choice, if complete resection is feasible. • Up to 80% of the liver can be resected if the remaining liver tissue is functional. • No effective surgical treatment exists for nodular or diffuse forms.
- Interventional techniques (chemoembolization) may be utilized for nonresectable solitary tumors.

MEDICATIONS

DRUG(S)

Chemotherapy—no effective protocol identified.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Medications requiring metabolism by the liver or rely upon enterohepatic should be used with caution if evidence of hepatic dysfunction is noted.

FOLLOW-UP

PATIENT MONITORING

Physical examination, lab work (especially liver enzymes), abdominal ultrasonography, and thoracic radiography every 3 months after tumor resection.

PREVENTION/AVOIDANCE

Anthelmintic therapy is warranted due to the potential association between canine bile duct carcinoma and infection with hookworms or whipworms.

POSSIBLE COMPLICATIONS

- Tumor rupture/hemorrhage, especially if the massive form. • Biliary obstruction.

EXPECTED COURSE AND PROGNOSIS

- Aggressive tumor; guarded to poor prognosis, especially if nonresectable. • High rate of metastasis (up to 88%) in both dogs and cats. Widespread intraperitoneal carcinomatosis common in cats. • Most patients die within 6 months of surgery due to local recurrence or metastasis.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Chemotherapy drugs may be carcinogenic and mutagenic.

ABBREVIATIONS

- CT = computed tomography • MRI = magnetic resonance imaging • PT = Prothrombin time • PTT = Partial thromboplastin time

BILE DUCT OBSTRUCTION (EXTRAHEPATIC)

BASICS

DEFINITION

Cholestasis caused by biliary tree obstruction at the level of the common bile duct (CBD) causing extrahepatic bile duct obstruction (EHBDO) or at the level of the hepatic ducts; may involve one, several, or all hepatic ducts.

PATHOPHYSIOLOGY

- Serious hepatobiliary injury—follows within weeks of duct obstruction secondary to accumulation of inflammatory mediators, neutrophils, noxious bile acids and other bile constituents accumulating in the periductal area, mechanical effect of duct distention (hydrostatic pressure), and oxidative injury.
- Gallbladder (GB) bile—may become colorless (white bile) if cystic duct obstruction impairs influx of canalicular green hepatic bile (contains bilirubin pigments).
- White bile—reflects increased mucin production, bilirubin exclusion, and sometimes, suppurative inflammation.
- Bacterial infection of bile—increased risk with stasis of bile flow (normal clearance of splanchnic-derived bacteria in the portal circulation).

SYSTEMS AFFECTED

Hepatobiliary

SIGNALMENT

Species

Dog and cat

Breed Predilection

- Animals predisposed to pancreatitis and choleliths: e.g., GB mucocele (GBM)—hyperlipidemic breeds (e.g., miniature Schnauzer, Shetland sheepdog).
- Animals with large duct ductal plate malformation (DPM) phenotype (Caroli's malformation) predisposed to infection and cholelithiasis.
- Choleliths appear more common in small-breed dogs and cats.

Mean Age and Range

Middle-aged to old animals with acquired disease; younger animals with DPM.

Predominant Sex

None

SIGNS

Historical Findings

- Depend on underlying disorder and “completeness” of EHBDO.
- Progressive lethargy and vague illness.
- Progressive jaundice.
- Pale (acholic) stools: complete EHBDO.
- Polyphagia: complete EHBDO causes nutrient malassimilation (fat).
- Bleeding tendencies: within 10 days of complete EHBDO, more severe/overt in cats.

Physical Examination Findings

- Depend on underlying cause

- Weight loss
- Severe jaundice
- Hepatomegaly unless biliary cirrhosis
- Cranial mass effect—extrahepatic biliary structures (small dogs and cats)
- Vague cranial abdominal discomfort
- Acholic feces—unless enteric bleeding (hemoglobin provides pigment)
- Bleeding tendencies—chronic EHBDO
- Orange urine: severe bilirubinuria

CAUSES

- Diverse primary disorders
- Cholelithiasis
- Choledochitis
- Neoplasia
- Bile duct malformations: choledochal cysts, polycystic hepatobiliary disease, DPM, Caroli's malformation, cystadenoma encroaching on porta hepatis (cats)
- Parasitic infestation: flukes (cats)
- Extrinsic compression: lymph nodes, neoplasia, pancreatitis, CBD entrapment in diaphragmatic hernia; foreign body obstruction of sphincter of Oddi in duodenum
- Duct fibrosis: trauma, peritonitis, pancreatitis; major duct involvement in feline cholangitis/cholangiohepatitis
- Duct stricture: blunt trauma, iatrogenic surgical manipulations

RISK FACTORS

See “Causes”

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mass lesions—primary or metastatic hepatobiliary neoplasia; in adjacent viscera
- Diffuse infiltrative liver disease—neoplastic, inflammatory, HL (cats, canalicular compression), amyloid (rare)
- Infectious hepatitis—bacterial, viral, flukes
- Decompensated chronic hepatitis
- Copper-associated hepatopathy
- Severe hepatic fibrosis/cirrhosis
- Fulminant hepatic failure
- Biliary cysts—choledochal (cats), cystadenoma, polycystic liver disease (cats) compressing CBD at porta hepatis; choledochal cyst (cats), DPM
- Pancreatitis: CBD stenosis, stricture
- Hepatic lipidosis (HL)—cats: canalicular collapse causes jaundice.
- Cholangitis/cholangiohepatitis—cats, esp. sclerosing or destructive cholangitis form.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Anemia—mild non-regenerative (chronic disease) or regenerative (enteric bleeding due to hypertensive splanchnic vasculopathy, ulcerations, coagulopathy due to portal hypertension)
- Microcytosis—uncommon

- Leukogram—variable, neutrophilic leukocytosis, left-shifted leukogram with sepsis
- Plasma—markedly jaundiced

Biochemistry

- Liver enzymes—variable; marked increases in ALP and GGT reflect ductal injury; high ALT and AST reflect hepatocyte injury.
- Total bilirubin—moderate to markedly high; less than observed with hemolysis or HL; bilirubin fractionation—overlaps with hemolytic and sepsis associated jaundice.
- Albumin—variable, usually normal except when EHBDO > 6 weeks (biliary cirrhosis); low albumin reflects synthetic failure.
- Globulins—normal or increased.
- Glucose—normal or low if biliary cirrhosis or sepsis; high if diabetes with pancreatitis.
- Hypercholesterolemia—common.

Urinalysis

- Bilirubinuria and bilirubin crystals.
- Absence of urobilinogen—unless enteric bleeding; unreliable definitive test for EHBDO.

OTHER LABORATORY TESTS

- Serum bile acids—always markedly increased; superfluous test if hepatobiliary jaundice already suspected.
- Coagulation abnormalities—within 10 days of EHBDO develop vitamin K deficiency (PIVKA and PT clotting times most sensitive); may develop DIC; cats more dramatic effect.
- Fecal examination—acholic stools suggest EHBDO; masked by small-volume melena; trematode eggs if fluke infestation.

IMAGING

- Abdominal radiography—hepatomegaly; variable mass lesion in area of gallbladder, pancreatitis pattern, mineralized cholelith(s).
- Cholecystography—rarely provides additional practical information.
- Abdominal ultrasonography—evidence of obstruction within 72–96h (distended, tortuous CBD, cystic duct, and intrahepatic bile ducts); may disclose underlying or primary disorder (e.g., pancreatitis, cystic lesions, mass lesions, choleliths). **Caution:** GB bile “sludge” and a full GB are common in anorectic or fasted patients—do not mistake for EHBDO.
- **Caution:** Feline CBC is serpiginous compared to the dog—always inspect liver image for distended intrahepatic bile ducts and confirm “tubes” are ducts rather than vasculature with color flow Doppler.

DIAGNOSTIC PROCEDURES

- Hepatic aspiration cytology—used to rule in HL (cats) or sample mass lesions; avoid aspiration of obstructed biliary structures as this may cause bile leakage and peritonitis.
- US guided-needle biopsy—strongly contraindicated; may cause iatrogenic bile peritonitis.

BILE DUCT OBSTRUCTION (EXTRAHEPATIC)

(CONTINUED)

B

- Laparotomy—best approach; allows tissue biopsy; biliary decompression; mass excision: cholelith or inspissated bile removal; creation of biliary-enteric anastomosis; stent insertion.

PATHOLOGIC FINDINGS

- Gross—distended, tortuous bile duct, distended GB: cause often grossly apparent; obstruction > 2 weeks: large, dark green or mahogany-colored liver; chronic complete obstruction of cystic duct associates with white or clear GB bile.
- Microscopic—early: biliary epithelial hyperplasia and bile ductule proliferation and dilation with intraluminal biliary debris (mucin, inflammatory cells, usually neutrophils) and periductular edema, and early fibrosis; chronic distention of biliary structures: leads to devitalized biliary epithelium with necrotic debris, intraluminal suppurative debris, mixed periportal inflammatory infiltrates, periductal edema with thick laminating circumferential fibrosis, multifocal parenchymal necrosis.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—surgical intervention for EHBDO unless the cause is pancreatitis with prospect for resolution with supportive care.

NURSING CARE

- Fluid therapy—depends on underlying conditions (see Pancreatitis); rehydrate and provide maintenance fluids before general anesthesia and surgical interventions; supplement polyionic fluids with potassium chloride and phosphate; judicious electrolyte adjustments based on electrolyte status.
- Water-soluble vitamins—in intravenous fluids; B complex (2 mL/L polyionic fluids).
- Initiate antibiotic therapy before surgery: see “Drugs of Choice.”
- Vitamin K₁: parenteral administration if EHBDO > 5–7 days (see “Drugs of Choice”).

ACTIVITY

Depends on patient status and coagulopathy.

NUTRITIONAL SUPPORT

- Maintain nitrogen balance—avoid protein restriction.
- Restrict fat—if overt fat malassimilation caused by lack of enteric bile acids in chronic EHBDO—rare incidence.
- Supplement fat-soluble vitamins: vitamins E and K most urgent; supplementing vitamins D and A can lead to toxicity.
- Water-soluble vitamin E—necessary in chronic EHBDO (see “Drugs of Choice”).

CLIENT EDUCATION

- Inform client that surgical biliary decompression is essential (unless resolvable pancreatitis or cholelith obstruction); EHBDO progresses to biliary cirrhosis within

6 weeks; exception is pancreatitis causing EHBDO that may self-resolve within 2–3 weeks.

- Warn client that surgical success is contingent on underlying cause, results of liver biopsy, infection, and individual variables.

SURGICAL CONSIDERATIONS

- Surgical exploration—imperative for treating and determining underlying cause unless obvious pancreatitis.
- Excise masses, remove choleliths and inspissated bile; ensure common duct patency.
- Resect GB—if necrotizing cholecystitis or GB mucocele.
- Biliary-enteric anastomosis—if irresolvable occlusion, fibrosing pancreatitis, or neoplasia; anastomotic stoma at least 2.5 cm wide. Chronic recurrent infection likely after biliary-enteric anastomosis. Temporary stent instead of biliary enteric anastomosis may be complicated by infection and stent obstruction, esp. in cats.
- Hypotension and bradycardia (vasovagal reflex)—may develop during biliary tree manipulation; ensure availability of emergency drugs (anticholinergics) and ventilatory support for rescue endeavors.
- Ensure IV catheter access and volume expansion—use colloids when necessary, plasma preferred; be prepared for hemorrhage (have blood available for transfusions).
- Surgical biopsies—submit tissue and bile for aerobic and anaerobic bacterial culture; submit tissue for histology.
- Cytology—make preps from tissue and bile; cytology may detect bacterial infections and fluke eggs not recognized in biopsy sections. Bile, biliary debris, and GB wall—more likely to culture organisms. Wright-Giemsa staining to detect bacteria, Gram stain to characterize bacterial morphology; may advise acute antimicrobial selection. Enteric opportunists are most common. *Bacteroides* may promote polymicrobial infection; may not culture all involved bacteria.
- Sclerosing or destructive feline cholangitis (intrahepatic ductopenia) may clinically emulate EHBDO; does not respond to biliary tree decompression; liver biopsy necessary.

MEDICATIONS

DRUG(S) OF CHOICE

Vitamin K₁

Provide 12–36h before surgery (0.5–1.5 mg/kg IM or SC), 3 doses at 12-h intervals. **Caution:** avoid IV, may cause anaphylaxis. If chronic EHBDO irresolvable, parenteral Vit. K₁ given chronically with frequency titrated using PIVKA or PT, too much vit. K₁ causes hemolytic (Heinz body) anemia in cats.

Vitamin E

- If chronic EHBDO irresolvable (rare) use polyethylene glycol alpha tocopherol succinate (TPGS-vitamin E) 10 U/kg/day PO and injectable Vitamin K₁ (see above).
- Treat early to allow response before surgery.

Antibiotics

Before surgery—broad-spectrum antimicrobials for potential biliary infections as surgical manipulations may disseminate bacteremia; initially use antibiotics with wide spectrum as follows—triad of: ticarcillin 25 mg/kg IV q8h, metronidazole 7.5 mg/kg IV or PO q12h, enrofloxacin 5 mg/kg PO q12–24h (24h dose in cats no greater than 5 mg/kg/24h to avoid retinopathy).

Antioxidants

- Vitamin E (α -tocopherol acetate)—10–100 IU/kg; a larger-than-normal (normal = 10 IU/kg /day) oral dose needed in chronic EHBDO because of fat malabsorption (lack of enteric bile acids); use of TPGS-Vitamin E preferred (see previous).
- S-Adenosylmethionine (SAME) with proven bioavailability and efficacy as GSH donor—20 mg/kg/day PO enteric-coated tablet 1–2 hours before feeding; provides numerous additional metabolic benefits.

Ursodeoxycholic Acid

10–15 mg/kg PO per day—AFTER biliary decompression as a choleretic; ensure adequate hydration to achieve choleresis; *inappropriate before* biliary decompression: can accelerate liver injury in EHBDO. Does not facilitate fat assimilation in chronic EHBDO. Beneficial effects: antifibrotic, anti-endotoxic, hepato-protectant, anti-apoptotic, immunomodulator.

Bowel Preparation Before Surgery

- May reduce endotoxemia potentiating perioperative hypotension.
- Mechanical cleansing of colon with water or crystalloid fluids.
- Acutely alter enteric flora to reduce enteric translocation of opportunistic pathogen with medications given either: PO or by high enema; neomycin: 22 mg/kg q8h, lactulose 1–2 mL/kg q8h; metronidazole 7.5 mg/kg q12h; rifaximin 5–10 mg/kg q12h; probiotic bacteria (empirical product dose); enrofloxacin 2.5 mg/kg q12h PO.

Gastrointestinal Protectants

Agents reducing gastric acidity—famotidine (H₂-blocker) or omeprazole (pump inhibitor) combined with sucralfate for local cytoprotection if PO medications tolerated and enteric bleeding recognized; stagger sucralfate administration from other oral medications to avoid drug interactions.

CONTRAINdications

- Provide biliary decompression before institution of ursodeoxycholic acid.
- Take care to reduce drug dosages for medications eliminated in bile if EHBDO.

(CONTINUED)

BILE DUCT OBSTRUCTION (EXTRAHEPATIC)**B****PRECAUTIONS**

See “hypotension and bradycardia (vasovagal reflex)” under “Surgical Considerations.”

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

- Depends on underlying condition—special monitoring for underlying disorders causing EHBDO; see appropriate conditions.
- Total bilirubin values acutely reflect biliary decompression; values normalize within days.
- Liver enzyme activities—decline slowly.
- CBC—repeat q2–3 days initially if septic.
- Bile peritonitis—evaluate abdominal girth, body weight, and fluid accumulation (e.g., by palpation, ultrasonography preferred, abdominocentesis).
- Determine necessity for pancreatic enzyme supplementation based on site of biliary-enteric anastomosis; patients with cholecystojejunostomies may benefit from enzyme supplementation; cannot rely on trypsin-like immunoreactive (TLI) substance to estimate pancreatic exocrine adequacy in this circumstance; evaluate body weight and condition; check feces for steatorrhea (fat malassimilation; suspend feces in water and microscopically examine for lipid globules—only relevant if animal is fed a normal fat-containing diet; if steatorrheic after biliary-enteric anastomosis and non-icteric, reduce dietary fat and supplement with pancreatic enzymes. Pancreatic enzymes can induce oral or esophageal ulcers especially in cats, must be mixed in food and followed by liquid or food to prevent mucosal injury.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Bile peritonitis
- Restenosis of bile duct—if not bypassed
- Stenosis of biliary-enteric anastomosis
- Severe enteric hemorrhage with EHBDO—hypertensive enteric vasculopathy with coagulopathy (vitamin K deficiency)
- Hemorrhage during surgery
- Septic bacteremia or SIRS during or after surgery
- Unresponsive hypotension during surgery
- Vasovagal reflex—biliary tree manipulation

EXPECTED COURSE AND PROGNOSIS

- Depends on underlying disease.
- Prognosis good if fibrosing pancreatitis and pancreatic inflammation resolves; bile duct patency may return.
- Be aware: biliary tree may appear distended on subsequent ultrasounds.
- Permanent peribiliary fibrosis from EHBDO.
- Cats with sclerosing cholangitis can appear to have EHBDO; but show no response to biliary decompression; liver biopsy essential for diagnosis.

CONSIDERATIONS/PRECAUTIONS

- Anticipate bleeding tendencies and vasovagal reflex during surgical procedures.
- Always submit liver and biliary tree biopsies for histology; all tissues and bile for bacterial culture (aerobic, anaerobic).

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- See “Causes”
- Sclerosing or destructive cholangitis (cats) confused with EHBDO

SEE ALSO

BILE PERITONITIS

B

BASICS

OVERVIEW

- Chemical peritonitis due to release of free bile into the abdominal cavity.
- Can involve focal or diffuse peritoneal inflammation depending on chronicity and causal factors, and omental adhesions.

SIGNALMENT

- More common in dog than in cat
- No age, breed, or sex predilection

SIGNS

Historical Findings

- Acute presentation if septic peritonitis
- May have chronic illness if non-septic
- Rare asymptomatic biliary rupture associated with omental encapsulation of leakage
- Abdominal discomfort: vague
- Lethargy
- Gastrointestinal signs: anorexia, vomiting, diarrhea
- Weight loss
- \pm Abdominal distention
- Variable jaundice
- Collapse, if septic

Physical Examination Findings

- Lethargy
- Variable (cranial) abdominal pain
- Jaundice
- Abdominal effusion
- \pm Fever
- \pm Endotoxic shock, if septic

CAUSES & RISK FACTORS

- Limited arterial perfusion (cystic artery) to GB fundus predisposes to ischemic necrosis and GB rupture.
- Trauma to biliary structures—auto-mobile injuries, surgical, animal bites, gunshot wounds, cystic artery laceration during cholecystocentesis.
- Common bile duct (CBD): common site of rupture with blunt trauma.
- Cholecystitis/choledochitis—may derive from GB mucocele (GBM); sepsis more common with necrotizing cholecystitis.
- EHBDO—may derive from neoplasia, cholelithiasis, pancreatitis, duct stricture.
- Focal, small-volume, bile peritonitis—associated with cholecystitis; may reflect omental entrapment of bile or transmural bile leakage without rupture.
- Chemical peritonitis due to bile—predisposes to septic peritonitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Conditions promoting inflammation/devitalization of biliary structures, e.g.,

cholecystitis, choledochitis, neoplasia, GBM, neoplasia, blunt trauma.

- Conditions causing EHBDO, e.g., neoplasia, choleliths, pancreatitis, duct stricture/fibrosis.
- Sepsis or endotoxemia.
- Ascites: in jaundiced cirrhotic patient.
- Non-hepatic conditions causing abdominal effusion and jaundice.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

Inflammatory leukogram—left shift and toxic neutrophils if necrotizing cholecystitis or sepsis; non-regenerative anemia if chronic inflammation.

Biochemistry

- High liver enzymes, especially ALP; hyperbilirubinemia; \pm hypoalbuminemia; \pm prerenal azotemia
- Electrolyte, fluid, and acid-base disturbances; hyponatremia common.

Urinalysis

Bilirubinuria

OTHER LABORATORY TESTS

Coagulation tests—abnormal if sepsis syndrome, DIC, or chronic EHBDO.

IMAGING

- Abdominal radiography—reduced abdominal detail, generalized or focal in GB area; cranial abdominal mass effect; rare mineralized cholelith or biliary gas (emphysematous cholecystitis).
- Thoracic radiography—rare bicavity effusion (pleural effusion), signs of trauma (e.g., fractured rib, hernia).
- Abdominal ultrasonography—effusion; EHBDO—distended GB or CBD; cholecystitis /choledochitis—thick GB or duct wall; necrotizing cholecystitis—segmental GB wall hyperechogenicity, laminated wall (represents necrosis); pericholecystic fluid; hepatic /pancreatic mass effect: common with bile peritonitis; choleliths or GBM ("kiwifruit sign"); gas in GB or bile ducts (emphysematous inflammation, implicates gas-forming organisms) casting acoustic shadow; ruptured GB may be difficult to image; liver size usually normal; variable parenchymal echogenicity reflects hepatic pathology (e.g., ascending cholangitis, CCHS).

DIAGNOSTIC PROCEDURES

- Abdominocentesis—physicochemical, cytologic, and culture evaluations; ultra-sound guidance optimizes sampling; sample close to biliary structures but avoid structure penetration.
- Cytology—impression smears of GB, liver, and bile (with particulate material) used for immediate detection of infection and neoplasia; modified transudate or exudate, phagocytized/free bile and bilirubin.

- Acellular mucinous material reflects biliary mucin production; GBM material may be free within abdominal cavity.

- Ratio of bilirubin in effusion:serum usually $\geq 2\text{--}3:1$.

- Bacterial aerobic/anaerobic culture and sensitivity—effusion, GB wall, liver, GB contents; Gram-negative enteric opportunists and anaerobes most common; polymicrobial infection possible.

- Exploratory laparotomy—appropriate for definitive diagnosis and treatment; permits cholecystectomy, cholecysto-enterostomy, duct or GB repair.

- Liver biopsy—important, evaluates for antecedent or coexistent disease, sample distant to the GB to avoid artifacts.

PATHOLOGIC FINDINGS

Depend on cause and site of rupture

TREATMENT

- Inpatient—expediency of surgery depends on patient condition: achieve euhydration, correct electrolyte and acid-base status, provide preoperative antimicrobial treatment for best survival.
- Abdominal lavage to reduce peritoneal contamination if surgery delayed; use warm polyionic fluids and aseptic technique.
- Surgical experience important for best outcome: complicated resections and anastomoses may be required.
- Need for cholecystectomy decided at surgery; discolored GB wall indicates ischemic devitalized wall.

MEDICATIONS

DRUG(S)

- Antimicrobials—in all patients, initiate broad-spectrum antimicrobials *before* surgical intervention; enteric Gram-negative and anaerobic organisms most common opportunists (good initial choices: ticarcillin, piperacillin, or third-generation cephalosporins, with enro-floxacin and metronidazole); customized antimicrobial treatment, thereafter based on cultures; continue antimicrobials $\geq 4\text{--}8$ weeks if signs of infection confirmed by culture or on cytology.
- Vitamin K₁ (0.5–1.5 mg/kg IM or SC q12h for up to 3 doses)—all jaundiced patients *before* surgery.
- Prepare for blood component \pm synthetic colloid therapy.
- Antiemetics if patient is vomiting—metoclopramide (0.2–0.5 mg/kg PO, SC q6–8h or 1–2 mg/kg/24h IV by CRI); ondansetron (0.5–1.0 mg/kg q12h, IV or PO, 30 minutes before feeding); maropitant

(CONTINUED)

BILE PERITONITIS**B**

(1.0 mg/kg/day IV, SC, PO, maximum of 5 days).

- H₂-receptor antagonists if gastric bleeding—famotidine (0.5–2.0 mg/kg PO, IV, SC q12–24h); sucralfate (0.25–1.0 g PO q8–12h).
- Ursodeoxycholic acid as choleretic and hepatoprotectant if GBM, choleliths, CCHS, or chronic hepatitis—may administer chronically if GBM or cholelithiasis: 10–15 mg/kg PO daily, divided, with food for best bioavailability.
- Antioxidants—Vitamin E (10 IU/kg/24h); S-adenosylmethionine (SAMe, with proven bioavailability and efficacy; (20 mg/kg PO daily 2h before feeding) until enzymes normalize, indefinitely if chronic hepatitis or CCHS, GBM, inspissated bile syndrome; choleretic influence requires higher dose (40 mg/kg/day).

**FOLLOW-UP****PATIENT MONITORING**

- Sequential hematologic, biochemical, and imaging tests.
- Repeat abdominocentesis to assess continued infection and/or bile leakage as indicated.

POSSIBLE COMPLICATIONS

- Cholangitis/cholangiohepatitis
- Pancreatitis
- Recurrent bacterial cholangitis if biliary-enteric anastomosis required

EXPECTED COURSE AND PROGNOSIS

- High survival rate for dogs with sterile bile peritonitis, if successful surgery, depending on underlying cause.
- Higher mortality in septic bile peritonitis (up to 73%).
- Anticipate slow clinical recovery and normalization of liver enzymes but rapid resolution of hyperbilirubinemia with successful surgery.

**MISCELLANEOUS****SEE ALSO**

- Cholecystitis
- Cholelithiasis
- Gallbladder Mucocele
- Hepatitis, Chronic

ABBREVIATIONS

- ALP = alkaline phosphatase
- CCHS = cholangitis/cholangiohepatitis
- CMD = common bile duct
- CRI = constant rate infusion
- EHBDO = extrahepatic bile duct obstruction
- GB = gallbladder
- GBM = GB mucocele

Consulting Editor Sharon A. Center

BILIUS VOMITING SYNDROME

B

BASICS

OVERVIEW

• Clinical entity associated with chronic intermittent vomiting of bile thought to be the result of reflux of intestinal contents (bile) into the stomach. The normal aboral gastric and intestinal motility along with a functional pylorus prevents the reflux of bile and other intestinal contents back into the stomach. When bile is refluxed into the stomach, it is normally rapidly removed by subsequent peristaltic contractions. Bile remaining in the gastric lumen along with the presence of gastric acid and pepsin can subsequently cause gastric mucosal damage. Bilius vomiting syndrome (BVS) is suspected to be secondary to alterations in normal gastrointestinal motility. • Clinical signs often occur early in the morning, suggesting that prolonged fasting or gastric inactivity may modify normal motility patterns, resulting in bile reflux.

SIGNALMENT

- Commonly observed in dogs, rarely in cats
- Most animals are middle-aged or older
- No breed or sex predisposition

SIGNS

- Chronic intermittent vomiting of only bile associated with an empty stomach. Signs generally occur late at night or early in the morning. Signs may occur daily but are usually more intermittent. Between episodes, the animal appears normal in all other respects, and most dogs appear healthy immediately after vomiting episodes.
- Results of physical examination are usually unremarkable.

CAUSES & RISK FACTORS

- Cause is unknown (idiopathic). • Primary gastric hypomotility or abnormal (oral-directed) intestinal peristaltic motility are suspected as the probable underlying causes. • Conditions causing gastritis, duodenitis or intestinal obstructive disease may be responsible for altered proximal gastrointestinal motility and can cause bile reflux. Investigate *Giardia*, inflammatory bowel disease, intestinal neoplasia, or obstructions as possible etiologies. • Previous pyloric opening or resection surgery will also increase the risk of enterogastric reflux.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Any number of gastrointestinal and non-gastrointestinal disorders can cause chronic vomiting. *Giardia* should be excluded

since the signs of this disease may mimic those of idiopathic bilius vomiting.

- Inflammatory bowel disease can result in bile reflux. • Intestinal obstruction or partial obstructions should be ruled out.

CBC/BIOCHEMISTRY/URINALYSIS

Results usually unremarkable

OTHER LABORATORY TESTS

Fecal examination to detect *Giardia* or other parasites

IMAGING

- A barium contrast study may reveal delayed gastric emptying, although must be interpreted with caution in the hospital setting. • Barium given with meals, radiopaque markers, or using special motility capsules (Smartpill) may also demonstrate delayed gastric motility.

DIAGNOSTIC PROCEDURES

- Endoscopic findings are frequently unremarkable and helps rule out underlying gastrointestinal disease. • There may be evidence of bile in the stomach or gastritis in the antral region of the stomach. • Endoscopy is useful to rule out structural or inflammatory disease of the stomach or duodenum.

TREATMENT

- It is generally not a serious debilitating disorder if major conditions such as gastritis, inflammatory bowel disease, or gastrointestinal neoplasia have been ruled out.
- The idiopathic bilius vomiting cases are generally treated symptomatically on an outpatient basis and treatment response supports the suspected diagnosis. • Feeding the animal multiple meals including a late evening meal often resolves clinical signs. Food possibly could act as a buffer to the refluxed bile or may in some way enhance gastrointestinal motility. • If diet modification fails, medical treatment should be considered.

MEDICATIONS

DRUG(S)

- Choices include agents for gastric mucosal protection against the refluxed bile or the use of gastric prokinetic agents to improve motility.
- Often a single evening dose of a medication may be all that is required to prevent clinical signs if the signs occur at night.
- Drugs for gastric mucosal protection include various antacids or sucralfate (1 g/25 kg).
- Drugs that block gastric acid production including famotidine (0.5–1.0 mg/kg q12h), ranitidine (1–2 mg/kg q8–12h), nizatidine (1–5 mg/kg q24h) and omeprazole (0.7–1.5 mg/kg q24h) may be beneficial. Ranitidine and nizatidine also have mild gastric prokinetic effects in vitro and may be beneficial.
- Specific gastric prokinetic agents include metoclopramide (0.2–0.4 mg/kg PO q6–8h) and cisapride (0.5 mg/kg PO q8–12h). Cisapride is only available through compounding pharmacies.
- Erythromycin (0.5–1 mg/kg q8h) given at physiologic doses stimulates gastric motility by activation of motilin receptors and may also resolve signs.

ranitidine (1–2 mg/kg q8–12h), nizatidine (1–5 mg/kg q24h) and omeprazole (0.7–1.5 mg/kg q24h) may be beneficial. Ranitidine and nizatidine also have mild gastric prokinetic effects in vitro and may be beneficial.

- Specific gastric prokinetic agents include metoclopramide (0.2–0.4 mg/kg PO q6–8h) and cisapride (0.5 mg/kg PO q8–12h). Cisapride is only available through compounding pharmacies.

- Erythromycin (0.5–1 mg/kg q8h) given at physiologic doses stimulates gastric motility by activation of motilin receptors and may also resolve signs.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Gastric prokinetic agents should not be administered in patients with gastrointestinal obstruction. • Metoclopramide is contraindicated with concurrent phenothiazine and narcotic administration and in animals with epilepsy. Metoclopramide can cause nervousness, anxiety, or depression.
- Cisapride at higher doses can cause vomiting, diarrhea, or abdominal cramping.
- Erythromycin can cause vomiting.

FOLLOW-UP

- Most patients respond to one of the above treatments and a clinical response supports the diagnosis. • Failure to respond suggests another underlying or causative factor.

BLASTOMYCOSIS

B

BASICS

DEFINITION

A systemic, mycotic infection caused by the dimorphic soil organism *Blastomyces dermatitidis*.

PATHOPHYSIOLOGY

- A small spore (conidia) is shed from the mycelial phase (*Ajellomyces dermatitidis*) of the organism growing in the soil and inhaled, entering the terminal airway.
- At body temperature, the spore transforms to its yeast form, which initiates the infection in the lungs.
- From this focus of mycotic pneumonia, the yeast disseminates hematogenously throughout the body.
- The immune response to the invading organism produces a pyogranulomatous infiltrate to control the organism.

SYSTEMS AFFECTED

- Respiratory—85% of affected dogs have lung disease.
- Eyes, skin, subcutaneous tissues, lymphatic system, testes, CNS, and bones—commonly affected.
- Prostate, mammary gland, nasal cavity, nasopharynx, gums, heart, and vulva—less commonly affected.
- Subclinical infection is uncommon.

INCIDENCE/PREVALENCE

Depends on environmental and soil conditions that favor growth of *Blastomyces*. Growth of the organism requires sandy, acid soil, and a proximity to water.

GEOGRAPHIC DISTRIBUTION

Most common along the Mississippi, Ohio, and Tennessee river basins. Also reported in the area of the Great Lakes and St. Lawrence River, southern Canada, mid-Atlantic states, and has been found outside the endemic area in Colorado.

SIGNALMENT

Species

- Predominantly dog
- Occasionally cat

Breed Predilections

Large-breed dogs weighing ≥ 25 kg, especially sporting breeds; may reflect increased exposure rather than susceptibility.

Mean Age and Range

- Dogs—most common in 1–5 years of age; uncommon after 7 years of age.
- Cats—no age predilection noted for cats.

Predominant Sex

- Dogs—males in most studies.
- Cats—none noted.

SIGNS

Historical Findings

- Weight loss; depressed appetite.
- Cough and dyspnea.
- Eye inflammation and discharge.
- Lameness.
- Draining skin lesions.
- Syncope if cardiac involvement.

Physical Examination Findings

Dogs

- Fever up to 104°F (40°C)—approximately 50% of patients.
- Harsh, dry lung sounds associated with increased respiratory effort—common.
- Generalized or regional lymphadenopathy with or without skin lesions or subcutaneous swellings.
- Uveitis with or without secondary glaucoma and conjunctivitis, ocular exudates, and corneal edema.
- Lameness—bone involvement in up to 30% cases.
- Testicular enlargement and prostatomegaly—occasionally seen.
- Murmur and AV block—with endocarditis and myocarditis.

Cats

- Increased respiratory effort
- Granulomatous skin lesions
- Visual impairment

RISK FACTORS

- Wet environment—banks of rivers, streams, and lakes or in swamps; most affected dogs live within 400 meters of water.
- Exposure to recently excavated areas.
- Blastomycosis has been reported in indoor-only cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Respiratory signs—bacterial pneumonia, neoplasia, heart failure, pleural effusion, or other fungal infection.
- Lymph node enlargement—similar to lymphoma.
- The combination of respiratory disease with ocular, bony, or skin/subcutaneous involvement in a young dog suggests the diagnosis.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC changes reflect mild to moderate inflammation; may note mild anemia in chronic cases.
- High serum globulins with borderline low albumin concentrations with chronic infection.
- Hypercalcemia (generally mild) in some dogs secondary to the granulomatous changes.
- *Blastomyces* yeasts may be found in the urine of dogs with prostatic involvement; mild proteinuria consistent with systemic inflammation/disease.

OTHER LABORATORY TESTS

- Urine or serum antigen testing—useful for making a diagnosis if organisms cannot be found on cytology or histopathology; positive test strongly supports diagnosis with a sensitivity of $> 90\%$; greater sensitivity reported with urine antigen test.
- Urine antigen test cross-reacts with some other fungal infections such as histoplasmosis.
- AGID—is not sensitive early in the disease but very specific for fungal infection.

IMAGING

Radiographs

- Lungs—generalized interstitial to nodular infiltrate but can see non-uniform distribution of lesions.
- Tracheobronchial lymphadenopathy—common.
- Changes—consistent with bacterial pneumonia; may resemble metastatic tumors, especially hemangiosarcoma.
- Chylothorax secondary to blastomycosis has been reported in dogs.
- Focal bone lesions—lytic and proliferative; can be mistaken for osteosarcoma.

DIAGNOSTIC PROCEDURES

- Cytology of lymph node aspirates, lung aspirates, tracheal wash fluid, or impression smears of draining skin lesions—best method for diagnosis.
- Histopathology of bone biopsies or enucleated blind eyes—identify the organism.
- Organisms—usually plentiful in the tissues; may be scarce in tracheal washes if there is no productive cough.

PATHOLOGIC FINDINGS

- Lesions—pyogranulomatous with budding yeast $5\text{--}20 \mu\text{m}$ diameter with a thick, refractile, double-contoured cell wall; occasionally very fibrous with few organisms found.
- Lungs with large amounts of inflammatory infiltrate do not collapse when the chest is opened.
- Special fungal stains—facilitate finding the organisms.

TREATMENT

NURSING CARE

Severely dyspneic dogs—require an oxygen cage/support for a protracted period (days to more than a week); about 25% of dogs have worsening of lung disease during the first few days of treatment, attributed to an inflammatory response after the *Blastomyces* organisms die and release their contents.

ACTIVITY

Patients with respiratory compromise must be restricted.

DIET

Palatable and high quality to stimulate the appetite.

CLIENT EDUCATION

- Inform owner that treatment is costly and requires a minimum of 60–90 days.
- Reassure owners that an infected dog is not contagious to other animals or people (although other dogs in the house may have also been environmentally exposed).

SURGICAL CONSIDERATIONS

- Removal of an abscessed lung lobe may be required when medical treatment cannot resolve the infection.
- Blind eyes should be enucleated to remove potential sites of residual infection.

B BLASTOMYCOSIS

(CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE

Itraconazole

- Dogs—5 mg/kg PO q12h with a fat-rich meal, such as canned dog food, for the first 3 days to achieve a therapeutic blood concentration as soon as possible; then reduce to 5 mg/kg q24h.
- Cats—5 mg/kg PO q12h; open the 100 mg capsules containing pellets and mix with palatable food.
- Avoid antacid drugs. as itraconazole absorption is best in an acidic environment.
- Treat for a minimum of 90 days or for 1 month after all signs of disease have disappeared (whichever is longer).
- Absorption of compounded itraconazole is highly unreliable and the use of compounded itraconazole is not recommended.

Fluconazole

- Dogs—5 mg/kg PO q12h; has been reported as efficacious.
- Cats—50 mg PO q12–24h.
- Cheaper alternative but may require longer treatment duration.

Intravenous Amphotericin B

- Dogs with neurologic signs or life-threatening disease should be treated with AMB.
- 0.5–1.0 mg/kg IV q48h in dogs that cannot take oral medication or that do not respond to azole therapy (see Histoplasmosis); use the lipid complex for dogs with renal dysfunction.

CONTRAINDICATIONS

Corticosteroids—usually contraindicated because the anti-inflammatory effects allow uninhibited proliferation of the organisms; patients with previous steroid therapy require a longer duration of treatment; for dogs with life-threatening dyspnea, dexamethasone (0.1–0.2 mg/kg daily) for 2–3 days may be lifesaving when given in conjunction with itraconazole treatment; taper and discontinue steroids as soon as possible.

PRECAUTIONS

Itraconazole and Fluconazole Toxicity

- Anorexia—most common sign; attributed to liver toxicity; monitor serum ALT monthly for duration of treatment or when anorexia occurs; temporarily discontinue drug for patients with anorexia and moderate ALT elevation; after appetite improves, restart at half the previously used dose.
- Ulcerative dermatitis—seen in some dogs; the result of vasculitis; dose-related condition; temporarily discontinue drug; when ulcers have resolved, restart at half the previously used dose.

Amphotericin B Toxicity

- Only absolute contraindication to therapy is anaphylaxis but the major limiting factor is

cumulative nephrotoxicity. • Monitor creatinine throughout therapy—elevation above normal or 20% greater than baseline is considered significant.

FOLLOW-UP

PATIENT MONITORING

Serum chemistry—monthly to monitor for hepatic toxicity or if anorexia develops.

Thoracic Radiographs

- Determine duration of treatment.
- Considerable permanent pulmonary changes (fibrosis/scarring) may occur after the infection has resolved, making determination of persistent active disease difficult.
- At 90 days of treatment—if active lung disease is seen, continue treatment for an additional 30 days.
- If lungs are normal, stop treatment and repeat radiographs again in 30 days.
- At 120 days of treatment—if the lungs are the same as day 90, changes are residual (fibrosis).
- If better than day 90, continue treatment for 30 more days, if lesions are significantly worse than at 90 days, change treatment to amphotericin B and then repeat radiographs.
- Continue treatment as long as there is improvement in the lungs; if there is no further improvement and no indication of active disease, the lesions are likely the result of scarring.

PREVENTION/AVOIDANCE

- Location of environmental growth of *Blastomycetes* organisms unknown, thus difficult to avoid exposure; exposure to lakes and streams could be restricted but is not very practical.
- Dogs that recover from the infection may be immune to reinfection.

EXPECTED COURSE AND PROGNOSIS

- Death—25% of dogs die during the first week of treatment; early diagnosis improves chance of survival.
- More severe pulmonary disease and invasion into the CNS decrease prognosis.
- Recurrence—about 20% of dogs; usually within 3–6 months after completion of treatment; may occur > 1 year after treatment; a second course of azole treatment cures most patients; drug resistance has not been observed.
- With early detection of blastomycosis, the prognosis in cats appears similar to dogs.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Yeast form is not spread from animals to humans, except through bite wounds; inoculation of organisms from dog bites has occurred.
- Avoid cuts during necropsy of infected dogs and avoid needle sticks when

aspirating lesions.

- Warn clients that blastomycosis is acquired from an environmental source and that they may have been exposed at the same time as the patient; the incidence in dogs is 10 times that in humans.
- Encourage clients with respiratory and skin lesions to inform their physicians that they may have been exposed to blastomycosis.

PREGNANCY/FERTILITY/BREEDING

Azole drugs can have teratogenic effects (embryotoxicity found at high doses) and should ideally be avoided during pregnancy (but the risk of not treating the mother needs to be balanced with the theoretical risk of azole therapy to the fetuses).

ABBREVIATIONS

- AGID = agar gel immunodiffusion
- ALT = alanine transaminase • AMB = amphotericin B • CBC = complete blood count • CNS = central nervous system

BLEPHARITIS

B

BASICS

DEFINITION

- Inflammation of the outer (skin) and middle (muscle, connective tissue, and glands) portions of the eyelid, usually with secondary inflammation of the palpebral conjunctiva.
- Anterior—most commonly associated with bacterial infection or self-trauma.
- Posterior—disorders of the meibomian glands.

PATOPHYSIOLOGY

- Same as virtually every condition that affects the skin in general.
- Mechanisms of inflammation—immune mediated, infectious, endocrine mediated, self- and external trauma, parasitic, radiation, and nutritional.
- Inflammatory response often exaggerated because eyelid conjunctiva is rich in mast cells and densely vascularized.
- Meibomian gland dysfunction—common; bacterial lipases alter meibomian lipids so they plug the gland; they also produce irritating fatty acids, enhance bacterial growth, and destabilize the tear film.

SYSTEMS AFFECTED

Ophthalmic

SIGNALMENT

See "Causes"

SIGNS

- Serous, mucoid, or mucopurulent ocular discharge.
- Blepharospasm.
- Eyelid hyperemia, edema, and thickening.
- Pruritus.
- Excoriation.
- Depigmentation—skin; hair.
- Alopecia.
- Swollen, cream-colored meibomian glands.
- Elevated, pinpoint meibomian gland orifices.
- Abscesses.
- Scales and crusts.
- Papules or pustules.
- Single or multiple nodular hyperemic swellings.
- Concurrent conjunctivitis and/or keratitis.
- In Siamese-type cats with color points, chronic blepharitis often causes lightening of hair on affected lids due to increased temperature of the skin.

CAUSES

Congenital

- Eyelid abnormalities—may promote self-trauma or moist dermatitis.
- Prominent nasal folds, medial trichiasis, and lower lid entropion—shih tzu, Pekingese, English bulldog, Lhasa apso, pug; Persian and Himalayan cat.
- Distichia—shih tzu, pug, golden retriever, Labrador retriever, poodle, English bulldog.
- Ectopic cilia.
- Lateral lid entropion—shar-pei, chow chow, Labrador retriever, rottweiler; adult cats (rare).
- Lagophthalmos—brachycephalic dogs; Persian, Himalayan, and Burmese cats.
- Deep medial canthal pocket—dolichocephalic dogs.
- Dermoids—rottweiler, dachshund, and others; Burmese cat.

Allergic

- Type I (immediate)—atopy, food, insect bite, inhalant, *Staphylococcus* hypersensitivity.
- Type II (cytotoxic)—pemphigus, pemphigoid, drug eruption.
- Type III (immune complex)—SLE; *Staphylococcus* hypersensitivity; drug eruption.
- Type IV (cell mediated)—contact and flea bite hypersensitivity; drug eruption.

Bacterial

- Hordeolum—localized abscess of eyelid glands, usually staphylococcal; may be external (sty in young dogs, involving glands of Zeis) or internal (in old dogs, involves one or more meibomian glands).
- Generalized bacterial blepharitis and meibomianitis—usually *Staphylococcus* or *Streptococcus*.
- Pyogranulomas.
- *Staphylococcus* hypersensitivity—young and old dogs.

Neoplastic

- Sebaceous adenomas and adenocarcinomas—originate from meibomian gland.
- Squamous cell carcinoma—white cats.
- Mast cell—may masquerade as swollen, hyperemic lesion.

Other

- External trauma—eyelid lacerations; thermal or chemical burns.
- Mycotic—dermatophytosis; systemic fungal granulomas.
- Parasitic—demodicosis; sarcoptic mange; *Cuterebra* and *Notoedres cati*. Note: *Demodex injai* has a propensity for sebaceous glands and can be associated with meibomian gland dysfunction in dogs, including chalazia and granulomatous blepharitis.
- Chalazia (singular, chalazion)—sterile, yellow-white, painless meibomian gland swellings caused by a granulomatous inflammatory response to escape of meibum into surrounding eyelid tissue.
- Nutritional—zinc-responsive dermatosis (Siberian husky, Alaskan malamute, puppies); fatty acid deficiency.
- Endocrine—hypothyroidism (dogs); hyperadrenocorticism (dogs); diabetic dermatosis.
- Viral—chronic blepharitis in cats secondary to FHV-1.
- Irritant—topical ocular drug reaction; nicotine smoke in environment; after parotid duct transposition.
- Familial canine dermatomyositis—collie and Shetland sheepdog.
- Nodular granulomatous episclerokeratitis—fibrous histiocytoma and collie granuloma in collies; may affect the eyelids, cornea, or conjunctiva.
- Eosinophilic granuloma—cats; may affect eyelids, cornea, or conjunctiva.
- Eyelid contact with tear overflow and purulent exudate (tear burn).
- Conjunctivitis.
- Keratitis.
- Dry eye.
- Dacryocystitis.
- Orbital disease.
- Radiotherapy.
- Drug contact irritant—any drug, often neomycin.
- Idiopathic—particularly in cats with chronic idiopathic conjunctivitis (especially Persians and Himalayans).

RISK FACTORS

- Breed predisposition to congenital eyelid abnormalities, e.g., entropion, ectropion, etc.
- Hypothyroidism—may promote chronic bacterial disease in dogs.
- Canine seborrhea—may promote chronic generalized meibomianitis, with predisposition for *Demodex injai* infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Clinical signs are diagnostic.

CBC/BIOCHEMISTRY/URINALYSIS

Usually non-diagnostic unless metabolic cause (e.g., diabetic dermatosis).

OTHER LABORATORY TESTS

- Indicated for suspected systemic disorder.
- Consider tests for hypothyroidism.

DIAGNOSTIC PROCEDURES

- If possible, avoid topical anesthetic or fluorescein before obtaining culture.
- Cytology—deep skin scrapings; conjunctival scrapings; expressed exudate from meibomian glands and pustules.
- Dermatophyte culture—deep skin scrapings.
- Wood's light evaluation—skin.
- KOH preparation—skin scrapings.
- Aerobic bacterial culture and sensitivity—exudate from skin; conjunctiva; expressed exudate from meibomian glands and pustules; often will not recover *Staphylococcus* from patients with chronic meibomianitis and suspected *Staphylococcus* hypersensitivity.
- IFA or PCR for FHV-1 and *Chlamydia*—conjunctival scrapings from cats with primary conjunctivitis or keratitis.
- Eye examination—potential inciting cause; corneal ulcer; foreign body; distichia; ectopic cilia; dry eye.
- Ancillary ocular tests—fluorescein application; Schirmer tear test.
- Thorough medical history and dermatologic examination—help identify generalized dermatologic disease.
- Full-thickness wedge biopsy of eyelid—histologic evaluation.
- Direct immunofluorescence for autoimmune disease; intradermal skin testing, RAST, ELISA, and food elimination diet for hypersensitivity-induced disease.
- Do not underestimate the value of referral to a dermatologist for refractory cases, especially when atopy is suspected.

PATHOLOGIC FINDINGS

- Routine histopathology often non-diagnostic in chronic disease.
- Carefully select patients based on history, ophthalmic exam, and response to medical therapy.

TREATMENT

APPROPRIATE HEALTH CARE

See "Nursing Care"

BLEPHARITIS

B

NURSING CARE

- Secondary disease—treat primary disease.
- Suspected self-trauma—Elizabethan collar.
- Topical gentamicin, neomycin, terramycin, and most ointments—may cause an irritant blepharoconjunctivitis (rare); withdrawal of agent may resolve condition.
- Cleanse eyelids—to remove crusts; warm compresses applied for 5–15 minutes 3–4 times daily, avoiding ocular surfaces; saline lactated Ringer's solution, or a commercial ocular cleansing agent (e.g., I-Lid n Lash); must clip periocular hair short.

DIET

Only with food allergy-induced disease.

CLIENT EDUCATION

- In cats with FHV-1-related blepharitis inform client that there is no cure and that clinical signs often recur when the animal is stressed.
- Inform client that there is no cure for FHV-1 and that clinical signs often recur when the animal is stressed.

SURGICAL CONSIDERATIONS

- Temporary everting eyelid sutures—spastic entropion; or in puppies before permanent surgical correction.
- Repair eyelid lacerations.
- Lancing—large abscesses only; lance and curette hordeola that resist medical treatment and chalazia that have hardened and come to a point, causing keratitis; manually express infected meibomian secretions.

MEDICATIONS

DRUG(S)

Antibiotics

- Systemic—generally required for effective treatment of bacterial eyelid infections; may try amoxicillin-clavulanic acid or cephalaxin; 20 mg/kg q8h.
- Topical—may try neomycin, polymyxin B, and bacitracin combination or chloramphenicol.

Congenital

- Topical antibiotic ointment—q6–12h; until surgery is performed to prevent frictional rubbing of eyelid hairs or cilia on the ocular surface.
- Saline, lactated Ringer's solution, or ocular irrigant—regularly flush deep medial canthal pocket debris.

External Trauma

- Topical antibiotic ointment—q6–12h; for spastic entropion secondary to pain and blepharospasm to reduce friction until entropion is surgically relieved.
- Systemic antibiotics indicated.

Allergic

- *Staphylococcus* hypersensitivity blepharitis—systemic broad-spectrum antibiotics and systemic corticosteroids (prednisolone 0.5 mg/kg q12h for 3–5 days, then taper); many patients respond dramatically to systemic corticosteroids alone. Systemic

cyclosporine if refractory to corticosteroids (5 mg/kg PO q24h until remission, then q48–72h).

- Infected meibomian glands—oral tetracycline (15–20 mg/kg PO q8h) or doxycycline (3–5 mg/kg PO q12h) or cephalaxin (22 mg/kg q8h) for at least 3 weeks (the former two are lipophilic and cause decreased production of bacterial lipases and irritating fatty acids); topical polymyxin B and neomycin with 0.1% dexamethasone (q6–8h to the eye) or topical 0.02% tacrolimus compounded ointment (q8–12h).

Note: Some affected dogs might also have concomitant Demodex injai infection and require treatment for demodicosis.

- Failure of treatment—may try injections of commercial *Staphylococcus aureus* bacterin (Staphage Lysate).
- Eyelid lesions associated with puppy strangles—usually benefit from treatment of the generalized condition.
- Atopy (see Atopy); consider Janus kinase inhibitor (oclacitinib; Apoquel) to control pruritus and self-trauma.

Bacterial

- Based on culture and sensitivity testing.
- While results are pending—topical polymyxin B and neomycin with 0.1% dexamethasone ointment (q4–6h); plus a systemic broad-spectrum antibiotic.

Mycotic

- *Microsporum canis* infection—usually self-limiting; treatment includes 2% miconazole cream, 1% clotrimazole cream, or diluted povidone-iodine solution (1 part to 300 parts saline) applied q12–24h for at least 6 weeks; do not use lotions.

Parasitic

- Demodicosis—localized disease: see Demodicosis. Some dogs require systemic treatment with moxidectin, ivermectin, or milbemycin oxime.
- *Notoedres* infection—lime sulfur dips.
- Sarcoptic mange—same as for generalized disease.

Idiopathic

- Clinical signs often controlled with topical polymyxin B and neomycin with 0.1% dexamethasone (q8–24h or as needed); occasionally may also need systemic prednisolone (0.5 mg/kg q12h for 3–5 days, then taper) and/or a systemic antibiotic.

CONTRAINDICATIONS

- Topical corticosteroids—do not use with corneal ulceration.
- Many cats with presumed idiopathic blepharoconjunctivitis have FHV-1 infection; topical and systemic corticosteroids may exacerbate the infection.
- Oral tetracycline and doxycycline—do not use in puppies and kittens.
- Neomycin—avoid topical use if suspect it is causing the blepharitis.

PRECAUTIONS

- Ectoparasitism—wear gloves; do not contact ocular surfaces with a drug topically

applied to skin; apply artificial tear ointment to the eyes for protection.

POSSIBLE INTERACTIONS

Staphylococcal bacterin for *Staphylococcus* hypersensitivity—anaphylactic reaction (rare).

FOLLOW-UP

PATIENT MONITORING

- Depends on cause and mode of therapy.
- Bacterial—treated with systemic and topical treatment for at least 3 weeks; should notice improvement within 10 days.
- Most common causes of treatment failure—use of subinhibitory antibiotic concentrations; failure to correct one or more predisposing factors; stopping medications too soon.

PREVENTION/AVOIDANCE

Depends on cause

POSSIBLE COMPLICATIONS

- Cicatricial lid contracture—results in trichiasis, ectropion, or lagophthalmos.
- Spastic entropion—because of blepharospasm and pain.
- Inability to open eyelids—owing to matting of discharge and hair.
- Qualitative tear film deficiency—result of loss of proper meibum secretion.
- Recurrence of bacterial infection or FHV-1 blepharoconjunctivitis.

EXPECTED COURSE AND PROGNOSIS

Depends on cause

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Dermatophytosis
- Sarcoptic mange

SEE ALSO

- Conjunctivitis—Cats
- Conjunctivitis—Dogs
- Epiphora
- Keratitis, Nonulcerative
- Keratitis, Ulcerative
- Red Eye

ABBREVIATIONS

- ELISA = enzyme-linked immunosorbent assay
- FHV-1 = feline herpesvirus type 1
- IFA = immunofluorescent antibody test
- PCR = polymerase chain reaction
- RAST = radioallergosorbent test
- SLE = systemic lupus erythematosus

BASICS

DEFINITION

Loss of vision in one or both eyes without ocular vascular injection or other externally apparent signs of ocular inflammation.

PATHOPHYSIOLOGY

Results from abnormalities in focusing images on the retina, the retina detecting an image, optic nerve transmission, or CNS interpretation of images.

SYSTEMS AFFECTED

- Nervous
- Ophthalmic

SIGNALMENT

- Dog and cat
- Any age, breed, or sex
- Many causes (e.g., cataracts and progressive retinal atrophy) have a genetic basis and are often highly breed- and age-specific
- SARDS—tends to occur in older dogs
- Optic nerve hypoplasia—congenital

SIGNS

Historical Findings

- Varies with underlying cause
- Bumping into objects
- Clumsy behavior
- Reluctance to move
- Impaired vision in dim light

Physical Examination Findings

- Varies with underlying cause
- Decreased or absent menace response
- Impaired visual placing responses

CAUSES

- Cataracts—entire lens must become opaque to produce complete blindness; incomplete opacification may reduce performance of visually demanding tasks.
- Loss of focusing power of the lens—rarely completely blinding; substantial hyperopia (far-sightedness) occurs when the optical power of the lens is not replaced after lens extraction or if the lens luxates posteriorly out of the pupillary plane and into the vitreous.
- Retina—SARDs; PRA; retinal detachment; taurine deficiency (cats), enrofloxacin toxicity (cats); ivermectin toxicity (dogs, cats).
- Optic nerve—optic neuritis; neoplasia of the optic nerve or adjacent tissues; trauma; optic nerve hypoplasia; lead toxicity; excessive traction on the optic nerve during enucleation resulting in trauma to the contralateral optic nerve or optic chiasm (especially cats and brachycephalic dogs).
- CNS (amaurosis)—lesions of the optic chiasm or tract; optic radiation; visual cortex. CNS-associated vision loss that occurs at a level higher than the optic chiasm often has vague visual disturbances in which the patient has some vision but clearly does not have normal vision.

RISK FACTORS

- Poorly regulated diabetes mellitus—cataracts.
- Related animals with genetic cataracts or PRA.
- Systemic hypertension—retinal detachment.
- CNS hypoxia—

blindness may become apparent after excessively deep anesthesia or revival from cardiac arrest.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Signs

- Anterior segment inflammation and glaucoma—conjunctiva typically injected.
- Young patients—may lack menace responses but will successfully navigate a maze or visually track hand movements or cotton balls.
- Postictal period—transient vision loss.
- Abnormal mentation—may be difficult to determine whether an animal is visual; other neurologic abnormalities help localize the lesion.

CAUSES

- Optic neuritis, retinal detachment, SARDs, or visual cortex hypoxia—sudden vision loss (over hours to weeks).
- SARDs—often preceded by polyuria, polydipsia, polyphagia, and weight gain.
- PRA—gradual vision loss, especially in dim light; apparently acute vision loss with sudden change in environment.
- Cataract—history of either gradual or rapidly increasing opacification and vision loss in a quiet eye.
- Optic nerve hypoplasia—congenital; may be unilateral or bilateral.
- Optic neuropathy or CNS disease—signs of other neurologic abnormalities.
- Pupillary light responses—usually normal with cataracts or visual cortex lesions; sluggish to absent with retinal or optic nerve diseases.
- Ophthalmoscopy—normal with SARDs, retrobulbar optic neuritis, and higher visual pathway lesions; abnormal with retinal detachment and neuropathies of the optic nerve head.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal, unless underlying systemic disease.
- Hyperglycemia or glucosuria—may note with diabetic cataracts.
- Elevated ALP and changes consistent with hyperadrenocorticism (Cushing's syndrome)—suggest SARDs.
- Retinal detachment secondary to systemic hypertension (cats)—mildly high BUN or serum creatinine; changes consistent with hyperthyroidism.

OTHER LABORATORY TESTS

- Blood lead and serology for deep fungal or viral infections—consider for suspected optic neuritis (see Optic Neuritis and Papilledema).
- LDDST—may help rule out Cushing's syndrome with SARDs.
- Sex hormone abnormalities are common in patients with SARDs.

IMAGING

- Ocular ultrasound—may demonstrate a retinal detachment (especially if the ocular media are opaque) or optic nerve mass lesion.
- Plain skull radiographs—seldom

informative.

- CT or MRI—often helpful with orbital or CNS lesions.

DIAGNOSTIC PROCEDURES

- Ophthalmic examination with a penlight—usually permits diagnosis of cataracts or retinal detachments severe enough to cause blindness.
- Ophthalmoscopy—may reveal PRA or optic nerve disease; normal examination suggests SARDs, retrobulbar optic neuritis, or a CNS lesion.
- Systemic blood pressure—determine in retinal detachments.
- Electrotoretinography—differentiates retinal from optic nerve or CNS disease when the diagnosis is in doubt.
- CSF tap—may be of value with a neurogenic cause of vision loss.

TREATMENT

- Try to obtain a definitive diagnosis on an outpatient basis before initiating treatment.
- Consider referral before attempting empirical therapy.
- Most causes are not fatal, but must perform a workup to rule out potentially fatal diseases.
- Reassure client that most causes of a blind quiet eye are not painful and that blind animals can lead relatively normal and functional lives.
- Warn client that the environment should be examined for potential hazards to a blind animal.
- Advise client that patients with progressive retinal atrophy or genetic cataracts should not be bred and that related animals should be examined.
- Retinal detachment—recommend severely restricted exercise until the retina is firmly reattached.
- Calorie-restricted diet—to prevent obesity; owing to reduced activity level.
- Cats with nutritionally induced retinopathy—ensure diet has adequate levels of taurine.
- SARDs, progressive retinal atrophy, optic nerve atrophy, and optic nerve hypoplasia—no effective treatment.
- Cataracts, luxated lenses, and some forms of retinal detachment—best treated surgically.

MEDICATIONS

DRUG(S) OF CHOICE

- Depends on cause.
- Workup is declined, infectious disease is unlikely, and the likely diagnosis is either SARDs or retrobulbar optic neuritis—consider systemic prednisolone (1–2 mg/kg/day for 7–14 days, then taper); may concurrently administer oral chloramphenicol or other systemic broad-spectrum antibiotic.

CONTRAINdicATIONS

Do not use systemic corticosteroids and other immunosuppressive drugs with optic neuritis and retinal detachments that are infectious in origin.

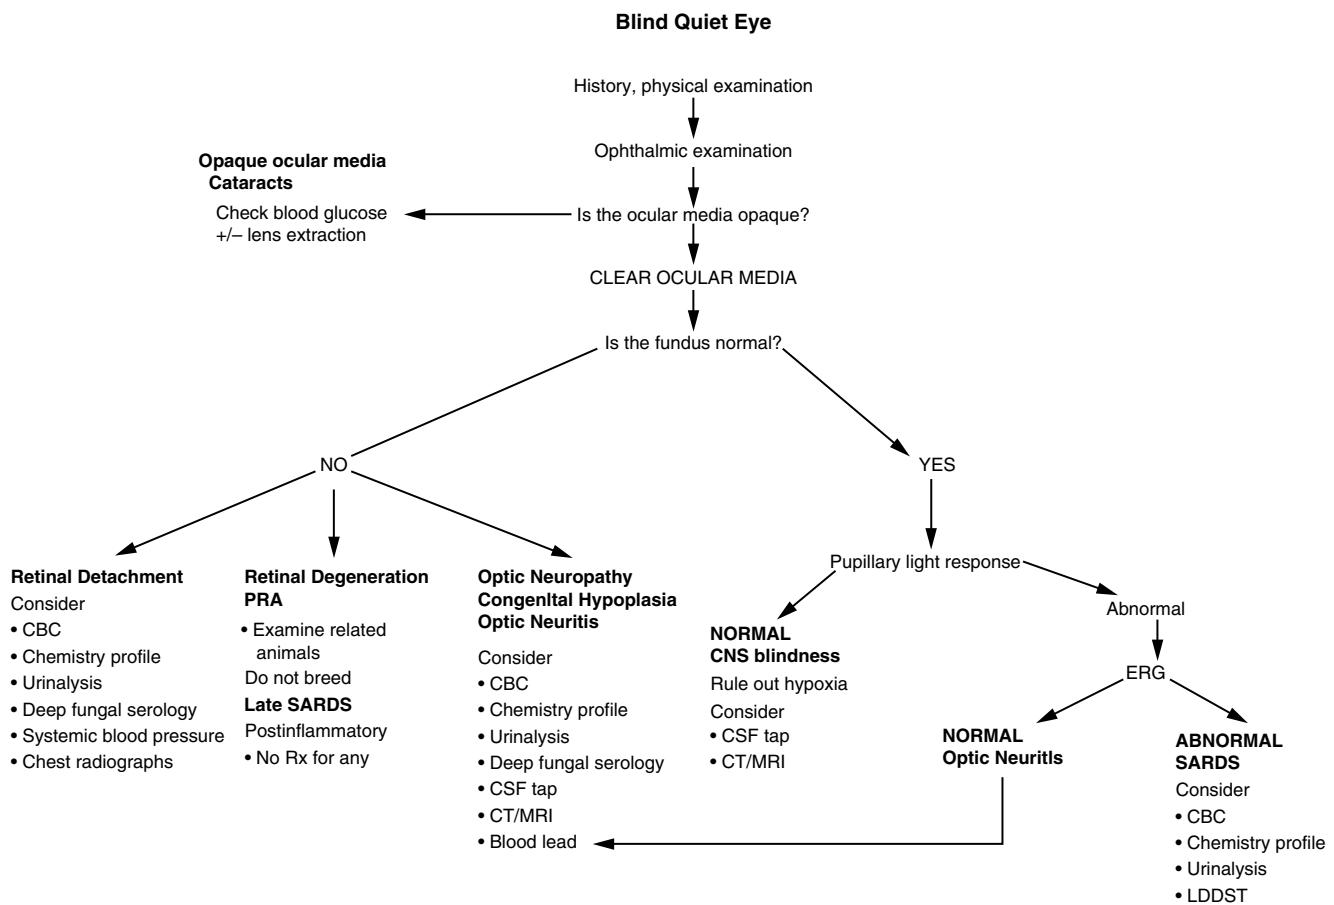

Figure 1.

PRECAUTIONS

Pretreatment with corticosteroids may mimic or mask liver enzyme changes in SARDs.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

• Flunixin meglumine (dogs)—may try a single dose (0.5 mg/kg IV) in place of corticosteroids if infectious causes have not been ruled out. • Oral azathioprine 1–2 mg/kg/day for 3–7 days, then taper; may be used to treat immune-mediated retinal detachments if systemic corticosteroids are not effective; perform a CBC, platelet count, and liver enzyme every 1–2 weeks for the first 8 weeks, then periodically.

**FOLLOW-UP****PATIENT MONITORING**

• Repeat ophthalmic examinations—as required to ensure that ocular inflammation is controlled, and, if possible, vision is maintained. • Recurrence of vision loss—common in optic neuritis; may occur weeks, months, or years after initial presentation.

POSSIBLE COMPLICATIONS

- Death
- Permanent vision loss.
- Loss of the eye
- Chronic ocular inflammation and pain
- Obesity from inactivity or as a sequela of SARDs

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- SARDs (dogs)—signs similar to those of hyperadrenocorticism. • Neurologic disease—may note seizures, behavior or personality changes, circling or other CNS signs. • Cardiomyopathy (cats)—taurine deficiency.

AGE-RELATED FACTORS

- PRA and many cataracts—breed-specific ages of onset. • SARDs—tends to occur in older dogs. • Optic nerve hypoplasia—congenital.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Corticosteroids and immunosuppressive drugs may complicate pregnancy.

ABBREVIATIONS

- ALP = alkaline phosphatase
- CNS = central nervous system
- CSF = cerebrospinal fluid
- CT = computed tomography
- LDDST = low-dose dexamethasone suppression test
- MRI = magnetic resonance imaging
- PRA = progressive retinal atrophy
- SARDs = sudden acquired retinal degeneration syndrome

BLOOD TRANSFUSION REACTIONS

BASICS

OVERVIEW

- Classified as acute or delayed, immune mediated or not immune mediated.
- Severe reactions usually occur during or shortly after transfusion.
- Can occur with any blood product, including hemoglobin-based oxygen-carrying solutions.

SIGNALMENT

- Dogs and cats
- No sex predilection
- All ages affected

SIGNS

Acute Hemolytic Reaction

- Restlessness
- Fever
- Tachycardia
- Vomiting
- Tremors
- Weakness
- Incontinence
- Collapse
- Shock
- Oliguria
- Loss of transfusion efficacy

Delayed Hemolytic Reaction

Loss of transfusion efficacy—usually no clinical signs.

Acute Non-hemolytic Reaction

- Anaphylactic reaction—fever, urticaria, erythema, angioedema, and pruritus.
- Transfusion of contaminated blood—acute septicemia, fever, and shock.
- Circulatory overload/rapid transfusion—vomiting, distended jugular veins, dyspnea, cough, cyanosis, and congestive heart failure.
- Citrate toxicity—hypocalcemia, myocardial depression, and weakness.
- Hyperammonemia—encephalopathy.
- Hypothermia—shivering and impaired platelet function.

CAUSES & RISK FACTORS

Purebred cats and previously transfused dogs have a higher risk of severe transfusion reaction than other animals.

Acute Hemolysis

- Blood group mismatch.
- Naturally occurring autoantibody (particularly in cats).
- Acquired autoantibody (IHA).
- Transfusion of damaged and hemolyzed RBCs (after inappropriate storage, excessive heating, freezing, or mechanical damage).

Delayed Hemolysis

- Immune reaction to minor red cell antigens; occurs after 3–14 days.

Acute Non-hemolytic Reaction

- Anaphylaxis and immune reaction to donor leukocytes or platelets, major histocompatibility complex antigens, or plasma antigens, resulting in release of inflammatory mediators and pyrogens.
- Transfusion of contaminated blood—lack of aseptic collection and storage conditions.
- Circulatory overload—rapid transfusion; excessive volume of blood in small patients or in patients with heart failure or oliguric renal failure.
- Citrate toxicity—after circulatory overload, particularly in small patients or in

patients with hepatopathy.

- Hyperammonemia—high ammonia concentration in stored blood; important only for animals with hepatopathy.
- Hypothermia—rapid transfusion of refrigerated blood to small or already hypothermic patients.

Delayed Non-hemolytic Reaction

- Transmission of blood-borne disease—use of infected donor (*hemotropic Mycoplasma* spp. DNA found in 10% of active donors in one study).
- Transfusion-associated graft vs. host disease—rare, but > 90% fatal complication of transfusion of blood components that contain immunocompetent donor T-lymphocytes. Has not been clearly reported in canine or feline patients yet.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hemolysis—rule out ongoing fulminant hemolytic disease (IHA, *Babesia*, *Mycoplasma*) and use of hemolyzed blood.
- Fever, hypotension—rule out underlying infectious and inflammatory diseases, bacterial contamination.

CBC/BIOCHEMISTRY/URINALYSIS

Hemoglobinemia, leukocytosis, bilirubinemia, hemoglobinuria, and bilirubinuria.

OTHER LABORATORY TESTS

- Repeat cross-match to confirm incompatibility.
- Bacterial culture or Gram staining of contaminated blood may reveal organism.
- *Mycoplasma* PCR in cats.

TREATMENT

- Immediately discontinue transfusion.
- Administer fluids to maintain blood pressure and renal blood flow; for hypotension, use isotonic crystalloids such as Plasmalyte (50–90 mL/kg/h, give 30% of the dose, then reassess).
- Additional supportive therapy for DIC, shock, or thromboembolism (see Disseminated Intravascular Coagulation; Shock, Septic; Aortic Thromboembolism; Pulmonary Thromboembolism).

MEDICATIONS

DRUG(S)

- For hemolysis—rapid-acting corticosteroid, such as prednisolone sodium succinate (11 mg/kg once) or dexamethasone sodium phosphate (2.2 mg/kg once); heparin (dose still controversial, 300 U/kg SC q6h; not for use in bleeding patients).
- For urticaria,

fever—diphenhydramine (1–2 mg/kg); dexamethasone sodium phosphate (0.2 mg/kg once); continue transfusion afterwards, if clinically indicated.

- For septicemia—broad-spectrum IV antibiotics
- For volume overload—furosemide 2–4 mg/kg IV, oxygen supplementation.

FOLLOW-UP

PATIENT MONITORING

- Check attitude, temperature, vital signs, lung sounds, PCV, total solids, and plasma color before, during, and after transfusion.
- For acute hemolytic reactions or septicemia—monitor CVP and urine output.
- If pulmonary thromboembolism is suspected, check chest radiographs and arterial blood gases frequently.

PREVENTION/AVOIDANCE

- Carefully record any transfusion reaction in the patient's medical file.
- Pretransfusion testing:
 - Screen donors for infectious disease.
 - Blood type donors and recipients.
 - Typing cards/cartridges (DMS, Alvedia, DMS/Agrolabo, DMS/Abaxis).
 - Crossmatching: Gel agglutination or strip tests (Diamed, DMS, Alvedia).
- Adhere to standard transfusion protocols (e.g., use of healthy donors; appropriate blood collection, storage, and administration techniques).
- Initially, transfuse at 0.5 mL/minute.

POSSIBLE COMPLICATIONS

- Fulminant hemolysis may cause acute renal failure, pulmonary thromboembolism, multiorgan thromboembolism, DIC, and cardiac arrhythmias.
- Volume overload may cause heart failure.
- Cardiac arrest.

EXPECTED COURSE AND PROGNOSIS

- Acute course in most animals.
- Prognosis good in stable animals, guarded in severely ill animals or when not recognized early.
- Cats with type B blood receiving mismatched blood have the worst prognosis.

MISCELLANEOUS

ABBREVIATIONS

- CVP = central venous pressure
- DIC = disseminated intravascular coagulation
- IHA = immune hemolytic anemia
- PCR = polymerase chain reaction
- PCV = packed cell volume
- RBC = red blood cell

BLUE-GREEN ALGAE TOXICOSIS

B

BASICS

OVERVIEW

- Cyanobacterial blooms can occur in fresh and brackish waters, and in backyard ponds where algal material is concentrated.
- Nutrient-rich runoff, increased water temperatures, and stagnant water conditions favor toxic bloom formation. • Blue-green algae exposure can lead to an acute hepato- or neurotoxicosis in animals and humans.
- Hepatotoxic blue-green algae poisonings are more frequently reported than neurotoxic algal intoxication. • Toxin-producing cyanobacteria include *Microcystis*, *Anabena*, *Aphanizomenon*, *Oscillatoria*, *Lyngbya*, and *Planktothrix* spp. • Microcystins are hepatotoxic blue-green algae toxins that have been found worldwide. • Anatoxins, which include anatoxin-a and anatoxin-a_s, are neurotoxic blue-green algae toxins.

SIGNALMENT

- Dogs: no breed, sex, or age predilection.
- Cats: no cases reported.

SIGNS

Hepatotoxic

- Diarrhea, weakness, shock. • Rapid progression to depression, coma, and death.

Neurotoxic

- Onset of rigidity and muscle tremors within minutes to a few hours after exposure. • Rapid progression to paralysis, cyanosis, and death.

CAUSES & RISK FACTORS

- Access to and ingestion of toxin-contaminated water and/or algal material.
- Blooms more common in nutrient-rich water in warmer months. • Blooms concentrated through wind or by removal into containers. • Certain algae reside in the benthic zone, e.g., in the sediment. Dogs mouthing material such as rocks from sediment can be at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Hepatotoxic

- Amanitins, xylitol, cycad palms, acetaminophen, manganese, pennyroyal oil, cocklebur. • Other causes of acute liver failure: infectious, metabolic, dietary.

Neurotoxic

- Strychnine, metaldehyde, avitrol, pyrethrins/pyrethroids, zinc phosphide, bromethalin. • Organophosphorus, carbamate, and organochlorine insecticides.
- Penitrem A, methylxanthines. • Poisonous plants (*Brunfelsia* spp., cyanide, oleander, poison hemlock). • Illicit substances (amphetamine & derivatives),

ephedra-containing compounds.

- Neurotoxic mushrooms.

CBC/BIOCHEMISTRY/URINALYSIS

Hepatotoxic

- Elevated serum liver enzymes (ALT, AST, ALP, bilirubin) • Hypoalbuminemia
- Hypoglycemia

Neurotoxic

No specific changes.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Morphologic algal ID in suspect water, algal material, or stomach content. Positive ID confirms hazard but is not confirmatory for the toxin because toxicity is strain specific.

Hepatotoxic

- Detection of algal material on fur or in stomach contents. • Analysis of stomach contents and water/algal source for microcystins.

Neurotoxic

- Detection of anatoxin-a in gastric contents, urine, bile and suspect source material.
- Depressed blood cholinesterase activity with anatoxin-a_s poisoning.

PATHOLOGIC FINDINGS

Hepatotoxic

- Detection of algal material on fur or in stomach contents. • Enlarged liver.
- Histologic detection of centrilobular hepatocellular necrosis and intrahepatic hemorrhage.

Neurotoxic

- Detection of algal bloom material in GI tract and/or on legs. • Typically no lesions.

TREATMENT

- No antidote available. • Rapid onset typically prevents timely therapeutic intervention. • GI decontamination with activated charcoal can be attempted but efficacy is not known. • Hepatotoxic: supportive care, close monitoring, and case-specific intravenous fluids to correct electrolytes and hypoglycemia, vitamin K1, and plasma transfusions. • Neurotoxic: supportive care and seizure control.

MEDICATIONS

DRUG(S)

- Activated charcoal: 1 g/kg PO q2–6h until 2–3 days post-ingestion. Mix activated charcoal in water at 1 g/5 mL of water.
- Intravenous fluids: maintain hydration, induce diuresis, correct hypoglycemia.
- Dextrose: 50% dextrose 1 mL/kg IV slow

bolus (1–3 min).

- Vitamin K1: 0.5–1.5 mg/kg SC or IM q12h; 1–5 mg/kg PO q24h.
- Blood products: dependent on hemostatic test results.
- Diazepam (2–5 mg/kg IV, repeat in 30 min if necessary) for seizure control.
- Phenobarbital (2–5 mg/kg IV q6–12h) for seizure control.
- Methocarbamol (55–220 mg/kg IV) for muscle relaxation.

ALTERNATIVE DRUGS

- S-adenosylmethionine (SAMe): antioxidant and hepatoprotectant; no data on efficacy in hepatotoxic cyanotoxin toxicosis available. Dose 20 mg/kg PO q24h.
- Ascorbic acid and cimetidine: hepatocyte protectors; no data on efficacy in hepatotoxic cyanotoxin poisoning available.
- N-acetylcysteine (NAC): antioxidant; no data on efficacy in hepatotoxic cyanotoxin toxicosis available.
- Glutathione precursor that can be included in the treatment regimen for acute hepatic failure at 140 mg/kg IV load, followed by 70 mg/kg IV q6h for 7 treatments.

CONTRAINdications/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Hepatotoxic: liver enzymes/function, coagulation status.
- Neurotoxic: thermoregulation, respiratory function, blood gases.

PREVENTION/AVOIDANCE

- Deny access to water with visible algal blooms
- Remove algal blooms from ponds immediately and discard material safely.

POSSIBLE COMPLICATIONS

- Hepatotoxic: hepatic encephalopathy, DIC.
- Neurotoxic: DIC, rhabdomyolysis, myoglobinuria with subsequent renal failure.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is poor to guarded. • Rapid onset and progression. Often lethal.

MISCELLANEOUS

ABBREVIATIONS

- ALP = alkaline phosphatase
- ALT = alanine transaminase
- AST = aspartate transaminase
- DIC = disseminated intravascular coagulation

BASICS

OVERVIEW

- Paralytic illness caused by a preformed neurotoxin produced by the bacterium *Clostridium botulinum* (Gram +, anaerobe) contained in uncooked food, carrion, and contaminated or improperly stored silage.
- Most cases in dogs are caused by *Clostridium botulinum* neurotoxin serotype C. The neurotoxin interferes with the release of acetylcholine at the neuromuscular junction, resulting in diffuse lower motor neuron signs.

SIGNALMENT

Dogs (naturally infected) and cats (experimentally infected except for one case report of natural *Clostridium botulinum* type C toxicosis).

SIGNS

Historical Findings

- Signs appear a few hours to 6 days after toxin ingestion
- Other dogs of the household, neighborhood, or kennel may be affected
- Acute progressive weakness develops, starting in the hind limbs and ascending to the trunk, front limbs, neck, and muscles innervated by the cranial nerves. Severe tetraparesis or tetraplegia ensues.

Physical Examination

- Possible increased or decreased heart rate
- In severe cases—diaphragmatic respiration.

Neurologic Examination Findings

- Mental status—normal
- Cranial nerves—may reveal sluggish pupillary light reflexes, diminished palpebral reflexes, decreased jaw tone, decreased gag reflex, salivation, and dysphonia.
- Gait and posture—a stiff, short-stride gait (no ataxia) is initially observed until recumbence develops (usually within 12–24 hours).
- Spinal reflexes—decreased to absent with decreased muscle tone (to atonia) and muscle atrophy
- Autonomic signs—mydriasis with decreased pupillary light reflexes, decreased lacrimation, ileus, and urine retention or frequent voiding of small volumes.
- No hyperesthesia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Acute canine polyradiculoneuritis (coonhound paralysis), myasthenia gravis, tick bite paralysis, coral snake venom toxicity, dumb form of rabies, lasalocid (growth promoter in ruminants) toxicosis.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

- Definitive diagnosis is based on detection of botulinum toxin in serum, feces, vomitus, or ingested food sample; by a neutralization test in small rodents; or by in vitro test that measures toxin antigenicity rather than toxicity
- Detection of anti-C botulinum neurotoxin antibodies may help support clinical diagnosis.

IMAGING

Thoracic radiographs—possible megaesophagus and/or signs of aspiration pneumonia.

DIAGNOSTIC PROCEDURES

- Electromyography may reveal fibrillation potentials and positive sharp waves in affected muscles.
- Motor nerve conduction velocity may be normal or decreased with reduced amplitude of evoked motor unit potentials.

TREATMENT

- If recent ingestion—gastric lavage, cathartics (avoid agents containing magnesium) or enemas may be useful.
- Mildly affected dogs recover over a period of several days with supportive treatment including passive and active physical therapy, frequent turning, good bedding (to prevent decubital sores), bladder care (expression or catheterization), and feeding from an elevated position (when megaesophagus present).
- Dogs with respiratory difficulties require intensive care monitoring with arterial blood gas, intermittent esophageal suction, alimentation by nasogastric or gastrostomy tube, and eventually ventilatory support.

MEDICATIONS

DRUG(S)

- Type C antitoxin may cause anaphylaxis; not effective when the toxin is already fixed at the nerve ending.
- Ophthalmic ointment prevents exposure corneal ulceration if keratoconjunctivitis sicca.
- Oral antibiotics are not recommended since they might make the disease worse by releasing more toxin through bacterial lysis or by promoting intestinal infection. To be used only if secondary infections (respiratory, urinary) occur.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Aminoglycosides, procaine penicillin, tetracyclines, phenothiazines, antiarrhythmic agents, and magnesium should be avoided

because they have the potential to block neuromuscular transmission.

FOLLOW-UP

PATIENT MONITORING

Monitor patients for respiratory failure, aspiration pneumonia, progressive lower motor neuron signs, urinary tract infection, and ocular complications.

PREVENTION/AVOIDANCE

- Prevent access to carrion and feed dogs cooked food.
- Avoid contact with spoiled raw meat.

POSSIBLE COMPLICATIONS

- Respiratory failure and death in severe cases
- Aspiration pneumonia from megaesophagus and regurgitations
- Keratoconjunctivitis sicca and corneal ulceration
- Prolonged recumbence—pulmonary atelectasia and infection; decubital sores; urine scalding.

EXPECTED COURSE AND PROGNOSIS

- Maximum severity of signs usually reached within 12–24 hours.
- Neurologic signs disappear in reverse order of appearance.
- Complete recovery usually occurs within 1–3 weeks, and requires the formation of new nerve terminals and functional neuromuscular junctions.

BRACHIAL PLEXUS AVULSION

B

BASICS

OVERVIEW

- Trauma with traction and/or severe abduction of a forelimb causes avulsion of nerve rootlets from their spinal cord attachment.
- Ventral (motor) nerve roots more susceptible than dorsal (sensory) roots.
- Rule out nerve root avulsions in traumatized animals unable to bear weight on a forelimb, especially before surgical repair of orthopedic injuries.

SIGNALMENT

- Dog and cat • No age, sex, or breed predilection

SIGNS

- Depend on the extent and distribution of rootlet damage.
- Motor signs—weakness (partial damage) to paralysis (ventral root avulsion).
- Sensory signs—decreased to absent pain perception (dorsal root avulsion).
- Muscle atrophy—begins within a week of injury.
- Complete avulsion—spinal nerves C5 to T2; most common.
- Cranial avulsion—spinal nerves C5 to C7: atrophy of supraspinatus and infraspinatus muscles, loss of shoulder movements, elbow flexion (dropped elbow), analgesia of the crano-dorsal scapula and medial forearm.
- Hemiplegia of the diaphragm may be seen by fluoroscopy (phrenic nerve roots C5 to C7). If roots C8 to T2 are preserved, weight bearing remains almost normal.
- Caudal avulsion—spinal nerves C7 to T2: inability to bear weight with knuckling over dorsum of paw. If C5 to C7 are spared, the limb is held in a flexed position and there is analgesia distal to the elbow (except for a small area on the medial aspect of forearm).
- T1 to T2 involvement: causes an ipsilateral partial Horner syndrome (anisocoria only) and lack of ipsilateral cutaneous trunci reflex (present contralaterally).
- Bilateral—rarely encountered, caused by significant fall with sternal landing and splaying of limbs.

CAUSES & RISK FACTORS

- Trauma—road accident; hung by foot; dragged; fall

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Brachial plexus trauma without avulsion—rare; temporary deficit owing to root contusion (neurapraxia).
- Brachial plexus tumor—usually chronic, progressive onset.
- Brachial plexus neuritis or neuropathy—acute onset; no trauma; bilateral deficits.
- Fibrocartilaginous embolic myelopathy—deficits of ipsilateral hind limb, and mild deficits of contralateral fore- and hind limbs

usually present. • Pure radial nerve paralysis caused by fracture of humerus or first rib—no nerve root sign. • Lateralized intervertebral disc protrusion—animal painful.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

IMAGING

CT or MRI—visualize lesion; rarely needed for diagnosis

DIAGNOSTIC PROCEDURES

- History—trauma with sudden onset of typical neurologic deficits.
- Spinal nerve root involvement—map motor and sensory deficits; note signs of Horner syndrome; determine if cutaneous trunci reflex present.
- EMG and NCS—denervation in affected muscles, starting 5–7 days post-injury; may help further define deficits and detect signs of recovery.

PATHOLOGIC FINDINGS

- Ventral and dorsal root avulsions—intradurally at the root-spinal cord junction (most fragile area because it lacks protective perineurium).
- Neuroma formation—on pial surface of the spinal cord.

TREATMENT

APPROPRIATE HEALTH CARE

- No specific treatment.
- Outcome depends on initial damage.
- Amputation of limb—may be necessary for patients showing complications (infections/self-mutilation, likely as a result of paresthesia) and no improvement.
- Carpal fusion (arthrodesis) and transposition of the biceps muscle tendon—consider only with adequate function of the triceps and musculocutaneous muscles.

NURSING CARE

- Protective wrap or boot over paw when patient walks on rough surfaces—increased skin fragility and lack of protective reflexes due to sensory deficits can result in severe excoriations from limb dragging.
- Early and sustained physical therapy—to prevent severe muscle atrophy and tendon contraction during recovery of reversible injuries; passive range of motion; massage therapy.
- Monitor non-complicated cases for 4–6 months before considering amputation.

MEDICATIONS

DRUG(S)

Prednisolone (prednisone)—1-week anti-inflammatory course may decrease early edema and favor healing of reversible injuries.

FOLLOW-UP

PREVENTION/AVOIDANCE

Serial clinical and electrophysiologic monitoring to assess improvement/severity.

PREVENTION/AVOIDANCE

Avoid free-roaming.

POSSIBLE COMPLICATIONS

- Skin excoriation and secondary infection—from trauma to unprotected paw.
- Trophic ulcers—thin, traumatized skin, especially over arthrodesis sites.
- Paresthesia may lead to self-mutilation.

EXPECTED COURSE AND PROGNOSIS

- Preserved pain sensation (dorsal roots intact)—suggests less severe injury to ventral nerve roots.
- Cranial avulsion—better prognosis with preserved sensation to distal limb and ability to bear weight.
- Complete avulsion—poor prognosis for recovery, amputation likely.
- Rarely, mild cases may resolve after 2–3 months.

MISCELLANEOUS

BRACHYCEPHALIC AIRWAY SYNDROME

B

BASICS

DEFINITION

Partial upper airway obstruction in brachycephalic breeds of dogs and cats caused by any of the following: stenotic nares, overlong soft palate, everted laryngeal saccules, and laryngeal collapse. Hypoplastic trachea can also be present and worsen respiratory distress.

PATHOPHYSIOLOGY

- In normal dogs, the upper airway accounts for 50–70% of total airway resistance. Brachycephalic breeds have increased upper airway resistance due to stenosis of nares, aberrant formation of nasal conchae, and presence of nasopharyngeal turbinates. Skull bones are shortened in length but normal in width, and soft tissues are not proportionately reduced, resulting in redundant tissue and narrowed air passages.
- Increased airway resistance leads to more negative intra-airway pressures—may result in secondary eversion of laryngeal saccules, further elongation of palate, and laryngeal collapse.
- Recruitment of pharyngeal dilator muscles (sternohyoid) becomes necessary to maintain airway patency. Sleep apnea may occur secondary to relaxation of these muscles.

SYSTEMS AFFECTED

- Respiratory—respiratory distress, hypoxemia, hypercarbia, hyperthermia, aspiration pneumonia, non-cardiogenic pulmonary edema from airway obstruction.
- Cardiovascular—cardiovascular collapse if complete airway obstruction or severe hyperthermia occurs.
- Gastrointestinal—may be reluctant to eat or drink, increased airway resistance can exacerbate hiatal hernia, gastroesophageal reflux, and esophagitis.

GENETICS

- Brachycephalic head shape—inherited defect in development of skull bones perpetuated by selective breeding.

INCIDENCE/PREVALENCE

- Dogs—common in brachycephalic breeds.
- Cats—less commonly severe enough to require treatment.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dogs—brachycephalic breeds (English bulldogs most common—up to 55% of breed, French bulldog, pug, Boston terrier). Norwich terriers and Cavalier King Charles spaniels affected by a variant of the syndrome.
- Cats—Persians and Himalayans.

Mean Age and Range

- Young adults, most diagnosed by 2–3 years.
- If diagnosed later than 4 years look for concurrent disease or exacerbating circumstances.
- Laryngeal collapse reported in brachycephalic breed puppies as young as 6–7 months.

Predominant Sex

No sex predilection

SIGNS

Historical Findings

- Snoring, stridor, stertorous breathing
- Tachypnea, frequent panting
- Coughing and gagging
- Difficulty eating and swallowing
- Ptyalism, regurgitation, and vomiting
- Syncope and episodes of collapse

Physical Examination Findings

- Stridor and stertorous breathing.
- Stenotic nares—medial collapse of lateral nasal cartilage.
- Increased respiratory effort—retraction of the commissures of lips, open-mouth breathing or constant panting, increased respiratory rate, abduction of forelimbs, increased abdominal component of respiration, recruitment of secondary muscles of respiration.
- In severe distress, may see paradoxical abdominal movement, inward collapse of intercostal muscles during inspiration, orthopnea, and cyanosis.
- Hyperthermia may be present.

CAUSES

- Inherited or congenital defects in conformation.
- Elongated soft palate—> 90% of surgical cases in dogs.
- Stenotic nares—about 50% of dogs. Most common defect in cats.
- Aberrant formation of rostral and caudal nasal conchae.
- Presence of nasopharyngeal turbinates (20% of dogs).
- Laryngeal disease—everted laryngeal saccules (> 50% of dogs) and/or laryngeal collapse (~10% of dogs).

RISK FACTORS

- Breed.
- Obesity—worsens airway obstruction, associated with poorer outcome postoperatively, and may contribute to gastroesophageal reflux resulting in aspiration pneumonia.
- Excitement and/or warm, humid weather—increased panting can lead to airway edema, further compromise of the lumen, and hyperthermia.
- Exercise—dogs are often exercise-intolerant due to airway compromise and hypoxia.
- Sedation—relaxation of muscles of pharynx and palate can cause complete airway obstruction.
- Respiratory infection or concurrent pulmonary disease—will cause further respiratory compromise.
- Endocrine disease (hypothyroidism and hyperadrenocorticism)—could worsen weight gain and cause excessive panting.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Foreign bodies of nasopharynx, larynx, or trachea.
- Infection—upper respiratory infection, nasopharyngeal abscess.
- Neoplasia obstructing the nasopharynx, glottis, larynx, or trachea.
- Laryngeal paralysis.
- Pharyngeal mucocoele.
- Nasopharyngeal polyp or cyst.

CBC/BIOCHEMISTRY/URINALYSIS

CBC—usually normal, but polycythemia can occur with chronic hypoxia, and leukocytosis if concurrent infection or severe stress.

OTHER LABORATORY TESTS

- Arterial blood gas—to diagnose respiratory acidosis and hypoxemia, and response to oxygen supplementation.
- Pulse oximetry—to diagnose hypoxemia.

IMAGING

Radiographic Findings

- If stable, cervical and thoracic radiographs recommended.
- Cervical radiographs may show thickened, elongated soft palate and suggest tracheal hypoplasia.
- Thoracic radiographs can reveal aspiration pneumonia, pulmonary edema, air in esophagus, and hypoplastic trachea (TD/TI = tracheal diameter at the level of thoracic inlet/thoracic inlet distance, which is the distance from the sternum to the ventral surface of TI. A ratio < 0.13 in bulldogs and < 0.16 in other brachycephalic breeds suggests hypoplastic trachea).

Fluoroscopy

Gives information about degree of dynamic pharyngeal obstruction by palate and concurrent disease such as collapsing trachea (uncommon in brachycephalic dogs).

DIAGNOSTIC PROCEDURES

Laryngoscopy/Pharyngoscopy

- Performed under general anesthesia, and because of risk of airway obstruction, owner should be prepared to proceed with surgical intervention if deemed necessary.
- An overlong soft palate extends more than just a few millimeters beyond tip of epiglottis and hangs down into glottis.
- The soft palate is often thickened and inflamed and there may be inflammation and edema of the arytenoid cartilages.
- Everted laryngeal saccules are diagnosed by visualizing two smooth, round, glistening masses in ventral half of laryngeal opening—they often obscure visualization of vocal folds.
- Laryngeal collapse can also be seen.
- Flexible endoscopy with retroflexed view of nasopharynx can detect nasopharyngeal turbinates.

Tracheoscopy

- Can reveal hypoplastic trachea with overlap of dorsal tracheal rings and dorsal tracheal membrane.
- Collapsing trachea can also be diagnosed.

BRACHYCEPHALIC AIRWAY SYNDROME

(CONTINUED)

B

TREATMENT

APPROPRIATE HEALTH CARE

- Surgery recommended for patients with significant clinical signs or to prevent progressive respiratory dysfunction.
- Emergency presentation in severe respiratory distress requires rapid intervention including O₂ supplementation, cautious use of antianxiety medication. • If hyperthermic, cool via convective losses by wetting patient with cool water and placing fan to blow over them. Administer IV fluids, up to a shock rate if extremely hyperthermic (T° > 106°F [41°C]). • If complete airway obstruction, immediate orotracheal intubation and/or temporary tracheostomy is indicated.
- Dexamethasone can be administered (0.1 mg/kg IV) to reduce inflammation.

NURSING CARE

- Patients require 24-hour monitoring because of risk of acute airway obstruction and death.
- Monitor respiratory rate, effort, heart rate, pulse quality, mucous membrane color, capillary refill time, temperature, and other physical parameters before and after surgery.
- Pulse oximetry and arterial blood gases, depending on severity of condition.
- Administer IV fluids at maintenance rate and minimize handling and stress.
- O₂ therapy and cooling as necessary.

ACTIVITY

Usually self-limited

DIET

- If overweight, weight loss is recommended.
- For obese, stable patients, weight loss is recommended prior to surgery.

CLIENT EDUCATION

- Avoidance of risk factors is critical.
- Inform owners that dogs with brachycephalic airway syndrome are at increased anesthetic risk, especially if obese, or have cardiac disease or aspiration pneumonia.
- Inform owners that surgery often improves but does not normalize airway.

SURGICAL CONSIDERATIONS

- Evaluation for elongated soft palate performed under general anesthesia when patient is stable.
- Temporary tracheostomy can be placed to facilitate exposure or to treat airway obstruction.
- Stenotic nares are corrected by resection of a wedge of the dorsolateral nasal cartilage and planum. Hemorrhage is controlled with pressure followed by closure of the surgical wound with 3 or 4 sutures of 3–0 or 4–0 absorbable suture material.
- Elongated soft palate is resected using scissors, carbon dioxide laser, or a bipolar sealing device. Remove only enough to allow contact of the center of the soft palate with the tip of the epiglottis.
- Sacculectomy performed by grasping tissue with Allis tissue

forceps and trimming all mucosal tissue with curved scissors.

- Severe laryngeal collapse might require cricoarytenoid and thyroarytenoid caudolateralization or permanent tracheostomy.

MEDICATIONS

DRUG(S)

- Dexamethasone given for 12–24h pre-or postoperatively at 0.1 mg/kg IV q12h to reduce edema and inflammation.
- Broad-spectrum antibiotics indicated if aspiration pneumonia present until culture and sensitivity results are obtained.
- Omeprazole 0.7 mg/kg q24h, cisapride 0.2 mg/kg q8h, and magnesium hydroxide 1 mL/kg after meals or sucrlafate 0.5–1 g q12h for dogs with concurrent esophagitis, gastritis, and/or duodenitis.

CONTRAINDICATIONS

Overuse of steroids can lead to panting, weight gain, and gastrointestinal ulceration, which can all exacerbate signs of brachycephalic airway syndrome.

PRECAUTIONS

Sedation for relief of anxiety, excitement, or fear should be used with caution because of risk of upper airway obstruction with muscle relaxation.

FOLLOW-UP

PATIENT MONITORING

Postoperatively, 24-hour monitoring to observe for airway swelling and obstruction that may require temporary tracheostomy.

PREVENTION/AVOIDANCE

- Selection by breeders for dogs without severe conformational changes—difficult because breed standards encourage these.
- Avoid risk factors, particularly weight gain.

POSSIBLE COMPLICATIONS

- Hyperthermia and heat stroke.
- Aspiration pneumonia.
- Death in about 10% of patients from airway disease.
- The most common postoperative complication is airway swelling and obstruction within the first 24 hours, may necessitate temporary tracheostomy.
- Continued respiratory difficulty after corrective surgery.
- Excessive resection of palate resulting in nasal aspiration of food contents due to inability to close pharynx during swallowing.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is good for improvement in breathing (80% have good to excellent results) but airway is still far from normal.
- Prognosis better for dogs other than English bulldogs and for dogs that have correction of

both stenotic nares and elongated soft palate.

- Without surgery, prognosis is poor due to continued progression of acquired components of brachycephalic airway syndrome.
- Life-long avoidance of risk factors recommended.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Aspiration pneumonia
- Heat stroke
- Hiatal hernia
- Hypoplastic trachea

AGE-RELATED FACTORS

Older dogs may have a worse outcome postoperatively but most have some improvement.

PREGNANCY/FERTILITY/BREEDING

Enlarged abdomen and pressure on the diaphragm in the pregnant bitch can further compromise respiratory function by decreasing tidal volume.

BASICS

DEFINITION

- Traumatic—caused by external forces.
- Non-traumatic—caused by non-violent forces (e.g., hypoxia, metabolic disorders, vascular disruption, infection, toxicity, neoplasia).
- Primary—direct initial insult when tissue and vessels are stretched, compressed or torn.
- Secondary—alterations of brain vasculature and tissue following primary injury.

PATHOPHYSIOLOGY

- Acceleration, deceleration, and rotational forces traumatize brain tissue.
- High oxygen and glucose requirements put the brain at risk for hypoxia.
- Oxygen delivery dependent on CBF and CPP (= MAP – ICP).
- Intracranial bleeding, edema (vasogenic and cytotoxic), vasodilation, and/or vasospasms increase ICP, causing low CBF, ischemia, brain swelling, and herniation; slow, progressive increase in ICP better tolerated than small, acute rise.
- Hypotension, hypoxia—major contributors to secondary injury.

SYSTEMS AFFECTED

- Nervous—altered mentation, cranial nerve deficits, seizures, twitching, postural changes.
- Cardiovascular—arrhythmias.
- Endocrine/Metabolic—alterations in ADH release and sodium concentration; central temperature dysregulation; insulin resistance; depletion of cortisol.
- Ophthalmic—changes in eye position, eye movements, pupillary light reflexes, papilledema.
- Respiratory—hyper- and hypocapnea; abnormal breathing patterns; neurogenic pulmonary edema.

GENETICS

None

INCIDENCE/PREVALENCE

- Head and neck injuries found in up to 34% of dogs and cats suffering blunt force trauma.
- Parenchymal and extradural hematomas found in 10% of dogs and cats with signs of mild head injury and in up to 80% with severe head injury.

GEOGRAPHIC DISTRIBUTION

Widespread

SIGNALMENT

Species

Dog and cat

SIGNS

Historical Findings

- Determine cause—trauma; cardiac arrest; heart failure; hypertension; toxins; coagulopathies; severe respiratory compromise; prolonged seizures; hypoglycemia.
- Decline in neurologic condition—implies progression from intracranial bleeding, cerebral edema,

ischemia.

- Seizure activity—cerebral or diencephalon involvement.

Physical Examination Findings

- Evidence of head trauma—open wounds, epistaxis, blood in the ear canals.
- Cardiac or respiratory insufficiency—hypoxia, cyanosis, hypoventilation.
- Poor perfusion—weak pulse, pale mucous membranes.
- Skull palpation—fractures, open fontanelles.
- Sustained bradycardia—midbrain, pontine, or medullary lesion.
- Cushing's reflex—bradycardia and hypertension.
- Ecchymosis, petechiae, retinal hemorrhages or distended vessels—hypertension, coagulopathy.
- Papilledema—cerebral edema.
- Retinal detachment—infectious, neoplastic, or hypertensive causes.

Neurologic Examination Findings

Mental Status

- Level of consciousness and cranial nerve deficits—localize lesion to cerebral cortex (better prognosis), midbrain/brainstem, or multifocal.
- Postural changes—decerebrate rigidity with midbrain lesion; decerebellate rigidity with cerebellar lesion.
- Peracute focal deficits suggest vascular or neoplastic causes.

Pupillary Light Reflexes

- Miotic responsive pupils—cerebral or diencephalic lesion (rule out traumatic uveitis, Horner's syndrome).
- Pinpointed unresponsive pupils—diencephalic, pontine or medullary lesion.
- Dilated unresponsive pupil(s) or midpoint fixed unresponsive pupils—midbrain lesion.

Cranial Nerves

- Normal with altered mentation—cerebrum-diencephalon lesion.
- CN II—Loss of menace and dazzle response with dilated unresponsive pupils—cranial forebrain.
- Loss of physiologic nystagmus—brainstem lesion
- CN III—midbrain lesion.
- CN V–XII—pontine or medullary lesion.

Respiratory Patterns

- Cheyne-Stokes—severe diffuse cerebral or diencephalon lesion.
- Hyperventilation—midbrain lesion.
- Ataxic or apneustic—pontine or medullary lesion.

CAUSES

- Trauma
- Prolonged hypoxia or ischemia
- Prolonged shock
- Severe hypoglycemia
- Prolonged seizures
- Severe hyperthermia or hypothermia
- Alterations in serum osmolality
- Toxins
- Neoplasia
- Hypertension
- Hemorrhage
- Inflammatory, infectious, immune-mediated diseases
- Thiamin deficiency
- Hydrocephalus
- Parasitic migration

RISK FACTORS

- Free-roaming—trauma, toxins
- Coexisting cardiac, respiratory, hemostatic, hepatic disease
- Diabetes mellitus—insulin therapy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Systemic causes of altered states of consciousness or central vestibular signs—metabolic disease; toxins; drugs; infection.

CBC/BIOCHEMISTRY/URINALYSIS

- Reflect systemic effects of neurologic signs
- Alterations in serum sodium suggest central ADH abnormalities

OTHER LABORATORY TESTS

- Arterial blood gas
- Coagulation profile
- Infectious disease titers

IMAGING

- Skull radiographs—detect fractures.
- CT—detects acute hemorrhage, infarcts, fractures, penetrating foreign bodies, hydrocephalus, herniation.
- MRI—detects cerebral edema, hemorrhage, mass, hydrocephalus, infiltrative diseases, inflammation, herniation, fractures.
- Ultrasound optic disk—if > 3 mm diameter, may be associated with brain edema.

DIAGNOSTIC PROCEDURES

- ECG—detects arrhythmias
- BP—determine perfusion
- CSF analysis—if cause unknown and no contraindications

PATHOLOGIC FINDINGS

- Brain edema or inflammation
- Herniation
- Hemorrhage
- Hydrocephalus
- Infarct
- Laceration, contusion
- Hematomas
- Skull fracture
- Necrosis
- Apoptosis

TREATMENT

APPROPRIATE HEALTH CARE

- Goals of therapy—maximize oxygenation and ventilation; support BP and CPP; decrease ICP; decrease cerebral metabolic rate.
- Maintain systolic BP > 90 mmHg and PCO₂ at 35–40 mm Hg; with suspected elevated ICP, hyperventilation to 32–35 mmHg.
- Maintain PaO₂ > 60 mmHg, SaO₂ > 90%, SpO₂ > 94%.
- Avoid cough or sneeze reflex during intubation or nasal oxygen supplementation; lidocaine (dogs: 1–2 mg/kg IV) before.
- Do not compress jugular veins.
- Orotracheal intubation if gag reflex lost.

NURSING CARE

- Aggressive therapy for midbrain/brainstem lesion or declining neurologic signs.
- Overzealous fluid resuscitation can contribute to brain edema.
- Small-volume fluid resuscitation techniques to maintain systolic BP > 90 mmHg with normal heart rate.
- Combination of isotonic crystalloids (10–20 mL/kg increments) with hydroxyethyl starch (5 mL/kg increments) over 5–8 minutes.
- Avoid hypertension.
- Level

BRAIN INJURY

B

head with body or elevate head and neck to a 20° angle. • Keep airway unobstructed; use suction and humidify if intubated; hyperoxygenate and consider IV lidocaine prior to suctioning. • Lubricate eye. • Reposition every 2–4 hours to avoid hypostatic pulmonary congestion. • Prevent fecal/urine soiling. • Maintain normal core body temperature. • Maintain hydration with a balanced electrolyte crystalloid solution. • Rehabilitation exercises.

ACTIVITY

- Restricted. • Consult rehabilitation specialist for appropriate exercises to maintain muscle tone.

DIET

Initiate trickle flow feeding to meet elevated metabolic demands.

CLIENT EDUCATION

- Neurologic signs may worsen before improving. • Neurologic recovery may not be evident for several days; possibly > 6 months for residual neurologic deficits. • Serious systemic abnormalities contribute to CNS instability.

SURGICAL CONSIDERATIONS

Depressed skull fracture, penetrating foreign body, uncontrollable ICP elevation (insufficient CSF drainage, hematoma/mass evacuation, herniation).

MEDICATIONS

DRUG(S) OF CHOICE

Elevated ICP

- Ensure systolic BP > 90 mmHg. Lower ICP by hyperventilation, drug therapy, drainage of CSF from the ventricles, or surgical decompression. • 7% hypertonic saline—2–4 mL/kg IV; can reduce fluid volume needed to reach resuscitation endpoints; combine with colloid. • Furosemide—0.75 mg/kg IV; may decrease CSF production; used in patients with congestive heart failure, volume overload, hyperosmolar diseases, or anuric renal failure; use before mannitol. • Mannitol—0.1–0.5 g/kg IV bolus repeated at 2-hour intervals 3–4 times in dogs, and 2–3 three times in cats; repeated doses must be given on time; improves brain blood flow and lowers ICP; may exacerbate hemorrhage. • Glucocorticosteroids—no benefit in acute management and long-term outcome in humans; higher morbidity. Anti-inflammatory doses (prednisone 1 mg/kg/day) may be of benefit with brain edema related to intracranial neoplasia and infectious meningitis. Immunosuppressive doses (2 mg/kg/day) in combination with additional immunosuppressive drugs in immune-mediated meningitis. • Provide analgesia/sedatives (e.g., fentanyl 3–5 µg/kg IV then 3–5 µg/kg/h CRI ± lidocaine 3–5 mg/kg/h) as indicated. Avoid agents that

can reduce CPP. • Thrashing, seizures, or uncontrolled motor activity—diazepam CRI (0.5–1 mg/kg/h), midazolam CRI (0.2–0.4 mg/kg IV), or propofol (3–6 mg/kg IV titrated to effect; 0.1–0.6 mg/kg/min CRI) monitor for hypotension; intubate if unable to protect airway. • Levetiracetam 20 mg/kg IV/IM/rectal q8h if seizure activity.

Other

- Reducing cerebral metabolic rate with heavy sedation using dexmedetomidine or medically induced coma using pentobarbital (up to 10 mg/kg IV over 30 minutes then 1 mg/kg/h) or propofol (2–4 mg/kg IV then 0.1–0.4 mg/kg/min); must intubate and support blood pressure, oxygenation, and ventilation. • Cooling the patient to 32–33 °C (89–91°F) for 48h may provide cerebral protection when administered within 6 hours of global ischemia or severe brain injury. • Glucose regulation. • Careful nasogastric tube feeding for early trickle flow feeding; cisapride (0.5 mg/kg PO q8–12h) and metoclopramide (1–2mg/kg/day) may promote GI motility. • Desmopressin for refractory hypernatremia. Emergency dosage not established for animals (dogs: 4 µg topical conjunctival q12h; cat: 5 µg SC q12h).

CONTRAINDICATIONS

- Drugs that cause hypertension, hypotension
- Drugs that cause hyperexcitability or increase in metabolic rate

PRECAUTIONS

- Avoid hypotension, hypoxemia, hypertension, hyperglycemia, hypoglycemia, hypernatremia, hypovolemia, hypervolemia.
- Keep head and neck above plane of body.
- Do not compress jugular veins.
- Furosemide, mannitol and hypertonic saline—can cause hypovolemia and hypotension. • Maintain PCO₂ > 32 mmHg; avoid hyperventilation in the first 24–8h and do not perform therapeutic hyperventilation (32–35 mmHg) for extended periods (> 48h).

FOLLOW-UP

PATIENT MONITORING

- Repeated neurologic examinations—deterioration warrants aggressive therapeutic intervention. • BP; maintain systolic BP > 90 mmHg. • Blood gases, pulse oximetry, end-tidal CO₂—to assess need for oxygen supplementation or ventilation. • Blood glucose—avoid severe persistent hyperglycemia and hypoglycemia.
- ECG—arrhythmias may affect perfusion, oxygenation, and CBF. • ICP—to detect elevations and monitor response to therapy.

PREVENTION/AVOIDANCE

Keep pets in a confined area or leashed.

POSSIBLE COMPLICATIONS

- Seizures • Brain herniation • Intracranial hemorrhage • Progression from cerebral

cortical to midbrain signs • Malnutrition

- Aspiration pneumonia • Hypostatic pulmonary congestion • Corneal desiccation
- Urine scalding • Airway obstruction from mucus • Arrhythmias • Hypotension
- Hypernatremia • Hypokalemia
- Respiratory failure • Residual neurologic deficits • Death

EXPECTED COURSE AND PROGNOSIS

- Young animals, minimal primary brain injury, and secondary injury consisting of cerebral edema—best prognosis. • No deterioration of neurologic status for 48 hours—better prognosis. • Rapid resuscitation of systolic BP to > 90 mmHg and avoiding hypoxemia—better neurologic outcome. • Glasgow Coma Score may offer prognostic insight.

MISCELLANEOUS

SYNOMYMS

- Head trauma • Traumatic brain injury

BASICS

DEFINITION

- Brain tumors of cats and dogs may be classified as either primary or secondary, depending on the cell type of origin.
- Primary brain tumors originate from cells normally found within the brain and meninges, including the neuroepithelium, lymphoid tissues, germ cells, endothelial cells, and malformed tissues.
- Secondary tumors are either neoplasms that have reached the brain by hematogenous metastasis from a primary tumor outside the nervous system, or neoplasms that affect the brain by local invasion, or extension, from adjacent non-neural tissues such as bone.
- Pituitary gland neoplasms (adenomas or carcinomas) and tumors arising from cranial nerves (e.g., nerve sheath tumor of the trigeminal, oculomotor, or vestibulocochlear nerves) are considered secondary brain tumors.

PATHOPHYSIOLOGY

- Brain tumors result in cerebral dysfunction by causing both primary effects, such as infiltration of nervous tissue or compression of adjacent anatomic structures, and secondary effects, such as hydrocephalus.
- Additional primary effects include disruption of cerebral circulation, or local necrosis, which may result in further damage to neural tissue.
- The most important secondary effects of a primary brain tumor include disturbance of cerebrospinal fluid (CSF) flow dynamics, elevated intracranial pressure (ICP), cerebral edema, or brain herniation.
- Secondary effects usually are more diffuse or generalized in their clinical manifestations and may mask the precise location of a focal intracranial lesion.

SYSTEMS AFFECTED

Nervous (brain)

GENETICS

- An unusually high incidence of meningiomas has been reported in cats with mucopolysaccharidosis type I.
- Specific genetic factors associated with breed predisposition have not been identified.
- Brachycephaly provisionally has been associated with the *SMOC-2* and *thrombospondin-2* genes on canine chromosome 1, and a component of glioma susceptibility provisionally has been mapped to a region on canine chromosome 2.
- Molecular and genetic classification of brain tumors may permit targeted therapies in the future.

INCIDENCE/PREVALENCE

- Brain tumors appear to be more common in dogs than in other domestic species.
- Reported incidence in dogs 14.5/100000.

- The most common sites for neoplasia to occur in immature dogs (< 6 months), in decreasing order, are the hematopoietic system, brain, and skin.
- Reported incidence in cats 3.5/100000.

SIGNALMENT

Breed Predilections

- Meningiomas occur most frequently in dolichocephalic breeds of dog.
- Glial cell tumors and pituitary tumors occur commonly in brachycephalic breeds of dog.
- Canine breeds overrepresented include the boxer, golden retriever, Doberman pinscher, Scottish terrier, and Old English sheepdog.
- There does not appear to be a breed predisposition for the development of brain tumors in cats.

Mean Age and Range

- Brain tumors occur in dogs and cats of any age.
- Most frequent in older dogs, with the greatest incidence in dogs > 5 years of age.
- Median age for diagnosis of meningiomas, gliomas, and choroid plexus tumors in dogs has been reported as 10–11 years, 8 years, and 5–6 years, respectively.

Predominant Sex

Older male cats appear to be most susceptible to meningiomas.

SIGNS

- Vary with tumor location.
- The most frequently recognized clinical sign associated with a brain tumor of a dog or cat is seizures, particularly should the first seizure occur after 5 years of age.
- Other clinical signs frequently associated with a brain tumor are abnormal behavior and mentation, visual deficits, circling, ataxia, head tilt, and cervical spinal hyperesthesia.
- Signs that result from a disease in a given location in the nervous system are similar, regardless of the precise cause.
- On the basis of signalment, history, and results of complete physical and neurologic examinations, it is possible to localize a problem to the brain and, in some cases, to determine the approximate location.

CAUSES

- Uncertain.
- Dietary, environmental, genetic, chemical, viral, traumatic, and immunologic factors may be considered.

RISK FACTORS

Uncertain

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Categories of disease that may result in clinical signs similar to those of a brain tumor include congenital disorders, infections, immunologic and metabolic disorders, toxicities, nutritional disorders, trauma, vascular disorders, degeneration, and idiopathic disorders.

CBC/BIOCHEMISTRY/URINALYSIS

The major objective in the completion of these tests is to eliminate extracranial causes for signs of cerebral dysfunction.

OTHER LABORATORY TESTS

N/A

IMAGING

- Survey radiographs of the thorax and abdominal ultrasound—to rule out a primary malignancy elsewhere in the body.
- Skull radiographs—of limited value; may detect neoplasms of the skull or nasal cavity that involve the brain by local extension.
- Occasionally, lysis or hyperostosis of the skull may accompany a primary brain tumor (e.g., meningioma of cats), or there may be radiographically visible mineralization within a neoplasm.
- CT—provides accurate determination of the presence, location, size, and anatomic relationships of many intracranial neoplasms.
- MRI—considered superior to CT in the localization and characterization of most brain tumors.

DIAGNOSTIC PROCEDURES

CSF Analysis

- CSF—may help to rule out inflammatory causes of cerebral dysfunction; in some cases may support a diagnosis of a brain tumor.
- Care should be used in the collection of CSF, because an increased ICP may be present in association with a brain tumor, and pressure alterations associated with CSF collection may lead to brain herniation.
- CSF collection usually is delayed until advanced imaging has been completed to evaluate factors such as the presence of cerebral edema or hemorrhage.
- In general, increased CSF protein content and a normal to increased CSF white blood cell count have been considered “typical” of a brain neoplasm.

Biopsy

- Cytologic evaluation of smear preparations from biopsy tissue, rapidly fixed in 95% alcohol and stained with hematoxylin and eosin, may be done within minutes of biopsy collection.
- Tissue biopsy remains the sole method available for the definitive diagnosis of brain tumor type in cats or dogs, and is an essential consideration prior to any type of therapy.
- Biopsy is not always attempted because of practical considerations, such as cost and morbidity.
- CT-guided stereotactic biopsy systems provide a relatively rapid and extremely accurate means of tumor biopsy, with a low rate of complications.

PATHOLOGIC FINDINGS

- The classification of CNS tumors in dogs and cats primarily is based on the characteristics of their constituent cell type, pathologic behavior, topographic pattern, and secondary changes present within and surrounding the tumor.
- Meningioma is the most common intracranial neoplasm of dogs.

BRAIN TUMORS

(CONTINUED)

B

and cats. • Classification of the glial subset of neuroepithelial tumors is based on the predominant cell type (e.g., astrocyte or oligodendrocyte).

Dogs

- Embryonal tumors have been consolidated under the single term “primitive neuroectodermal tumors” (or PNETs) to accommodate their anaplastic nature.
- Brain tumors arising from lymphoreticular cells traditionally have been grouped under a heading of reticulosarcoma or histiocytic lymphoma.
- Skull tumors that affect the brain by local extension include osteosarcoma, chondrosarcoma, and multilobular osteochondrosarcoma.
- The most frequently seen secondary tumors of dogs include local extension of nasal adenocarcinoma; metastases from mammary, prostatic, or pulmonary adenocarcinoma; metastases from hemangiosarcoma; and extension of pituitary adenoma or carcinoma.
- Nerve sheath tumors arising from cranial nerves (particularly oculomotor nerve and trigeminal nerve) may occur in dogs.

Cats

- Meningiomas involving multiple intracranial sites (including the third ventricle) are relatively common in cats.
- Primary brain tumors other than meningiomas occur infrequently in cats.
- Tumors that have been reported include astrocytoma, ependymoma, oligodendroglioma, choroid plexus papilloma, medulloblastoma, lymphoma, olfactory neuroblastoma, and gangliocytoma.
- Lymphoma of the brain may be primary or secondary, or may be an aspect of multicentric lymphoma of cats.
- Secondary tumors that have been reported to occur in the brain of cats include pituitary macroadenomas and macrocarcinomas, and metastatic carcinoma.
- Local extension may occur either from tumors of the middle ear cavity (e.g., squamous cell carcinoma), the nasal cavity (e.g., nasal adenocarcinoma), or the skull (e.g., osteosarcoma).

TREATMENT

APPROPRIATE HEALTH CARE

- Beyond general efforts to maintain homeostasis, the major goals of therapy for a brain tumor are to control secondary effects, such as increased ICP or cerebral edema, and to eradicate the tumor or reduce its size.
- Beyond palliative care, three methods of therapy for a brain tumor currently are available for use in dogs and cats: surgery, irradiation, and chemotherapy.

Surgery

- Neurosurgical intervention is an essential consideration in the management of brain tumors in cats or dogs, whether for complete excision, partial removal, or biopsy.
- Meningiomas, particularly those located over the cerebral convexitities or in the frontal lobes of the cerebrum, may be completely (or almost completely) removed by surgery, especially in cats.
- Primary calvarial tumors also may be removed surgically prior to other types of therapy.

Radiation Therapy

- Irradiation may be used either alone or in combination with other treatments for either primary or secondary brain tumors.
- Careful treatment planning by a qualified and experienced radiation therapist is essential to the success of radiation therapy.
- A major development in radiation therapy is the emergence of more precise protocols that spare tissues surrounding the brain tumor (e.g., stereotactic radiotherapy).

Chemotherapy

Alkylating agents (e.g., carmustine (BCNU), lomustine (CCNU) and temozolamide), antimetabolic agents (e.g., cytosine arabinoside), and ribonucleotide reductase inhibitors (e.g., hydroxyurea) may result in reduction of tumor size and in improvement of clinical signs in dogs with glial cell tumors; however, evidence of efficacy in animals is lacking.

MEDICATIONS

DRUG(S)

- Glucocorticoids may be used for edema reduction and, in some cases (e.g., lymphoma), for retardation of tumor growth.
- Some animals with a brain tumor demonstrate dramatic improvement in clinical signs for weeks or months with sustained glucocorticoid therapy.
- Antiepileptic drugs (e.g., phenobarbital, bromide, levetiracetam) may be utilized for the control of generalized seizures.
- Mannitol or hypertonic saline are the agents best suited for effective reduction of increased ICP.

FOLLOW-UP

PATIENT MONITORING

- Serial neurologic examinations • Serial CT or MRI examinations

POSSIBLE COMPLICATIONS

- Aspiration pneumonia due to depressed swallowing reflexes associated with increased ICP • Seizures

EXPECTED COURSE AND PROGNOSIS

- Little information is available concerning the survival times of dogs or cats with a brain tumor that have received only palliative therapy (i.e., therapy to control the secondary effects of a tumor without an attempt to eradicate the tumor).
- The results of one study indicate a mean and median survival of 81 days and 56 days, respectively, following CT diagnosis of a primary brain tumor in each of 8 dogs.
- The results from several studies confirm that the prognosis for a dog or cat with a primary brain tumor may be significantly improved by surgical removal and irradiation, either alone or in combination.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Dogs that have been treated for a brain tumor may develop a second type of tumor elsewhere in the body.

ABBREVIATIONS

- CSF = cerebrospinal fluid • CT = computed tomography • ICP = intracranial pressure • MRI = magnetic resonance imaging

BASICS

DEFINITION

Timing of insemination(s) to maximize pregnancy risk and litter size.

PATHOPHYSIOLOGY

Dogs

- Must determine ovulation day so that breeding(s) occur(s) at the proper time.
- Fresh, chilled, or frozen semen—usually limited to one or two inseminations; insemination must be timed relative to ovulation for maximum fertility.
- Ovulation may vary relative to onset of standing heat (estrus), vaginal cytology.
- Luteinizing hormone—controls ovulation; peaks on same day or after full cornification is observed; ovulation occurs approximately 2 days after the peak; 2–3 days (54–72 hours) more required for oocyte maturation; mature oocytes viable for a minimum 2–3 days; thus fertile period is 4–8 days after the LH peak, and maximum fertility is 5–6 days after the LH peak.
- Physical signs alone—unreliable for precise determination of fertile period.
- Onset of estrus—usually associated with a change in the vaginal discharge from sanguineous to barely red and decreased vulvar edema; sanguineous discharge may continue during estrus and cease only at the onset of diestrus (fertile period has passed; bitch no longer receptive; cervix closed).
- Receptivity—may be detected by touching the perineum near the vulva; if receptive, female will “flag” by elevating the tail to one side.
- Vaginal cytologic examination—better but imprecise indicator of fertile period; cornification of the vaginal epithelium controlled by estrogen; full cornification with a clear background usually coincides with sexual receptivity.
- Serum progesterone—increase closely associated with the LH peak; useful for estimating ovulation, and thus the fertile period; concentration < 1 ng/mL (3.18 nmol/L) before the LH peak, 1.5–4 ng/mL (4.8–12.7 nmol/L) at LH peak, 4–10 ng/mL (12.7–31.8 nmol/L) at ovulation; continues to rise during diestrus/pregnancy. Commercial laboratories use various methods of progesterone concentration measurement so values indicative of LH and ovulation vary among labs. Documenting a rapid rise in progesterone subsequent to the initial rise is a more reliable indicator of ovulation than is the single measurement of the LH peak or the initial rise in progesterone.

Cats

- Ovulation—usually induced; timing of breeding is not as critical as with dogs; depends on adequate GnRH and then LH release triggered by vaginal stimulation.

- Adequate stimulation—characterized by a copulatory cry and a post-coital reaction; frequency of coital stimuli important in determining adequacy of coital contact.
- LH—peak concentration and duration of the elevation determine ovulation; higher concentration with multiple copulations; response to copulation depends on the day of estrus (greater release on estrus day 3 than on estrus day 1); release partially depends on duration of exposure to estrogen.

SYSTEMS AFFECTED

Reproductive

GENETICS

SIGNALMENT

Dog and cat

SIGNS

General Comments

Dogs

- Average bitch—sanguineous vulvar discharge becomes lighter in amount and color during estrus; vulvar edema of proestrus decreases during estrus; receptive to male during estrus.
- If limited number of breedings—must know ovulation day.

Cats

- LH response to a single mating—may vary substantially.

Historical Findings

Dogs

- Refusal to accept male at the expected time.
- Sanguineous vulvar discharge during estrus.

Cats

- Return to estrus in < 30 days may indicate failure to ovulate; interestrus usually 8–10 days, but highly variable even within queen; also some queens will breed while pregnant.

Physical Examination Findings

Dogs

- Interest shown by male
- Vulva less turgid
- Vaginal discharge—less color and amount
- Flagging
- Fully cornified and crenulated pale vaginal epithelium

Cats

- Fully cornified vaginal epithelium
- Interest shown by male
- No changes in external genitalia
- Vocalizes, rubs objects,
- Lordosis

CAUSES

Dogs

- Limited number of breedings
- Female unreceptive to male
- Artificial insemination (fresh, chilled, or frozen semen)

Cats

- Coitus—too early or too late in estrus; too few times
- Artificial insemination

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vaginal discharge—proestrus or estrus; vaginitis; neoplasia, pyometra, urinary tract infection.
- Refusal to allow intromission—anatomic issue of abnormalities of Müllerian duct development, vulvovestibular or vestibulovaginal junction, acquired abnormality from dystocia or breeding trauma, vaginal hyperplasia, behavioral problem.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Dogs

- In-house semiquantitative progesterone ELISA—as adjunct to vaginal cytologic examination
- Quantitative progesterone testing preferred when breeding with frozen semen; especially useful in bitch or male with reduced fertility.
- LH testing—must sample daily to observe the LH peak, can use serum progesterone to signal when to start testing or as a surrogate for the LH peak.

Cats

Progesterone testing to verify ovulation.

IMAGING

Ultrasonographic imaging of the ovaries—may help determine ovulation; perform daily, best if using color flow Doppler.

DIAGNOSTIC PROCEDURES

Dogs

- Behavior—flagging, male very interested, females mounting one another.
- Vaginal discharge much less hemorrhagic, vulva softer, less swollen.
- Palpation of vagina *per digitum* may be resented by bitch in proestrus improving throughout proestrus until estrus.
- May feel edematous mass on floor of caudal vagina, just cranial to urethral os that should shrink as optimal breeding period approaches.
- Vaginal cytologic examination—proestrus (in breeder terms, “day 1” at first sign of hemorrhagic vaginal discharge), most epithelial cells are non-cornified; percentage of cornified cells (cells with angular cytoplasm and pyknotic nuclei or nuclei that fail to take up stain) increases during proestrus, often reaching 90% or more by estrus (individuals vary). (Breeders refer to this stage by day, rather than using the term “estrus”; this is usually about day 10–18 in breeder terms.)
- Background of slide is free of debris during estrus.
- Diestrus, an abrupt decline in the percentage of cornified cells (20–50%) occurs in a single day—day 1 of diestrus (D1);

BREEDING, TIMING

(CONTINUED)

B

normal to see neutrophils on days 1–4 of diestrus. • Vaginoscopy—edematous vaginal folds until the LH peak, then vagina pale with slight wrinkling (crenulation) as edema decreases with estradiol decline, by optimum breeding period obvious wrinkles until diestrus when folds are very flat and edema disappears. • Serologic test for *B. canis* (dogs)—rapid slide agglutination test used as a screen (D-TEC® CB; Zoetis, (888)963-8471) sensitive but not specific, looks at antibodies so need 4 to 8 weeks post-exposure for a positive test; confirm by agar gel immunodiffusion test (Cornell University Diagnostic Laboratory, (607)253-3900) or bacterial culture of whole blood or lymph node aspirate.

TREATMENT

APPROPRIATE HEALTH CARE

Dogs

- Fresh semen: multiple breedings; inseminate q48h after the initial rise in progesterone is observed until D1.
- Two vaginal breedings fresh semen: inseminate either on days 3 and 5 or on days 4 and 6 after the LH peak or initial rise in progesterone; use standard AI pipettes or modified Foley catheters (several sizes available); vaginal insemination on or after day 5 may be associated with reduced pregnancy rates and litter sizes due to beginning of cervical closure.
- Frozen or chilled semen: frozen semen is less viable than chilled, thus timing is more critical; one or two intrauterine inseminations most common: inseminate on day 5 or 6 after the LH peak or initial rise in progesterone (day 0) or 3 days after progesterone $\geq 5 \text{ ng/mL}$ (16 nmol/L); intrauterine insemination (via transcervical endoscopy (TCI) or “Norwegian” catheter or surgical insemination).
- Progesterone on day of insemination should be $\geq 12 \text{ ng/mL}$ (38 nmol/L).
- Timing of insemination based on progesterone improves chance of conception and increased litter size.
- Blood collection and vaginal examination q48h are adequate in most cases.

Cats

- Increase the likelihood of ovulation and litter size by maximizing the number of matings; breed on successive days.
- Breed at least four times daily at least 2–3 hours apart on days 2 and 3 of estrus to maximize LH release.
- May induce ovulation by administration of exogenous hormones—GnRH or hCG after mating.

ACTIVITY

- No alteration in activity necessary.
- Must keep strictly away from unintended sexually intact males.

CLIENT EDUCATION

Client education on the physical, behavioral and endocrinologic changes that occur during the estrous cycle, and how variable the timing of these changes can be from animal to animal, can improve owner compliance and satisfaction.

SURGICAL CONSIDERATIONS

Surgical artificial insemination requires standard postoperative care.

MEDICATIONS

DRUG(S) OF CHOICE

Cats—hCG (100–500 IU IM); GnRH (25–50 μg IM)

FOLLOW-UP

PATIENT MONITORING

- Dogs—continue vaginal cytology to determine D1; ovulation is 6 days before D1.
- Dogs—whelping is 65 days from the LH peak, 63 days from ovulation, or 57 days from D1. For fresh, chilled or frozen semen: repeat quantitative progesterone after initial progesterone rise or LH peak to verify $> 10 \text{ ng/mL}$ (32 nmol/L).
- Cats—use progesterone assay one week post insemination to verify ovulation.
- Cats—queening is 62–71 days from first breeding.

PREVENTION /AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Dogs

- Vaginal cytologic examinations—compare D1 with the prospective estimation based on progesterone; if the estimates differ, pregnancy rates are reduced.
- Semiquantitative progesterone kits—must come to room temperature before use; false high values common when using a cold kit.
- Serum progesterone—allow blood to clot at room temperature; separate cells from serum 20 minutes after collection; false low values occur when using serum mixed with RBCs (progesterone binds to RBCs).
- A hemolyzed or lipemic specimen—may give a false low progesterone value.
- Quantitative (chemiluminescence, fluorescence, enzyme immunoassay) progesterone assay—more accurate when performed by a commercial laboratory than semiquantitative kits; in-house analyzers are available; turn-around times should be less than 24h.
- Do not use serum separator tubes—false elevation if progesterone measured by chemiluminescent assay; type of anticoagulant may affect

reported value (serum $>$ heparin plasma $>$ EDTA plasma).

MISCELLANEOUS

ASSOCIATED CONDITIONS

Müllerian duct developmental abnormalities and vulvovestibular, vestibulovaginal strictures

AGE-RELATED FACTORS

Split heats in young bitches—period of proestrus (may be prolonged to 6 weeks or more), followed by cessation of signs, and subsequent resumption of the estrus cycle (1–3 weeks later); no initial rise in progesterone or LH occurs with the first proestrus/estrus; subsequent estrus is usually normal.

ZOONOTIC POTENTIAL

Brucella canis—see chapter, Brucellosis.

PREGNANCY/FERTILITY/BREEDING

Ultrasound—conceptuses can first be detected 19–20 days after LH peak (requires high resolution, high frequency) or a few days earlier in cats; commonly done 4 weeks post breeding; recommend earlier exam in bitches with history of pregnancy loss or infertility.

B BRONCHIECTASIS

BASICS

OVERVIEW

- Clinical condition seen primarily in dogs; irreversible dilatation of the bronchi; caused by chronic infectious or inflammatory airway disease or associated with primary ciliary dyskinesia.
- Occurs occasionally in cats as a sequela to long-standing inflammatory lung disease or neoplasia.
- Airways are pulled open by surrounding lung tissue; pooling of secretions can occur, which perpetuates lung damage and allows colonization by bacteria.
- Can be cylindrical or saccular, focal or diffuse.

SIGNALMENT

- Primarily dogs and rarely cats.
- Cocker spaniels and perhaps West Highland white terriers predisposed.
- Young animals (<1 year) with primary ciliary dyskinesia.
- Middle-aged to old dogs with chronic pulmonary disease.

SIGNS

- Chronic cough—usually moist and productive; hemoptysis.
- Recurrent fever.
- Exercise intolerance.
- Tachypnea or respiratory distress.
- Chronic nasal discharge or sinusitis, particularly with primary ciliary dyskinesia.
- Moist, harsh inspiratory crackles; loud expiratory lung sounds or wheezes on physical exam.
- Tracheal hypersensitivity.

CAUSES & RISK FACTORS

- Primary ciliary dyskinesia.
- Inadequately treated infectious or inflammatory lung conditions (pneumonia, bronchitis, or eosinophilic lung disease).
- Smoke inhalation, aspiration pneumonia, radiation injury, and inhalation of environmental toxins—predispose animal to airway injury and colonization by bacteria.
- Chronic bronchial obstruction or foreign body pneumonia—development of bronchiectasis distal to the obstructed region common.
- Signs related to bronchiectasis may not be recognized until long after the primary injury.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Recurrent bacterial bronchopneumonia
- Fungal pneumonia
- Chronic bronchitis
- Infectious or parasitic bronchitis
- Foreign body pneumonia
- Neoplasia

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilia and monocytosis
- Hyperglobulinemia
- Proteinuria—may be seen with secondary amyloidosis, glomerulonephritis, or sepsis.

OTHER LABORATORY TESTS

Arterial blood gas analysis—hypoxemia; widened alveolar-arterial oxygen gradient.

IMAGING

- Radiography—insensitive for the diagnosis. Abnormalities visible late in the course of disease include dilatation of the lobar bronchi with lack of normal tapering in the periphery; diffuse thickening of bronchial walls; mixed bronchial, interstitial, and alveolar pattern.
- Changes can be focal or diffuse.
- CT—bronchus > two times the width of the adjacent pulmonary artery in dogs, abnormally dilated bronchi near the lung periphery; thickened airways; cystic dilatations of the bronchi with or without fluid accumulation.

DIAGNOSTIC PROCEDURES

- Bronchoscopy—saccular or tubular dilatation of the airways.
- Airway sampling—cytologic examination of bronchoalveolar lavage fluid or tracheal wash specimens; culture for aerobic and anaerobic bacteria and *Mycoplasma*; typically find suppurative inflammation with high numbers of neutrophils, or increased eosinophils may be observed indicating eosinophilic bronchopneuropathy; may culture a mixed population of bacteria; some cases appear to have sterile inflammation.

PATHOLOGIC FINDINGS

- Dilated bronchi
- Diffuse peribronchial and alveolar inflammation and fibrosis
- Squamous metaplasia of bronchial epithelium

TREATMENT

- Inpatient—severe condition: intravenous fluids and antibiotics; oxygen administration.
- Airway nebulization and coupage to facilitate removal of viscid pulmonary secretions.
- Gentle activity enhances clearance of secretions.
- Long-term antibiotic administration.
- Stress to owner the importance of appropriate follow-up care.
- Single affected lung lobe or bronchial obstruction—lung lobectomy can be curative.

MEDICATIONS

DRUG(S)

- Intravenous antibiotics—may be required initially; good choices: ampicillin (10–20 mg/kg IV q6–8h) and enrofloxacin (5–10 mg/kg q24h). Broad-spectrum agents with efficacy against both aerobes and anaerobes and that offer good penetration of pulmonary tissue—preferred; combination of

enrofloxacin (5–20 mg/kg PO q24h) and clindamycin (5–11 mg/kg PO q12h) or amoxicillin-clavulanate often effective.

- Azithromycin can be a good alternative antibiotic.
- Long-term use of antibiotics (2 months to life-long)—based on bacterial culture and sensitivity testing; may be required even if culture of airway specimens yields no growth.
- Bronchodilators—may be beneficial, although animals usually have irreversible airflow limitation; extended-release theophylline advised.
- Eosinophilic lung disease requires treatment with glucocorticoids.
- Nebulization and coupage highly beneficial in removing secretions.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Theophylline derivatives and fluoroquinolones—concurrent use causes high and possibly toxic plasma theophylline concentration.
- Furosemide—avoid; dries airway secretions.
- Cough suppressants—avoid; will trap secretions and bacteria in lower airway and perpetuate damage.

FOLLOW-UP

PATIENT MONITORING

- Clinical response—outpatient
- Serial CBC, blood gas analysis, and thoracic radiographs

PREVENTION/AVOIDANCE

- Antibiotics—complete a full course of therapy in patients that appear to have parenchymal infection.
- Early recognition and resolution of foreign body pneumonia.
- Appropriate treatment of eosinophilic pneumonia.

POSSIBLE COMPLICATIONS

Chronic recurrent pulmonary infection likely.

EXPECTED COURSE AND PROGNOSIS

- Chronic and recurrent clinical signs expected; some degree of coughing will always be present.
- Animals can live for years with bronchiectasis if treated properly.
- Patient may succumb to respiratory failure.
- Other organs may fail if bacteremia or glomerulonephritis develops.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Primary ciliary dyskinesia
- Chronic sinusitis
- Chronic bronchitis
- Pneumonia—bacterial, eosinophilic aspiration, foreign body
- Smoke inhalation

Author Lynelle R. Johnson

Consulting Editor Lynelle R. Johnson

BRONCHITIS, CHRONIC

B

BASICS

DEFINITION

- Chronic coughing for longer than 2 months that is not attributable to another cause (e.g., neoplasia, congestive heart failure, eosinophilic pneumonia, or infectious bronchitis).
- Partly non-reversible and often slowly progressive condition owing to accompanying pathologic airway changes.

PATOPHYSIOLOGY

- Recurrent airway inflammation suspected, but a specific cause is rarely determined.
- Persistent tracheobronchial irritation—causes chronic coughing; leads to changes in the tracheobronchial epithelium and submucosa.
- Airway inflammation, epithelial edema, and thickening—prominent.
- Excess production of a thickened mucus is a hallmark.
- In severe, very chronic cases—probable increased lung resistance; decreased expiratory airflow, especially in cats. In dogs, possible sequelae such as broncholamacia and bronchiectasis.

SYSTEMS AFFECTED

- Respiratory • Cardiovascular—pulmonary hypertension, cor pulmonale • Nervous—syncope (infrequent)

INCIDENCE/PREVALENCE

Common in dogs and cats

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dogs—small and large breeds.
- Cocker spaniels—bronchiectasis common after a long history of chronic bronchitis.
- Siamese cats and domestic shorthairs affected.

Mean Age and Range

Commonly middle-aged and old animals

Predominant Sex

N/A

SIGNS

Historical Findings

- Coughing—hallmark of tracheobronchial irritation; usually harsh and dry; post-tussive gagging common (owners often misinterpret this as vomiting).
- Exercise intolerance, difficult breathing, wheezing (in cats).
- Cyanosis and syncope can be noted in severe cases.

Physical Examination Findings

- Patients usually bright, alert, and afebrile.
- Tracheal palpation—typically results in coughing because of increased tracheal sensitivity.
- Small airway disease—assumed when an expiratory abdominal push (during

quiet breathing) or end-expiratory wheezing is detected.

- Increased bronchovesicular lung sounds, end-inspiratory crackles, and wheezing can be heard.
- Loud end-expiratory snap is suggestive of concurrent airway collapse.
- Cardiac auscultation—murmurs secondary to valvular insufficiency common in dogs but not always associated with congestive heart failure; chronic bronchitis usually results in a normal or slower than normal resting heart rate and pronounced sinus arrhythmia. In cats, tachycardia is possible.
- Obesity—common; important complicating factor.
- Severe dental disease may predispose to lower airway colonization and possible infection (dogs).

CAUSES

Chronic airway inflammation initiated by multiple causes although specific cause rarely identified.

RISK FACTORS

- Long-term exposure to inhaled irritants.
- Obesity.
- Recurrent bacterial infection.
- Dental disease and laryngeal disease—result in bacterial showering of the lower airways.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bronchiectasis.
- Eosinophilic bronchopneumopathy.
- Foreign bodies.
- Heartworm disease.
- Bacterial, pneumonia.
- Neoplasia—metastatic more common than primary.
- Pulmonary parasites or parasitic larval migration.
- Pulmonary fibrosis—cats and dogs.
- Congestive heart failure—typically associated with a high resting heart rate, left atrial enlargement, pulmonary venous engorgement, and hilar pulmonary edema (dogs).

CBC/BIOCHEMISTRY/URINALYSIS

- Rarely diagnostic.
- Neutrophilic leukocytosis common.
- Absolute eosinophilia—suggests but not diagnostic for parasitic or allergic bronchitis.
- Polycythemia secondary to chronic hypoxia—can be seen.
- Liver enzymes and bile acids may be elevated due to passive congestion.

OTHER LABORATORY TESTS

- Fecal and heartworm tests—rule out pulmonary parasites.
- Pulse oximetry—useful for detecting hemoglobin desaturation.
- Arterial blood gas analysis—collect, ice, and have analyzed at a local hospital; mild-moderately low PaO₂ seen with severe condition; aids in prognosis and monitoring treatment.

IMAGING

Thoracic Radiography

Common features (in descending order of frequency)—bronchial thickening; interstitial

pattern; middle lung lobe consolidation (cats); atelectasis; hyperinflation and diaphragmatic flattening (primarily cats).

Echocardiography

- Helps rule out cardiac disease as a cause of coughing.
- Can reveal right heart enlargement with pulmonary hypertension. Doppler echocardiography to evaluate.

DIAGNOSTIC PROCEDURES

Electrocardiography (Dog)

Wandering atrial pacemaker, marked sinus arrhythmia, P pulmonale, occasionally evidence of right ventricular enlargement.

Evaluation of Airway Secretions

- Must collect from lower airways—helps to establish underlying cause if present or to determine the severity of inflammation.
- Throat swab cultures are not representative of lower airway flora.
- Tracheal aspiration or bronchoalveolar lavage—collect specimens for cytologic examination and bacterial/mycoplasmal culture.
- Quantitated aerobic BAL cultures help differentiate infection versus airway colonization; reported cutoff is $> 1.7 \times 10^3$ CFU for infection in dogs.
- Anaerobic and *Mycoplasma* cultures recommended as well.
- Cytology—
- inflammation primary finding; most cells are neutrophils, eosinophils, or macrophages; evaluate for bacteria, parasites, neoplastic cells, and contamination with foreign material.

Bronchoscopy

- Preferred test for assessing the lower airways.
- Allows direct visualization of structural as well as functional (dynamic) changes; allows selected airway sampling (e.g., biopsy and lavage).
- Gross changes—excess mucoid to mucopurulent secretions; epithelial edema or thickening with blunting of bronchial bifurcations; irregular or granular mucosa; mucosal polypoid proliferations can indicate chronic bronchitis or chronic eosinophilic pneumonia.
- Large airway caliber changes (e.g., static or dynamic airway collapse and bronchiectasis)—can be detected as complicating problems.

PATHOLOGIC FINDINGS

Histopathology of bronchial nodules reveals neutrophilic inflammation and fibrotic changes; markers of irreversible damage.

TREATMENT

APPROPRIATE HEALTH CARE

- Usually outpatient—oxygen can be given at home in chronic cases.
- Inpatient—if requires oxygen therapy, parenteral medication, or aerosol therapy; patients that owners cannot keep calm at home during initial stages of therapy.

(CONTINUED)

NURSING CARE

Consider saline nebulization followed by coughing and/or gentle exercise to encourage removal of airway secretions.

ACTIVITY

- Exercise—moderate (not forced) useful in clearing secretions; assists with weight loss.
- Limit if exertion causes excessive coughing.
- Use a harness instead of a collar.

DIET

Weight loss critical—improves PaO_2 , attitude, and exercise tolerance in obese patients; reduces cough frequency.

CLIENT EDUCATION

- Warn client that chronic bronchitis is an incurable disease and complete suppression of all coughing is an unattainable goal.
- Stress that aggressive treatment—including weight control, avoiding risk factors, and medical treatment—minimizes the severity of the coughing and slows disease progression in most patients.

SURGICAL CONSIDERATIONS

Treat severe dental disease to minimize secondary bacterial complications.

**MEDICATIONS****DRUG(S) OF CHOICE****Corticosteroids**

- Diminish airway inflammation and coughing regardless of the underlying cause.
- Indicated for non-infectious conditions.
- Require long-term administration; attempt to wean off steroids or determine lowest effective dosage.
- Prednisolone preferred in cats.
- Prednisone or prednisolone usually initiated at 0.5–1 mg/kg PO q12h for a variable time, with tapering of the dosage based on clinical signs.
- Inhaled agents (e.g., budenoside or fluticasone 1–3 puffs a day; variable concentrations exist) are often effective and can be used to reduce systemic side effects of corticosteroids. These drugs are delivered via spacer chamber and face mask (e.g., AeroDawg); however, the most appropriate dose is not clearly established.

Bronchodilators

- Commonly prescribed, although limited evidence of efficacy.
- Beneficial effects: (Theophylline—bronchodilation; increased mucociliary clearance; improvement in diaphragmatic contractility; lowered pulmonary artery pressure).
- Sustained-release theophylline—oral administration; only generic sustained release products currently available. Consider dosing dog, 10 mg/kg PO q12h; cat, 15–20 mg/kg/day in the evening.
- Aminophylline—immediate-release tablets or injectable formulations are not recommended.
- β -agonists—terbutaline (1.25–5 mg/dog PO q8–12h; 0.625 mg/cat

PO q12h) and albuterol (0.02–0.05 mg/kg PO q8–12h in dogs). Can also be administered by inhalation via a spacer and face mask (salbutamol), immediate but transient effect, dose is unclear, can be used for acute relief but not for prolonged treatment.

Antibiotics

- Select on the basis of quantitated culture and sensitivity test results.
- Bacterial culture results unavailable—choose an agent with a good Gram-negative spectrum, with good tissue and secretion penetration that is bactericidal with minimal toxicity (e.g., potentiated sulfa/trimethoprim, amoxicillin/clavulanic acid, or enrofloxacin). Consider drugs suitable for management of *Mycoplasma*, e.g., doxycycline or chloramphenicol.
- Associated chronic aspiration or dental disease—prefer antibiotic with anaerobic and Gram-positive spectrum.

Antitussives

- Indicated for non-productive, paroxysmal, continuous, or debilitating cough associated with airway collapse. Use when inflammation is controlled.
- Dogs—butorphanol (0.55 mg/kg PO q6–12h; 0.055–0.11 mg/kg SC); hydrocodone (2.5–5 mg/dog q6–24h PO); codeine (0.1–0.3 mg/kg q6–8h PO). Over-the-counter cough suppressants are rarely effective.

CONTRAINDICATIONS

Lasix and atropine—do not use because of drying effects on tracheobronchial secretions.

PRECAUTIONS

- β -agonists (e.g., terbutaline and albuterol)—can cause tachycardia, nervousness, and muscle tremors; typically transient.
- Theophylline—can cause tachycardia, restlessness, excitability, vomiting, and diarrhea; evaluate EDTA plasma sample for peak plasma concentration (ideally 5–20 $\mu\text{g}/\text{mL}$). Toxicity may be more common with generic formulations (unpredictable metabolism).

POSSIBLE INTERACTIONS

Fluoroquinolones decrease theophylline clearance in dogs and can result in theophylline toxicity.

ALTERNATIVE DRUG(S)

- Metered dose inhalers (poorly metabolized steroids—fluticasone or budesonide) can be used. These should be administered via face mask and spacing chamber.
- Cyclosporine-induced immune suppression—insufficient evidence to advise this medication in practice.

**FOLLOW-UP****PATIENT MONITORING**

- Follow abnormalities revealed by physical examination and selected diagnostic

BRONCHITIS, CHRONIC

B

tests—determine response to treatment.

- Monitor weight; arterial blood gases usually improve after significant weight loss.

PREVENTION/AVOIDANCE

Avoid and address risk factors (see “Risk Factors”).

POSSIBLE COMPLICATIONS

- Syncope—frequent complication of chronic coughing, particularly in toy-breed dogs.
- Pulmonary hypertension and cor pulmonale—most serious complications.
- Bronchectasis and airway remodeling.

EXPECTED COURSE AND PROGNOSIS

- Progressive airway changes—syncopal episodes, chronic hypoxia, right ventricular hypertrophy, and pulmonary hypertension.
- Acute exacerbations—common with seasonal changes, air quality changes, worsened inflammation, and potentially the development of secondary infection.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Syncope—secondary to chronic coughing or development of pulmonary hypertension.
- Increased susceptibility to airway infection, chronic hypoxia, pulmonary hypertension, and cor pulmonale.

PREGNANCY/FERTILITY/BREEDING

Safety in pregnant animals not established for most of the recommended drugs.

SYNOMYS

- Chronic bronchitis
- Chronic obstructive lung disease (COLD)
- Chronic obstructive pulmonary disease (COPD)

BRUCELLOSIS

B

BASICS

DEFINITION

- Contagious disease of dogs caused by *Brucella canis*, a small, intracellular, Gram-negative organism.
- Characterized by abortion and infertility in females and epididymitis and testicular atrophy in males.

PATHOPHYSIOLOGY

B. canis—an intracellular parasite; has a propensity for growth in lymphatic, placental, and male genital (epididymis and prostate) tissues.

SYSTEMS AFFECTED

- Hemic/Lymph/Immune—lymph nodes and spleen; bone marrow; mononuclear leukocytes.
- Reproductive—target tissues of gonadal steroids (gravid uterus, fetus, testes [epididymides], prostate gland).
- Other tissues—intervertebral discs, anterior uvea, meninges (uncommon).

GENETICS

- No known genetic predisposition.
- Occurs most commonly in beagles.

INCIDENCE/PREVALENCE

- Incidence unknown.
- Seroprevalence rates—not accurately defined; false-positive results common with agglutination tests.
- Prevalence—relatively low (1–18%) in the United States and Japan; in the United States, higher in rural areas of the south; in Mexico and Peru, 25–30% in stray dogs.

GEOGRAPHIC DISTRIBUTION

Stray dogs, pets, and kennels—United States (mostly beagles), Mexico, Japan, and several South American countries; seen in Spain, Tunisia, China, and Bulgaria; individual outbreaks in Germany and the former Czechoslovakia (some traced to the importation of dogs).

SIGNALMENT

Species

Dogs and, infrequently, humans

Breed Predilections

- No evidence of breed susceptibility, but exceptionally high prevalence in beagles.
- Infected Labrador retrievers and several other breeds found in commercial kennels (“puppy mills”).

Mean Age and Range

- No age preference.
- Most common in sexually mature dogs.

Predominant Sex

- Both sexes are affected.
- More common in females.

SIGNS

General Comments

Suspect whenever female dogs experience abortions or reproductive failures or males have genital disease.

Historical Findings

- Affected animals, especially females, may appear healthy or have vague signs of illness.
- Lethargy.
- Loss of libido.
- Swollen lymph nodes.
- Back pain.
- Abortion—commonly at 6–8 weeks after conception, although pregnancy may terminate at any stage.

Physical Examination Findings

- Males—swollen scrotal sacs, often with scrotal dermatitis; enlarged and firm epididymides.
- Chronic infection—unilateral or bilateral testicular atrophy; spinal pain; posterior weakness; ataxia.
- Chronic and recurrent unilateral anterior uveitis without other systemic signs of disease; also includes iris hyperpigmentation, vitreal infiltrates, and multifocal chorioretinitis.
- Fever rare.
- Enlarged superficial lymph nodes (e.g., retropharyngeal, external inguinal) common.
- Vaginal discharge may last for several weeks after an abortion.

CAUSES

B. canis—Gram-negative coccobacillus; morphologically indistinguishable from other members of the genus; unlike other *Brucella* spp. (e.g., *B. abortus*, *B. suis*, and *B. melitensis*) can result in a high rate (50%) of false-positive reactions with commonly used tests.

RISK FACTORS

- Breeding kennels and pack hounds.
- Risk increases when popular breeding animals become infected.
- Contact with strays in endemic areas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Abortions—maternal, fetal, or placental abnormalities.
- Systemic infections—canine distemper, canine herpesvirus infection, *B. abortus* infection, hemolytic streptococci, *E. coli*, leptospirosis, and toxoplasmosis.
- Inguinal hernias—may be provoked by epididymitis and scrotal edema; also caused by blastomycosis and other granulomatous infections, and Rocky Mountain spotted fever.
- Discospondylitis—fungal infections, actinomycosis, staphylococcal infections, nocardiosis, streptococci, or *Corynebacterium diphtheroides*.

CBC/BIOCHEMISTRY/URINALYSIS

- Generally normal in uncomplicated cases.
- Chronically infected dogs may show hyperglobulinemia (with concurrent hypoalbuminemia).
- CSF—pleocytosis mainly consisting of neutrophils, and elevated protein in meningoencephalitis but normal in discospondylitis.
- Urinalysis usually normal even if bacteria can be cultured from urine.

OTHER LABORATORY TESTS

Serologic testing—most commonly used diagnostic method; subject to error;

false-positive reactions to lipopolysaccharide antigens of several species of bacteria common with the RSAT and mercaptoethanol tube agglutination tests.

RSAT

- Commercially available; simple and rapid.
- Detects infected dogs 3–4 weeks after infection; accurate in identifying non-infected (“negative”) dogs.
- Suffers a high rate (50%) of false-positive reactions.
- Results must be confirmed by other tests.

Mercaptoethanol Tube Agglutination Test

- Semiquantitative.
- Generally performed by commercial diagnostic laboratories.
- Provides information similar to the RSAT.
- Suffers from lack of specificity; good screening test.

AGID Tests

- Cell wall antigen test—employs a lipopolysaccharide antigen derived from the cell walls of *B. canis*; highly sensitive; test conditions not standardized; frequent false positives; not recommended.
- Soluble antigen test—employs soluble antigens that consist of proteins extracted from the bacterial cytoplasm; antigens highly specific for antibodies against *Brucella* spp. (including *B. canis*, *B. abortus*, and *B. suis*); reactive antibodies appear 4–12 weeks after infection and persist for a long time; may give precipitin lines after other tests become equivocal or negative; highly recommended.
- ELISA—using purified cytoplasmic antigens but not yet commercially available.
- PCR—shown to be more sensitive than blood culture and serology in detecting infection in human patients. Sensitive in identifying early infections but not yet commercially available.

IMAGING

- Radiographic evidence of discospondylitis—test for brucellosis.
- Radiographic changes are slow to develop and may not be present even when spinal pain is present.

DIAGNOSTIC PROCEDURES

Isolation of Organism

- Blood cultures—when clinical and serologic findings suggest the diagnosis; *Brucella* are readily isolated from the blood of infected dogs if they have not received antibiotics; onset of bacteremia occurs 2–4 weeks after oral-nasal exposure and may persist for 8 months to 5.5 years.
- Cultures of vaginal fluids—after an abortion; usually give positive results.
- Cultures of semen or urine—not practical for routine diagnosis, because overgrowth of contaminants is common.
- Contaminated samples—media that contain antibiotics (e.g., Thayer-Martin medium) have proven useful.

Semen Quality

- Sperm motility, immature sperm, inflammatory cells (neutrophils)—with epididymitis.
- Abnormalities—usually

(CONTINUED)

BRUCELLOSIS**B**

evident by 5–8 weeks post-infection; conspicuous by 20 weeks. • Aspermia without inflammatory cells—common with bilateral testicular atrophy.

Lymph Node Biopsy

- Reveal lymphoid hyperplasia with large numbers of plasma cells. • If done in a sterile manner, tissues should be cultured on appropriate media. • Intracellular bacteria—may be observed in macrophages with special stains (e.g., Brown-Brenn stain).
- Histopathologic examination of the testes—often reveals necrotizing vasculitis, infiltration of inflammatory cells, and granulomatous lesions.

PATHOLOGIC FINDINGS

- Gross findings—lymph node enlargement; splenomegaly; males: enlarged and firm epididymides, scrotal edema, or atrophy of one or both testes; chronic infection: anterior uveitis and discospondylitis. • Microscopic changes—relatively consistent; diffuse lymphoreticular hyperplasia; chronic infection: lymph node sinusoids with abundant plasma cells and macrophages that contain bacteria—diffuse lymphocytic infiltration and granulomatous lesions in all genitourinary organs (especially prostate, epididymis, uterus, and scrotum); may be extensive inflammatory cell infiltration and necrosis of the prostate parenchyma and seminiferous tubules. • Ocular changes—granulomatous iridocyclitis; exudative retinitis; leukocytic exudates in the anterior chamber.

**TREATMENT****APPROPRIATE HEALTH CARE**

Outpatient

ACTIVITY

Restrict working dogs

CLIENT EDUCATION

- Client should be aware that the goal of treatment is the eradication of *B. canis* from the animal (seronegative status and no bacteremia for at least 3 months), but sometimes the result is persistent low antibody titers with no systemic infection.
- Inform client that antibiotic treatment, especially minocycline and doxycycline, is expensive, time-consuming, and controversial (because outcomes are uncertain).
- Treatment is not recommended for breeding or commercial kennels; it is recommended only for non-breeding dogs or those that have been spayed or castrated. • Before treatment is attempted for an intact household pet or breeding dog, the client must clearly agree that the animal must be neutered or destroyed if treatment fails.

SURGICAL CONSIDERATIONS

Neutering/spaying plus treatment—when euthanasia is unacceptable to an owner.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Several therapeutic regimens have been evaluated, but results have been equivocal.
- Most successful—combination of a tetracycline (tetracycline hydrochloride, chlortetracycline, or minocycline at 25 mg/kg PO q8h for 4 weeks) or doxycycline (10 mg/kg PO q12h for 4 weeks) and dihydrostreptomycin (10 mg/kg IM q8h during weeks 1 and 4).
- Enrofloxacin (5 mg/kg PO q24h for 4 weeks) alone shows poor efficacy.

CONTRAINdications

- Tetracyclines—do not use in immature pups. • Gentamicin—contraindicated with kidney disease.

PRECAUTIONS

Gentamicin—monitor renal function closely.

ALTERNATIVE DRUG(S)

Gentamicin—3 mg/kg q12h; limited success; insufficient data on the efficacy combined with tetracycline.

**FOLLOW-UP****PATIENT MONITORING**

- Serologic tests—monthly for at least 3 months after completion of treatment; continuous, persistent decline in antibodies to negative status indicates successful treatment.
- Recrudescent infections (rise in antibody levels and recurrence of bacteremia after therapy)—retreat, neuter and re-treat, or euthanize. • Blood cultures—negative for at least 3 months after completion of treatment.

PREVENTION/AVOIDANCE

- Vaccine—none; would complicate serologic testing. • Testing—all brood bitches, before they come into estrus if a breeding is planned; males used for breeding, at frequent intervals.
- Quarantine and test all new dogs twice at monthly intervals before allowing them to enter a breeding kennel.

POSSIBLE COMPLICATIONS

- Owners may be reluctant to neuter or destroy valuable dogs, regardless of treatment failure. • Remind owners of ethical considerations and their obligation not to sell or distribute infected dogs.

EXPECTED COURSE AND PROGNOSIS

- Prognosis guarded. • Infected for <3–4 months—likely to respond to treatment. • Chronic infections—males may fail to respond to therapy. • Discospondylitis

cases—may need repeated drug treatment but surgical intervention is rarely needed.

- Multiple drug combination therapy with gentamicin or streptomycin, doxycycline, enrofloxacin, and rifampin has been successful in treating ocular disease in dogs.
- Successfully treated (seronegative) dogs—fully susceptible to reinfection.

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

- Human infections—reported; usually mild; respond readily to tetracyclines. • However, an outbreak in six members of a family living in close contact with an infected bitch has been reported.

PREGNANCY/FERTILITY/BREEDING

- Abortions at 45–60 days of gestation typical. • Pups from infected bitches may be infected or normal.

SYNONYMS

Contagious canine abortion

CALCIUM CHANNEL BLOCKER TOXICOSIS

BASICS

OVERVIEW

- Calcium channel blockers (CCBs) are class IV antidysrhythmics used commonly to treat systemic hypertension, cardiac disease, tachydysrhythmias, and potentially oliguric/anuric renal failure in dogs and cats.
- CCBs inhibit movement of calcium (Ca) through L-type voltage-gated slow Ca channels located on cardiac muscle, AV and SA nodes, vasculature smooth muscle, and pancreatic beta cells.
- Three classes of CCBs: phenylalkylamine, benzothiazepine, dihydropyridine. CCB class determines the effect on the body.

SIGNS

- Systems affected include:
- Cardiovascular—bradycardia, AV dissociation and AV block (1st, 2nd, or 3rd degree block), hypotension
 - Gastrointestinal—vomiting, diarrhea, ileus
 - Respiratory—pulmonary edema
 - Nervous—decreased mentation, weakness, collapse, seizures
 - Endocrine/metabolic—hyperglycemia, metabolic acidosis secondary to hypoperfusion

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Beta blocker antagonist toxicosis
- Cardiac disease with secondary bradyarrhythmias
- Cardiovascular drug overdose (e.g., clonidine, digoxin toxicosis)
- Sedative overdose (e.g., opioid or baclofen toxicosis)
- Sick sinus syndrome
- Hyperkalemia
- Decompensated shock/sepsis

CBC/CHEMISTRY/URINALYSIS

- Hyperglycemia
- Azotemia and elevated liver enzymes with prolonged hypoperfusion

OTHER LABORATORY TESTS

Blood gas—metabolic acidosis secondary to hypoperfusion

IMAGING

Chest radiographs to evaluate for intravascular (IV) volume status and pulmonary edema

DIAGNOSTIC PROCEDURES

- ECG—1st, 2nd, and 3rd degree AV block, prolonged PR, QRS and QT intervals
- Echocardiogram—negative inotropy, decreased cardiac output

TREATMENT

- Emesis if asymptomatic and < 2 hours after exposure.
- Gastric lavage if decreased mental status or large number of pills ingested.
- Whole bowel irrigation for extended (XR) or sustained release (SR) medications.

- Central line placement for CVP monitoring, frequent glucose monitoring, and dextrose administration during HDI therapy.
- Temporary pacing considered when medical therapy fails.
- IV fluid administration for hypotension: cats, 10–20 mL/kg over 15–30 minutes; dogs, 20–30 mL/kg over 15–30 minutes.

MEDICATIONS

DRUGS

- Activated charcoal (1–2 g/kg) orally.
- Atropine (0.02–0.04 mg/kg IV) for sinus bradycardia.
- Calcium infusion is the first line therapy despite normocalcemia to increase Ca availability for muscle function and improve contractility.
 - Ca gluconate 10% bolus 0.5–1.5 mL/kg IV over 5–10 minutes followed by a CRI of 0.5–1.5 mL/kg/h, titrated to effect. Monitor continuous ECG and infusion should be slowed or stopped if bradycardia or conduction blockade worsens.
 - Ca chloride 10% bolus 0.15–0.5 mL/kg IV. Central line recommended due to risk of tissue injury secondary to drug extravasation.
 - Serum ionized Ca levels should be maintained at 1.5–2 × the normal range.
- Intravenous fat emulsion (IFE). Used to treat lipid-soluble drug intoxication.
 - Three possible mechanisms: (1) Provide a lipid sink for fat soluble drugs; (2) Supply fatty acid source for cardiac performance; (3) Increase intracellular Ca via activation of voltage gated Ca channels to improve myocyte function.
 - IFE dose: 1.5 mL/kg IV bolus of a 20% solution over 1 minute. Follow with a CRI of 0.25 mL/kg/min for 30–60 minutes. Can repeat bolus every 3–5 minutes as needed up to 3 mL/kg, not to exceed a total dose of 8 mL/kg.

- High dose insulin (HDI)/dextrose administration

◦ Exact mechanism of HDI is unknown but appears to improve uptake and utilization of carbohydrates as an energy source and increase myocardial cell cytosolic Ca levels to increase cardiac contractility and cardiac output. May not improve blood pressure even though clinical signs and perfusion improve.

◦ Recommended treatment: (1) Check blood glucose (BG) concentration and administer dextrose if BG is < 100 mg/dL for dogs and < 200 mg/dL in cats. (2) Administer regular insulin at 1 unit/kg IV. Follow with a CRI IV of regular insulin at 2 units/kg/h. May increase every 10 minutes up to a maximum dose of 10 units/kg/h. When signs resolved, decrease insulin by

- 1–2 units/kg/h. (3) Monitor BG every 10 minutes while titrating insulin dose. Once stabilized, check BG every 30–60 minutes. Dextrose supplementation will be needed to maintain BG concentrations and continued up to 24 hours after discontinuation of the insulin therapy.
- (4) Monitor potassium concentration every hour. Administer potassium chloride to keep potassium concentrations in the low therapeutic range.
- Glucagon—increases inotropy by increasing myocardial cAMP levels. May not be as effective as HDI or ILE. Dose is 0.05–0.2 mg/kg slowly IV bolus followed by a CRI of 0.05–0.1 mg/kg/h.

CONTRAINDICATION/POSSIBLE INTERACTIONS

Vasopressors—may not be as effective as other therapies (Ca infusion, ILE, and HDI) and may make patients less responsive to other therapy.

FOLLOW-UP

PATIENT MONITORING

Monitor heart rate/ECG, blood pressure, ionized Ca, and BG for 12 hours with immediate release preparations and 24 hours for XR/SR preparations.

EXPECTED COURSE AND PROGNOSIS

- Ingestion of immediate release preparations typically result in clinical signs in 8–12 hours.
- SR or XR preparations may take 12–24 hours for clinical signs to develop.
- Prognosis depends on the dose ingested and response to therapy.
- Toxicosis normally results in bradycardia, hypotension, and in severe cases decreased mental status, coma, and apnea.

MISCELLANEOUS

ABBREVIATIONS

- BG = blood glucose
- Ca = calcium
- CCB = calcium channel blocker
- CRI = continuous rate infusion
- CVP = central venous pressure
- ECG = electrocardiogram
- HDI = high dose insulin
- ILE = Intravenous fat emulsion
- IV = intravenous
- SR = sustained release
- XR = extended release

CAMPYLOBACTERIOSIS

C

BASICS

OVERVIEW

- *Campylobacter jejuni*—fastidious, microaerophilic, Gram-negative curved bacteria; often isolated from the intestine of healthy dogs, cats, and other mammals; may cause superficial erosive enterocolitis.
- Infection—fecal-oral route from contamination of food, water, fresh meat (poultry, beef), and the environment; localized in crypts of intestine; darting motility essential for colonization; produces enterotoxin, cytotoxin, cytolethal-distending toxin, invasin. • Invasion gut mucosa—hematochezia; leukocytes in feces; ulceration; edema; congestion of intestine; bacteremia; occasionally septicemia; bacteria shed in feces for weeks to months. • Up to 49% of dogs without diarrhea and 45% of normal cats carry *C. jejuni* and shed it in feces. • In younger dogs (but not cats), more animals with diarrhea shed *Campylobacter* than in diarrheic controls. • *Campylobacter* spp. (and *Salmonella* spp.) often found in raw meat diets (especially chicken).

SIGNALMENT

- Dogs; less commonly cats. • Prevalence—higher in puppies and kittens from birth to 6 months. • Can result in chronic disease.

SIGNS

- Diarrhea—ranges from mucous-like and watery to bloody or bile-streaked; common; may be chronic. • Tenesmus common.
- Fever (mild or absent), anorexia, and intermittent vomiting (3–15 days in duration) may accompany diarrhea. • Young animals (up to 6 months of age)—clinical signs most severe; from enterocolitis/diarrhea.
- Adults—usually asymptomatic carriers.

CAUSES & RISK FACTORS

- *C. jejuni*, *C. coli*, *C. upsaliensis*. • Kennels with poor sanitation/hygiene and fecal buildup in the environment. • Young animals—debilitated, immunosuppressed, or parasitized (e.g., *Giardia*, *Toxocara*, *Isospora*). • Nosocomial infection may develop in hospitalized patients. • Adults—concurrent intestinal infections (e.g., *Salmonella*, parvovirus, hookworms).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bacterial enterocolitis—*Salmonella*, *Yersinia enterocolitica*, *Clostridium difficile*, and *Clostridium perfringens*. • Parasitic: helminths (particularly whipworms) and protozoa (*Giardia* and *Isospora*). • Viral: parvovirus; signs often more severe than with *Campylobacter*. • Dietary indiscretion or

intolerance. • Drugs and toxins. • Acute pancreatitis. • Severely affected patients—also consider viral gastroenteritis, intussusception, and other causes of abdominal pain. • Distinguish from other causes of chronic diarrhea. • Primary intestinal disease.

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis—if the strain is invasive and bacteremia develops • Biochemistry abnormalities—effects of diarrhea and dehydration (e.g., azotemia, electrolyte disturbances).

DIAGNOSTIC PROCEDURES

- Fecal leukocytes—in gastrointestinal tract and stool. • Fecal culture—submit feces in Amies Transport Medium with charcoal or Cary-Blair Medium kept refrigerated at 4°C in transit. • Species-specific quantitative PCR (qPCR).

Direct Examination of Feces

- Gram stain—make a smear of watery stool. • Wet mount—drop a small amount of stool on glass slide; cover slip; see large numbers of highly motile bacteria (characteristic darting motility).

PATHOLOGIC FINDINGS

- Gross—diffuse colon thickening, congestion/edema; hyperemia of small intestine; enlarged mesenteric lymph nodes. • Thickening of intestinal smooth muscle has been described in infected cats.

TREATMENT

MILD ENTEROCOLITIS

- Outpatient • Usually self-limiting

SEVERE ENTEROCOLITIS

- Inpatient, especially neonatal and immature patients. • Severe neonatal disease—isolate; confine to cage; monitor; encourage rest. • NPO for 24 hours; then bland diet. • Mild dehydration—oral fluid therapy with an enteric fluid replacement solution. • Severe dehydration—intravenous fluid therapy with balanced polyionic isotonic solution. • Plasma transfusion may be required if serum albumin < 2 g/dL. • Locally acting intestinal adsorbents/protectants.

MEDICATIONS

DRUG(S)

- Antibiotics—recommended for signs of systemic illness (e.g., high fever or dehydration) when diarrhea or abnormal clinical signs persist > 7 days and in immune-suppressed patients. • Erythromycin 10–20 mg/kg PO q8h for 5 days; drug of choice. • Enrofloxacin: dog, 5–20 mg/kg q24h PO, IV, IM. Adverse effect of arthropathy in dogs

4–28 weeks of age. Cat, 5 mg/kg q24h PO, IM.

- Tylosin 11 mg/kg PO q8h for 7 days; may be effective.
- Neomycin 10–20 mg/kg PO q6–12h for 5 days; may be ineffective.
- Penicillins and ampicillin—potentially ineffective.
- Septicemia—parenteral antibiotics with aminoglycoside (e.g., amikacin) and cephalosporin may be initiated.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Antidiarrheal drugs that reduce intestinal motility are contraindicated.
- Enrofloxacin—may induce arthropathy in dogs < 28 weeks of age. Do not administer to cats at doses > 5 mg/kg, or give IV.

FOLLOW-UP

PATIENT MONITORING

Repeat fecal culture after treatment.

PREVENTION/AVOIDANCE

- Good hygiene (hand washing). • Routinely clean and disinfect runs, food, and water bowls. • Do not feed raw meat diets to companion animals.

EXPECTED COURSE AND PROGNOSIS

- Adults—usually self-limiting. • Juveniles with severe or persistent enterocolitis—treat with antibiotics.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Concurrent infection with other pathogenic bacteria, enteric parasites, or viruses.

ZOONOTIC POTENTIAL

High potential (*C. jejuni*, *C. coli*, *C. upsaliensis*)

PREGNANCY/FERTILITY/BREEDING

- Erythromycin—safe to use in early pregnancy. • Chloramphenicol and gentamicin—do not use in pregnant animals.

ABBREVIATION

- PCR = polymerase chain reaction

Consulting Editor Stephen C. Barr

CANDIDIASIS

BASICS

OVERVIEW

- *Candida*—dimorphic fungus with the yeast phase (*Candida* spp.) being part of the normal flora of the mouth, nose, ears, and gastrointestinal and genital tracts of dogs and cats. • *C. albicans* and *C. parapsilosis* most commonly cultured from clinically healthy dogs.
- Recovery from mucosal surfaces does not imply disease; opportunistic infection, colonizing damaged tissues or invading normal tissues of immunosuppressed animals.
- Pathogenic role is determined by identifying a fungemia, infiltration of organisms into the tissues, or signs of organisms in presumed sterile sites (e.g. urinary bladder).
- Conditions that suppress the immune system increase the likelihood of isolation in asymptomatic animals; isolated from throat cultures five times more often in FIV-infected cats than in asymptomatic, non-FIV-infected cats of a similar age and sex.

SIGNALMENT

Cats and dogs of any age and breed.

SIGNS

- Non-healing ulcers in the oral, upper respiratory, GI, or urogenital mucosa—signs frequently reflect the location/extent of disease.
- Urinary bladder involvement—cystitis.
- Ear infection—head shaking and scratching.
- Oral cavity involvement—drooling.
- Inflammation around IV catheters or gastrostomy tubes.
- Ulcerative, red skin lesions.
- Systemic disease with fever, cardiac and/or neurologic signs can be seen.

CAUSES & RISK FACTORS

- Infection—rare; associated with neutropenia, parvovirus infection, diabetes mellitus, hyperadrenocorticism, retrovirus-induced immunosuppression, glucocorticoid therapy, gastrostomy tubes, indwelling urinary catheters/urethrostomy, IV catheters, and incomplete emptying of the bladder.
- Bacterial bladder infection and cystic calculi may predispose to fungal infection.
- Occasionally local or systemic *Candida* infection is seen in animals without predisposing conditions.
- Skin damaged by burns, trauma, or necrotizing dermatitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Considered whenever the primary condition does not respond as expected.

CBC/BIOCHEMISTRY/URINALYSIS

- Reflect the underlying condition.
- Urinalysis—may show yeast form or clumps of mycelial elements (pseudohyphae)

accompanied by an increase in inflammatory cells; a bacterial urinary tract infection often occurs with the fungal infection.

- Neutropenic patients—Inflammatory response may be absent.

OTHER LABORATORY TESTS

- Cytology—spherical to oval yeast cells 5–7 µm in diameter; pseudohyphae and septate hyphae are 3–5 µm wide.
- Culture—grows well on blood agar and often is isolated from specimens submitted for bacterial culture; more easily isolated from urine than blood.
- PCR and antigen tests are available.

DIAGNOSTIC PROCEDURES

- Lesions—biopsy for histopathologic study to determine if *Candida* is truly a pathogen (samples obtained from mucosal or cutaneous surfaces may not represent true infection); requires demonstration of organisms penetrating the tissues.
- Urine sample—obtain by cystocentesis; culture of a number of colonies of *Candida* strongly supports the diagnosis.
- Otitis (dogs)—culture of *Candida* spp. or identification of yeast or mycelial elements on ear cytology suggests the diagnosis.
- In febrile patients culture tips of catheters for both bacteria and fungi.

PATHOLOGIC FINDINGS

- White cheesy foci in the infected tissue may be noted.
- Usually large numbers of both yeast and pseudohyphae in the tissues surrounded by necrosis and a suppurative inflammatory reaction.
- May be pyogranulomatous in more chronic sites of infection.

TREATMENT

- Regulate diabetes mellitus and control hyperadrenocorticism.
- Remove indwelling catheters.
- Improve immune suppression, if possible.

MEDICATIONS

DRUG(S)

- Topical therapy for mucosal lesions—nystatin or amphotericin B.
- Fluconazole—5 mg/kg PO q12h (dogs and cats); very effective; excreted unchanged in the urine, achieving a high concentration in commonly infected sites.
- Itraconazole—effective; use if the organism becomes resistant to fluconazole; not recommended for urinary tract infection because it is not excreted in the urine.
- In lower urinary tract *Candida* infections resistant to fluconazole; infuse 10–30 mL of 1% clotrimazole into the bladder every other day for three treatments.

- *Candida* may develop drug resistance; consider drug sensitivity testing if suspected.

FOLLOW-UP

PATIENT MONITORING

- Fluconazole and itraconazole—hepatotoxicity; monitor serum ALT monthly and check if patient becomes anorexic.
- After signs have resolved—re-culture sites of infection; continue treatment for 2 weeks more; repeat cultures 2 weeks after completion of treatment and again if signs recur.

EXPECTED COURSE AND PROGNOSIS

- Should resolve within 2–4 weeks of treatment with correction of immunosuppression.
- Control of the underlying disease is necessary to prevent recurrence.
- May resolve spontaneously if the underlying condition is corrected.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Genetic similarities between human and animal isolates suggest a potential for transfer of *C. albicans* between species.

ABBREVIATIONS

- ALT = alanine transaminase
- GI = gastrointestinal
- PCR = polymerase chain reaction
- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus

CANINE CORONAVIRUS INFECTIONS

BASICS

OVERVIEW

- CCoV—sporadic outbreaks of vomiting and diarrhea in dogs; worldwide distribution.
- CRCoV—associated with canine infectious respiratory disease complex (“kennel cough”); worldwide distribution. • Infection with CCoV—usually inapparent; mild to severe enteritis may occur, from which most dogs recover; death reported in young pups; restricted to the upper two-thirds of the small intestine and associated lymph nodes; unlike CPV-2 infection, crypt cells spared.
- Simultaneous infection with CPV-2 may occur; more severe; often fatal.
- Coronaviruses undergo rapid evolution, are highly variable, and differences in virulence between individual isolates are likely.

SIGNALMENT

- Only dogs susceptible to disease. • CCoV may cause inapparent infections in cats.
- CRCoV infections more common in the winter. • All ages and breeds. • Disease more severe in young animals.

SIGNS

- Vary greatly. Rarely virulent isolates that cause systemic disease can occur. • Adults—most infections inapparent. • Puppies—may develop mild to severe, occasionally fatal enteritis. • Incubation period 1–3 days.
- Sudden onset of vomiting, usually only once. • Diarrhea—may be explosive; yellow-green or orange; loose or liquid; typically malodorous (characteristic); may persist for a few days up to > 3 weeks; may recur later. • Coughing; CRCoV associated with canine kennel cough complex. • Young pups—may suffer severe, protracted diarrhea and dehydration. • Anorexia and depression common. • Fever rare. • Mild respiratory effects. • Signs included pyrexia, anorexia, depression, vomiting, hemorrhagic enteritis, respiratory distress, and leukopenia that persisted > 1 week. Ataxia and seizures also occurred in pups, with deaths in 2 days after onset of symptoms.

CAUSES & RISK FACTORS

- CCoV—closely related to FIP virus, feline enteric coronavirus, and transmissible gastroenteritis virus of swine; pig and cat viruses not known to cause natural illness in dogs; readily inactivated by common disinfectants. • CRCoV—genetically and serologically distinct from CCoV; more closely related to bovine coronavirus and human coronavirus OC43. • Stress (e.g., intensive training, crowding)—greatest risk; sporadic outbreaks have occurred in dogs attending shows and in kennels where introductions of new dogs are frequent; crowding and unsanitary conditions promote

clinical illness. • For CCoV, feces primary source of infection; virus shed for about 2 weeks. • For CRCoV, respiratory secretions and fomites are likely sources of infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infections caused by enteric bacteria, protozoa, or other viruses and other agents associated with kennel cough complex.
- Other causes of mild to moderate upper respiratory disease. • Food intoxication or intolerance.

CBC/BIOCHEMISTRY/URINALYSIS

Normal; lymphopenia with more virulent CCoV isolates.

OTHER LABORATORY TESTS

- Serologic tests—available; not standardized.
- Antibody titers—generally low; may not indicate recent infection because of high rate of asymptomatic infection.

DIAGNOSTIC PROCEDURES

- Viral isolation for CCoV—from feces in feline cell cultures at onset of diarrhea. Viral isolation for CRCoV is difficult and not recommended. • PCR—using type-/strain-specific probes. • Immunofluorescence of the small intestine—fatal cases; may reveal viral antigen in cells lining the villous epithelium.

PATHOLOGIC FINDINGS

- Gross—may be dilated loops of small intestine filled with gas and watery green-yellow material. • Bowel loops may be congested or hemorrhagic; mesenteric lymph nodes usually enlarged and edematous.
- Typical microscopic changes—atrophy and fusion of intestinal villi; deepening of the crypts; increased cellularity of the lamina propria; flattening of epithelial cells with increased goblet cells. • Lesions—commonly obscured by post-mortem autolysis. • The “Pantrropic” strains described in Europe caused hemorrhagic lesions in the lungs, small intestines, kidneys and lymph nodes, and serosanguineous abdominal fluid.

TREATMENT

- Most affected dogs recover without treatment. • For CCoV, supportive fluid and electrolyte treatment if dehydration is severe.
- For CRCoV, treatment as for canine kennel cough complex.

MEDICATIONS

DRUG(S)

Antibiotics—not usually indicated, except with enteritis, sepsis, or respiratory illness.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Vaccines—controversial; inactivated and live viral vaccines available; appear to be safe; efficacy unknown, except for brief periods (2–4 weeks) after vaccination. Not recommended. Vaccines for CCoV do not cross-protect against CRCoV. • Strict isolation and sanitation are essential in kennels. • CCoV and CRCoV—highly contagious; spread rapidly.

POSSIBLE COMPLICATIONS

Diarrhea with CCoV—may persist 10–12 days; may recur.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—normally good, except severe infections of young pups. • Majority recover after a few days of illness.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Infection with canine parvovirus or other agent may occur concurrently. • Infections with other respiratory pathogens are commonly associated with CRCoV.

ABBREVIATIONS

- CCoV = canine enteric coronavirus
- CPV = canine parvovirus • CRCoV = canine respiratory coronavirus • FIP = feline infectious peritonitis • PCR = polymerase chain reaction

C CANINE DISTEMPER

BASICS

DEFINITION

- An acute to subacute, contagious, febrile, and often fatal disease with respiratory, urogenital, gastrointestinal, ocular, and CNS manifestations.
- Caused by CDV, a Morbillivirus in the Paramyxoviridae family.
- Affects many different species of the order Carnivora; mortality rate varies greatly among species.

PATOPHYSIOLOGY

- Natural route of infection—airborne and droplet exposure; from the nasal cavity, pharynx, and lungs, macrophages carry the virus to local lymph nodes, where virus replication occurs; within 1 week, viral shedding occurs (mainly in respiratory exudates but also urine) and virtually all lymphatic tissues become infected; spreads via viremia to the surface epithelium of respiratory, gastrointestinal, and urogenital tracts and to the CNS.
- Fever for 1–2 days and lymphopenia may be the only findings during initial period; further disease progression depends on the virus strain and the host's immune response.
- Strong cellular and humoral immune response—host may remain subclinical.
- Weak immune response—subacute infection; host may survive longer.
- Failure of immune response—acute death of host within 2–4 weeks after infection; convulsions and other CNS disturbances frequent causes of death.
- Viral excretion can occur up to 2–3 months but usually shorter.

SYSTEMS AFFECTED

- Multisystemic—all lymphatic tissues; surface epithelium in the respiratory, alimentary, and urogenital tracts; endocrine and exocrine glands.
- Nervous—skin; gray and/or white matter of brain and/or spinal cord in the CNS.

INCIDENCE/PREVALENCE

- Dogs—restricted to sporadic outbreaks.
- Wildlife (raccoons, skunks, fox, tigers)—fairly common.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

- Most species of the order Carnivora—Canidae, Hyaenidae, Mustelidae, Procyonidae, Viverridae.
- Felidae families—large cats in California zoos and in Tanzania.

Mean Age and Range

Young, especially unvaccinated animals are more susceptible than are adults.

SIGNS

- Fever—first peak 3–6 days after infection, may pass unnoticed; second peak several days later (and intermittent thereafter), usually associated with nasal and ocular discharge, depression, and anorexia.
- Gastrointestinal and/or respiratory signs—follow, often exacerbated by secondary bacterial infection.

- CNS—many infected dogs; often, but not always, after systemic disease; depends on the virus strain; either acute gray or white matter disease.
- Gray matter disease: affects cerebral cortex, brainstem, and spinal cord and may cause a non-suppurative meningitis, seizures, stupor, hysteria, and ataxia. Dogs may die in 2–3 weeks; some dogs recover (associated with prompt humoral and cell-mediated immunity), others progress to develop white matter disease.
- White matter disease: variable signs of multifocal disease, commonly cerebellovestibular signs, spinal cord paresis and ataxia, occasionally myoclonus; some dogs die 4–5 weeks after initial infection with non-inflammatory, demyelinating disease; some dogs may recover with minimal CNS injury.
- Optic neuritis and retinal lesions may occur; sometimes infected scleral blood vessels from anterior uveitis.
- Hardening of the footpads (hyperkeratosis) and nose—some virus strains; but relatively uncommon.
- Enamel hypoplasia of the teeth after neonatal infection common.

CAUSES

- CDV, a Morbillivirus within the Paramyxoviridae family; closely related to measles virus, rinderpest virus of cattle, and phocine (seal) and dolphin distemper viruses.
- Incompletely attenuated vaccines (rare).
- Secondary bacterial infections frequently involve the respiratory and gastrointestinal systems.

RISK FACTORS

Contact of non-immunized animals with CDV-infected animals (dogs or wild carnivores).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diagnosis usually based on clinical suspicion (typical history in a 3- to 6-month-old unvaccinated puppy showing multifocal signs).
- Kennel cough—can mimic the respiratory disease.
- Enteric signs—differentiate from canine parvovirus and coronavirus infections, parasitism (giardiasis), bacterial infections, gastroenteritis from toxin ingestion, inflammatory bowel disease.
- CNS form—differentiate from autoimmune meningoencephalitis (granulomatous meningoencephalomyelitis, necrotizing encephalitis), protozoal (e.g., toxoplasmosis, neosporosis), fungal (e.g., cryptococcosis), and rickettsial (e.g., ehrlichiosis, Rocky Mountain spotted fever) meningoencephalitis.

CBC/BIOCHEMISTRY/URINALYSIS

Lymphopenia during early infection; intracytoplasmic inclusions in WBCs and RBCs.

OTHER LABORATORY TESTS

- Serology—limited value; positive antibody tests do *not* differentiate between vaccination and exposure to virulent virus; patient may die from acute disease before neutralizing antibody is produced; IgM responses may occur up to 3 months after exposure to virulent virus and for up to 3 weeks after vaccination.
- CDV antibody in CSF—indicative, but not always diagnostic, of distemper encephalitis.

IMAGING

- Radiographs—may determine the extent of pneumonia.
- CT and MRI—may or may not disclose lesions. MRI sensitive for visualization of demyelination.

DIAGNOSTIC PROCEDURES

- Immunohistochemical detection in haired skin, nasal mucosa, and footpad epithelium.
- Viral antigen or viral inclusions—in buffy coat cells, urine sediment, conjunctival or vaginal imprints (negative results do not rule out the diagnosis).
- RT-PCR—on buffy coat, urine sediment cells, conjunctival swabs and CSF.
- CSF—moderate pleocytosis of mononuclear cells (lymphocytes and macrophages), CDV-specific antibody, interferon, and viral antigen early in disease course.
- Post-mortem diagnosis—histopathology, immunofluorescence and/or immunocytochemistry, virus isolation, and/or RT PCR; preferred tissues from lungs, stomach, urinary bladder, lymph nodes, and brain.

PATHOLOGIC FINDINGS

Gross

- Thymus—in young animals greatly reduced in size; sometimes gelatinous.
- Lungs—patchy consolidation as a result of interstitial pneumonia.
- Footpads and nose—rarely hyperkeratosis.
- Mucopurulent discharges—from eyes and nose, bronchopneumonia, catarrhal enteritis, and skin pustules; probably caused by secondary bacterial infections; commonly seen.

Histologic

- Intracytoplasmic eosinophilic inclusion bodies—frequently found in epithelium of the bronchi, stomach, and urinary bladder; also seen in reticulum cells and leukocytes in lymphatic tissues.
- Inclusion bodies in the CNS—glial cells and neurons; frequently intranuclear; can also be found in cytoplasm.
- Staining by fluorescent antibody or immunoperoxidase may detect viral antigen where inclusion bodies are not seen.

(CONTINUED)

CANINE DISTEMPER**TREATMENT****APPROPRIATE HEALTH CARE**

Inpatients and in isolation, to prevent infection of other dogs. Unlike systemic signs, presenting neurologic signs are usually not reversible.

NURSING CARE

- Symptomatic.
- Intravenous fluids—with anorexia and diarrhea.
- Once fever and secondary bacterial infections are controlled, patients usually begin to eat again.
- Clean away ocular discharges.

ACTIVITY

Limited

DIET

Depends on the extent of gastrointestinal involvement

CLIENT EDUCATION

- Inform client that mortality rate is about 50%.
- Inform client that dogs that appear to recover from early catarrhal signs may later develop fatal CNS signs.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Antiviral drugs—none known to be effective.
- Broad-spectrum antibiotics—to reduce secondary bacterial infection, because CDV is highly immunosuppressive. Ampicillin, tetracycline, and chloramphenicol are good choices.
- Anticonvulsant therapy—phenobarbital, potassium bromide; to control seizures.

CONTRAINDICATIONS

Corticosteroids—use anti-inflammatory doses with caution; may provide short-term control; immunosuppressive doses may enhance viral dissemination.

PRECAUTIONS

Tetracycline and fluorinated quinolones—best avoided in young and growing animals.

**FOLLOW-UP****PATIENT MONITORING**

- Monitor for CNS signs, because seizures often follow.
- Monitor for signs of pneumonia or dehydration from diarrhea in the acute phase of the disease.

PREVENTION/AVOIDANCE

- Vaccination is key.
- Isolate puppies to prevent infection from wildlife (e.g., raccoons, foxes, skunks) or from CDV-infected dogs.
- Recovered dogs are not carriers.

Vaccines

- MLV-CD—prevents infection and disease; two types available:
 - Canine tissue culture-adapted vaccines (e.g., Rockborn strain)—induce complete immunity in virtually 100% of susceptible dogs; rarely, a post-vaccinal fatal encephalitis develops 7–14 days after vaccination, especially in immunosuppressed animals.
 - Chick embryo-adapted vaccines (e.g., Lederle strain)—safer; post-vaccinal encephalitis does not occur; only about 80% of susceptible dogs seroconvert.
- Other species—chick embryo can safely be used in a variety of wildlife species (e.g., gray fox); Rockborn type fatal in these animals.
- Killed vaccines—useful for species in which either type of MLV-CD is fatal (e.g., red panda, black-footed ferret).
- Canarypox recombinant CDV vaccine.
- Duration of immunity from most vaccines is over 3 years.

Maternal Antibody

- Important.
- Most puppies lose protection from maternal antibody at 6–12 weeks of age; 2–3 vaccinations should be given during this period.
- Heterotypic (measles virus) vaccination—recommended for puppies that have maternal antibody; induces protection from disease but not from infection.

POSSIBLE COMPLICATIONS

Possibility of occurrence of CNS signs for 2–3 months after catarrhal signs have subsided.

EXPECTED COURSE AND PROGNOSIS

- Depends on the strain and the individual host response—subclinical, acute, subacute, fatal, or nonfatal infection.
- Mild CNS signs—patient may recover; myoclonus may continue for several months or indefinitely.
- Death—2 weeks to 3 months after infection; mortality rate approximately 50%.
- Euthanasia—owner may elect if or when neurologic signs develop; indicated when uncontrollable seizures occur.
- Fully recovered dogs do not shed CDV.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Persistent or latent *Toxoplasma gondii* infections—reactivated because of the immunosuppressive state.
- Respiratory infections with *Bordetella bronchiseptica* (a major cause of kennel cough).

AGE-RELATED FACTORS

- Young puppies—more susceptible; mortality rate is higher.
- Non-immunized old dogs—highly susceptible to infection and disease.

ZOONOTIC POTENTIAL

- Possible that humans may become subclinically infected with CDV;

immunization against measles virus also protects against CDV infection.

- Once speculated that CDV triggers MS but several studies have refuted this proposition.

PREGNANCY/FERTILITY/BREEDING

In utero infection of fetuses—occurs in antibody-negative bitches; rare; may lead to abortion or to persistent infection; infected neonates may develop fatal disease by 4–6 weeks of age.

SYNONYMS

- Canine distemper
- Hard pad disease
- Hundestaupe
- Maladie de Carré

SEE ALSO

Myoclonus (although not unique to CDV)

ABBREVIATIONS

- CDV = canine distemper virus
- CNS = central nervous system
- CSF = cerebrospinal fluid
- CT = computed tomography
- MLV-CD = modified live virus of canine distemper
- MRI = magnetic resonance imaging
- MS = multiple sclerosis
- RT-PCR = reverse transcriptase polymerase chain reaction

C CANINE INFECTIOUS RESPIRATORY DISEASE

BASICS

DEFINITION

A multifaceted disease whereby infectious disease and environment contribute to the genesis of cough and other respiratory signs in dogs.

PATHOPHYSIOLOGY

Initiated by injury to the respiratory epithelium by viral infection followed by invasion of damaged tissue by bacterial, mycoplasmal, or other virulent organisms, resulting in further damage and clinical signs.

SYSTEMS AFFECTED

Respiratory—upper and lower airways can be involved. Multisystemic—cases that develop sepsis.

GENETICS

None

INCIDENCE/PREVALENCE

Most common in areas of high density with immunologically naïve or immunosuppressed patients (i.e., training homes, shelters, veterinary hospitals).

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog

Breed Predilections

None

Mean Age and Range

- Most severe in puppies 6 weeks–6 months old.
- Can develop in dogs of all ages, particularly with preexisting airway disease.

Predominant Sex

None

SIGNS

General Comments

- Related to the degree of respiratory tract damage and age of the affected dog and virulence of infectious organism.
- Can be subclinical, mild, or severe with pneumonia.
- Most viral, bacterial, and mycoplasmal agents spread rapidly from seemingly healthy dogs to others in the same environment; signs usually begin about 3–7 days after exposure to the infecting agent(s).

Historical Findings

- Uncomplicated—acute-onset cough in an otherwise healthy animal; dry and hacking, soft and dry, moist and hacking, or paroxysmal, followed by gagging, retching, and expectoration of mucus; excitement, exercise, and pressure on the trachea induce coughing spells.
- Complicated (severe)—inappetance to anorexia; cough is moist and productive; lethargy, difficulty breathing, hemoptysis, and exercise intolerance can occur.

Physical Examination Findings

- Uncomplicated—cough readily induced with minimal tracheal pressure; lung sounds

often normal; systemically healthy.

- Complicated—low-grade, or intermittent fever (39.4–40.0°C, 103–104°F); increased intensity of normal lung sounds, crackles or wheezes possible.

CAUSES

- Viral—canine distemper virus; CAV-2; CPIV; canine respiratory coronavirus, canine reovirus; canine herpesvirus-1; canine influenza virus (H3N8 or H3N2); canine bovacivirus, canine hepacivirus; canine pneumovirus.
- Most viral pathogens (except CHV and CDV) primarily infect epithelial and lymphoid tissue of the upper and lower respiratory tract; in severe cases, cause desquamation of the epithelium and aggregation of inflammatory cells in the lungs leading to secondary bacterial colonization and infection; canine respiratory coronavirus infection leads to loss of cilia associated with the respiratory epithelium, increasing the severity and duration of secondary infections.
- Bacterial—*Bordetella bronchiseptica*, with no other respiratory pathogens, produces clinical signs indistinguishable from those of other bacterial causes; *Streptococcus equi* subsp *zooepidemicus* is associated with a particularly virulent course that can progress to death; *Pseudomonas*, *Escherichia coli*, *Klebsiella*, *Pasteurella*, *Streptococcus*, *Mycoplasma*, and other species equally likely.

RISK FACTORS

- Substandard hygienic conditions and overcrowding—encountered in some pet shops, shelters, research facilities, and boarding and training kennels.
- Coexisting subclinical airway disease—congenital anomalies; chronic bronchitis; bronchiectasis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- In systemically well dogs—parasitic bronchitis, irritant tracheobronchitis, tracheal foreign body, airway collapse.
- In a dog with systemic signs—fungal pneumonia, primary or metastatic neoplasia, congestive heart failure, migrating foreign body.
- Provisional diagnosis of infectious tracheobronchitis is made in a dog with compelling clinical signs and a history of exposure to the implicated organisms.
- See chapter, Cough.

CBC/BIOCHEMISTRY/URINALYSIS

- Early, mild leukopenia (5,000–6,000 cells/dL)—can be detected; suggests viral cause.
- Neutrophilic leukocytosis with a toxic left shift—frequently found with severe pneumonia.

OTHER LABORATORY TESTS

Pulse oximetry and arterial blood gas analysis—can reveal hypoxemia in pneumonia.

IMAGING

- Uncomplicated disease: radiographs—unremarkable; most useful for ruling out other differential diagnoses.
- Complicated disease: radiographs—interstitial and alveolar lung pattern with a cranoventral distribution typical of bacterial pneumonia; can see diffuse interstitial lung pattern typical of viral pneumonia; mixed lung pattern can be present.

DIAGNOSTIC PROCEDURES

- In cases with severe disease—ideally perform bronchoalveolar lavage via bronchoscopy for cytology and microbial culture; tracheal wash sample acceptable but increased likelihood for upper airway contamination.
- Antimicrobial sensitivity pattern of cultured bacteria—identification aids markedly in providing an effective treatment plan.
- PCR can be used to detect virus in BAL fluid, though there are limited reports of sensitivity and specificity.

PATHOLOGIC FINDINGS

- CPI—causes few to no clinical signs; lungs of infected dogs 6–10 days after exposure may contain pertracheal hemorrhages that are evenly distributed over the surfaces; detected by immunofluorescence in columnar epithelial cells of the bronchi and bronchioles 6–10 days after aerosol exposure.
- CAV-2—lesions confined to the respiratory system; large intranuclear inclusion bodies found in bronchial epithelial cells and alveolar septal cells; clinical signs tend to be mild and short-lasting; lesions persist for at least a month after infection.
- Canine influenza virus (H3N8)—fulminant disease characterized by secondary *Mycoplasma* infection and pulmonary hemorrhage.
- Canine respiratory coronavirus—characterized by marked inflammation of the trachea and nares with cilia loss in the former; detected by immunohistochemistry of the trachea or bronchioles.
- *Streptococcus equi* subsp *zooepidemicus* infection—acute, fibrinosuppurative pneumonia with large numbers of cocci found within the pulmonary parenchyma and, often, septic thromboemboli.
- Bordetellosis and severe bacterial infection—evidence of purulent bronchitis, tracheitis, and rhinitis with hyperemia and enlargement of the bronchial, mediastinal, and retropharyngeal lymph nodes; may see large numbers of Gram-positive or -negative organisms in the mucus of the tracheal and bronchial epithelium.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—strongly recommended for uncomplicated disease.
- Inpatient—strongly recommended for complicated disease and/or pneumonia.

(CONTINUED)

CANINE INFECTIOUS RESPIRATORY DISEASE

NURSING CARE

Fluid administration—indicated for complicated disease and/or pneumonia.

ACTIVITY

Enforced rest—14–21 days with uncomplicated disease; for at least the duration of radiographic evidence of pneumonia in severely affected dogs.

DIET

Good-quality commercial food

CLIENT EDUCATION

- Isolate patient from other animals; infected dogs can transmit the agent(s) before onset of clinical signs and afterward until immunity develops.
- Dogs with uncomplicated disease should respond to treatment in 10–14 days.
- Once infection spreads in a kennel, it can be controlled by evacuation for 1–2 weeks and disinfection with commonly used chemicals, such as sodium hypochlorite (1:30 dilution), chlorhexidine, and benzalkonium.

MEDICATIONS

DRUG(S) OF CHOICE

- Amoxicillin/clavulanic acid (12.5–25 mg/kg PO q12h) or doxycycline (5 mg/kg PO q12h)—initial treatment of uncomplicated disease.
- Penicillin (ampicillin 10–20 mg/kg IV q6–8h or ticarcillin 40–50 mg/kg IV q6–8h) with aminoglycoside (gentamicin 2–4 mg/kg IV, IM, SC q6–8h or amikacin 6.5 mg/kg IV, IM, SC q8h) or fluoroquinolone (enrofloxacin 5–10 mg/kg PO, IM, IV q24h)—usually effective for severe disease.
- Antimicrobial therapy—continue for at least 10 days beyond radiographic resolution.
- *B. bronchiseptica* and other resistant species—some antimicrobials may not reach adequate therapeutic concentrations in the lumen of the lower respiratory tract, so oral or parenteral administration may have limited effectiveness; nebulization with gentamicin (3–5 mg/kg) can decrease bacterial numbers when administered daily for 3–5 days. Use in conjunction with systemic antibiotics in dogs with parenchymal disease.
- Butorphanol (0.55 mg/kg PO q8–12h) or hydrocodone bitartrate (0.22 mg/kg PO q6–8h)—effective suppression of dry, non-productive cough not associated with bacterial infection.
- Bronchodilators (e.g., terbutaline 0.625–5 mg/dog q8–12h)—may use to control bronchospasm and wheeze.

CONTRAINDICATIONS

- Do not use cough suppressants in patients with pneumonia.
- Employ glucocorticoids only in cases with significant inflammatory disease refractory to conventional supportive care.

PRECAUTIONS

None

POSSIBLE INTERACTIONS

Fluoroquinolones and theophylline derivatives—concurrent use causes high and possibly toxic plasma theophylline concentration. Dose reduce theophylline while concurrently administering fluoroquinolones.

ALTERNATIVE DRUG(S)

None

FOLLOW-UP

PATIENT MONITORING

- Uncomplicated disease—should respond to treatment in 10–14 days; if patient continues to cough 14 days or more after establishment of an adequate treatment plan, question the diagnosis of uncomplicated disease.
- Complicated disease—repeat thoracic radiography until at least 7 days beyond resolution of all clinical signs.

PREVENTION/AVOIDANCE

Shedding of the causative agent(s) of infectious respiratory disease in airway secretions of dogs undoubtedly accounts for the persistence of this problem in kennels, animal shelters, boarding facilities, and veterinary hospitals.

Viral and Bacterial Vaccines

- Modified live CDV and CAV-2 vaccines provide reliable protection and are considered core vaccines for all puppies; can be administered at 6 weeks of age, every 2–4 weeks.
- *B. bronchiseptica* and CPiV vaccine—can vaccinate puppies mucosally or intranasally as early as 2–4 weeks of age without interference from maternal antibody and follow with annual revaccination; can vaccinate mature dogs with a one-dose intranasal vaccination (at the same time as their puppies or when they receive their annual vaccinations).
- Inactivated *B. bronchiseptica* parenteral vaccine—administered as two doses, 2–4 weeks apart; initial vaccination of puppies is recommended at or about 6–8 weeks of age; revaccinate at 4 months of age.
- Inactivated canine influenza vaccine available to reduce severity and duration of clinical signs, but considered noncore; can be administered starting at 6 weeks as two doses, 2–4 weeks apart. Results in seroconversion.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Natural course of uncomplicated disease, if untreated—10–14 days; simple restriction of exercise and prevention of excitement shortens the course.
- Typical course of severe disease—2–6 weeks; patients that die often

developed severe pneumonia that affected multiple lung lobes and multiple organ dysfunction due to sepsis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

May accompany other respiratory tract anomalies

AGE-RELATED FACTORS

Most severe in puppies 6 weeks–6 months old and in puppies from commercial pet shops and humane society shelters.

ZOONOTIC POTENTIAL

Potential zoonotic risk of *Streptococcus equi* subsp *zooepidemicus* reported in a single case report.

PREGNANCY/FERTILITY/BREEDING

High risk in dogs on extensive medical treatment; especially risky for dogs in overcrowded breeding facilities.

SYNOMYNS

Kennel cough, infectious tracheobronchitis—uncomplicated disease

ABBREVIATIONS

- CAV = canine adenovirus • CDV = canine distemper virus • CHV = canine herpes virus
- CPiV = canine parainfluenza

CANINE INFLUENZA

BASICS

OVERVIEW

- An acute to subacute contagious viral disease with an almost exclusive respiratory manifestation caused by canine influenza viruses (CIV), orthomyxoviruses with a direct genetic link to equine influenza virus H3N8 (US) or to avian H3N2 and H5N2 viruses (East Asia).
- Natural route of infection is airborne particles or oral contact with contaminated surfaces. Replication of the virus appears to be restricted to epithelial cells of the upper and lower airways with possible involvement of alveolar macrophages. Antibody response detectable by 8 days post-infection and titers remain detectable for > 1 year. Protective immune responses have not been defined.
- H3N8 CIV activity was first detected in all areas with greyhound racetracks in the United States in 2004. Virus is currently enzootic in non-racing dogs in the eastern seaboard from Connecticut to Virginia with sporadic incursions into other areas through the movement of infected dogs.
- H3N2 CIV was first detected in Korea in 2007, but existed in China several years earlier. Genetic lineage is of avian origin and probably arose in the live animal markets of East Asia.

SIGNALMENT

- Natural infections of H3N8 CIV currently limited to dogs: H3N2 virus is capable of infecting cats.
- All breeds of dog are susceptible and there is no age restriction on susceptibility.
- Greyhounds sometimes show more severe signs with H3N8 CIV infections, but factors other than breed may contribute to the disease pattern.
- H3N2 CIV infections show more severe clinical signs than H3N8 CIV.

SIGNS

- 60–80% of infected dogs develop clinical signs.
- Incubation period 2–4 days post-infection.
- Modest febrile response 39.4–40°C (103–104°F) 3–6 days post-infection.
- Clear nasal discharge, which can progress to thick, mucoid discharge, most frequently caused by secondary bacterial colonization.
- More severe form of disease shows higher temperatures with development of

pneumonia and increased respiration rate 6–10 days post-infection.

- Many dogs develop a cough that can last for several weeks.

CAUSES & RISK FACTORS

- Respiratory infection caused by canine influenza viruses.
- Most cases have a history of group housing: kennels, day care centers, and rescue shelters, or contact with dogs that have recently been in group housing.
- As CIV is a relatively new viral infection of dogs, virtually all dogs are susceptible.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- On an individual basis, the early signs of canine influenza are indistinguishable from signs of kennel cough.
- Distinction from typical respiratory pathogens of dogs is found in group settings in which 60–80% of dogs can show clinical signs.
- Later in disease course—pneumonia may develop with or without secondary bacterial infections.

CBC/BIOCHEMISTRY/URINALYSIS

- Generally normal.
- CBC may reflect stress initially, then bacterial pneumonia later in disease (leukocytosis, left shift).

OTHER LABORATORY TESTS

Hemagglutination inhibition test on serum can be used to assess exposure to CIV.

DIAGNOSTIC PROCEDURES

- In acute phase of disease (1–3 days post-onset of clinical signs), a nasal swab may be used to detect the agent by a RT-PCR test or viral isolation.
- More than 7 days post-onset of clinical signs—serum collected for hemagglutination inhibition test can determine exposure to CIV.
- Antigen-capture ELISA tests—give unacceptable levels of false negatives.

PATHOLOGIC FINDINGS

Primary lesion caused by the infection is the destruction of the ciliated epithelial cell layer in the upper airways with extension into the lungs. Areas of lung consolidation can be found 6–10 days post-infection.

TREATMENT

- Affected animals should be managed to prevent infection of other dogs.
- Contagious period for CIV extends to approximately 6 days post-onset of clinical signs.
- Continued coughing of affected animal beyond 6 days is not a sign of virus shed.
- Strongly recommend treating uncomplicated cases as outpatients to prevent hospital contamination.
- Only hospitalize those with pneumonia that require IV fluid support.
- Enforced rest—for at least 14–21 days (uncomplicated cases); 2 months in cases of pneumonia.
- If dogs develop *Bordetella bronchiseptica* bacterial pneumonia, they may be infectious for this bacterium even up to months after recovery.

MEDICATIONS

- Antiviral drugs have not been tested for efficacy.
- Treatment with broad-spectrum antibiotics may be necessary to prevent and control secondary bacterial infections—amoxicillin/clavulanic acid, doxycycline, or trimethoprim-sulfadiazine.
- Severe cases, resistant to first-choice antibiotic therapies above—combination therapy of an aminoglycoside (gentamicin or amikacin) with a cephalosporin (cefazolin). May use enrofloxacin as alternative to gentamicin.
- In severe cases (bronchopneumonia)—continue antibiotic therapy at least 2 weeks past radiographic resolution of signs.
- Resistant bacteria (*B. bronchiseptica* and others)—important to culture and establish the bacterial sensitivity; may need to deliver antibiotics by nebulization (kanamycin 250 mg; gentamicin 50 mg; polymixin B 333,000 IU) for 3–5 days.
- Cough suppressants (butorphanol or hydrocodone bitartrate)—often effective in suppressing a dry non-productive cough.
- Bronchodilators (theophylline or aminophylline)—offer little help but may relieve wheezing.

(CONTINUED)

FOLLOW-UP

- If infection is established in a kennel situation, evacuate the kennel for 1–2 weeks and disinfect with sodium hypochlorite (1:30 dilution), chlorhexidine, or benzalkonium.
- Uncomplicated cases should resolve within 10–14 days; if patient continues to cough beyond 14 days, question the diagnosis of uncomplicated disease.
- Dogs recovering from *B. bronchiseptica* infection are immune for at least 6 months.
- Mortality rate is highly variable and is most likely linked to the degree of secondary bacterial infection, strain of virus, and intensity of veterinary care.

- Currently there are two licensed vaccine for H3N8 CIV for use in dogs.

MISCELLANEOUS

ZOONOTIC POTENTIAL

There is no evidence to indicate that CIV can infect humans.

RISK TO OTHER ANIMALS

Given the close genetic link to equine H3N8, there is the potential for H3N8 CIV to infect horses. Cats can be experimentally infected with H3N8 CIV; H3N2 virus was isolated from cats in an animal shelter.

CANINE INFLUENZA

ABBREVIATIONS

- CIV = canine influenza virus
- ELISA = enzyme-linked immunosorbent assay
- HI = hemagglutination inhibition assay
- RT-PCR = reverse transcriptase polymerase chain reaction

C

C CANINE PARVOVIRUS INFECTION

BASICS

DEFINITION

- CPV-2 infection is an acute systemic illness characterized by vomiting and hemorrhagic enteritis.
- Often fatal in pups, that may collapse in a “shock-like” state and die suddenly without enteric signs, after only a brief period of illness.
- The myocardial form was observed in pups during the early outbreaks in the late 1970s when the dog population was fully susceptible, and is now rare.
- Most pups are now protected against neonatal infection by maternal antibodies.
- Monoclonal antibodies have revealed antigenic changes in CPV-2 since its emergence in 1978 and CPV2a, b, and c strains have been identified.
- The original virus is now virtually extinct in the domestic dog population.
- CPV2c viruses are more virulent than the original isolates, and case mortality rates appear to be higher than in the earliest outbreaks.

PATOPHYSIOLOGY

- CPV-2 is very closely related to feline panleukopenia virus (FPV) and several other parvoviruses that infect carnivores.
- Parvoviruses, including CPV-2, require actively dividing cells for growth.
- After ingestion of virus there is a 2- to 4-day period of viremia, with concomitant growth in lymphatic tissues throughout the body.
- Early lymphatic infection is accompanied by lymphopenia and precedes intestinal infection and clinical signs.
- By the third post-infection (PI) day, the rapidly dividing crypt cells of the small intestine are infected.
- Viral shedding in the feces starts ~3–4 days PI, and peaks about the time clinical signs first appear.
- Virus ceases to be shed in detectable amounts by PI days 8–12.
- Absorption of bacterial endotoxins from the damaged intestinal mucosa is believed to play a role in CPV-2 disease.
- Intensity of illness appears to be related to the viral dose and the antigenic type.

SYSTEMS AFFECTED

- Cardiovascular—myocarditis with sudden death (now rare).
- Gastrointestinal—small intestinal crypt cells and adjacent mucosal epithelium; severe hemorrhagic diarrhea, vomiting, dehydration; hypovolemic and septic/endotoxic shock.
- Hemic/Lymphatic/Immune—thymus, lymph nodes, spleen, Peyer's patches.

GENETICS

Unknown

INCIDENCE/PREVALENCE

Most common in breeding kennels, animal shelters, pet stores, or wherever pups are reared. Rates vary.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog

Breed Predilections

Certain breeds have been shown to be at increased risk for severe CPV enteritis, including rottweiler, doberman pinscher, American pit bull terrier, Labrador retriever, German shepherd, and Yorkshire terrier. A recent Australian study demonstrated higher case fatality rates in hounds, gundogs and non-sporting pedigree groups than in mixed breed dogs.

Mean Age and Range

- Illness may occur at any age.
- Most severe illness occurs in pups 6–24 weeks of age.

Predominant Sex

None

SIGNS

General Comments

Suspect CPV-2 infection whenever pups have an enteric illness, especially with sudden onset lethargy, vomiting, and/or diarrhea.

Historical Findings

- Sudden onset of bloody diarrhea, anorexia, and repeated episodes of vomiting.
- Rapid weight loss.
- Some pups may collapse in a shock-like state and die without enteric signs.
- In breeding kennels, several littermate pups may become ill simultaneously or within a short period of time.
- Occasionally, one or two pups in a litter have minimal or no signs, followed by the death of littermates that presumably encounter greater amounts of virus.

Physical Examination Findings

- Dehydration, weight loss and abdominal discomfort are consistent features.
- Often there is severe hemorrhagic diarrhea.
- Fluid-filled intestinal loops may be palpated.
- Occasionally enlarged mesenteric lymph nodes are palpable.
- May have fever or hypothermia.

CAUSES

Canine parvovirus

RISK FACTORS

- Unvaccinated dogs from kennels, animal shelters, pet shops, or elsewhere where dogs have congregated.
- Pups < 4 months of age are at higher risk of severe infection.
- Co-pathogens such as parasites, viruses, and certain bacterial species (e.g., *Campylobacter* spp., *Clostridium* spp.) are hypothesized to exacerbate illness.
- Severe, often fatal, parvoviral infections have been demonstrated in pups exposed simultaneously to CPV-2 and canine coronavirus.
- Crowding and poor sanitation increases the risk of infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Canine coronavirus infection
- Salmonellosis; colibacillosis; other enteric bacterial infections
- Gastrointestinal foreign bodies
- Gastrointestinal parasites
- Hemorrhagic gastroenteritis
- Intussusception
- Toxin ingestion

CBC/BIOCHEMISTRY/URINALYSIS

- Lymphopenia—characteristic of CPV-2 infection; commonly occurs between PI days 4–6.
- Severely affected dogs often exhibit severe neutropenia concurrently with the onset of intestinal damage.
- Hemograms are an important part of the diagnostic regimen.
- Leukocytosis is common during recovery.
- Serum chemistry profiles help assess electrolyte disturbances (especially hypokalemia), the presence of azotemia associated with dehydration, panhypoproteinemia, and hypoglycemia.

OTHER LABORATORY TESTS

Serologic tests are not diagnostic because dogs often have high titers from vaccination and/or maternal antibodies.

IMAGING

- Abdominal radiographs often reveal generalized small intestinal ileus; exercise caution to prevent misdiagnosis of an intestinal obstruction.
- Typical ultrasonographic changes include fluid-filled, atonic small and large intestines; duodenal and jejunal mucosal layer thinning with or without indistinct wall layers and irregular luminal-mucosal surfaces; extensive duodenal and/or jejunal hyperechoic mucosal speckling; and duodenal and/or jejunal corrugations.
- Intussusceptions can also occur.

DIAGNOSTIC PROCEDURES

- May detect virus antigen in stool or intestinal contents at the onset of disease and for 2–4 days afterward by use of commercial solid phase ELISA assays in which sensitivity and specificity appear high.
- Electron microscopy is another method of detecting fecal virus during the early stages of infection.
- Samples for virus detection should be submitted during the acute phase of infection; ship specimens refrigerated, not frozen.

PATHOLOGIC FINDINGS

- Gross changes include subserosal congestion and hemorrhage or frank hemorrhage into the small intestinal lumen.
- Some dogs exhibit intestines that are empty or contain yellow or blood-tinged fluid.
- Mesenteric lymph nodes are often enlarged and edematous, with hemorrhages in the cortex.
- Thymic atrophy is common in young dogs.
- Pulmonary edema and hydropericardium may be the only gross change in pups with myocarditis and acute heart failure.
- Histopathology reveals

(CONTINUED)

CANINE PARVOVIRUS INFECTION

C

intestinal inflammation and necrosis, with severe villus atrophy.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Symptomatic and supportive (refer to sections on treatment of acute vomiting, acute diarrhea, and hemorrhagic gastroenteritis). Therapies include intravenous fluids, antibiotics, antiemetics and analgesics.
- Intensity depends on the severity of signs on examination. • Goals are to provide intestinal nutrients, restore and maintain fluid and electrolyte balance, and resolve shock, sepsis and endotoxemia. • Prompt, intensive in-patient care leads to treatment success.
- Proper, strict isolation procedures are essential. • Exercise care to prevent the spread of CPV-2, a very stable virus.

NURSING CARE

- Hospitalize patients and monitor for dehydration and electrolyte imbalance.
- Fluids are usually supplemented with potassium chloride, 5% dextrose, and possibly sodium bicarbonate (if severe metabolic acidosis).

ACTIVITY

Restrict until symptoms abate.

DIET

Puppies receiving early enteral nutrition via a nasoesophageal tube, compared to puppies that received nil PO until vomiting cease, show earlier clinical improvement, significant weight gain, as well as improved gut barrier function, which could limit bacterial or endotoxin translocation.

CLIENT EDUCATION

- Inform about the need for thorough disinfection, especially if other dogs are on the premises. Strict sanitation is essential. • A 1:30 dilution of bleach (5% sodium hypochlorite) destroys CPV-2 in a few minutes. • If possible, isolate pups until they reach 3 months of age and vaccinate repeatedly; typical protocol involve vaccination at 6, 9, and 12 weeks of age.
- Pups can be infected with virulent virus before any vaccine will engender immunity.
- CPV-2 is shed for less than 2 weeks after infection; no carrier state has been substantiated.

SURGICAL CONSIDERATIONS

- Exercise caution to prevent misdiagnosis of an intestinal obstruction, especially if vomiting is the only clinical sign. • Although uncommon, intussusceptions can occur.

**MEDICATIONS**

Refer to sections on treatment and management of acute vomiting, acute diarrhea, and hemorrhagic gastroenteritis.

DRUGS OF CHOICE

Additional recommended drugs include parenteral antibiotics (ampicillin and gentamicin) and antiemetics (e.g., ondansetron, maropitant).

PRECAUTIONS

Gentamicin can cause renal toxicity in dehydrated puppies.

**FOLLOW-UP****PATIENT MONITORING**

There seems to be an increased incidence of discospondylitis in pups that had parvovirus infection.

PREVENTION/AVOIDANCE

- Inactivated and live vaccines are available for prophylaxis and vaccines differ in their capacity to immunize pups with maternal antibodies. • Results of a recent study indicated that vaccination with a modified live vaccine at 4 weeks of age in pups with high maternally-derived antibody concentrations resulted in seroconversion rates of up to 80% that may lead to a reduction in the window of susceptibility with respect to CPV infection and might be used as an adjunct control method in contaminated environments. • Control of CPV-2 requires efficacious vaccines, isolation of puppies, and stringent hygiene.

POSSIBLE COMPLICATIONS

- Septicemia/endotoxemia • Secondary bacterial pneumonia • Intussusception • Discospondylitis

EXPECTED COURSE AND PROGNOSIS

• Prognosis is guarded in severely affected puppies. • Prognosis is good for dogs that receive prompt initial treatment and survive the initial crisis of illness—approximately 80% survival rate. • A patient is likely to have a poor prognosis if it is purebred, has a low bodyweight, and, after 24 hours of intensive therapy, the following biomarker levels are present: severe persistent leuko- and lymphopenia, a persistently elevated or rising serum cortisol concentration ($> 8.1 \text{ ug/dL}$), severe hypothyroxinemia ($< 0.2 \text{ ug/dL}$), hypocholesterolemia ($< 100 \text{ mg/dL}$), and persistently elevated serum CRP ($> 97.3 \text{ mg/L}$) and/or TNF concentrations.

• Conversely, the literature would suggest that puppies with a good prognosis are those that are of mixed breed, > 6 months old, and show the following biomarker values: total leukocyte count $> 4.5 \times 10^3/\mu\text{L}$, lymphocyte

count $> 1 \times 10^3/\mu\text{L}$, and mature neutrophil count $> 3 \times 10^3/\mu\text{L}$, all associated with a 100% survival when measured at 24 hours post-admission; a serum cortisol $< 8.1 \text{ ug/dL}$ is associated with a 96% survival when measured at 48 hours after admission and a serum thyroxine concentration $> 0.2 \text{ ug/dL}$ associated with 100% survival when measured at 24 hours after admission as well as a HDL-cholesterol of $> 50.2 \text{ mg/dL}$ is associated with a 100% survival when measured at admission.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Coinfection with intestinal helminths and *Giardia* are indicative of unhygienic housing conditions and can worsen the clinical picture and contribute to morbidity if not treated.

AGE-RELATED FACTORS

Infection is less likely in dogs older than 1 year of age, but can still occur, especially if the dogs are unvaccinated.

ZOONOTIC POTENTIAL

Parvovirus per se is not zoonotic, but these puppies may harbour coinfections with *Giardia* parasites which can be zoonotic.

PREGNANCY/FERTILITY/BREEDING

Pregnant animals are likely to abort due to the septicemia.

C CANINE SCHISTOSOMIASIS (HETEROBILHARZIASIS)

BASICS

OVERVIEW

- *Heterobilharzia americanum* schistosomatid parasite of raccoons.
- Eggs passed in the feces of raccoons hatch to release miracidia that penetrate freshwater snail hosts. After a period of development and asexual multiplication, the snails release cercariae that infect the next host (can be dogs) by skin penetration. After penetrating the skin, the larvae undergo a migration to the lung and then make their way to the mesenteric veins, where separate males and females form pairs. Eggs laid by female worms are carried to the intestinal wall, where they erode their way through to the lumen to be passed in the feces. Other eggs are carried to the liver or other organs by the bloodstream, where they lodge and cause granulomatous disease.
- Dogs infected when in contact with freshwater containing cercariae.
- Restricted to raccoons in southeastern United States; canine cases reported from Kansas, North Carolina, Florida, Louisiana, and Texas.

SIGNALMENT

Dogs, typically adult, that have access to swampy areas or bayous.

SIGNS

- Lethargy (most common sign), weight loss, and decreased appetite are the most common sign at presentation.
- Other signs include vomiting, diarrhea, anorexia, and polyuria/polydipsia; more rarely melena and borborygmus.

CAUSES & RISK FACTORS

Swimming in freshwater in areas contaminated with cercariae from miracidia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Coccidiosis
- Bacterial diarrhea
- Viral enteritis

CBC/BIOCHEMISTRY/URINALYSIS

- Mild anemia and eosinophilia
- Proteinuria
- Hypercalcemia

OTHER LABORATORY TESTS

ELISA—performed by private laboratory, College of Veterinary Medicine, North Carolina State University.

IMAGING

Contrast radiographs and ultrasound may reveal thickened bowel walls; calcified eggs disseminated into tissues may give the false impression of soft-tissue mineralization.

DIAGNOSTIC PROCEDURES

- Eggs with miracidia can be identified in feces, but feces must be kept in saline—not water—or miracidia will spontaneously hatch, making diagnosis impossible.
- Fecal sedimentation methods are preferred to fecal flotation. Routine fecal flotation will not detect these heavy eggs; if used, requires flotation with sugar solution of specific gravity 1.3.
- Several cases have been diagnosed after laparotomy.
- PCR on feces for DNA detection (Texas A&M Gastrointestinal Laboratory).

TREATMENT

Inpatient care for the first few days of treatment is probably warranted, as the response to worm kill may require supportive care.

MEDICATIONS

DRUG(S)

- Praziquantel (50 mg/kg, PO, once)
- Fenbendazole (50 mg/kg PO q24h for 10 days)

FOLLOW-UP

Check feces after 12 months to ensure that it does not contain eggs.

MISCELLANEOUS

In Japan and other countries with endemic *Schistosoma japonicum*, dogs can be infected with this human and zoonotic species.

ZOONOTIC POTENTIAL

Stages in the dog pose no threat to staff or owners. People entering the same waterways could develop lesions.

SYNONYM

Schistosomiasis

ABBREVIATION

ELISA = enzyme-linked immunosorbent assay

CAPILLARIASIS (PEARSONEMA)

BASICS

OVERVIEW

- *Pearsonema* and *Capillaria* are used interchangeably and appear to be identical in taxonomy and biologic behavior.
- *Pearsonema (Capillaria) plica* are small, thread-like, yellowish parasites that invade the mucosa or submucosa of the bladder and rarely the renal pelvis and ureter causing a mild inflammatory response.
- *P. plica* in dogs and cats and *P. feliscati* in cats have been uncommonly associated with signs of lower urinary tract disease.
- *P. plica* passes ova with bipolar plugs in urine. After earthworms ingest embryonated ova, the parasite develops into the infective stage. Ingestion of an infective earthworm results in a patent infection in dogs in 58–88 days. Some investigators have provided evidence of a direct life cycle.
- The life cycle of *P. feliscati* is poorly understood.

SIGNALMENT

- Dogs—no predilection reported. Reported in dogs, foxes, coyotes, raccoons, martens, mink, badgers, otters, bobcats, weasels, and wolves.
- Cats—affected cats almost always > 8 months old.

SIGNS

- Usually none.
- Pollakiuria, hematuria, stranguria, and dysuria in heavily infected animals.

CAUSES & RISK FACTORS

Dogs

- High prevalence of infection (up to 50%) in the natural hosts (e.g., foxes, raccoons) in the southeastern United States may predispose animals in this geographic region.
- In kennels, high infection rates are associated with contaminated soil surfaces.

Cats

Rare in United States; infection prevalence of 18–34% is reported in Australia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Consider other, more common causes of lower urinary tract disease, such as urolithiasis, urinary tract infection, trauma, and neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

- Colorless, slightly pitted ova with bipolar plugs in urine sediment are diagnostic.
- Consider the possibility of fecal contamination of urine with *Trichuris vulpis* or other morphologically similar ova if free-catch urine specimens are used, or if inadvertent rectal puncture and aspiration of feces with *T. vulpis* occurs during cystocentesis.
- Alternatively, in an affected animal, urine contamination of feces can produce false fecal examination findings.
- Symptomatic infections are usually associated with evidence of inflammation (red blood cells, white cells, and proteinuria). Bacterial urine cultures are typically sterile.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Infection is usually self-limiting in both cats and dogs.
- If infected dogs are isolated, after 10–12 weeks ova are no longer detectable in the urine sediment.
- Replacing soil surfaces with sand, gravel, or concrete may reduce prevalence of infection in kennels contaminated with *P. plica* and *P. feliscati*.

MEDICATIONS

DRUG(S)

- Consider anthelmintic therapy if clinical signs are present and persist; monitor therapeutic success by examining urine sediment for ova and observing status of clinical signs.
- Multiple courses of treatment may be necessary to eliminate the infection.

- Fenbendazole (50 mg/kg PO q24h for 3 days) has been reported to result in disappearance of ova from urine sediment in dogs and cats.

- Ivermectin (0.2 mg/kg SC once) has been suggested as an alternative therapy, but objective information on its efficacy in this disease is limited.
- Oral treatment with albendazole (50 mg/kg PO q12h for 30 days) was reported to be effective in dogs.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Monitor treatment success by examining urine sediment for ova and observing status of clinical signs.
- In the absence of reinfection, urinary capillariasis may be self-limiting. Therefore, isolation of dogs and cats from earthworms should be sufficient to eliminate a *Capillaria* bladder infection in 90 days.

MISCELLANEOUS

PUBLIC HEALTH RISK

Capillaria spp. pose no known public health risks.

SYNONYMS

Pearsonema

CAR RIDE ANXIETY—DOGS AND CATS

BASICS

DEFINITION

Car ride anxiety is excessive or disruptive distress, fear or panic associated with vehicle travel. Anxiety exhibited during travel can be mistaken for excitement or enthusiasm.

PATHOPHYSIOLOGY

The pathophysiology of car ride anxiety is often unknown or cannot be definitively determined. Lack of car ride experiences, generalized anxiety disorder or lessons learned from previous experiences; underlying nausea, a traumatic event during travel (e.g., accident or storms) or experiences with poor drivers during a car ride can result in acute or chronic car ride anxiety.

SYSTEMS AFFECTED

- Behavioral
- Gastrointestinal
- Neuromuscular

GENETICS

May be a genetic basis but early experience is probably the more significant contributor.

INCIDENCE/PREVALENCE

The incidence/prevalence of car ride anxiety is unknown and may be underreported. Owners may desire to take pets to destinations (e.g., veterinary visits, grooming, boarding, or training) but anxiety may prevent travel, even for important medical care.

SIGNALMENT

Dog and cat

Breed Predilections

None

Mean Age and Range

Any. Young or ill animals may be predisposed to motion sickness.

Predominant Sex

None

SIGNS

Historical Findings

- Signs of fear and anxiety vary between individuals.
- Frequent owner complaints include: pacing, restlessness, inappetance, vigilance, excitability and vocalization.
- Distress vocalization by dogs may include whining or high-pitched barking.
- Cats may growl, hiss, meow or yowl.
- Locomotion signs of fear and anxiety vary between individuals: some animals may pace while another may remain immobile. Immobility should not be mistaken for calmness.
- Owner reports may not identify all symptoms of anxiety and those that interfere with the driver may be reported more than those symptoms that result in freezing.
- Owners may report their cat's troublesome behaviors such as vocalization, vomiting, or

elimination in the carrier while overlooking the association with car ride anxiety.

- Owners often transport cats in carriers, so severe anxiety that manifests as freezing may be under recognized. Similarly, a large dog pacing or panicking in a car might draw more attention while even severe anxiety displayed by a small dog may be under recognized.

Physiologic and physical signs

Physiologic signs include panting, rapid heart rate, drooling, urination, vomiting, and defecation.

Physical Examination

No abnormal findings unless underlying medical problems

CAUSES AND RISK FACTORS

- Behavioral causes for car ride anxiety include: unruliness, limited prior experience outside the home; inadequate prior experience traveling; insufficient adaptation to carriers, leashes or restraint devices; fear and reactivity to visual stimulus such as people, animals, bikes or cars; and generalized anxiety.
- Prior stressful car rides or fearful consequences such as veterinary visits or shelter relinquishment may contribute to learning and exacerbate car ride anxiety.
- Traumatic events such as sudden stops or car accidents.
- Medical conditions may influence progression or manifest as car ride anxiety. Motion sickness, musculoskeletal pain or discomfort, osteoarthritis, dental disease or pain, gastrointestinal upset, and sensory hypersensitivity may all exacerbate travel anxiety.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fear and anxiety-related behaviors.
- Manifestation of pain, nausea or physical discomfort.
- Acute onset or abrupt change in car ride anxiety warrants a complete physical examination to consider possible contributory medical conditions.

CBC/BIOCHEMISTRY/URINALYSIS

Only if indicated by clinical signs

IMAGING

Only if indicated by clinical signs

OTHER LABORATORY TESTS

Only if indicated by clinical signs

TREATMENT

ACTIVITY

Normal. Recommend adequate exercise and play before car ride.

DIET

- Normal.
- Provision of highly palatable foods during car travel may distract, reduce stress, and promote a positive association with car travel.
- If the pet has experienced nausea or vomiting in association with car travel then fasting is recommended.

CLIENT EDUCATION

A complete behavior program includes environmental management, anxiety reduction and behavior modification.

Compassion

Give thoughtful preparation and consideration for the pet's perspective before traveling. Avoid reprimands or scolding for fear-related behaviors. Allow enough time for travel and be patient. Anticipate and avoid evoking the pet's fears to prevent exacerbating established fears. For example: when carrying a pet inside a carrier, consider their view point and the unsettling motion which may be experienced. Avoid forcing a crated animal to be adjacent to an animal which may show aggression.

Management and safety

Provide stable footing and secure resting locations. Consider crating if pet is already acclimated to crate confinement. Seat belts, barriers and seat slings can also be beneficial. Unruly, hypervigilant or excitable dogs may benefit from a head halter or front attaching body harness. Animals should never receive corrections from shock, prong, or choke collars while traveling.

Anxiety reduction

Multimodal comforting and anxiolytic support provides the best outcome. Restricting views using window shades, covered crates or solid wall carriers may alleviate visual reactivity. The effect of visual stimuli may be reduced by use of a ThunderCap, a sheer panel of fabric which is worn over the cat's or dog's eyes to filter visual stimuli. Some dogs may wear Doggles to reduce the impact of visual stimuli. Psychoacoustically designed music (e.g., Through a Dog's Ear; Through a Cat's Ear) utilizes principle of simple sound intentionally selected, arranged and recorded to provide useful auditory assimilation. Classical music may also be calming. Music therapy may also obscure perception of fear-evoking sounds. Comforting pressure wraps apply a gentle, constant pressure on a dog's torso (e.g., Anxiety Wrap, ThunderShirt) which may alleviate anxiety. Synthetic pheromone analogues (Adaptil, Feliway) may also reduce anxiety. Anxiety-reducing supplements or medications should be considered, especially for severe or persistent anxiety.

Behavior modification

Rehearse settle and relax positions when not traveling. Teach the dog to get in and out of the car by positive reinforcement (e.g., food

Midazolam	up to 0.2 mg/kg IV, IM, SC	up to 0.2 mg/kg IV, IM, SC
Oxazepam	0.2–1 mg/kg PO q12–24h	0.2–0.5 mg/kg PO 12–24h

or toy reward). Teach cats and small dogs to go in and out of carriers willingly. Practice training sessions when travel is not imminent. Use positive reinforcement training methods and avoid reprimand or intimidation training. Cats and small dogs should be acclimated to the motion of being in a carrier that is being carried. During travel, provide comforting activities: chew toys, food chews or feeding puzzles. These activities may distract the pet, reduce anxiety or even countercondition the pet to enjoy car rides.

MEDICATIONS

DRUG(S) OF CHOICE

General Comments

- Psychotropic medications, supplements or pheromones may be a beneficial or even a necessary adjunct to the behavior program. Short-acting anxiolytics are appropriate for pets travelling occasionally. Administer anxiolytics such that optimal effect precedes the onset of mild to moderate anxiety and distress. The effect of all anxiolytics may be overcome by severe anxiety or distress. Extreme distress may not be completely manageable by medication. Low doses for mild anxiety may be very safe, but high or repeated doses, extreme anxiety, and other medical conditions increase the risk for profound sedation and drug interactions.
- Correction based training or management strategies such as verbal reprimands, shock collars and other forms of punishment should not be utilized in conjunction with anxiolytic medications.
- Address concurrent behavioral conditions (e.g. Separation Distress Syndrome; Fears, Phobias, and Anxieties) that may warrant longer-acting anxiolytics (e.g. TCAs or SSRIs) to treat pets with multiple manifestations of anxieties in addition to travel-related anxiety. See Table 1.

Benzodiazepines

- Potentiate the effects of GABA an inhibitory neurotransmitter.

- Give 30–60 minutes prior to travel and titrate to effect with future travel based on therapeutic response as time to onset, dose, and duration of effect will vary.
- Side effects might include sedation, hyperphagia, muscle relaxation, and an amnesia effect.
- An amnesia effect may be desirable for traumatic car rides but may interfere with learning during purposeful behavior modification sessions.
- Hyperphagia may be advantageous for pets with stress anorexia especially if food is offered as part of the behavior modification program.
- Clonazepam, oxazepam, and lorazepam have no active intermediate metabolites and may be safer when hepatic function is compromised. Midazolam is available as injectable medication that may be useful if administered when the pet is leaving the veterinary hospital and rapid onset is desired.

Maropitant

- NK-1 neurokinin receptor antagonist.
- Canine dose for motion sickness: 8 mg/kg PO 2 hours before travel every 24 hours for up to 2 days in a row. The dose for motion sickness is higher than the antiemetics dose. Fast 1 hour prior to administration. Avoid high fat foods.
- Feline dose for emesis: 1 mg/kg SC daily for up to 5 days.

Trazodone

Serotonin receptor antagonist and reuptake inhibitor (SARI). Dog: 2–10 mg/kg PO. Begin at 2–5 mg/kg and titrate upward to 5–10 mg/kg based on effect and tolerance. Even higher doses may be utilized by experienced clinicians. Absorption is more rapid in fasted subjects, with peak blood concentrations occurring approximately 1 hour after administration versus 2 hours with food.

Acepromazine

- Antipsychotic.
- Dog and cat: 0.55–2.2 mg/kg PO. Sedative but not anxiolytic. Consider combination with an anxiolytic (e.g., a benzodiazepine, pheromones).
- Poor choice for monotherapy.

Pheromone

Feliway or Adaptil sprayed onto a blanket or into the pet's carrier.

Natural supplements

- Anxitane, Composure, Harmonease, and Zylkene may exert an anxiolytic effect.
- Lavender essential oils may have a calming effect in dogs but avoid lavender for cats since floral scents may be aversive to cats.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Caution should be used when combining drugs that enhance serotonin transmission (e.g trazodone, SSRIs, TCAs) which may pose an increased risk for serotonin syndrome.

PRECAUTIONS

- All listed medications are considered extra-label or off-label (except Cerenia).
- Benzodiazepines: May cause sedation, paradoxical excitability, incoordination and amnesia that might interfere with learning during behavior modification. Diazepam has been associated with acute liver failure in rare cases in cats.
- Trazodone: Potential adverse effects: sedation; lethargy; incoordination; cardiac conduction disturbances; increased anxiety.
- Clonidine: Use with caution in patients with cardiac disease or compromised liver or kidney function.
- Acepromazine: ataxia, inhibits thermoregulation, peripheral vasodilation, muscle tremor or spasm, decreased social behaviors.

ALTERNATIVE DRUG(S)**Clonidine**

- An alpha-2 agonist, antihypertensive agent, which might be used alone or together with ongoing medications such as an SSRI or a TCA, in the treatment of anxiety.
- Dog: 0.01–0.05 mg/kg PO. Begin at low dose and titrate to the most effective dose if not sufficiently effective. Maximum effect may take one-half to two hours with faster absorption on an empty stomach.
- Cat: Dose not established.

CAR RIDE ANXIETY—DOGS AND CATS

(CONTINUED)

Trazodone

Cats: Although not extensively evaluated, trazodone dosing for cats of 25–100 mg/cat may warrant consideration for car travel.

**FOLLOW-UP****PATIENT MONITORING**

Ask about travel-related distress as part of overall wellness assessment, and recommend early intervention and prevention.

Travel-related difficulties pose a barrier for bringing pets to the veterinary hospital.

PREVENTION/AVOIDANCE

May be necessary to avoid travel for severely affected pets.

EXPECTED COURSE AND PROGNOSIS

May habituate spontaneously but more likely to worsen if untreated.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Generalized anxiety disorder, noise-related fears and phobias, separation anxiety related distress, hyper attachment.

AGE-RELATED FACTORS

Cognitive decline may exacerbate anxiety.

ZOONOTIC POTENTIAL

A distressed pet may cause distraction and put drivers at risk for automobile accidents.

PREGNANCY/FERTILITY/BREEDING

Drug use in breeding, pregnant or lactating animals should be avoided. Distress during pregnancy may adversely affect the neurologic development of the unborn offspring.

SEE ALSO

CARBON MONOXIDE TOXICOSIS

BASICS

OVERVIEW

- Carbon monoxide (CO)—odorless, colorless, non-irritating gas produced by inefficient combustion of carbonaceous fuels.
- Common sources are fires, automotive exhaust, and leaking coal, oil, or natural gas/propane furnaces, gas appliances or fireplaces, and some paint strippers or paint sprays. • Absorbed into the blood, forming carboxyhemoglobin (COHb) and reducing blood oxygen, causing hypoxia of brain and heart. • Lethal concentration is approximately 1,000 ppm (0.1%) for 1 hour. • Affinity of CO for hemoglobin is approximately 240 times that of oxygen. • Carboxyhemoglobin cannot bind oxygen and impairs release of oxygen from remaining hemoglobin. • Major effect is acute cellular hypoxia leading to death. • Survivors may have cardiac necrosis, brain damage, or delayed neurotoxicity.

SIGNALMENT

- Dogs and cats are equally susceptible.
- Exposures from fossil fuel heater malfunction, radiant heaters, gas/wood fireplaces or stoves may affect humans and pets living in the same space. • Other high-risk areas are kennels using unvented gas or kerosene heaters in poorly ventilated buildings, and transport in vehicles with exhaust leaks.

SIGNS

Historical Findings

- Exposure to automobile exhaust indoors or fumes from indoor carbon-based fuel heating devices for 5–10 minutes. • Building fires produce high concentrations of CO that cause death quickly.

Physical Findings

Acute Exposure

- Acute signs progress within minutes to hours and include drowsiness, lethargy, decreased mentation, and weakness.
- Tachycardia and tachypnea commonly occur. • Dyspnea and clonic seizures can precede depression. • Deafness, incoordination, and coma signal fatal outcome. • Hypotension, arrhythmia, premature ventricular contractions, and acidosis develop. • Red skin and mucous membranes are rarely apparent in animals.

Chronic Exposure

- Chronic exposure can cause nausea, vomiting, acidosis, and cough; may mimic “flu” or infectious disease. • Low exercise tolerance. • Disturbance of postural and position reflexes and gait also follow chronic moderate exposure. • Deafness of variable persistence may occur in survivors.

CAUSES & RISK FACTORS

- Incomplete combustion of carbon fuels.
- Poor ventilation or blocked exhaust vents or chimneys. • Automobile exhaust in closed spaces. • Unvented/faulty furnaces, gas appliances, kerosene space heaters.
- Fires—carbon monoxide may reach 10% inside a burning building. • Animals with impaired cardiac or pulmonary function.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Barbiturate, ethanol, ethylene glycol, petroleum hydrocarbons, lead poisoning; cyanide, or hydrogen sulfide gas toxicosis
- Smoke inhalation, cerebral hemorrhage or neoplasia, and metabolic disease.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC, serum biochemistry profile, urinalysis, blood gases, and anion gap.
- Creatine kinase—high due to muscle ischemia. • ECG. • Pulse oximetry may overestimate saturated hemoglobin because carboxyhemoglobin and oxyhemoglobin absorb light at the same wavelength.

OTHER LABORATORY TESTS

- Carboxyhemoglobin percentage in whole blood; may return to normal levels within a few hours after carbon monoxide exposure stops. Know advance location of a carboxyhemoglobin lab, either human or veterinary. • Blood pH is lower than normal due to metabolic acidosis. • Acidemia and increased lactate in blood. • Pa_O₂—normal, but not indicative of oxyhemoglobin saturation.

DIAGNOSTIC PROCEDURES

ECG—ST-T wave changes consistent with myocardial hypoxia/anoxia may be present.

TREATMENT

- Restore adequate oxygen to brain and heart.
- Supplemental 100% oxygen via endotracheal tube—promotes four-fold faster recovery against ability of CO to bind haemoglobin. • Eucapnic hyperoxic hyperpnea has been used to increase CO elimination by two to three fold more than 100% oxygen at normal breathing rate. Hyperbaric oxygen is not generally available for veterinary use. • Rapid therapy is important to avoid permanent damage to the CNS (malacia, demyelination) and cardiac muscle necrosis. • Provide fresh air and provide artificial respiration if necessary.
- Supportive fluids to correct acidosis and maintain blood flow and perfusion of brain.

MEDICATIONS

DRUG(S)

Prompt 100% oxygen therapy.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Avoid respiratory depressants. • Limit 100% oxygen to < 18 hours to avoid oxygen toxicosis. • Monitor for delayed neurotoxicity.

FOLLOW-UP

- Significant response to therapy—expected in 1–4 hours, depending on damage from hypoxia. • Signs persisting for 24 hours or more suggest a poor prognosis. • Monitor cardiac, pulmonary, neurologic function; limit physical activity for 2 weeks. • Eliminate source of carbon monoxide; recommend in-home CO detectors.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Humans in the same CO-contaminated environment are at risk.

PREGNANCY/FERTILITY/BREEDING

- CO—reduces oxygen-carrying ability of maternal blood, producing fetal hypoxia, abortion, or neurologic impairment of the fetus. • Pregnant animals in late gestation abort dead fetuses with only minimal effects in the dam.

ABBREVIATIONS

- CNS = central nervous system • CO = carbon monoxide • ECG = electrocardiogram

CARCINOID AND CARCINOID SYNDROME

BASICS

OVERVIEW

• Siegfried Oberndorfer coined the term karzinoide ("carcinoma-like") in 1907 to describe a gastrointestinal tumor in a human with the unique feature of behaving like a benign tumor. Carcinoid tumors are neuroendocrine tumors that arise from amine precursor uptake and decarboxylation (APUD) cells. • The origins of carcinoids are most commonly the enterochromaffin and enterochromaffin-like cells of the gastrointestinal tract, but they can also be found in the liver, tracheobronchial tree, pancreas, and genitourinary system due to embryologic origins. • Carcinoids may secrete a variety of amines such as histamine, serotonin, and peptides such as bradykinins and tachykinins. In humans, these secretory substances can cause a well-recognized "carcinoid syndrome" and/or "carcinoid crisis" in approximately 5–10% of patients with carcinoid tumors once metastasis has occurred in the liver and hepatic degradation is bypassed. The human carcinoid syndrome is most commonly characterized by flushing, abdominal pain, diarrhea, bronchospasm, and cyanosis. Domestic small animals have not been reported to date to show these clinical signs, although a dog has been recently reported to have episodic collapse and melena in association with an ileocecal carcinoid.

Morbidity and mortality are more often a function of tumor size and gastrointestinal blockage in dogs and cats with carcinoid.

- Primary carcinoid tumors have been reported in the stomach, small intestine, colon, lung, gallbladder, and liver in dogs. In cats, carcinoids have been found in the stomach, small intestine, liver, and heart.

SIGNALMENT

- Dog—rare, generally > 8–9 years of age
- Cat—rare, generally > 7–8 years of age

SIGNS

- Clinical signs generally depend on the location of the primary tumor and/or metastases and may include:
 - Anorexia ◦ Vomiting ◦ Dyschezia ◦ Melena
 - Episodic collapse ◦ Ascites ◦ Weight loss
 - Signs of hepatic failure. • Carcinoid heart disease is a syndrome in humans with advanced carcinoid syndrome that occurs due to the development of fibrotic endocardial plaques and secondary valvular dysfunction in response to excess secretion of serotonin.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentials include primary gastrointestinal diseases such as other neoplasia, infection,

inflammation, parasites, foreign body ingestion, dietary indiscretion, or liver/biliary disease.

CBC/BIOCHEMISTRY/URINALYSIS

- Results can appear normal except for a mild anemia that is generally non-regenerative.
- Electrolyte abnormalities and elevated liver enzymes can be present depending on the location and clinical presentation.

OTHER LABORATORY TESTS

• Serum serotonin, serum chromogranin A, and urinary 5-hydroxyindoleacetic acid are measured in humans suspected of carcinoid tumors. These tests appear more diagnostic than direct measurement of serum amine and peptide levels. • Serum serotonin levels were found to be increased ten-fold in a dog with an intestinal carcinoid with multiple metastases. Other serum and urinary testing has not been documented in animals with carcinoid tumors.

IMAGING

• Ultrasound has been used to identify both primary tumors and metastases in the abdomen and the thorax of dogs and cats. • CT scans and MRI have been used with mild to moderate success for localization of carcinoids in humans. • Newer and more sensitive molecular imaging modalities include (1) radiolabeled somatostatin receptor scintigraphy ("OctreoScan"), (2) radioiodinated metaiodobenzylguanidine (MIBG) imaging, and (3) PET scans.

DIAGNOSTIC PROCEDURES

- Biopsy of the affected tissue with histopathologic examination often confirms the diagnosis. • If histopathologic results are equivocal, electron microscopy and/or immunohistochemistry (looking for chromogranin A and/or synaptophysin expression) may be used to determine the amines and peptides actively secreted to aid in the confirmation of a carcinoid diagnosis.

PATHOLOGIC FINDINGS

These tumors typically have a fine fibrovascular stroma with minimal-to-moderate cellular pleomorphism. The cytoplasm is eosinophilic and usually contains secretory granules that often stain argyrophilic and/or argentaffin-positive.

TREATMENT

In many cases, surgical excision can be curative, especially when there is no evidence of metastasis. Debulking can decrease hormone secretion in humans, and it may relieve gastrointestinal signs in animals that are obstructed because of tumor size.

MEDICATIONS

DRUG(S)

- Octreotide, a somatostatin analog, is often used in humans for palliative therapy when surgery is not an option. Octreotide inhibits hormone secretion from the tumor cells. As carcinoid syndrome does not appear to be the primary mechanism of disease in the animals that have been reported with carcinoid tumors, octreotide may be of little benefit in veterinary patients with carcinoids.
- High-dose radioiodinated MIBG is being used with moderate success in humans with non-resectable and/or metastatic carcinoid.
- Interferons have demonstrated limited success in humans with carcinoid tumors. The use of interferons for the treatment of dogs or cats with carcinoids has not been reported to date.
- Chemotherapy and radiotherapy have been reported to have minimal efficacy in humans with carcinoid tumors, as carcinoids are believed to be relatively chemoresistant and radioresistant.
- The use of adjuvant carboplatin has been reported in a dog with a completely excised non-metastatic jejunal carcinoid.

FOLLOW-UP

- Blood work should be serially monitored postoperatively to delineate destructive hepatic metastasis. • Abdominal ultrasound and three-view chest radiographs should be serially performed postoperatively to delineate liver and/or other organ metastasis.

MISCELLANEOUS

ABBREVIATIONS

- CT = computed tomography • MIBG = metaiodobenzylguanidine • MRI = magnetic resonance imaging

CARDIAC GLYCOSIDE PLANT TOXICOSIS

BASICS

OVERVIEW

- Cardiotoxic cardenolides are aglycone constituents of cardiac glycosides.
- Present the same toxic profile as digoxin, in particular cardiovascular (CV) and gastrointestinal (GI) signs.
- Over 400 different cardenolides exist with digoxin, digitoxin, and ouabain the most widely known and used.
- All plant parts, fresh or dry, are considered toxic, but the concentration of cardenolides varies depending on specific plant and plant part.
- Plants are best identified by scientific name.
- Common plants include:
 - *Adenium obesum* (desert rose)
 - *Apocynum cannabinum* (dogbane)
 - *Asclepias* spp. (milkweed)
 - *Convallaria majalis* (lily of the valley)
 - *Digitalis lanata* (woolly foxglove)
 - *Digitalis purpurea* (common or purple foxglove)
 - *Kalanchoe* spp. (mother of millions)
 - *Nerium oleander* (oleander)
 - *Ornithogalum umbellatum* (star of Bethlehem).

SIGNALMENT

- Cats are more sensitive to some of the plant toxins than dogs.
- Dogs with the ABCB1-1 Δ gene mutation may be more sensitive to toxins but this has not been well documented.

SIGNS

- CV—bradycardia (rarely tachycardia), AV block, all forms of arrhythmias, death from asystole.
- GI—hypersalivation, vomiting, diarrhea.
- Neuromuscular (NM)—coma, tremors, seizures (rarely); may be related to decreased cardiac output.

CAUSES & RISK FACTORS

- Animals with a prior history of cardiac or renal disease are at a higher risk as are those receiving digoxin or other cardiac glycoside drugs.
- Consumption of cardiac glycoside containing plants results in the release of cardiotoxic cardenolides which interfere with the ATPase sodium/potassium pump. Intracellular sodium is increased and potassium is decreased; the normal resting membrane potential of the heart is decreased and loss of normal myocardial function occurs.
- Increased intracellular (myocyte) calcium results in increased cardiac contractions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Beta blocker or calcium channel blocker toxicosis.
- Cardiac disease in general.
- Digoxin/digitoxin toxicosis.
- Ingestion of medications with known cardiac effects.
- Ingestion of plants with known cardiac effects such as *Taxus* spp. (yew), *Rhododendron*

spp. (azalea, rhododendron), *Kalmia* spp. (mountain laurel, lambkill), and *Pieris japonica* (Japanese pieris).

CBC/BIOCHEMISTRY/URINALYSIS

Serum chemistry, hyperkalemia early and severe, may switch to hypokalemia.

OTHER LABORATORY TESTS

Serum digoxin levels may be useful in some ingestions.

DIAGNOSTIC PROCEDURES

- Presence of plant pieces in vomit or stool
- ECG monitoring for cardiac arrhythmias

PATHOLOGIC FINDINGS

Sudden death is common. Plant pieces are often found in the stomach and small intestine. Clotted blood may be present in the ventricles with a mottled appearance to the epicardium. Histopathology findings are similar to digoxin toxicosis.

TREATMENT

- Animals consuming any amount of cardiac glycoside-containing plants should be decontaminated with emesis quickly after the ingestion.
- Activated charcoal (1–2 g/kg) with a cathartic should be given as a single dose followed by activated charcoal without a cathartic every 6–8 hours for 2–3 subsequent doses.
- Asymptomatic animals should be hospitalized for 12 hours and monitored for clinical signs.
- Symptomatic animals should be monitored with an ECG for 24 hours and IV fluids administered judiciously to maintain blood pressure but not overload the CV system. Blood pressure should be monitored closely as hypotension may be persistent.
- Hyperkalemia may be severe and appropriate IV fluids chosen.

MEDICATIONS

DRUGS

- Digoxin-specific Fab fragments (Digibind) may be useful in some cases such as oleander toxicosis. The cost is often prohibitive.
- Antiemetics if vomiting is severe or persistent: Maropitant 1 mg/kg SQ q24h in dogs and cats; ondansetron 0.1–0.2 mg/kg IV q8–12h in dogs and cats.
- Bradycardia: Atropine 0.02–0.04 mg/kg IV, IM, SQ in dogs and cats. Repeat every 4–6 hours as needed.
- Antiarrhythmics may be necessary in patients that have ventricular dysrhythmias, evidence of poor perfusion, or who remain tachycardic despite IV fluid therapy. Lidocaine – dogs, 2–8 mg/kg IV to effect while continuous ECG monitoring.
- GI protectants as needed: H2 blockers such as famotidine (0.5–1 mg/kg PO, SQ, IM, IV

q12h); omeprazole (0.5 mg/kg PO daily), or sucralfate (0.25–1 g PO q8h).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Beta-blockers and calcium channel blockers may have an additive effect on AV conduction and cause complete heart block.

FOLLOW-UP

PATIENT MONITORING

- ECG strips for first 24 hours, then prn
- Frequent blood pressure monitoring • Strict attention to serum electrolytes

PREVENTION/AVOIDANCE

- Identify and recognize plants.
- Oleander grows seemingly everywhere in parts of the SW United States and off-leash dogs and cats should be monitored closely.

POSSIBLE COMPLICATIONS

Sudden death

EXPECTED COURSE AND PROGNOSIS

- Good nursing care for 5–7 days.
- Prognosis is good with early and appropriate care.
- Cardiac arrhythmias prolong treatment and hospitalization.

MISCELLANEOUS

ABBREVIATIONS

- AV = atrioventricular
- ECG = electrocardiogram
- Fab = fragment antigen binding

CARDIOMYOPATHY—BOXER (ARRHYTHMOGENIC RIGHT VENTRICULAR)

BASICS

OVERVIEW

A myocardial disease commonly characterized by ventricular tachyarrhythmias that can be accompanied by syncope or sudden death. A small percentage (<5%) develop congestive heart failure with systolic dysfunction, comparable to the dilated cardiomyopathy observed in other breeds.

SIGNALMENT

- Dog. • Specific to the boxer, although a similar presentation is infrequently observed in the English bulldog. • Usually observed in mature dogs between 5 and 8 years of age. Dogs as young as 6 months have been reported and some affected dogs may not develop clinical signs until > 10 years of age.

SIGNS

- Usually 1 of 3 presentations:
 - Asymptomatic dog with ventricular premature complexes (VPCs) detected on routine examination.
 - Syncope with VPCs detected on an ECG or Holter monitor.
 - Signs of left heart failure (e.g., coughing, tachypnea) or biventricular failure (e.g., ascites, tachypnea, coughing) with VPCs. This presentation is the least common.
- Sudden death may occur before development of obvious clinical signs.

CAUSES & RISK FACTORS

- Adult onset, inherited (autosomal dominant). • A genetic mutation (deletion) in a cardiac desmosomal gene (Striatin) is associated with the development of the disease. Dogs that are homozygous for the striatin deletion appear to be more likely to be more severely affected with a higher number of VPCs and are more likely to have cardiac dilation and myocardial dysfunction. It is not yet known if this is the only genetic cause or if additional genetic mutations will be identified.
- At least one family of boxers with VPCs, ventricular dilation, and systolic dysfunction was found to have decreased myocardial l-carnitine levels and demonstrated some clinical improvement when supplemented with l-carnitine. The cause and effect of this relationship is unclear, and response to this supplementation does not occur in all dogs with myocardial dysfunction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Aortic stenosis—moderate and severe forms can be associated with VPCs.
- Uncommon forms of acquired cardiac disease (neoplasia, endocarditis).
- Abdominal disease (especially splenic disease) can be associated with VPCs.
- Echocardiography and abdominal

ultrasonography can be used to differentiate other causes of cardiac and abdominal disease.

OTHER LABORATORY TESTS

- Genetic testing can now be performed to screen for the genetic mutation (<http://www.ncstatevets.org/genetics/>) associated with boxer cardiomyopathy. Submission samples can be either a blood sample in an EDTA tube or a buccal swab of the oral mucosal surface.
- Plasma l-carnitine levels may be evaluated in boxers with ventricular dilation and systolic dysfunction. However, plasma levels are not always reflective of myocardial levels. If plasma levels are not low, it is still possible to have low myocardial levels, and supplementation with l-carnitine might be considered.

IMAGING

Thoracic Radiography

- Normal in most affected dogs.
- Dogs with ventricular dilation and systolic dysfunction may have cardiac enlargement and evidence of heart failure (e.g., pulmonary edema).

Echocardiography

- Normal in most affected dogs.
- A small percentage of dogs have ventricular dilation and systolic dysfunction particularly if they are homozygous of the deletion mutation.

DIAGNOSTIC PROCEDURES

Electrocardiogram

- Many dogs will not have VPCs on an ECG of brief duration since the arrhythmia can be intermittent. However, some dogs will have one or more upright VPCs on a brief lead II ECG.
- In either case, if suspicion of disease is present, Holter monitoring is recommended to determine the severity and complexity of the arrhythmia and to have a baseline for comparison once treatment is started. If Holter monitoring is not available and the dog is symptomatic with upright VPCs on an ECG, therapy should be considered.

PATHOLOGIC FINDINGS

- Gross pathology is non-specific in most cases. In a small percentage of cases, left and right ventricular dilation may be observed.
- Histopathologic abnormalities include a fatty and fibrous infiltrate into the right ventricular (and sometimes interventricular and left ventricular) free wall.

TREATMENT

- The goals of therapy include reduction of the number of VPCs, reduction of clinical signs, and reduction of the risk of sudden cardiac death. Unfortunately, there is no evidence that therapy can reduce the risk of sudden death. The decision to start therapy in the asymptomatic boxer with VPCs is controversial, since all antiarrhythmics have the potential to make the arrhythmia worse.

However, dogs with as few as 300 VPCs/24 hours have been observed to die suddenly. In general, initiate therapy drugs if there are > 1,000 VPCs/24 hours and/or significant runs of ventricular tachycardia or other signs of arrhythmia complexity (e.g., bigeminy, couplets), or clinical signs (syncope, exercise intolerance) related to the VPCs.

- Syncope and sudden cardiac death may be more frequently associated with stress and excitement. Reduce stress and effort when possible. There is no direct relationship between exercise restriction and survivability. Some dogs die while asleep. Thus, strict exercise restriction is not recommended.

MEDICATIONS

DRUG(S)

- The two best choices for treating the ventricular arrhythmia are sotalol (1.5–3.5 mg/kg PO q12h) or mexiletine (5–6 mg/kg PO q8h). Some cases continue to have significant ventricular ectopy after treatment with one of the above; these cases seem to respond well to the combination of sotalol and mexiletine. These drugs have different mechanisms and appear to work in a safe and complimentary fashion.
- In dogs with systolic dysfunction and heart failure, consider treatment with furosemide, enalapril, pimobendan, spironolactone, and l-carnitine.

CONTRAINdications/POSSIBLE INTERACTIONS

Any antiarrhythmic drug has the potential to make an arrhythmia worse.

FOLLOW-UP

- If possible, repeat the Holter monitor 2 weeks after starting therapy to evaluate for a response. Affected dogs can have an 85% day-to-day variability in VPC number before medications; therefore, a good response to therapy would be an 85% reduction in VPC number. However it may not always be possible to achieve this reduction; in those cases an improvement in arrhythmia complexity and clinical signs would be reasonable goals.
- Annual Holter monitoring and echocardiography are suggested since in some cases the disease can be progressive.
- Advise owners that dogs are always at risk of sudden death. However, the majority of affected dogs can be maintained on antiarrhythmics for years with good quality of life. Dogs with systolic dysfunction and dilation have the worst prognosis, although some of these dogs do show improvement and a decreased rate of progression on l-carnitine supplementation.

Author Kathryn M. Meurs

CARDIOMYOPATHY, DILATED—CATS

BASICS

DEFINITION

- Dilated cardiomyopathy is a disease of the heart muscle characterized by systolic myocardial failure and a dilated, volume overloaded heart that leads to signs of congestive heart failure or low cardiac output.
- Before 1987, dilated cardiomyopathy was the second most commonly diagnosed heart disease in cats. Most cats had a secondary dilated cardiomyopathy as a result of taurine deficiency. Primary idiopathic dilated cardiomyopathy is now an uncommon cause of heart disease in cats.

PATOPHYSIOLOGY

Histopathologically, the myocardium of cats with idiopathic DCM has evidence of myocytolysis, fibrosis, myofibril fragmentation, and vacuolization. Gross examination reveals global eccentric enlargement of all four cardiac chambers. These anatomic changes are associated with progressive myocardial systolic failure, decreased contractility, decreased compliance and secondary mitral valve regurgitation due to mitral valve annular dilation. These changes are typically identified by echocardiography. Eventually, the chronic myocardial dysfunction leads to congestive heart failure and clinical signs.

SYSTEMS AFFECTED

- Cardiovascular**—DCM is a primary myocardial disease and primarily affects the heart and its ability to maintain an adequate cardiac output to maintain the body's needs.
- Musculoskeletal**—cats with DCM can present with aortic thromboembolism, which causes acute paraparesis or monoparesis.
- Renal/Urologic**—cats with DCM and congestive heart failure often have poor renal perfusion and commonly have prerenal azotemia.
- Respiratory**—cats usually present with tachypnea or dyspnea due to congestive heart failure with DCM. These cats can develop both pulmonary edema and pleural effusion.

GENETICS

Because of the human experience with DCM, it is likely that feline DCM has a genetic mutation, either inherited or de novo, as the cause of their disease. No definitive mutation has been identified in the cat to date. Additionally, a quantitative genetic evaluation of a large cattery suggested an inherited factor in the development of DCM.

INCIDENCE/PREVALENCE

Idiopathic feline DCM is relatively uncommon now that taurine is adequately supplemented in cat foods. A retrospective survey 106 cats with feline myocardial disease from 1994 to 2001 from Europe revealed that DCM was diagnosed in approximately 10%

of the cases in this series. In the author's experience, the prevalence of feline idiopathic DCM may be less than 10%.

SIGNALMENT

Species

Cat

Breed Predilections

Because the prevalence is low, breed predictions are not clearly defined. That said, the Burmese cat may have an increased incidence.

Mean Age and Range

9 years (5–13 years)

Predominant Sex

None. (One study cites a male predisposition while another states a female overrepresentation.)

SIGNS

General Comments

- Cats with idiopathic DCM usually present for signs of congestive heart failure.
- They are rarely diagnosed prior to onset of clinical signs.

Historical Findings

- Signs related to low cardiac output:
 - Anorexia
 - Weakness
 - Depression
- Signs related to congestive heart failure:
 - Dyspnea
 - Tachypnea
- Signs related to thromboembolism:
 - Sudden-onset pain and paraparesis

Physical Examination Findings

- Heart rate can be fast, normal, or slow
- Soft systolic heart murmur
- Weak left cardiac impulse
- Gallop rhythm
- Possible arrhythmia
- Hypothermia
- Prolonged capillary refill time
- Tachypnea
- Quiet lung sounds (pleural effusion)
- Crackles (pulmonary edema)
- Ascites
- Hypokinetic femoral pulses
- Possibly, posterior paresis and pain as a result of aortic thromboembolism

CAUSES

The underlying etiology of idiopathic dilated cardiomyopathy remains unknown, although a genetic predisposition has been identified in some families of cats. Taurine deficiency was a common cause of secondary myocardial failure before 1987.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Taurine deficiency dilated cardiomyopathy. Because primary idiopathic dilated

cardiomyopathy and taurine deficiency have similar clinical presentations, cats with myocardial failure should be assumed to have taurine deficiency until shown to be unresponsive to taurine.

- Myocardial failure secondary to long-standing congenital or acquired left ventricular volume overload diseases.
- End-staged remodeled hypertrophic cardiomyopathy may manifest with a dilated hypocontractile heart.
- Arrhythmogenic right ventricular cardiomyopathy.

CBC/BIOCHEMISTRY/URINALYSIS

Many cats will have prerenal azotemia related to low cardiac output.

OTHER LABORATORY TESTS

- Ensure that thyroid concentrations are normal.
- Plasma taurine concentrations less than 40 nmol/L or whole blood taurine concentrations less than 250 nmol/L are subnormal and suggestive of taurine-deficiency dilated cardiomyopathy. Taurine assays are performed at a limited number of institutions and require special handling.
- Cardiac biomarkers such as plasma amine terminal B-type natriuretic peptide (NT-proBNP) and cardiac troponin I (cTnI) concentrations would be elevated in a cat with congestive heart failure due to idiopathic dilated cardiomyopathy.

IMAGING

Radiographic Findings

- Radiography often shows pleural effusion or pulmonary edema.
- Generalized cardiomegaly.

Echocardiographic Findings

- Diagnostic modality of choice.
- Characteristic findings include thin ventricular walls, enlarged left ventricular end systolic and end diastolic dimensions, left atrial enlargement, and low fractional shortening.
- Pleural and pericardial effusion may be visualized.
- Spontaneous echocardiographic contrast or a thrombus may be visualized.

DIAGNOSTIC PROCEDURES

Electrocardiography

- Electrocardiography may be normal or may show left atrial or ventricular enlargement patterns.
- Both ventricular and supraventricular arrhythmias can be seen.

Pleural Effusion Analysis

Pleural effusion typically is a modified transudate with total protein < 4 g/dL and nucleated cell counts of less than 2,500/mL. Chylous effusion may also be present. Analysis of the pleural effusion is important to rule out other causes of pleural effusion such as pyothorax, infectious peritonitis, or lymphosarcoma.

CARDIOMYOPATHY, DILATED—CATS

(CONTINUED)

PATHOLOGIC FINDINGS

- Heart:body ratio is increased.
- All four cardiac chambers are dilated. Ventricular walls are thin and left ventricular lumen is enlarged.
- Valve anatomy is normal.
- Histopathology shows myocytolysis and myocardial fibrosis.

TREATMENT

APPROPRIATE HEALTH CARE

These cats usually present in congestive heart failure and should be treated as inpatients, typically in an intensive care setting until more stable.

NURSING CARE

- Thoracocentesis is often utilized for both therapeutic and diagnostic purposes.
- Supplemental oxygen therapy is beneficial for cats in congestive heart failure to decrease the work of breathing.
- If hypothermic, cautious external heat (incubator or heating water pad) is recommended.

ACTIVITY

Indoors only after hospital discharge to reduce stress. Let cat dictate its own activity.

DIET

These cats typically are anorexic, thus tempting their appetite with many types of food may be necessary. Eventually, a low-sodium diet is recommended.

CLIENT EDUCATION

Some cats will need chronic intermittent thoracocentesis to manage large amount pleural effusion despite medical therapy.

MEDICATIONS

DRUG(S) OF CHOICE

- Furosemide is recommended to manage pulmonary edema and pleural effusion. Recommended dose range is 1–4 mg/kg q8–12h. Initially, administer parenterally then switch to oral. Chronically the lowest effective dose of furosemide is recommended.
- Pimobendan, an inodilator, is also recommended to strengthen contractility and provide some vasodilation. Recommended dose range is 0.1–0.3 mg/kg PO q12h. Although pimobendan is not currently licensed for use in cats, several recent publications have demonstrated its safety in cats and possibly a beneficial effect, albeit in retrospective studies. One study in cats with non-taurine responsive dilated cardiomyopathy who were treated with pimobendan had a median survival time that

was four times longer than the cats not treated with pimobendan (49 vs. 12 days).

- Taurine supplementation is recommended initially in all cats with dilated cardiomyopathy at 250 mg PO q12h until it is demonstrated that the patient is unresponsive to taurine or is not taurine deficient based on diagnostic testing.
- Nitroglycerin (2% ointment) one-fourth to one-half inch applied topically can be used in conjunction with diuretics in the acute management of severe congestive heart failure to further reduce preload. Nitroglycerin will lower the dose of furosemide and is particularly useful in patients with hypothermia or dehydration.
- Enalapril or benazepril, at a dose of 0.25–0.5 mg/kg PO q24h is recommended to reduce afterload and preload as soon as the cat is able to take oral medications and is clinically stable. Use with caution and possibly avoid if creatinine > 2.5 mg/dL.
- Digoxin is optionally recommended to strengthen contractility and for its positive neurohumoral effects at a dose of 0.03 mg/cat (one-fourth of a 0.125-mg tablet) or 0.01 mg/kg PO q48h. Digoxin can be given concurrently with pimobendan. However, digoxin is often omitted when pimobendan is given because of the difficulties in giving a cat several pills and digoxin's side-effect profile.
- Dobutamine at extremely low dosages can be given to a patient with severe signs of congestive heart failure and low cardiac output that cannot take oral medications. Dose varies 0.25–5 µg/kg/minute IV CRI. ECG monitoring is recommended.

- Because thromboembolic disease is a concern, an antithrombotic agent is also recommended. Clopidogrel given at a dose of 18.75 mg (one-fourth of a 75-mg tablet) PO q24h is generally the author's preferred antithrombotic agent. Other options include aspirin 81 mg PO q72h (with food) or low molecular weight heparin (e.g., dalteparin 100–150 units/kg SC q8–24h or enoxaparin 1 mg/kg SC q12–24h).
- Antiarrhythmic drugs may also be needed to control supraventricular or ventricular arrhythmias. If hemodynamically significant supraventricular tachycardia or rapid atrial fibrillation is present, diltiazem is recommended. Usually, diltiazem is given orally in either a non-sustained-release formulation (7.5 mg/cat PO q8h) or a sustained-release oral formulation (Cardizem CD at 10 mg/kg PO q24h or Dilacor 30 mg/cat [or 1/2 of an inner 60-mg tablet] PO q12h). Diltiazem is also available in an injectable formulation for urgent control of a supraventricular arrhythmia in a cat that cannot take oral medications (0.05–0.1 mg/kg slow IV, repeated PRN up to 0.25 mg/kg). If rapid and sustained ventricular tachycardia, lidocaine slow IV

0.2–0.5 mg/kg (repeat once or twice max) or sotalol PO 2 mg/kg q12h is recommended.

- Beta-blockers, such as atenolol, may be useful in the chronic management of both supraventricular and ventricular arrhythmias. Beta-blockers are used in the long-term management of dilated cardiomyopathy in humans because of their positive myocardial effects and survival benefit. Clinical experience is limited in feline dilated cardiomyopathy and they must be used cautiously as they acutely decrease contractility and could worsen congestive heart failure. Recommended dose ranges from 3.125 to 6.25 mg PO q12–24h. Start low and titrate up based on heart rate and clinical signs.

PRECAUTIONS

- Unless needed for acute cardiac rhythm control, drugs such as calcium channel blockers (diltiazem) or β -adrenergic blockers may reduce contractility and lower cardiac output. Use cautiously.
- Overzealous diuretic and vasodilation therapy may cause azotemia and electrolyte disturbances.
- Digoxin should not be used if renal insufficiency is documented or suspected.
- Enalapril or benazepril should be used with caution and possibly withheld if serum creatinine is > 2.5 mg/dL.
- Dobutamine may cause seizures and cardiac tachyarrhythmias.

FOLLOW-UP

PATIENT MONITORING

- Repeat examination with ideally a blood pressure, diagnostic imaging (either a thoracic radiograph or focused thoracic ultrasound for fluid assessment) and chemistry panel within 1 week to determine response of therapy.
- Home resting respiratory rate monitoring is helpful to determine need for diuretic dose adjustment or thoracocentesis.
- Periodically monitor electrolyte and renal parameters. Periodically monitoring of congestive heart failure fluid accumulation with diagnostic imaging.
- If using digoxin, serum blood concentrations should be measured approximately 10–14 days after initiating therapy. Therapeutic range is 0.5–1.5 ng/dL 8–12 hours post-pill.
- Repeat diagnostic echocardiogram in 2–3 months after initiating taurine supplementation to determine echocardiographic response to therapy. Although echocardiographic response may take 2–3 months to assess, one should see dramatic clinical response within 2 weeks of initiating taurine therapy if cat has taurine responsive dilated cardiomyopathy.

(CONTINUED)

CARDIOMYOPATHY, DILATED—CATS

C

PREVENTION/AVOIDANCE

Ensure that cats eat a high-protein diet with sufficient dietary taurine. No vegetarian diets.

POSSIBLE COMPLICATIONS

Thromboembolism is the most feared complication of any feline myocardial disease.

EXPECTED COURSE AND PROGNOSIS

- These cats have a poor prognosis despite intensive therapy. If cat is not taurine-responsive, survival is usually weeks to months.
- Congestive heart failure can be medically refractory and recurrent despite appropriate medical therapy.
- Repeated thoracocentesis is not uncommon.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Congestive heart failure, thromboembolism, pleural effusion, cardiac arrhythmias.

CARDIOMYOPATHY, DILATED—DOGS

BASICS

DEFINITION

Characterized by left- and right-sided dilation, normal coronary arteries, normal (or minimally diseased) atrioventricular valves, significantly decreased inotropic state, and myocardial dysfunction occurring primarily during systole; however, progressive diastolic dysfunction with restrictive physiology may represent an independent negative predictor of survival.

PATOPHYSIOLOGY

- Myocardial failure leads to reduced cardiac output and CHF.
- A-V anulus dilation and altered papillary muscle function promote valvular insufficiency.
- Although left-sided signs commonly predominate, evidence of severe right-sided disease is common late in the clinical course.

SYSTEMS AFFECTED

- Cardiovascular
- Renal/Urologic—prerenal azotemia
- Respiratory—pulmonary edema
- All organ systems are affected by reductions in cardiac output

GENETICS

Genetic cause or heritable susceptibility strongly suspected in most breeds and documented in some (Portuguese water dog, boxer, and Doberman pinscher) with variable forms of inheritance. A genetic test is commercially available for the causative mutation in boxer dogs (striatin) and Doberman pinscher (pyruvate dehydrogenase kinase). These mutations do not appear to be causative in other predisposed breeds. Complete characterization of the correlation between genotype and phenotype in each breed will require further study.

INCIDENCE/PREVALENCE

Estimated at 0.5–1.1% in predisposed breeds and perhaps higher in specific geographic regions.

GEOGRAPHIC DISTRIBUTION

None with the exception of Chagas' cardiomyopathy, which is limited to the southern United States (Gulf Coast).

SIGNALMENT

Species

Dog

Breed Predilections

- Doberman pinscher, boxer
- Giant breeds: Scottish deerhound, Irish wolfhound, Great Dane, Saint Bernard, Afghan hound, Newfoundland
- Cocker spaniel, Portuguese water dog

Mean Age and Range

4–10 years

Predominant Sex

Males > females in most but not all breeds

SIGNS

Historical Findings

- Respiratory—tachypnea, dyspnea, coughing.
- Weight loss.
- Weakness, lethargy, anorexia.
- Abdominal distention.
- Syncope (usually associated with important arrhythmias).
- Some dogs are asymptomatic; having what is termed preclinical dilated cardiomyopathy, the diagnosis of which in specific breeds is well described.
- Breed-specific echocardiographic parameters coupled with cardiac biomarkers (NT-proBNP; cTnI) may help identify dogs in the preclinical stage of the disease.

Physical Examination Findings

- May be completely normal with preclinical disease.
- Weakness, possibly cardiogenic shock.
- Hypokinetic femoral pulse from low cardiac output.
- Pulse deficits with atrial fibrillation, ventricular or supraventricular premature contractions, and paroxysmal ventricular tachycardia.
- Jugular pulses from tricuspid regurgitation, arrhythmias, or right-sided CHF.
- Breath sounds—muffled with pleural effusion; crackles with pulmonary edema.
- S3 or summation gallops.
- Mitral and/or tricuspid regurgitation murmurs are common but usually focal and soft.
- Auscultatory evidence of cardiac arrhythmia is common.
- Slow capillary refill time, infrequent cyanosis.
- Hepatomegaly with or without ascites.

CAUSES

- Most authors believe that the majority of cases represent familial abnormalities of structural, energetic or contractile cardiac proteins many of which have been identified.
- Nutritional deficiencies (taurine and/or carnitine) have been documented in several breeds including golden retriever, boxer, Newfoundland, Doberman pinscher, and cocker spaniel.
- Viral, protozoal, and immune-mediated mechanisms have been proposed.
- Toxic doxorubicin.
- Hypothyroidism and persistent tachyarrhythmias (sometimes associated with congenital tricuspid valve malformation) may cause reversible myocardial failure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Endocardiosis
- Congenital heart disease
- Heartworm disease
- Bacterial endocarditis
- Cardiac tumors and pericardial effusion
- Airway obstruction—foreign body, neoplasm, laryngeal paralysis
- Primary pulmonary disease—bronchial disease, pneumonia, neoplasia, aspiration, vascular disease (e.g., heartworms)
- Pleural effusions (e.g., pyothorax, hemothorax, chylothorax)
- Trauma resulting in diaphragmatic hernia, pulmonary hemorrhage, hemothorax, pneumothorax

CBC/BIOCHEMISTRY/URINALYSIS

Routine hematologic tests and urinalysis are usually normal unless altered by severe reductions in cardiac output or severe elevations in venous pressures (e.g., prerenal azotemia, high ALT, hyponatremia), therapy for heart failure (e.g., hypokalemia, hypochloremia, and metabolic alkalosis from diuresis), or concurrent disease.

OTHER LABORATORY TESTS

Cardiac biomarkers including NT-proBNP and cTnI are elevated in both the preclinical and clinical stages of the disease. Clinical studies investigating the use of these markers for diagnosis, prognosis, and optimization of therapy are ongoing.

IMAGING

Radiographic Findings

- May be completely normal in the preclinical phase.
- Generalized cardiomegaly and signs of CHF are common.
- Left ventricular enlargement and left atrial enlargement may be most evident in early cases.
- In some cases, the degree of cardiomegaly may be less than might be expected with the severity of clinical signs.
- The degree of cardiomegaly is often substantially less than would be expected in a dog with primary valvular heart disease and comparable clinical signs.
- Pleural effusion, hepatomegaly, ascites.

Echocardiographic Findings

- Left ventricular dilation often precedes overt reductions in indices of systolic function.
- Gold standard for diagnosis.
- Ventricular and atrial dilation.
- Echocardiographic indices of myocardial systolic function (low FS%, ejection fraction, area shortening, and mitral annular motion;

(CONTINUED)

CARDIOMYOPATHY, DILATED—DOGS

C

tissue Doppler imaging [TDI]) may be reduced.

- Spectral Doppler studies may confirm decreased velocity and/or acceleration of tran-saortic flow as well as mitral regurgitation and/or tricuspid regurgitation.
- Doppler evidence of restrictive LV filling is an independent predictor of decreased survival.

DIAGNOSTIC TESTS***Electrocardiography***

- Sinus rhythm or sinus tachycardia with isolated atrial or ventricular premature complexes.
- Atrial fibrillation and ventricular tachycardia (paroxysmal or sustained) are very common in Doberman pinschers.
- Boxers commonly have isolated ventricular arrhythmias without evidence of functional or anatomic heart disease.
- Prolonged QRS (> 0.06 second), possible increased voltages ($R > 3$ mV lead II), suggesting LV enlargement.
- May have "sloppy" R wave descent with ST-T coving, suggesting myocardial disease or LV ischemia.
- May have low voltages (pleural or pericardial effusion, concurrent hypothyroidism).

PATHOLOGIC FINDINGS

- Dilatation of all chambers with thinning of the chamber walls.
- Slightly thickened endocardium with pale areas within the myocardium (necrosis, fibrosis).
- Two histologically distinct forms—(1) fatty infiltration: degenerative type seen in boxers and Doberman pinschers; and (2) an attenuated wavy fiber type: seen in many giant-, large-, and medium-sized breeds, including some boxers and Doberman pinschers.

**TREATMENT****APPROPRIATE HEALTH CARE**

With the exception of severely affected dogs, most therapy can be administered on an outpatient basis.

ACTIVITY

Allow the dog to choose its own level of activity.

DIET

- During initial therapy for clinical signs, simply maintain adequate caloric intake is paramount.
- Goal—reduce dietary sodium intake to $< 12\text{--}15$ mg/kg/day.
- Severe sodium restriction is typically not necessary when using potent cardioactive therapy and may adversely affect appetite.
- Best to use commercially prepared diets.

CLIENT EDUCATION

- Emphasize potential signs associated with progression of disease and adverse side effects of medication.
- Monitoring sleeping respiratory rate often gives insight into impending decompensation.

**MEDICATIONS****DRUG(S) OF CHOICE**

First identify patient problems—CHF (left- or right-sided), arrhythmia, hypothermia, renal failure, shock.

Preclinical Disease

- There is clinical evidence (PROTECT Trial) that early intervention with pimobendan monotherapy substantially changes the course of preclinical disease in Doberman pinschers.
- These results should not be extrapolated to other diseases and other breeds.
- Critical evaluation suggests that early intervention with monotherapy with ACEi is of minimal survival benefit.

Initial Stabilization

- Treat hypoxemia with oxygen administration; prevent heat loss if hypothermic (warm environment); administer IV or SC fluids (D_5W or 0.45% NaCl with 2.5% dextrose) only after pulmonary edema is controlled or pleural effusion has been aspirated.
- If there is pulmonary edema—furosemide (2–4 mg/kg IM or IV, then 1–2 mg/kg q6–12 hours for the first 1–3 days), or a CRI 1–2 mg/kg/h.
- 2% topical nitroglycerin for the first 24–48 hours for severe pulmonary edema—apply 1 inch–2 inches q8h (beware of hypotension).
- If there is significant pleural effusion, drain each hemithorax with an 18- to 20-gauge butterfly catheter.
- If there is severe heart failure and cardiogenic shock, dobutamine may be indicated. This may predispose to malignant arrhythmias, particularly in the hypoxic dog. Oral pimobendan (see dosing below) may have important acute (2–4 hours) hemodynamic benefit as well.
- Digoxin—oral therapy (see below).
- Dobutamine 5–15 μ g/kg/min infused for 24–72 hours with care (start low and gradually up-titrate based on response).
- If paroxysmal ventricular tachycardia is present, administer lidocaine slowly in 2 mg/kg boluses (up to 8 mg/kg total) to convert to sinus rhythm. Follow with lidocaine infusion (50–75 μ g/kg/minute).
- If lidocaine is ineffective, administer procainamide slowly at a dose of 10–25 mg/kg to convert to sinus rhythm. Follow with a 25–50 μ g/kg/minute CRI (beware of proarrhythmia).

Maintenance Therapy

- ACE inhibitors (enalapril, benazepril, lisinopril) are considered a cornerstone of therapy for DCM.
- Enalapril (0.25–0.5 mg/kg PO q12h), benazepril (0.5 mg/kg PO q12–24h), or lisinopril (0.5 mg/kg PO q 12–24h) should be initiated early in the therapeutic regimen.
- A daily maintenance dose of 0.375–0.50 mg of digoxin (divided q12h) is given to some giant-breed dogs. Do not exceed 0.015 mg/kg/day and do not exceed 0.375 mg/day in Doberman pinschers. Therapeutic drug monitoring should be utilized in any dog receiving digoxin. Pimobendan has replaced digoxin as the positive inotropic of choice with digoxin used primarily for control of ventricular response rate in atrial fibrillation (see below).
- Furosemide (0.5–3 mg/kg PO q8–q24h) is used to control pulmonary edema, pleural effusion, or ascites.
- Spironolactone (0.5–1 mg/kg PO q12h) may impart independent survival benefit by blocking aldosterone. Higher doses can be used for refractory heart failure (1–2 mg/kg PO q12h). Hydrochlorothiazide (1–2 mg/kg PO q12h) may be beneficial as a third diuretic.
- Beta-blockers can be used cautiously once heart failure is controlled with other drugs (see "Precautions"). If tolerated, they may improve myocardial function with chronic use. Carvedilol (0.25–1.25 mg/kg PO q12h) is an alpha- and beta-blocker with antioxidant activity. Start at the low end of the dose range and gradually up-titrate over a 6-week period if tolerated. Consult with a cardiologist before using beta-blockers in clinical DCM patients as it can result in rapid and profound clinical deterioration.
- Pimobendan (0.25–0.3 mg/kg PO q12h) is a calcium-sensitizing drug that is a vasodilating positive inotropic that, when added to furosemide, ACE inhibitor, and digoxin, improves functional heart failure class and in Doberman pinschers increases survival time. The author has administered pimobendan 0.25–0.3 mg/kg PO q8h in refractory cases with perceived clinical benefit.
- The role of carnitine and taurine in the therapy of DCM remains controversial. However, American cocker spaniels with dilated cardiomyopathy generally respond favorably to taurine and l-carnitine supplementation but still require additional cardiac medications.

Arrhythmias

- In the case of atrial fibrillation, slowing of the ventricular rate response typically achieved with chronic administration of extended release diltiazem (Dilacor) 2–7 mg/kg PO q12h , or atenolol 0.75–1.5 mg/kg PO q12h (never start in a patient with active CHF), sometimes combined with digitalis.

CARDIOMYOPATHY, DILATED—DOGS

(CONTINUED)

- The therapeutic goal is obtaining a resting ventricular rate of 100–140 bpm.
- The above therapy merely controls the ventricular rate, by depressing AV nodal conduction; it generally does not convert the rhythm from atrial fibrillation to sinus rhythm.
- Amiodarone (10–15 mg/kg PO q24h for 7–10 days followed by 5–10 mg/kg PO q24h) may either control ventricular response rate or in some cases result in conversion to normal sinus rhythm.
- Chronic oral therapy for ventricular tachycardia includes procainamide (8–20 mg/kg PO q6–8h), mexiletine (5–10 mg/kg PO q8h), amiodarone (5–10 mg/kg PO q24h) or sotalol (1–2 mg/kg PO q12h).
- Procainamide and mexiletine can be combined with a beta-blocker if necessary.

CONTRAINDICATIONS

Digoxin should be avoided in severe uncontrolled paroxysmal ventricular tachycardia, in animals with compromised renal function and in animals with important hypokalemia.

PRECAUTIONS

- Beta-blockers and calcium channel blockers are negative inotropes and may have an acute adverse effect on myocardial function. Numerous human studies, however, have suggested that chronic administration of beta-blockers may be of benefit in DCM.
- The combination of diuretics and ACE inhibitors may result in azotemia, especially in patients with severe heart failure or preexisting renal dysfunction.

POSSIBLE INTERACTIONS

- Quinidine, amiodarone, and diltiazem may increase serum digoxin levels and predispose to digitalis intoxication.
- Renal dysfunction, hypothyroidism, and hypokalemia predispose to digitalis intoxication.

ALTERNATIVE DRUG(S)

- Other vasodilators, including hydralazine and amlodipine, may be used instead of or in

- addition to an ACE inhibitor (beware of hypotension).
- The role of co-enzyme Q10 remains to be determined.

FOLLOW-UP

PATIENT MONITORING

- Serial clinical examinations, thoracic radiographs, blood pressure measurements, routine serum biochemical evaluations (including electrolytes), and ECG are most helpful.
- Repeat echocardiography is rarely informative or indicated.
- Serial evaluation of serum digoxin levels (therapeutic range = 0.5–1 ng/mL) taken 6–8 hours post-pill and serum biochemistries may help prevent iatrogenic problems.

POSSIBLE COMPLICATIONS

- Sudden death due to arrhythmias.
- Iatrogenic problems associated with medical management (see above).

EXPECTED COURSE AND PROGNOSIS

- Always fatal.
- Death usually occurs 6–24 months following diagnosis.
- Dobermanns typically have a worse; however, with the addition of pimobendan, survival following identification in the preclinical stage averages over 700 days.
- Atrial fibrillation, paroxysmal ventricular tachycardia, Doppler evidence of restrictive LV filling, and markedly decreased FS% are believed to be markers for short survival and sudden death.

CARDIOMYOPATHY, HYPERTROPHIC—CATS

BASICS

DEFINITION

Inappropriate concentric hypertrophy of the ventricular free wall and/or the interventricular septum of the non-dilated left ventricle. The disease occurs independently of other cardiac or systemic disorders.

PATHOPHYSIOLOGY

- Diastolic dysfunction results from a thickened, non-compliant left ventricle.
- High left ventricular filling pressure develops, causing left atrial enlargement.
- Pulmonary venous hypertension causes pulmonary edema. Some cats develop biventricular failure (i.e., pulmonary edema, pleural effusion, small volume pericardial effusion without tamponade, and, rarely, ascites). • Stasis of blood in the large left atrium predisposes the patient to ATE.
- Dynamic aortic outflow obstruction and systolic anterior mitral motion (SAM) with secondary mitral insufficiency may occur.

SYSTEMS AFFECTED

- Cardiovascular—CHF, ATE, and arrhythmias
- Pulmonary—dyspnea if CHF develops
- Renal/urologic—prerenal azotemia

GENETICS

Some families of cats have been identified with a high prevalence of the disease, and the disease appears to be an autosomal dominant trait in Maine coon cats and ragdoll cats, due to a mutation in the MyBPC gene. The genetics have not been definitively determined in other breeds; however, the Maine coon and ragdoll mutations have not been identified in affected Sphynx, Norwegian forest cats, Bengals, Siberians, or British shorthair cats.

INCIDENCE/PREVALENCE

Unknown, but relatively common. May be as high as 15% of the population.

SIGNALMENT

Species: Cat

Breed Predilections

Maine coon cats, ragdolls, Sphynx, British and American shorthairs, and Persians.

Mean Age and Range

5–7 years with reported ages of 3 months–17 years. Some breeds of cats including ragdolls and Sphynx may develop the disease at a younger age (average of 2 years of age). HCM is most often a disease of young to middle-aged cats; unexplained murmurs in geriatric cats are more likely associated with hyperthyroidism or hypertension.

Predominant Sex: Male

SIGNS

Historical Findings

- Dyspnea.
- Anorexia.
- Exercise intolerance.
- Vomiting.
- Collapse.
- Sudden

death. • Coughing is uncommon in cats with cardiomyopathy and usually suggests pulmonary disease.

Physical Examination Findings

- Gallop rhythm (S3 or S4).
- Systolic murmur in many animals.
- Apex heartbeat may be exaggerated.
- Muffled heart sounds, lack of chest compliance, and dyspnea characterized by rapid shallow respirations may be associated with pleural effusion.
- Dyspnea and crackles if pulmonary edema is present.
- Weak femoral pulse.
- Acute pelvic limb paralysis with cyanotic pads and nailbeds, cold limbs, and absence of femoral pulse in animals with ATE. Emboli rarely affect thoracic limbs.
- Arrhythmia in some animals.
- May have no clinical signs.

CAUSES

- Usually unknown—multiple causes exist
- MyBPC mutations in some cats with HCM

Possible Causes

- Abnormalities of the contractile protein myosin or other sarcomeric proteins (e.g., troponin, myosin binding proteins, tropomyosin).
- Abnormality affecting catecholamine-influenced excitation contraction coupling.
- Abnormal myocardial calcium metabolism.
- Collagen or other intercellular matrix abnormality.
- Growth hormone excess.
- Dynamic left ventricular outflow obstruction may contribute to secondary left ventricular hypertrophy.

RISK FACTORS

Offspring of animals with familial mutations of MyBPC

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other forms of cardiomyopathy
- Hyperthyroidism
- Aortic stenosis
- Systemic hypertension
- Acromegaly
- Non-cardiac causes of pleural effusion

CBC/BIOCHEMISTRY/URINALYSIS

- Results usually normal
- Prerenal azotemia in some animals

OTHER LABORATORY TESTS

- MyBPC assay. Mutation differs for Maine coon cats and ragdoll cats.
- In cats > 6 years old, check thyroid hormone concentration. Hyperthyroidism causes myocardial hypertrophy that might be confused with HCM.
- Serum BNP concentrations are higher in cats with HCM than in normal cats, and higher still in cats with symptomatic HCM. The positive predictive value of this test to differentiate normal cats from those with asymptomatic HCM is unknown in the general population, and this test should therefore not be used to screen all asymptomatic cats. Serum BNP testing is useful, in identifying cats with a high

suspicion of HCM from an asymptomatic population of cats with abnormal physical exam findings (e.g., murmur).

IMAGING

Radiography

- Dorsal ventral radiographs often reveal a valentine-appearing heart because of biatrial enlargement and a left ventricle that comes to a point.
- Pulmonary edema, pleural effusion, or both in some animals.
- Radiographs may be normal in asymptomatic cats.
- The different forms of cardiomyopathy cannot be reliably differentiated by radiography.

Echocardiography

- Hypertrophy of the interventricular septum or the left ventricular posterior wall (diastolic wall thickness > 6 mm).
- Hypertrophy may be symmetric (affecting IVS and posterior wall) or asymmetric (affecting IVS or posterior wall, but not both).
- Hypertrophy of the papillary muscles.
- Normal or high fractional shortening.
- Normal or reduced left ventricular lumen.
- Left atrial enlargement.
- Systolic anterior motion of the mitral valve (some animals).
- Left ventricular outflow obstruction (some animals).
- Specialized Doppler studies performed by experienced sonographers often reveal left ventricular relaxation abnormalities (e.g., mitral inflow E:A wave reversal).
- Thrombus in the left atrium (rare).
- Note: There is some overlap between normal cats (especially ketaminized and dehydrated) and cats with mild HCM. Correlate echo findings with physical findings. Presence of left atrial enlargement favors HCM.

DIAGNOSTIC PROCEDURES

Electrocardiography

- Sinus tachycardia (HR > 240) is common with heart failure; however, some cats with severe heart failure and hypothermia are bradycardic.
- Atrial and ventricular premature complexes seen more often in cats with cardiomyopathy, but are also occasionally seen in normal cats.
- Atrial fibrillation is seen in some advanced cases.
- A left axis deviation is often seen.
- Cannot differentiate different forms of cardiomyopathy. May be normal.

Systemic Blood Pressure

- Normotensive or hypotensive.
- Evaluate blood pressure in all patients with myocardial hypertrophy to rule out systemic hypertension as the cause of hypertrophy.

PATHOLOGIC FINDINGS

- Non-dilated left ventricle with hypertrophy of intraventricular septum or left ventricular free wall.
- Hypertrophy of papillary muscles.
- Left atrial enlargement.
- Mitral valve thickening.
- Myocardial hypertrophy with disorganized alignment of myocytes (myofiber disarray).
- Interstitial fibrosis.
- Myocardial scarring.
- Hypertrophy and luminal narrowing of intramural coronary arteries.

CARDIOMYOPATHY, HYPERTROPHIC—CATS

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

Cats with CHF should be hospitalized.

NURSING CARE

- Minimize stress • Oxygen if dyspneic
- Warm environment if hypothermic

ACTIVITY

Restricted with CHF

DIET

Modest to moderate sodium restriction in animals with CHF

CHF CLIENT EDUCATION

- Many cats diagnosed while asymptomatic eventually develop CHF and may develop ATE and die suddenly. • If cat is receiving warfarin, dalteparin, lovenox, or a combination of clopidogrel and any of those medications, minimize potential for trauma and subsequent hemorrhage.

MEDICATIONS

DRUG(S) OF CHOICE

Furosemide

- Dosage—1–2 mg/kg PO, IM, IV q8–24h.
- Critically dyspneic animals often require high dosage (4 mg/kg IV). This dose can be repeated in 1 hour if the cat is still severely dyspneic. Indicated to treat pulmonary edema, pleural effusion, and ascites.
- Cats are sensitive to furosemide and prone to dehydration, prerenal azotemia, and hypokalemia.
- Once pulmonary edema resolves, taper to the lowest effective dose.

Pimobendan

- Dosage—0.25–0.3 mg/kg PO q12h.
- Appears to be useful in the management of congestive heart failure (e.g., pulmonary edema or pleural effusion) in cats with HCM, possibly by enhancing diastolic function.
- Pimobendan is not used in the management of asymptomatic HCM at this time.

ACE Inhibitors

- Dosage—enalapril or benazepril 0.25–0.5 mg/kg PO q24h.
- Indications in cats with HCM not well defined—authors currently use for CHF.

Beta-Blockers

- Dosage—atenolol (6.25–12.5 mg/cat PO q12h).
- Beneficial effects may include slowing of sinus rate, correcting atrial and ventricular arrhythmias, platelet inhibition.
- More effective than diltiazem in controlling dynamic outflow tract obstruction.
- Role in asymptomatic patients unresolved, but authors generally use if dynamic outflow obstruction and hypertrophy present.
- Contraindicated in the presence of CHF.

Diltiazem

- Dosage—7.5–15 mg/cat PO q8h or 10 mg/kg PO q24h (Cardizem CD) or 30 mg/cat q12h (Dilacor XR).
- Beneficial effects may include slower sinus rate, resolution of supraventricular arrhythmias, improved diastolic relaxation, coronary and peripheral vasodilation, platelet inhibition.
- May reduce hypertrophy and left atrial dimensions in some cats.
- Role in asymptomatic patients unresolved.

Aspirin

- Dosage—81 mg/cat q2–3 days if severe atrial enlargement.
- Depresses platelet aggregation, hopefully minimizing the risk of thromboembolism.
- Warn owners that thrombi can still develop despite aspirin administration. Aspirin appears to be not as effective as clopidogrel (1/4 of a 75-mg tablet PO q24h) in the prevention of ATE, at least in cats with a previous embolic episode.

Nitroglycerin Ointment

- Dosage—one-fourth inch/cat topically applied q6–8h or 2.5 mg/24-hour patch.
- Often used in the acute stabilization of cats with severe pulmonary edema or pleural effusion.
- When used intermittently, it may be useful for long-term management of refractory cases.

CONTRAINDICATIONS

Avoid beta-blockers in cats with emboli; these agents cause peripheral vasoconstriction. If beta-blockers must be used in this setting for arrhythmia control, choose a beta-1 selective blocker such as atenolol.

PRECAUTIONS

Use ACE inhibitors cautiously in azotemic animals.

ALTERNATIVE DRUG(S)

Spironolactone

- Dosage—1 mg/kg q12–24h.
- Used in conjunction with furosemide in cats with CHF.
- May cause facial pruritis.

Warfarin and Low Molecular Weight Heparin

- Used sometimes in cats at high risk for thromboembolism.
- See chapter, Aortic Thromboembolism.

Clopidogrel

Dosage—18.75 mg/cat/day. Platelet function inhibitor, superior to aspirin in cats with previous ATE.

Beta-Blocker Plus Diltiazem

- Cats that remain tachycardic on a single agent can be treated cautiously with a combination of a beta-blocker and diltiazem.
- Monitor for bradycardia and hypotension.

FOLLOW-UP

PATIENT MONITORING

- Observe closely for dyspnea, lethargy, weakness, anorexia, and painful posterior

paralysis or paresis.

- If treating with warfarin, monitor prothrombin time.
- If treating with an ACE inhibitor or spironolactone, monitor renal function and electrolytes.
- Repeat echocardiogram in 6 months to assess efficacy of treatment for hypertrophy. If a beta-blocker or diltiazem was prescribed in an asymptomatic animal and there is evidence of progressive hypertrophy/left atrial enlargement, consider switching to another class of medications (or adding ACEI) and recheck 4–6 months later.

Echocardiographic evaluations that reveal LA diameters > 2 cm or loss of LV systolic function should prompt more aggressive prophylaxis against ATE (e.g., clopidogrel with low molecular weight heparin).

PREVENTION/AVOIDANCE

Avoid stressful situations that might precipitate CHF.

POSSIBLE COMPLICATIONS

- Heart failure • ATE and paralysis • Cardiac arrhythmias/sudden death

EXPECTED COURSE AND PROGNOSIS

- Animals homozygous for MyBPC mutations more likely to develop severe HCM and at earlier age than heterozygous animals.
- Prognosis varies considerably, probably because there are multiple causes. In one study of cats with HCM living at least 24 hours following presentation:
- Asymptomatic cats: median survival 563 days (range 2–3,778 days)
- Cats with syncope: median survival 654 days (range 28–1,505 days)
- Cats with CHF: median survival 563 days (range 2–4,418 days).
- Cats with ATE: median survival 184 days (range 2–2,278 days).
- Older age and larger left atria predicted shorter survival.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Aortic thromboembolism

PREGNANCY/FERTILITY/BREEDING

- High risk of complications • Avoid aspirin

CARDIOMYOPATHY, HYPERTROPHIC—DOGS

BASICS

OVERVIEW

Hypertrophic cardiomyopathy has been defined as “inappropriate myocardial hypertrophy of a non-dilated left ventricle, occurring in the absence of an identifiable stimulus for the hypertrophy.” HCM is a rare disease in dogs characterized by left ventricular concentric hypertrophy (increased wall thickness). The primary disease process is confined to the heart and only affects other organ systems when congestive heart failure is present. Increased LV wall thickness leads to impaired ventricular filling (due to lack of compliance and abnormal relaxation) with a resultant increase in LV end-diastolic pressure and left atrial pressure. The left atrium usually enlarges in response to increased LV end-diastolic pressure. Mitral insufficiency and/or dynamic LV outflow tract obstruction commonly occur secondary to structural and/or functional changes of the mitral valve apparatus caused by papillary muscle malalignment secondary to the hypertrophy.

SIGNALMENT

- The incidence of HCM in dogs is very low, such that accurate accounts of signalment are lacking.
- Young (<3 years) male dogs.
- Rottweiler, Dalmatian, and German shepherd and pointer breeds are overrepresented.
- HCM is also encountered with some regularity in mature Boston terrier dogs.

SIGNS

Historical Findings

- Most are asymptomatic.
- Signs of left congestive heart failure predominate in symptomatic dogs.
- Syncope, generally during activity or exercise.
- Sudden death is the most commonly reported clinical sign.

Physical Examination Findings

- Systolic heart murmur.
- Cardiac gallop rhythm.
- Signs of left congestive heart failure (e.g., cough, dyspnea, cyanosis, exercise intolerance).

CAUSES & RISK FACTORS

The cause of hypertrophic cardiomyopathy is unknown. Genetic abnormalities in genes coding for myocardial contractile proteins have been documented in humans and in cats, but not in dogs. A genetic basis is suspected in that most affected dogs are young, but none has been proven.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Systemic hypertension
- Infiltrative cardiac disorders
- Other causes of congestive heart

failure

- Thyrotoxicosis
- Congenital mitral dysplasia

IMAGING

Radiography

- May be normal.
- May show LA or LV enlargement.
- Pulmonary edema is present in dogs with left congestive heart failure.

Echocardiography

- Dogs with severe HCM usually have markedly thickened left ventricular walls, papillary muscle hypertrophy, and an enlarged left atrium. The hypertrophy is usually global, affecting all areas of the left ventricular wall, but can be more regional or segmental (asymmetric). Milder forms may have subtle LV hypertrophy.
- Systolic anterior motion of the mitral valve, suggesting dynamic LV outflow tract obstruction, is common in dogs with HCM.

OTHER DIAGNOSTIC PROCEDURES

Electrocardiography

- May be normal.
- ST segment and T wave abnormalities have been reported.
- Atrial or ventricular ectopic arrhythmias may rarely occur.

Blood Pressure

Usually normal. Should be evaluated to rule out systemic hypertension as the cause of LV hypertrophy.

PATHOLOGIC FINDINGS

- Abnormal heart:body weight ratio.
- Left ventricular concentric hypertrophy.
- There may be an impact lesion on the interventricular septum, displaying a range of appearances from a small opaque lesion to a thickened plaque.
- The mitral valve itself is often thickened and elongated.
- Varying degrees of left atrial enlargement may be present

TREATMENT

Outpatient management unless in congestive heart failure. Exercise restriction and sodium restriction are beneficial.

MEDICATIONS

DRUG(S)

- Treatment is generally only pursued if there is evidence of congestive heart failure or severe arrhythmias or in patients with frequent syncope.
- In patients with left congestive heart failure, diuretics and ACE inhibitor therapy are advocated.
- In dogs with high LV-aorta pressure gradients due to dynamic LV outflow obstruction, administration of a β -adrenergic blocker or calcium channel blocker has been

advocated; however, benefit has not been proven.

- Beta-adrenergic blockers or calcium channel blockers may also improve myocardial oxygenation, reduce heart rate, improve LV diastolic function, and control arrhythmias and therefore may also be beneficial in dogs with left congestive heart failure.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Positive inotropic drugs should be avoided as they may worsen dynamic LV outflow obstruction.
- The use of a calcium channel blocker in combination with a beta-blocker should be avoided, as clinically significant bradycardia can develop.
- The use of potent arteriolar dilators should be avoided in patients with dynamic LV outflow tract obstruction. However, the use of milder vasodilators such as ACE inhibitors in patients with congestive heart failure is generally well tolerated.

FOLLOW-UP

Reevaluation depends on the severity of the clinical signs. Reevaluation with radiography and echocardiography may be useful to characterize disease progression and make appropriate medication adjustments.

- Due to the rarity of this condition in dogs, information regarding prognosis is lacking. In dogs with severe congestive heart failure or other complications, prognosis is generally guarded.

CARDIOMYOPATHY, RESTRICTIVE—CATS

BASICS

DEFINITION

A rare, primary heart muscle disease characterized *functionally* by severe diastolic dysfunction with restrictive left ventricular filling and normal to near normal systolic function, *morphologically* by a non-dilated non-hypertrophied left ventricle with increased endocardial and/or myocardial fibrosis and severe atrial enlargement, and *clinically* by advanced heart failure, thromboembolic disease, and cardiac death.

PATOPHYSIOLOGY

- Increased cardiomyofilament calcium sensitivity leading to severely impaired relaxation and high myocardial stiffness due to endomyocardial fibrosis (endomyocardial type) and/or interstitial fibrosis (myocardial type), and disorganized myofiber architecture (disarray; both types) are main characteristics of primary RCM. RCM-like myocardial changes and clinical syndromes can result from myocardial remodeling and dysfunction secondary to other causes (e.g., endomyocarditis, immune-mediated disease, or end-stage hypertrophic cardiomyopathy).
- Diastolic heart failure and arterial thromboembolism lead to high mortality.

SYSTEMS AFFECTED

- Cardiovascular • Respiratory

GENETICS

Primary RCM can be a spontaneous or familial disease but is generally considered of genetic cause in humans with an autosomal dominant pattern of inheritance. Several genes encoding α -actin, β -myosin heavy chain, cTnI, and cTnT can be affected. RCM-causing mutations have not been identified in cats.

INCIDENCE/PREVALENCE

Primary feline RCM is rare. Prevalence ranging from present 1–15% of all myocardial diseases in cats has been reported.

SIGNALMENT

- Cats • No breed predilection • Middle-aged to older cats • Male predisposition

SIGNS

Historical Findings

- If cat does not have CHF: ° Lethargy, weakness, weight loss ° Syncope (usually indicates relevant arrhythmia) ° Paresis or paralysis (i.e., signs of arterial thromboembolism)
- If cat has CHF: ° Laboring breathing ° Tachypnea ° Ascites ° Jugular venous distension ° Cyanosis

Physical Examination Findings

- If not in CHF: ° Depression ° Tachycardia ° Arrhythmias ° Prominent gallop sounds
- Heart murmur uncommon • If in CHF: above signs plus the following: ° Tachypnea

- ° Labored breathing ° Panting ° Cyanosis
- ° Hepatomegaly or ascites with jugular venous distention ° Pulmonary crackles ° Muffled cardiac or respiratory sounds if cat has pleural effusion ° Paralysis or paresis with loss of femoral pulses; one or more extremities cold and painful (arterial thromboembolism).

CAUSES

- Primary RCM: Currently unknown; genetic cause documented in humans.
- Secondary RCM: Late or end stage of underlying disease (e.g., hypertrophic cardiomyopathy), link between prior interstitial pneumonia and feline endomyocarditis suspected in one study.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Advanced stages of other feline cardiomyopathies: ° Hypertrophic, dilated, arrhythmogenic right ventricular, unclassified, and tachycardia-induced cardiomyopathy
- Myocardial infarct ° CHF secondary to thyrotoxicosis or hypertensive heart disease.

CBC/BIOCHEMISTRY/URINALYSIS

Routine chemistry panel and urinalysis helpful to document concurrent or complicating conditions (e.g., prerenal azotemia and potassium depletion).

OTHER

LABORATORY TESTS

- Plasma T4 concentration in cats \geq 6 years old
- Plasma cardiac troponin I concentration (more specific if ischemic heart disease or myocarditis suspected).

IMAGING

Thoracic Radiography

- Cardiomegaly with severe bi-atrial enlargement (“valentine” heart on v/d projections).
- Interstitial or alveolar infiltrates or pleural effusion with pulmonary venous distention if in CHF.

Echocardiography

- Note:* Definitive diagnostic criteria are poorly defined and remain controversial. Early (non-congestive) RCM has rarely been documented in cats.
- Anatomical findings:
 - Severe bi-atrial enlargement
 - Non-hypertrophied, non-dilated left ventricle (normal chamber dimension, normal wall thickness)
 - Severe enlargement of the left atrium with spontaneous echocardiographic contrast or thrombi frequently seen
 - Prominent, often diffuse echogenic scar (“moderator bands”, false tendons) leading to a small left ventricular lumen size and narrowing of the mid-ventricle (endomyocardial fibrosis)
 - Focal areas of highly echogenic and often thin myocardium indicative of ischemia or scarring
 - Myocardium can appear normal with pure myocardial form of RCM
 - Pleural effusion

and mild to moderate pericardial effusion may be present.

- Functional findings:
 - Severe left ventricular diastolic dysfunction (restrictive left ventricular filling with an E:A ratio > 2.0 , short isovolumic relaxation time (< 37 msec), shortened deceleration time of E (< 50 msec), and E:E' $\gg 15$)
 - Normal to low normal left ventricular systolic function (in some cases LV systolic dysfunction is present)
 - Regional wall motion abnormalities possible.
 - Severe left atrial appendage enlargement with evidence of blood stasis
 - Midventricular obstruction with flow turbulence in cats with bridging endomyocardial fibrosis
 - In cats with secondary RCM, characteristics of the underlying disease can predominate; however, severe atrial enlargement and restrictive LV filling will be present in nearly all cats.

DIAGNOSTIC PROCEDURES

Electrocardiography

- Note:* ECG findings are neither sensitive nor specific.
- Sinus tachycardia is common, but cats with severe CHF and hypothermia may be bradycardic.
- Ventricular or supraventricular ectopic beats, paroxysmal or sustained supraventricular or ventricular tachycardia, or atrial fibrillation
- Atrial or ventricular enlargement patterns
- ST segment elevation or depression.

Pathology

- Note:* Histopathologic confirmation is needed in the definitive diagnosis of RCM.
- Increased heart weight (> 19 g)
- Severe bi-atrial dilatation
- Locally or diffusely thickened opaque endocardium
- False tendons (“moderator bands”) present in some cats
- Normal luminal size of the left and right ventricle (enlargement possible with secondary RCM or CHF)
- Diffuse or focal cardiomyocyte disarray
- Increased interstitial and replacement fibrosis
- Abnormal intramural coronary arterioles with medial hypertrophy and narrowed lumen
- Increased number of inflammatory cells seen only in cats with acute endomyocarditis—this finding is commonly absent in cats with endocardial fibrosis.

TREATMENT

APPROPRIATE HEALTH CARE

- Patients with acute, severe CHF are hospitalized for emergency care.
- Mildly symptomatic animals can be treated with outpatient medical management.

NURSING CARE

- Dyspneic animals should receive oxygen.
- Sedation and preload-reducing drugs are mandatory.
- Thoracocentesis if relevant pleural effusion.
- Low-sodium fluids are only administered if dehydration present and kidney function is compromised.
- Maintain

(CONTINUED)

CARDIOMYOPATHY, RESTRICTIVE—CATS

C

a low-stress environment (e.g., cage rest, minimize handling). • Heating pad for hypothermic patients. • Respiratory rate should be used to monitor the immediate success of treatment.

ACTIVITY

- Cage rest is suggested for CHF patients.

DIET

- In acute heart failure, maintain intake with hand feeding if necessary.

CLIENT EDUCATION

- The owner should be counseled regarding the technique of pill administration in cats, possible adverse effects of medications, the importance of maintaining stable food and water intake, and monitoring their cat's resting respiratory rate at home.

**MEDICATIONS****DRUG(S) OF CHOICE*****Acute Congestive Heart Failure***

- Parenteral administration of furosemide (0.5–2 mg/kg IV, IM, SC q1–6h). CRI may be considered. • Dermal application of nitroglycerin ointment (2%, one eighth—one fourth inch q12h). • Oxygen delivered by cage, mask, nasal tube. • Thoracocentesis as necessary to reduce or eliminate pleural effusion. • Dobutamine only if cats are hypotensive (systolic blood pressure < 90 mmHg); 1–5 µg/kg/minute as continuous rate infusion, start a lower dose and increase over 0.5 to 1 hour). • Severe supraventricular tachyarrhythmias can be treated with regular diltiazem (1.5–2.5 mg/kg PO q8h) or long-acting diltiazem (10 mg/kg PO q24h). • Ventricular tachycardia may resolve with resolution of CHF. • Acute therapy of ventricular tachycardia may include lidocaine (0.25–0.5 mg/kg IV SLOWLY); monitor closely for neurologic signs of toxicity. • Pimobendan (1.25 mg/cat PO q12h) may be helpful to increase cardiac performance in acute heart failure but is only used in animals that cannot be stabilized and systemic hypotension cannot be corrected.
- Note:* Pimobendan is not approved for clinical use in cats and clinical safety and efficacy data are limited. Antiplatelet medication (Clopidogrel bisulfate, 18.75 mg PO q24h) or anticoagulants (e.g., unfractionated heparin, 150–250 IU/kg SC q6h) may be administered, in particular in cats with severe left atrial enlargement and spontaneous echocardiographic contrast.

Chronic Therapy

- Furosemide is gradually decreased to lowest effective dose. • Angiotensin-converting enzyme inhibitors (ACEIs) may reduce fluid retention, decrease the need for diuretics, and counterbalance adverse effects of diuretics

(e.g., enalapril 0.25–0.5 mg/kg PO q12–25h). • Diltiazem decreases heart rate and improves supraventricular arrhythmias in affected cats. The addition of digoxin (0.007 mg/kg PO q48h) may allow better control of ventricular response rate in cats with atrial fibrillation. Cats with hemodynamically important ventricular and supraventricular ectopy can also benefit from sotalol (0.5–2.0 mg/kg PO q12h). • Pimobendan (0.625–1.25 mg/cat PO q12h) may be helpful in the management of chronic heart failure. *Note:* Pimobendan is not approved for clinical use in cats. • Treat associated conditions (e.g., dehydration, hypothermia, hypokalemia). • Clopidogrel (one fourth of a 75-mg tablet PO q24h) to inhibit platelet chronically. Aspirin (25 mg/kg PO q72h) may also be considered but efficacy is questionable. In cases of echogenic smoke or prior thromboembolism, both drugs (clopidogrel and aspirin) may be used concurrently. • Treatment of cats with preclinical RCM has rarely been reported but includes ACEIs and antiplatelet drugs. There is currently no specific treatment for left ventricular diastolic dysfunction available.

CONTRAINdications

- For beta-blocking drugs—should not be administered in cats with RCM. • For diltiazem—bradycardia, atrioventricular block, myocardial failure, and hypotension.
- For furosemide—severe dehydration, severe hypokalemia, and moderate to severe azotemia. • For ACEIs—moderate to severe azotemia, hypotension, and hyperkalemia.

POSSIBLE INTERACTIONS

- Use of ACEIs in cats on high doses of furosemide may result in hypotension, azotemia, and hyperkalemia. • Chronic aspirin therapy may increase risk of renal side effects of ACEIs and may lead to inappetence and gastrointestinal upset.

**FOLLOW-UP****PATIENT MONITORING**

- Frequent physical re-examinations to assess response to treatment and resolution of CHF.
- Frequent re-evaluation of hydration status and renal function is important in the first few days of therapy to avoid dehydration, hypokalemia, and azotemia. • Repeated thoracocentesis if necessary. • “Hands-off” hourly assessment of respiratory rate in first 12–24 hours can be used to monitor efficacy of CHF therapy. • Radiographs may be repeated in 12–24 hours to monitor pulmonary infiltrate resolution. • Repeat physical examination and analysis of blood biochemistries after 3 to 7 days of treatment of acute CHF. • ECG and radiographs repeated at clinician’s discretion. • Stable patients are reevaluated every 2–4 months or

more frequently if problems occur. Repeat echocardiograms are indicated every 6 to 9 months.

PREVENTION/AVOIDANCE

- No known preventative measures for RCM.

POSSIBLE COMPLICATIONS

Tissue necrosis or loss of function in limbs affected by thromboembolic complications, adverse effects of medications, sudden death, and euthanasia due to refractory heart failure.

EXPECTED COURSE AND PROGNOSIS

- Somehow variable, but most cats have a grave prognosis.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Aortic thromboembolism

AGE-RELATED FACTORS

Hyperthyroidism should be ruled out with appropriate testing in feline cardiovascular patients ≥ 6 years of age.

SYNONYMS

- Intermediate cardiomyopathy • Unclassified cardiomyopathy

SEE ALSO

CARDIOPULMONARY ARREST

BASICS

DEFINITION

- Cessation of effective perfusion and ventilation because of the loss of coordinated cardiac and respiratory function.
- Cardiac arrest invariably follows respiratory arrest if not recognized and corrected.

PATHOPHYSIOLOGY

- Generalized or cellular hypoxia may be the cause or effect of sudden death.
- After 1–4 minutes of airway obstruction, breathing efforts stop while circulation remains intact.
- If obstruction continues for 6–9 minutes, severe hypotension and bradycardia lead to dilated pupils, absence of heart sounds, and lack of palpable peripheral pulse.
- After 6–9 minutes, myocardial contractions cease even though the ECG may look normal—pulseless electrical activity (formerly electrical mechanical dissociation).
- Ventricular fibrillation, ventricular asystole, and pulseless electrical activity are rhythms indicating cessation of myocardial contractility.

SYSTEMS AFFECTED

- All systems are affected, but those requiring the greatest supply of oxygen and nutrients are affected first.
- Cardiovascular.
- Renal/Urologic.
- Neurologic.

SIGNALMENT

- Dog and cat
- Any age, breed, or sex

SIGNS

- Lack of response to stimulation
- Loss of consciousness
- Dilated pupils
- Cyanosis
- Agonal gasping or absence of ventilation
- Absence of peripheral pulses
- Hypothermia
- Absence of audible heart sounds

CAUSES

- Hypoxemia caused by ventilation perfusion mismatch, diffusion barrier impairment, hypoventilation, or shunting.
- Poor oxygen delivery due to anemia or vasoconstriction.
- Myocardial disease—infectious, inflammatory, infiltrative, traumatic, neoplastic, or embolic.
- Acid-base abnormalities.
- Electrolyte derangements—hyperkalemia, hypocalcemia, and hypomagnesemia.
- Hypovolemia.
- Shock.
- Anesthetic agents.
- Sepsis/septic shock.
- CNS trauma.
- Electrical shock.

RISK FACTORS

- Cardiovascular disease
- Respiratory disease
- Trauma
- Anesthesia
- Septicemia
- Endotoxemia
- Ventricular arrhythmias—ventricular tachycardia, R on T phenomenon, multifocal ventricular complexes
- Increased parasympathetic tone—gastrointestinal disease, respiratory disease, manipulation of eyes, larynx, or abdominal viscera
- Prolonged seizing
- Invasive cardiovascular

manipulation—pericardiocentesis, surgery, angiography

DIAGNOSIS

- Sudden cardiovascular collapse associated with inadequate cardiac output can lead to severe consequences.
- Quick assessment and diagnosis are critical.
- Assess the ABCs—airway, breathing, circulation.

DIFFERENTIAL DIAGNOSIS

- Severe hypovolemia and absence of palpable pulses.
- Pericardial effusion with cardiac tamponade, decreased cardiac output, and muffled heart sounds.
- Pleural effusion with respiratory arrest.
- Respiratory arrest can be confused with CPA.
- Upper airway obstruction can rapidly progress to CPA.

CBC/BIOCHEMISTRY/URINALYSIS

May help identify an underlying cause for CPA but should not be part of initial triage.

OTHER LABORATORY TESTS

- Arterial blood gas evaluation may be useful during or after resuscitative procedures, but is not part of initial emergency management.
- Venous blood gas evaluation may be more useful during resuscitation than arterial blood gas and provides electrolyte and lactate concentrations.

IMAGING

- Thoracic FAST (TFAST) focused assessment with sonography for trauma may be useful in identifying underlying disease.
- Abdominal FAST (AFAST) focused assessment with sonography for trauma may be useful in identifying underlying disease.
- Thoracic radiographs may help identify underlying disease processes but only consider after the patient has been stabilized.
- Echocardiography may confirm pericardial effusion or underlying myocardial disease but should not interfere with resuscitative procedures.
- Abdominal radiographs or ultrasound may be useful once patient is stabilized to identify underlying disease.

DIAGNOSTIC PROCEDURES

Once CPA has developed, continuous ECG monitoring, blood pressure monitoring, pulse oximetry, and capnography may be useful in monitoring effectiveness of resuscitative procedures.

TREATMENT

- Institute cardiopulmonary resuscitation (CPR) immediately upon diagnosing CPA; CPR can be divided into Basic Life Support and Advanced Life Support.
- Current (2010) American Heart Association recommendations are published and electrical defibrillation was

introduced into Basic Life Support in the 2000 recommendations.

- The Reassessment Campaign on Veterinary Resuscitation (RECOVER) published evidence based guidelines in 2012.

BASIC LIFE SUPPORT

Immediate recognition of CPA

A—Airway

- Assessment—visualize the airway by extending the patient's head and neck and pulling the tongue forward; clear any debris (e.g., secretions, blood, or vomitus), manually or with suction.
- Establish an airway by either oral endotracheal intubation or, if complete obstruction exists, emergency tracheostomy.
- Correct endotracheal placement should be confirmed visually, by auscultation and/or capnography.

B—Breathing

- Assessment—make sure animal is not breathing.
- Institute artificial ventilation—administer two short breaths of ~2 seconds in duration each and reassess; if no spontaneous respiration occurs, continue ventilations at a rate of approximately 10 breaths per minute with a tidal volume of 10 mL/kg and an inspiratory time of 1 second. Peak airway pressures should not exceed 20 cm H₂O.
- Techniques for ventilation include mouth to mouth, mouth to nose, or mouth to endotracheal tube; these techniques provide ~16% oxygen; use of a mechanical resuscitator (Ambu bag) and room air provides 21% oxygen.
- The preferred technique is endotracheal intubation and ventilation with 100% oxygen using an Ambu bag or an anesthesia machine.
- The suggested rate of oxygen administration is 150 mL/kg/minute.

C—Circulation

- Assessment—palpate peripheral pulses and auscultate heart to confirm CPA.
- External thoracic compression provides at best ~30% of normal cardiac output; internal cardiac compression is two to three times more effective in improving cerebral and coronary perfusion.
- Hemodynamic studies in animal models suggest that several different mechanisms exist for generation of blood flow during chest compressions (artificial systole); during external cardiac massage the cardiac pump theory takes advantage of direct compression of the heart in patients weighing <7 kg; in patients >7 kg the thoracic pump theory is used; this technique uses increases in intrathoracic pressures to increase cardiac output via indirect effects on the major

COMPRESSION/VENTILATION TECHNIQUES

- Perform CPR in continuous, uninterrupted, 2-minute cycles when possible.
- Perform chest compressions rapidly, at a rate of between 100 and 120 compressions/minute;

(CONTINUED)

CARDIOPULMONARY ARREST

C

the chest should be displaced ~30%. • Use the cardiac pump in patients weighing < 10 kg body weight; with the patient in right lateral recumbency, perform compressions directly over the heart (intercostal spaces 3–5); this can be performed using one or two hands. • Use the thoracic pump for patients weighing > 10 kg body; with the patient in right lateral recumbency, apply thoracic compressions at the widest portion of the thorax. • Different compression and ventilation regimes have been reported. • Providing appropriate compressions (100–120 per minute) and appropriate ventilations (10 per minute) without stopping compressions for ventilations and without trying to synchronize ventilations with compressions is the goal. • Try to minimize discontinuing compressions to interpret ECG. • Avoid leaning on patient during chest compressions and allow full chest wall recoil. • Interposing abdominal compressions between chest compressions enhances cerebral and coronary blood flow by increasing aortic diastolic pressure. This technique has not been shown to improve survival but should be considered if adequate personnel are available.

OPEN-CHEST CPR

- Indicated if closed-chest CPR is ineffective or pre-existing conditions such as flail chest, obesity, diaphragmatic hernia, pericardial effusion or other significant intrathoracic disease preclude closed-chest techniques.
- Perform through a left thoracotomy at the fifth or sixth intercostal space. • Perform a pericardectomy. • The palmar surface of the fingers and thumb are used to push the ventricular blood toward the great vessel; digital compression of the descending aorta may help improve coronary and cerebral perfusion.

ADVANCED LIFE SUPPORT**D—Drugs**

- Base drug selection on the arrhythmia present. • Atropine and epinephrine are most often correct selections. • Atropine—0.04 mg/kg IV (0.54 mg/mL) ~1 mL/10 kg patient. • Epinephrine low dose—0.01 mg/kg IV (1:10,000) 1 mL/10 kg patient. • Other agents such as vasopressin (0.8 U/kg IV) may be considered if initial therapy fails. • Drugs can be administered every other CPR cycle (approximately every 4 minutes).

E—ECG

- Accurate ECG interpretation is imperative.
- Check ECG leads. • Minimize discontinuation of chest compressions while reading ECG

F—Fibrillation Control and Fluids

- Defibrillation is time-dependent; perform immediately. • Administer fluids cautiously unless known hypovolemia has led to CPA. Crystalloids, colloids, or blood products may be considered, including Oxyglobin.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Base drug selection on the arrhythmia present.
- Administer drugs via central vein, intratracheal, intraosseous, or peripheral vein, in descending order of preference. Volumes should be doubled if administering via the intratracheal route and diluted in saline.
- Use intracardiac drug administration only as a last resort unless open-chest CPR is being performed. Administration of agent into the left ventricle with concurrent digital or mechanical compression of descending aorta is optimal.

PRECAUTIONS

Only use high rates of fluid administration if there is a known history of hypovolemia; excessive fluid administration may lead to decreased coronary perfusion.

**FOLLOW-UP****PATIENT MONITORING**

- Maintain normal heart rate and blood pressure with fluids and inotropic agents.
- Arterial blood pressure. • Central venous pressure. • Blood gas analysis. • Support respiration with artificial ventilation and supplemental oxygen. • Neurologic status—if signs of increased intracranial pressure develop, consider mannitol, corticosteroids, and furosemide. • ECG—continuously.
- Urine output. • Body temperature.
- Radiograph thorax to assess resuscitative injury. • Diagnose and correct factors that led to initial CPA.

PREVENTION/AVOIDANCE

Careful monitoring of all critically ill patients

POSSIBLE COMPLICATIONS

- Vomiting • Aspiration pneumonia
- Fractured ribs or sternebrae • Pulmonary contusions and edema • Pneumothorax
- Acute renal failure • Neurologic deficits
- Cardiac arrhythmias

EXPECTED COURSE AND PROGNOSIS

- Prognosis depends on underlying disease process. • Rapid return to spontaneous cardiac and respiratory function improves the prognosis. • Overall prognosis is poor; < 10% of patients are discharged.

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

None

SYNONYMS FOR CPA

CARNITINE DEFICIENCY

BASICS

OVERVIEW

L-carnitine is a quaternary amine that is an important part of the enzyme systems that transport fatty acids into mitochondria so that they can be oxidized to make energy available to the cell. It also has other important metabolic and scavenging functions within the cell. In the heart and other organs that depend on the oxidation of fatty acids to supply their high energy requirements for contraction or other work, L-carnitine deficiency results in inadequate production of energy to meet those needs. Carnitine deficiency complicates some cases of dilated cardiomyopathy in dogs. The presence of L-carnitine deficiency in association with cardiomyopathy does not mean that the deficiency is the sole cause of the myopathy, although correcting the deficiency (if possible) makes medical and physiologic sense.

L-carnitine is not synthesized in heart or skeletal muscle and must therefore be transported into those cells from plasma. In the dog, dietary carnitine intake influences plasma concentrations significantly, and oral carnitine supplementation is usually an effective means of raising plasma and subsequently muscle carnitine levels. The FDA has approved the addition of physiologic amounts of carnitine to commercial dog foods for the prevention of plasma (and subsequently muscle) carnitine deficiency. This action is prudent based on current knowledge regarding the lack of L-carnitine in most commercial dog food and the effect of those diets on canine carnitine plasma levels. It is not known whether this action will affect the prevalence of dilated cardiomyopathy or other manifestations of carnitine deficiency.

SIGNALMENT

Dogs

- Boxer, Doberman pinscher, Great Dane, Irish wolfhound, and other large- and giant-breed dogs appear to be most commonly affected with dilated cardiomyopathy.
- At least some American cocker spaniels with DCM are carnitine-deficient, and a blinded, placebo-controlled trial suggests that L-carnitine supplementation combined with taurine supplementation is beneficial in the medical management of these patients.

SIGNS

- Clinical signs of carnitine deficiency can be diverse; mitochondria in all tissues use L-carnitine to produce energy from fatty acids.
- Signs range from heart muscle failure and dilated cardiomyopathy (most frequently

recognized) to skeletal muscle pain, weakness, exercise intolerance, and/or lethargy.

- See Cardiomyopathy, Dilated—Dogs.

CAUSES & RISK FACTORS

• Some dogs with cardiomyopathy have been documented to have carnitine transport defects, in which muscle carnitine is low even in the face of adequate plasma carnitine concentrations. In order to transport fatty acids or other compounds (such as acetyl Co-A) into or out of the mitochondria, free L-carnitine is esterified to the substance, forming a carnitine ester. With some mitochondrial enzyme defects (e.g., multiple Co-A dehydrogenase defects), free L-carnitine is used to "scavenge" potentially toxic metabolites, which appear harmlessly in the urine as carnitine esters. In these cases, the total amount of carnitine (free carnitine plus esterified) in the plasma or muscle may be normal or even high, but the ratio of free carnitine to esterified carnitine is decreased. This situation is known as carnitine insufficiency (because even though the concentration of free carnitine may be within the normal range, it is insufficient to meet the body's pathologically increased need for free carnitine).

- Certain families of boxers appear to be at especially high risk of developing symptomatic dilated cardiomyopathy in association with and probably caused by carnitine deficiency.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

Plasma carnitine concentrations appear to be a specific but insensitive indicator of myocardial or skeletal muscle carnitine deficiency. Plasma free carnitine concentrations of less than 8 micromoles/L are considered diagnostic of systemic carnitine deficiency. Plasma concentrations in the normal or supernormal range do not rule out myocardial carnitine deficiency or insufficiency.

DIAGNOSTIC TEST

Endomyocardial biopsy specimens must be blotted dry and snap frozen in liquid nitrogen. Measurement of free and esterified L-carnitine concentrations normalized to the amount of non-collagenous protein in the biopsy remains the only definitive diagnostic test. Myocardial free carnitine concentrations of less than 3.5 nanomoles/mg of non-collagenous protein are considered diagnostic of myocardial carnitine deficiency. Ratios of esterified to free carnitine > 0.4 are

considered diagnostic of carnitine insufficiency.

TREATMENT

Treatment with L-carnitine does not replace conventional treatment for DCM, even in most dogs with carnitine deficiency. Some dogs, including some families of carnitine-deficient boxers, fail to respond clinically to supplementation. While supplementation dramatically improves a small percentage (about 5%, in the author's experience) of dogs with dilated cardiomyopathy, the overall efficacy of L-carnitine supplementation for the treatment of dilated cardiomyopathy is untested. If a trial of metabolic supplementation is desired in the absence of known L-carnitine deficiency, the combination of L-carnitine with taurine (500 mg q8–12h), and Co-Q10 (100 mg q8–12h) seems prudent.

MEDICATIONS

DRUG(S)

Carnitine Supplementation

- Large-breed dogs—2 g (approximately 1 tsp L-carnitine powder) q8–12h.
- American cocker spaniels—(in combination with taurine) 1 g (approximately one-half tsp L-carnitine powder) q8–12h.

FOLLOW-UP

Repeat echocardiogram 3–6 months after initiating L-carnitine supplementation to assess the efficacy of treatment.

CATARACTS

BASICS

DEFINITION

Opacification of the lens (focal or diffuse).

PATHOPHYSIOLOGY

- The normal lens is composed of perfectly aligned lens fibers that create a transparent structure. A clear capsule surrounds the cortex and nucleus. New lens fibers are continually produced at the equatorial region of the lens cortex throughout life. The aqueous humor provides nutrition to the lens.
- A cataract occurs when there is derangement of lens fibers due to alterations in lens nutrition, energy metabolism, protein synthesis or metabolism, or osmotic balance.
- Anterior uveitis is a common cause of alteration of lens nutrition. Genetics can result in altered protein and energy metabolism, or protein synthesis, in the lens.
- Diabetes mellitus will affect the osmotic balance within the lens of the dog. Hyperglycemia increases glucose in the aqueous and lens overwhelming the normal glycolysis pathway; glucose is then shunted to the sorbitol pathway; when sorbitol is produced it creates an osmotic gradient that draws water into the lens, resulting in the rapid formation of a cataract from lens fiber swelling and derangement. Because the sorbitol pathway requires aldose reductase enzyme, the more aldose reductase in the lens, the more readily diabetic cataracts will form. Dogs have more aldose reductase than cats, making cats more resistant to developing diabetic cataracts. There is some variability between individual dogs, which may explain why some diabetic dogs are more resistant to cataract development.

SYSTEMS AFFECTED

Ophthalmic

GENETICS

- Inheritance has been established for many dog breeds (see "Suggested Reading"); the most common mode of inheritance is autosomal recessive.
- Inheritance has been established in the Himalayan cat (autosomal recessive).

INCIDENCE/PREVALENCE

- Cataract is one of the leading causes of blindness in dogs.
- The prevalence of genetic cataracts varies significantly between breeds; it has been reported as high as 10% in some breeds.
- Most diabetic dogs will develop cataracts regardless of their diabetic control.
- Cataracts are rare in cats.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Over 135 dog breeds are suspected as being predisposed to hereditary cataracts.

Mean Age and Range

Cataracts can develop at any age; genetic cataracts can develop as early as 6 months of age.

SIGNS

Historical Findings

- The owner may notice the cloudy/white appearance of the lens.
- Vision loss may be noted by the owner when the cataracts are bilateral, especially diabetic cataracts that have a rapid, bilateral onset.
- Polyuria/polydipsia is usually noticed by the owner prior to cataract development in diabetic dogs.

Physical Examination Findings

- General physical examination findings: unremarkable unless the dog is an undiagnosed diabetic.
- Ophthalmic examination findings: opacification in one or both lenses.
 - Incipient stage: small, focal opacity/opacities in the lens that does not interfere with the view of the fundus; no vision deficits.
 - Immature stage: diffusely cloudy appearance to the lens with the tapetal reflection still visible and some portions of the fundus visible through a dilated pupil; the menace reflex is positive but tracking may be negative.
 - Mature stage: completely opaque lens with no tapetal reflection visible; blind.
 - Hypermature stage: wrinkled lens capsule, areas of dense white mineralization, may have portions of liquefied cortex (white, sparkly to clear); deep anterior chamber; blind unless there is a large area of clear liquefied cortex.
 - Intumescent mature cataract: opaque, swollen lens usually due to the hyperosmotic effect of diabetes; shallow anterior chamber.

CAUSES

- Hereditary—most common cause in dogs.
- Diabetes mellitus.
- Anterior uveitis—either by altered nutrition of the lens from the abnormal aqueous, or by posterior synechia and inflammatory debris causing opacification of the anterior lens capsule.
- Trauma—perforating injury that disrupts the anterior lens capsule, most commonly a cat claw injury, especially in puppies and kittens.
- Senile—slowly progressive cataract in geriatric animals usually beginning as dense nuclear sclerosis followed by gradual spoke-like opacities extending into the cortex.
- Congenital—due to heredity, *in utero* insult, or associated with other congenital ocular anomalies such as persistent pupillary membranes, persistent hyperplastic primary vitreous/persistent tunica vasculosa lentis, or a hyaloid artery attachment.

- Surgery—transpupillary laser energy, intraocular instrument trauma.

- Toxic—from long-term ketoconazole therapy; suspected secondary to toxic by-products of degenerating photoreceptors in dogs with progressive retinal atrophy.
- Radiation—when the eye is in the radiation treatment field for head neoplasia.
- Hypocalcemia—can cause bilateral, diffuse punctate or incipient cataracts.
- Nutritional—use of unbalanced milk replacers in bottle-fed puppies and kittens.
- Electrical shock—chewing electrical cords or lightning strike.

RISK FACTORS

- Diabetes mellitus is a great risk factor in dogs.
- Chronic anterior uveitis.
- Progressive retinal atrophy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Lenticular nuclear sclerosis—normal aging change in the lens of dogs and cats starting at 6 years of age due to compression of older lens fibers in the center of the lens; gradually becomes more visible with age and can be mistaken for a cataract in geriatric patients; definitive diagnosis can be made using mydriasis (1% tropicamide) and the observation of a perfectly round, bilaterally symmetrical, homogeneous nucleus in the center of each lens, and the ability to view the fundus through the lens; vision is rarely affected and treatment is not indicated.

CBC/BIOCHEMISTRY/URINALYSIS

Dogs with diabetic cataracts may have hyperglycemia and glucosuria.

IMAGING

Ocular ultrasound can be used to evaluate the posterior lens capsule for any sign of rupture and can evaluate for retinal detachment prior to cataract surgery.

DIAGNOSTIC PROCEDURES

Electroretinogram is performed prior to cataract surgery to evaluate for retinal degeneration when the fundus is not visible due to the cataract.

TREATMENT

ACTIVITY

For safety, blind animals should not be allowed access to an in-ground swimming pool or elevated decks with open railings; use caution near stairs; restrict outside activity to fenced yards or leash walks.

CATARACTS

(CONTINUED)

CLIENT EDUCATION

- Cataract surgery is routinely performed with an overall 80–90% success rate.
- Once the cataracts are removed they cannot return.
- Artificial lens implants will restore essentially normal vision.
- Evaluation for surgery should be done early in the course of cataract development to avoid complications that may result in the cataract becoming inoperable, to allow time to plan for the surgery, and in some cases to eliminate the need and extra cost for an ocular ultrasound and electroretinogram.

SURGICAL CONSIDERATIONS

- Phacoemulsification (removal of the cataract through a 3 mm corneal incision using ultrasonic waves to emulsify and then aspirate the lens cortex and nucleus) is the most common technique for cataract removal.
- The ideal time for cataract surgery is the immature/early mature stage.
- Inherited, diabetic, and senile cataracts are potentially good candidates for surgery; cataracts secondary to anterior uveitis are normally poor surgical candidates.
- Artificial intraocular lenses are routinely placed inside the patient's lens capsule; lens implants restore normal focus and help minimize posterior capsular fibrosis; if a lens cannot be implanted (e.g., due to an unstable lens capsule or luxated lens), the dog or cat will still have very functional vision.
- Traumatic lens perforation with release of lens cortex into the anterior chamber requires immediate removal of the lens to avoid a severe granulomatous anterior uveitis and vision loss.

MEDICATIONS

DRUG(S) OF CHOICE

- Topical anti-inflammatory medication is recommended q6–24h to help prevent or treat lens-induced uveitis with immature, mature, and hypermature cataracts; this can be a topical NSAID such as flurbiprofen, diclofenac, or ketorolac, or a topical steroid such as prednisolone acetate 1% or dexamethasone 0.1%; topical NSAIDs may be preferable in diabetic patients unless the uveitis is severe.
- Topical atropine q8–24h is indicated for lens-induced uveitis; *atropine is contraindicated with glaucoma.*

- Oral NSAIDs (carprofen, meloxicam, deracoxib) are also used to treat lens-induced uveitis.
- Topical antioxidants are advertised as able to reverse cataract changes; to date there has been no published data conclusively showing a significant reversal, or delay in progression, of a cataract with antioxidant therapy; unfortunately time spent trying medical therapy will delay evaluation for surgery, resulting in surgery being performed at a suboptimal stage, or complications from the cataract making it inoperable.
- Topical aldose reductase inhibitors are currently under investigation and may prove helpful in delaying the onset of diabetic cataracts in dogs in the future.

FOLLOW-UP

PATIENT MONITORING

- Incipient or early immature cataracts should be monitored regularly for progression in order to select the ideal time for surgery and to avoid complications associated with cataracts.
- Postoperative monitoring by the surgeon is critical for the success of surgery and should be clearly discussed with the owner prior to surgery.

PREVENTION/AVOIDANCE

Do not breed animals with cataracts.

POSSIBLE COMPLICATIONS

- Lens-induced uveitis—associated with hypermature cataracts and cataracts that progress very rapidly; caused by antigenic lens proteins leaking through the lens capsule. Clinical signs can be very subtle (e.g., low intraocular pressure) to extreme (granulomatous uveitis with dense aqueous flare, miosis, synechia, keratic precipitates); preoperative lens-induced uveitis increases the risk of postoperative complications.
- Secondary glaucoma—impaired aqueous outflow from intraocular changes associated with lens-induced uveitis, or from an intumescent cataract causing a forward displacement of the iris narrowing the iridocorneal angle.
- Retinal detachment—associated with hypermature cataracts and cataracts in young dogs with a rapid onset and cortical liquefaction.

- Lens luxation—associated with hypermature cataracts in which the lens and capsule shrink, causing the zonules to stretch and break, resulting in a lens subluxation or luxation.

EXPECTED COURSE AND PROGNOSIS

- Most cataracts are progressive, although the rate of progression can vary widely depending on age, breed, and location of the cataract.
- Long-term prognosis following cataract surgery is very good; however, some patients have increased risk for postoperative complications; preexisting anterior uveitis (even when medically controlled), genetic predisposition for glaucoma, and unstable peripheral retina or undetected peripheral retinal tears increase the risk for postoperative chronic uveitis, glaucoma, and retinal detachment, respectively.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Retinal detachment
- Lens-induced uveitis
- Congenital ocular anomalies

AGE-RELATED FACTORS

- Immediate referral for cataracts in young dogs (< 2 years of age) is recommended because the cataract can progress very rapidly with partial cortical liquefaction followed by retinal detachment.
- Nuclear sclerosis is prominent in geriatric animals; a dilated exam may be necessary to definitively distinguish nuclear sclerosis from cataract.

CEREBELLAR DEGENERATION

BASICS

OVERVIEW

- Progressive, breed-specific, genetically induced premature aging and death of cerebellar cortical neurons due to failure in neuronal energy supply, excitotoxicity, and inflammation; neonatal, postnatal, and (rare) adult onset.
- Non-progressive disorder due to *in utero* or neonatal viral infection in cats (feline panleukopenia) and dogs (canine herpesvirus).

SIGNALMENT

Progressive

- Dog and cat. • Autosomal recessive mode of inheritance—Finnish hound (signs at 9 weeks), Kerry blue terrier and Chinese crested (signs at 12–16 weeks), rough-coated collie (signs at 1–2 months), Old English sheepdog and Gordon setter (signs at 6–36 months), American Staffordshire terrier (signs at 1.5–9 years), and domestic shorthair cats (signs at 7–9 weeks). • Suspected autosomal recessive mode of inheritance—beagle and samoyed (signs at 3 weeks), English bulldog (signs at 5–8 months), Bern running dog, and Irish setter, Brittany spaniel (signs at 7–13 years). • X-linked mode of inheritance—probable in English pointer because only males affected. • Rhodesian ridgeback—cerebellar degeneration and coat color dilution reported in one family.
- Adult-onset cerebellar cortical abiotrophy with retinal degeneration reported in a domestic shorthair cat. • Cerebellar cortical abiotrophy described in two Havana brown kittens—signs observed at 4 and 5 weeks, inherited disorder suspected.

Non-progressive

- Dog and cat. • Coton de Tulear—autosomal recessive mode of inheritance.
- Signs appear when patient is 2–5 weeks old.

SIGNS

- Hypermetria. • Broad-based stance.
- Swaying of body. • Intention tremors.
- Lack of menace responses with normal vision and pupillary light reflexes. • Head tilt and episodes of vestibular ataxia with resting or positional nystagmus. • Diffuse tapetal hyperreflectivity on funduscopic exam.
- Decerebrate posture—opisthotonus with extensor rigidity of the forelimbs and flexed hind limbs. • Altered mentation, proprioceptive deficits, and paresis are not features of this condition. • Progression of signs varies. • Use caution in interpreting progression of signs. As a puppy or kitten with cerebellar degeneration due to *in utero* or neonatal infection grows and becomes more

active, cerebellar ataxia may appear to worsen, but the disease itself is non-progressive.

CAUSES & RISK FACTORS

- Feline panleukopenia or canine herpesvirus infection *in utero* or neonatally. • Poor vaccination history or exposure to modified live virus during gestation.
- Breeding affected animals or animals with familial history of cerebellar degeneration.
- A syndrome of hepatocerebellar degeneration was described in a litter of Bernese mountain dogs.
- Paraneoplastic cerebellar degeneration has been reported in humans.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lysosomal storage diseases—diffuse diseases of the CNS; differentiate by signs related to other parts of the CNS besides the cerebellum.
- Toxicity (e.g., hexachlorophene)—differentiate by history of exposure.
- Inflammatory diseases—*infectious* (e.g., canine distemper and FIP); frequently accompanied or preceded by systemic signs of illness. Immune diseases (dogs); in both cases, differentiate by MRI and CSF analysis.
- Cerebellar cyst—differentiate by imaging (MRI or CT). • Medulloblastoma (cerebellar tumor)—reported in dogs and cats < 1 year old; differentiate by imaging (MRI or CT) and CSF analysis.
- Other primary and metastatic tumors in adult dogs—differentiate by imaging (MRI or CT) and CSF analysis.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

IMAGING

MRI—cerebellum may be smaller than normal.

DIAGNOSTIC PROCEDURES

- CSF analysis—normal with non-progressive disease; normal or high protein concentration and normal cell counts with progressive disease. • Cerebellar biopsy—may be only definitive means of antemortem diagnosis.

TREATMENT

- Amantadine has potentiating effects on dopaminergic neurotransmission in the CNS and anticholinergic activity; buspirone is a serotonin agonist; research models demonstrate some promise for progressive cerebellar degeneration. • Neuroprotective agents that may have promising effects such as coenzyme Q10 and acetyl-L-carnitine.

- Outpatient—unless severe deficits preclude nursing care at home. • Restrict activity to safe areas; avoid stairs, proximity to swimming pools, etc. • Diet—normal; restrict intake if vestibular episodes are accompanied by emesis (to avoid aspiration pneumonia).
- Non-progressive disease—patient may show some improvement as animal learns to compensate for disabilities.

MEDICATIONS

DRUG(S)

N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Neurologic status—examine at weekly to monthly intervals if progression of signs is uncertain; consider videotaping patient to determine progression objectively.
- Progression of signs—rate varies; depends on signalment; ranges from days to years.
- Do not vaccinate pregnant animals with modified live virus. • Do not breed animals with a familial history of cerebellar disease.

MISCELLANEOUS

ABBREVIATIONS

- CNS = central nervous system • CSF = cerebrospinal fluid • CT = computed tomography • FIP = feline infectious peritonitis • MRI = magnetic resonance imaging

Consulting Editor Joane M. Parent

CEREBELLAR HYPOPLASIA

BASICS

OVERVIEW

Caused by incomplete development of parts of the cerebellum owing to intrinsic (inherited) or extrinsic (infectious, toxic, or nutritional) factors.

SIGNALMENT

- Symptoms may not be visible until puppies and kittens begin to stand/walk (usually by 6 weeks old).

• Hereditary in Airedale, chow chow, Boston terrier, Labrador retriever, weimaraner, shih-tzu, miniature schnauzer, and bull terrier.

SIGNS

- Symmetrical, non-progressive cerebellar disorder—head bobbing; limb tremors; aggravated by movement or eating and disappear during sleep (intention tremors).
- Cerebellar ataxia, wide-base stance.
- Dysmetria and disequilibrium—falling, flipping over.

CAUSES & RISK FACTORS

- Cats—usually transplacental or perinatal infection with panleukopenia virus (wild or from modified live virus used in some vaccines), which selectively attacks rapidly dividing cells, e.g., external germinal layer of the cerebellum at birth and for 2 weeks post-natal.
- Dogs—hereditary in some breeds (autosomal recessive).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Age, breed, history, typical symmetrical and non-progressive symptoms—usually sufficient for tentative diagnosis.
- Early cerebellar abiotrophy—postnatal degeneration after normal development; slow progression of signs over weeks to months; neonatal onset (beagle, Samoyed, Rhodesian ridgeback, Irish setter, Jack Russell terrier, miniature poodle) or postnatal onset

(Australian kelpie at 5–6 weeks; Kerry blue terrier at 8–16 weeks; rough-coated collie at 4–8 weeks; bullmastiff at 4–9 weeks).

- Neuroaxonal dystrophy—slowly progressive cerebellar signs starting around 5 weeks of age in cats and 7 weeks in Chihuahuas.
- Cerebellar sequels of systemic canine herpesvirus infection—follow systemic illness.
- Concomitant seizures or other cerebral signs—suggest other malformations, such as lissencephaly (wirehaired fox terrier and Irish setter) or hydrocephalus.
- Final diagnosis possible only at necropsy.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

IMAGING

Magnetic resonance imaging—cerebellar atrophy or malformation (incomplete or asymmetrical filling of the caudal cranial fossa by the cerebellum); rule out other malformations.

PATHOLOGIC FINDINGS

- Cerebellum—normally very small in newborn kitten or puppy (cerebellar development continues for up to 10 weeks post-natal); subtle to marked atrophy; as necropsy is performed weeks to months after birth, there is no sign of active inflammation.
- Transverse fibers of the pons—decreased size associated with marked cortical cerebellar atrophy.
- Hydrocephalus—may be concomitant, resulting from multifocal inflammation or multiple malformations (e.g., Dandy-Walker syndrome).
- Microscopic—depletion of cerebellar cortex cellular layers.

TREATMENT

None

PREVENTION

Avoid using modified live panleukopenia vaccines in reproducing female cats and keep cats vaccinated against panleukopenia.

MEDICATIONS

DRUG(S)

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Slight improvement may occur as patient compensates for deficits.
- Deficits—permanent; do not progress; compatible with a normal lifespan.
- Some patients may be acceptable indoor pets.

CARE

- Restrict environment to prevent injuries and road accidents—no climbing, falling, or escaping.
- Nutritional support as needed.
- Euthanasia—severely affected animals that are unable to feed, groom, or be house-trained.

CEREBROVASCULAR ACCIDENTS

C

BASICS

DEFINITION

- Sudden onset of non-progressive focal brain signs.
- Signs must remain for > 24 hours for a diagnosis of CVA.
- Permanent brain damage usually ensues.
- Called transient ischemic attack or "TIA" if clinical signs resolve within 24 hours.

PATOPHYSIOLOGY

- Cerebrovascular diseases are the underlying cause of CVA.
- Brain abnormality resulting from a pathologic process that compromises the blood supply to the brain.
- Lesions affecting the cerebral blood vessels are divided into two broad categories:
 - Hemorrhagic stroke—ruptured blood vessel with hemorrhage into or around the brain
 - Ischemic stroke—abrupt disruption of blood flow from blockage of an artery depriving the brain tissue of oxygen and glucose.

SYSTEMS AFFECTED

- Nervous
- Multisystemic—if underlying cause present

INCIDENCE/PREVALENCE

Unknown; supposed low compared to human

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Ischemic stroke—Cavalier King Charles spaniel and greyhound seem predisposed; small breed (≤ 15 kg) more likely to have cerebellar infarct; large breed (> 15 kg) more likely to have midbrain or thalamic infarct.
- Hemorrhagic stroke—unknown.

Mean Age and Range

Unknown

Predominant Sex

Unknown

SIGNS

Historical Findings

- Ischemic stroke—peracute to acute non-progressive focal brain signs.
- Hemorrhagic stroke—acute to subacute focal or multifocal brain signs that can progress over a short period of time.

Physical Examination Findings

- Fundus examination—may reveal tortuous vessels (systemic hypertension), hemorrhage (coagulopathy or systemic hypertension), or papilledema (elevated ICP).
- Coagulation defects—may underlie hemorrhagic stroke and cause hemorrhage in any tissue or organ and anemia.

Neurologic Examination Findings

- Ischemic stroke—signs depend on the localization of the vascular insult

(prosencephalon, midbrain, pons, medulla, cerebellum). • Hemorrhagic stroke—signs relate to increased ICP with nonspecific forebrain and/or brainstem disturbance.

CAUSES

Ischemic Stroke

Dogs

- Unknown in 50% of cases.
- Endocrine diseases—hyperadrenocorticism, hypothyroidism, diabetes.
- Embolism, thromboembolism—neoplastic (hemangiosarcoma, lymphoma), infectious (associated with bacterial endocarditis or other sources of infection), and aortic or cardiac.
- Systemic hypertension—chronic kidney disease, protein losing enteropathy.
- Fibrocartilaginous embolism.
- Intravascular lymphoma.
- Parasite migration (*Cuterebra*) or embolism (*Dirofilaria immitis*).

Cats

- Parasite migration (*Cuterebra* or heartworms)
- Systemic hypertension—hyperthyroidism, chronic kidney disease, heart disease
- Neoplastic embolism

Hemorrhagic Stroke

Dogs

- Ruptured congenital vascular anomalies
- Primary and secondary brain tumors
- Inflammatory disease of arteries and veins (vasculitis)
- Intravascular lymphoma
- Brain hemorrhagic infarction
- Impaired coagulation

Cats

- Primary and secondary brain tumors
- Inflammatory disease of arteries and veins (vasculitis)
- Brain hemorrhagic infarction
- Impaired coagulation—cerebral amyloid angiopathy
- Systemic hypertension

RISK FACTORS

- Ischemic stroke—systemic hypertension, systemic condition associated with hypercoagulability syndrome.
- Hemorrhagic stroke—systemic hypertension, coagulopathy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Head trauma—history and physical findings suggestive of trauma.
- Decompensation from primary or metastatic brain tumor—signs are progressive.
- Infectious and non-infectious encephalitis—acute to subacute clinical signs that gradually worsen.
- Neurotoxicity—bilateral, symmetrical neurologic deficits.

CBC/BIOCHEMISTRY/URINALYSIS

Most often normal; may show changes reflecting underlying cause.

OTHER LABORATORY TESTS

- Cerebrospinal fluid—unlikely to confirm CVA, may help rule out inflammatory CNS disease. Variable findings; either normal, or

mild mononuclear or neutrophilic pleocytosis; protein concentration occasionally elevated.

- Prothrombin time—screening test for extrinsic mechanism defects.
- Activated partial thromboplastin time—screening test for intrinsic mechanism defects.
- Bleeding time—prolonged in patients with von Willebrand's disease; normal with most other coagulation defects, except disseminated intravascular coagulation.
- Thromboelastography, D-dimer assay and antithrombin III—screening tests for hypercoagulability syndrome as possible cause of ischemic stroke.
- Endocrine testing—hyperadrenocorticism, thyroid disease, and pheochromocytoma.
- Renal disease—urine protein/creatinine ratio.

IMAGING

Ischemic Stroke

- CT—often normal during acute phase.
- MRI—within 12–24 hours of onset to distinguish hemorrhage from infarction. T2-weighted and fluid-attenuated inversion recovery (FLAIR) images particularly useful. T2*-weighted (gradient echo) images to show presence of or exclude intracranial hemorrhage. DWI sequence: ideal for identification of hyperacute stroke, excluding stroke mimics. Perfusion-weighted MRI can be used to depict brain regions of hypoperfusion and derive the tissue at risk by comparing the results with the findings on DWI. Time of flight magnetic resonance angiography and contrast-enhanced MRA can be used to assess intracranial vascular status of stroke patients.

Hemorrhagic Stroke

- CT—very sensitive for detection of acute hemorrhage; hyperdensity due to hyperattenuation of X-ray beam by the globin portion of blood. Attenuation decreases until the hematoma is isodense at about 1 month from onset. Periphery of hematoma contrast-enhances from 6 days to 6 weeks after onset due to revascularization.
- MRI—signal intensity of intracranial hemorrhage is influenced by several intrinsic (time from ictus, source, size and location of hemorrhage) and extrinsic (pulse sequence and field strength) factors. As hematoma ages, oxyhemoglobin in blood breaks down sequentially into several paramagnetic products (deoxyhemoglobin, methemoglobin, hemosiderin) with each different MRI signal intensities. Compared to other conventional sequences, T2*-weighted (gradient echo) images demonstrate readily detectable hypointensity regardless of the time from ictus, the source and location of hemorrhage, or the field strength.
- Multiple hemorrhagic lesions— < 5 mm most often associated with hyperadrenocorticism, hypertension, chronic kidney disease or hypothyroidism. Single hemorrhagic lesion—most often associated

CEREBROVASCULAR ACCIDENTS

(CONTINUED)

with *Angiostrongylus vasorum*. Multiple hemorrhagic lesions— ≥ 5 mm most often associated with *Angiostrongylus vasorum*, primary extracranial neoplasia with metastases (haemangiosarcoma).

DIAGNOSTIC PROCEDURES

Diagnosis of potential underlying causes.

Ischemic Stroke

Evaluate for hypertension (and potential underlying causes), endocrine disease (hyperadrenocorticism, hypothyroidism, hyperthyroidism, diabetes mellitus), chronic kidney disease (especially protein-losing nephropathy), protein-losing enteropathy, heart disease and metastatic diseases (particularly hemangiosarcoma).

Hemorrhagic Stroke

- Evaluate for coagulopathy (and potential underlying causes), hypertension (and potential underlying causes) and metastatic diseases (particularly hemangiosarcoma).

PATHOLOGIC FINDINGS

Ischemic Stroke

• Ischemic necrosis centered on grey matter due to selective vulnerability. • Lesions limited to brain area vascularized by the affected vessel with sharply demarcated borders; normal surrounding brain tissue; minimal to no mass effect. • Global brain ischemia usually affects a dense area of selectively vulnerable neurons. Specific anatomical areas including cerebral cortex, hippocampus, certain basal nuclei (e.g., caudate nuclei), thalamus and cerebellar Purkinje cell layers are more susceptible to hypoxic injury. • Early ischemic cell changes occur rapidly and are a result of energy deprivation with swelling of the mitochondria and endoplasmic reticulum, which causes cytoplasmic microvacuolation. More chronic lesions are characterized by post-necrotic atrophy of the brain parenchyma, endothelial proliferation in viable capillaries and accumulation of Gitter cells.

Hemorrhagic Stroke

• Parenchymal bleeding results from rupture of the small penetrating brain arteries. Most acute cases reveal fresh hemorrhage and acute neuronal necrosis that is slowly removed by macrophages, leaving over time a cystic cavity lined by fibrillary astrocytes. • Histology is characterized by presence of edema, neuronal damage, macrophages and neutrophils in the region surrounding the hematoma. • While some cerebral hemorrhages stop quickly as a result of clotting and tamponade by the surrounding regions, others tend to expand over time. The latter is a result of continued bleeding from the primary source and to the mechanical disruption of surrounding vessels. The hemorrhage spreads between planes of white-matter cleavage with minimal destruction, leaving nests of intact neural

tissue within and surrounding the hematoma.

TREATMENT

APPROPRIATE HEALTH CARE

- Any identified underlying disease should be treated. • Provide supportive care, maintain adequate tissue oxygenation, and manage neurologic and non-neurologic complications.
- More specific therapies aim at preventing further neurologic deterioration.

NURSING CARE

Ischemic Stroke

- Monitoring and correction of basic physiologic variables (e.g., oxygen level, fluid balance, blood pressure, body temperature).
- Maintenance of systemic arterial blood pressure within physiologic range; aggressive lowering of blood pressure should be avoided during the acute stages unless the patient is at high risk of end-stage organ damage (systolic blood pressures > 180 mmHg). • No evidence that glucocorticoid provides beneficial neuroprotection; most neuroprotective agents tested have either failed to prove their efficacy in clinical trials or are awaiting further investigation.

Hemorrhagic Stroke

- Patient stabilization (airway protection, monitoring and correction of vital signs).
- Assessment and monitoring of neurologic status. • Determination and treatment of potential underlying causes of hemorrhage.
- Assessment for the need of specific treatment measures including management of raised ICP, which revolves around reducing cerebral edema, optimizing cerebral blood volume and eliminating space-occupying mass. • Risk of neurologic deterioration and cardiovascular instability highest during the first 24 hours after onset of intracranial hemorrhage as the space-occupying lesion slowly expands and cerebral vasogenic edema develops.

MEDICATIONS

DRUG(S) OF CHOICE

Ischemic Stroke

- Antihypertensive—consider if systemic BP > 180 mmHg on serial evaluation and/or severe ocular manifestations of hypertension.
- ACE inhibitor—enalapril (0.25–0.5 mg/kg q12h) or benazepril (0.25–0.5 mg/kg q12h) and/or calcium channel blockers such as amlodipine (0.1–0.25 mg/kg q24h).
- Prevention of clot formation—consider in proven cardiac sources of embolism; antiplatelet therapy with low-dose aspirin

(0.5 mg/kg PO q24h) or clopidogrel (2–4 mg/kg PO q24h) and low molecular weight heparin can be used prophylactically. Low molecular weight heparin 80–150 IU/kg SC can be used in suspected or confirmed case of hypercoagulable state. Anti-factor Xa activity should be monitored although this may not be practical.

Hemorrhagic Stroke

Mannitol—if suspected elevated ICP unresponsive to extracranial stabilization measures (0.25–1 g/kg IV over 10–20 minutes).

FOLLOW-UP

PATIENT MONITORING

Frequent neurologic evaluations in the first 48–72 hours to monitor progress.

POSSIBLE COMPLICATIONS

Relapse of ischemic stroke.

EXPECTED COURSE AND PROGNOSIS

- Maximum severity of signs usually reached within 24h for ischemic stroke. • Resolution of signs—gradual within 2–10 weeks. Some dogs/cats may be left with permanent neurologic signs due to irreversible brain damage. • Dogs with causal medical condition significantly more likely to relapse and have significant shorter survival time than dogs with no identifiable medical condition.
- Prognosis for global brain ischemia difficult to predict as there are no controlled studies.

MISCELLANEOUS

CERUMINOUS GLAND ADENOCARCINOMA, EAR

BASICS

OVERVIEW

- Most common primary malignant tumor of the external auditory meatus arising from modified apocrine sweat glands (ceruminous glands).
- Often locally invasive but associated with a low metastatic rate.

SIGNALMENT

- Uncommon overall but the most common malignant tumor of the ear canal in both dogs and cats, followed by squamous cell carcinoma.
- Cocker spaniels are overrepresented.
- Mean age—dogs, 10 years; cats, 11 years.
- No known sex predisposition.

SIGNS

- Similar to chronic, recurrent otitis externa: discharge, odor, pruritus, inflammation.
- Early appearance—pale pink, friable, ulcerative, bleeding nodular mass(es) within the external ear canal.
- Late appearance—large mass(es) filling the canal and invading through canal wall into surrounding structures.
- Regional lymph node enlargement.
- Neurologic signs (vestibular signs, Horner's syndrome) may be present secondary to middle ear involvement.
- Signs of pain and discomfort; pain upon opening the mouth.

CAUSES & RISK FACTORS

Chronic inflammation and ceruminous gland hyperplasia/dysplasia appear to play a role in tumor development.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Proliferative chronic otitis externa.
- Nodular hyperplasia.
- Inflammatory polyps (cats).
- Other tumors including squamous cell carcinoma, basal cell tumor, mast cell tumor, papilloma, sebaceous gland tumor, ceruminous gland adenoma.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

- Ear swab cytology for bacteria and yeast.
- Bacterial culture and sensitivity as needed.

IMAGING

- Skull radiography to assess potential involvement of the tympanic bulla.
- Thoracic radiography to evaluate for pulmonary metastasis.
- CT or MRI is most useful for loco-regional staging and before surgery and radiation therapy; providing greater detail than with radiographs.

DIAGNOSTIC PROCEDURES

- Cytologic examination of aspirate from regional lymph nodes
- Biopsy and histopathology

PATHOLOGIC FINDINGS

- Histopathologic characteristics—apocrine type differentiation from ceruminous glands and local invasion into stroma.
- Tumor cells—show moderate to marked nuclear atypia with frequent mitotic figures.

TREATMENT

- Total ear canal ablation and lateral bulla osteotomy (TECABO) is the preferred surgical approach over lateral ear resection.
- Radiation therapy may be considered for either large (palliative intent) or incompletely excised masses (curative intent).

MEDICATIONS

DRUG(S)

- Chemotherapy not evaluated but occasionally considered based on histologic information and clinical staging results.
- Multimodal therapy incorporating NSAIDs and other analgesics.
- Antibiotic therapy based on culture and sensitivity results.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Physical examination and thoracic radiography at regular intervals following therapy (every 3–4 months) is recommended for the first year postoperatively.
- Serial CT or MRI to monitor for local tumor regrowth may be recommended.

POSSIBLE COMPLICATIONS

- Permanent or transient Horner's syndrome secondary to surgery.
- Permanent or transient facial paralysis following surgery (more frequent in cats).

EXPECTED COURSE AND PROGNOSIS

- Median survival after lateral ear resection is around 10 months for both dogs and cats.
- Median survival after TECABO is greater than 3 years in both dogs and cats.
- Median survival after radiation therapy is > 3 years, but published information is on small numbers only.
- Poor prognosis associated with extensive tumor involvement (advanced stage), preoperative neurologic signs, and conservative therapy (e.g., lateral ear canal ablation alone).

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Otitis externa
- Peripheral vestibular disease, Horner's syndrome
- Chronic pain

ABBREVIATIONS

- CT = computed tomography
- MRI = magnetic resonance imaging
- NSAID = nonsteroidal anti-inflammatory drug
- TECABO = total ear canal ablation and bulla osteotomy

CERVICAL SPONDYLOMYELOPATHY (WOUBLER SYNDROME)

BASICS

DEFINITION

- Cervical spondylomyelopathy or wobbler syndrome is a disease of the cervical spine of large- and giant-breed dogs.
- CSM is characterized by compression of the spinal cord and/or nerve roots, which leads to neurologic deficits and/or neck pain.

PATHOPHYSIOLOGY

- Compressive lesion caused by intervertebral disc herniation, osseous malformation, or both, in a stenotic vertebral canal.
- Disc-associated compression—dogs > 3 years. The intervertebral disc degeneration and subsequent protrusion might be secondary to abnormal articular facet articulation in Doberman pinschers, which predisposes to increased rotational strain in the intervertebral discs.
- Vertebral malformation (bony associated compression)—most commonly seen in giant breeds of dogs, usually in young adult dogs (< 3 years). The osseous malformation can compress the spinal cord dorsoventrally (vertebral arch malformation), dorsolaterally (articular process malformation), or laterally (pedicular malformation).
- Dynamic spinal cord compression (one that changes with movements of the cervical spine) is always a component of the pathophysiology with any type of compression.
- Current evidence does not suggest that instability has a primary role in the pathogenesis of CSM.

SYSTEMS AFFECTED

Nervous

GENETICS

- Inheritable basis proposed for Borzoi and Basset hound.
- Recent evidence suggests that the disease is inherited as an autosomal dominant trait (with incomplete penetrance) in Doberman pinscher.

INCIDENCE/PREVALENCE

CSM is probably the most common neurologic disorder of the cervical spine of large- and giant-breed dogs.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Breed Predilections

- Doberman pinscher dogs are the most commonly affected, with approximately 50% of the cases seen in this breed.
- Other breeds with a high incidence include Great Dane, Rottweiler, Weimaraner, and Dalmatian. CSM can be seen in any breed, including small-breed dogs.

Mean Age and Range

- Doberman pinschers and other large-breed dogs are usually presented > 3 years of age, with a mean age of 6 years.
- Giant-breed

dogs are usually presented < 3 years of age, although late presentations can be seen.

Predominant Sex

Males slightly overrepresented, primarily in giant-breed dogs.

SIGNS

General Comments

The classic clinical presentation is a slowly progressive pelvic limb ataxia with less severe thoracic limb involvement.

Historical Findings

- Chronic, slowly progressive gait dysfunction is characteristic. Acute presentations are usually associated with neck pain.
- Occasionally, acute worsening of a dog with chronic history is observed.
- Neck pain or cervical hyperesthesia is a common historical finding. It occurs in approximately 65–70% of Dobermanns, and 40–50% of other breeds.

Neurologic Examination Findings

- Neck pain is the primary complaint in only approximately 5% of patients.
- Gait changes are characterized by proprioceptive ataxia and paresis (weakness). The ataxia and paresis are more obvious in the pelvic limbs with lesions in the caudal cervical spine (C5–6, C6–7).
- Compressive lesions in the mid-cervical spine tend to cause ataxia in all four limbs.
- The thoracic limb gait can appear short-strided, spastic with a floating appearance, or very weak.
- Proprioceptive positioning deficits are usually present, but dogs with chronic ataxia may not display them.
- The gait exam (presence of ataxia) provides a more sensitive indication of myelopathy than proprioceptive positioning deficits.
- Dogs can present non-ambulatory.
- Supraspinatus muscle atrophy and worn toenails can be seen in some cases.
- Extensor muscle tone is commonly increased in all four limbs.
- Patellar reflexes are normal or increased.
- Flexor reflex may be difficult to elicit in the thoracic limbs due to increased extensor tone.

CAUSES

- Inpatient if surgical treatment is elected.
- Nutrition—excess protein, calcium, and caloric intake were proposed in Great Danes. Nutrition does not appear to play a role in the development of CSM in large breed dogs.
- The cause of CSM is likely multifactorial.

RISK FACTORS

- Body conformation—large head and long neck have been proposed, but later studies found no correlation between body dimensions and incidence of CSM.
- Fast growth rate has been proposed but not confirmed by other studies.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Orthopedic conditions such as hip dysplasia and cruciate ligament rupture. Differentiated

by the neurologic examination (absence of ataxia).

- Spinal neoplasia, spinal subarachnoid diverticulum, spinal synovial cysts, discospondylitis, osteomyelitis, meningomyelitis, trauma. Differentiated by results of survey radiographs, CSF, myelography, CT, CT-myelography or MRI findings.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

IMAGING

Survey Cervical Radiographs

- Survey radiographs serve as a screening tool to rule out bony disorders. Although intervertebral disc narrowing or vertebral tipping can be seen, these findings are not specific for CSM since they can be observed in clinically normal large-breed dogs.
- Osteoarthritic changes of the articular processes can be seen in giant breeds.

Myelography

Myelography can define the location(s) and direction (ventral, dorsal, lateral) of the spinal cord compression. Stressed views (flexion or extension) may cause significant risk of neurologic deterioration. Linear traction myelography is a safer procedure and can distinguish a static from dynamic lesion.

Advanced Imaging

- CT myelography—cross-sectional visualization of the spinal cord compression and determination of sites with spinal cord atrophy.
- MRI—visualization of the spinal cord parenchyma, intervertebral disc, soft tissues, and nerve roots; images can be obtained in sagittal, transverse and dorsal planes. Spinal cord signal changes allow more precise identification of the main site of compression than CT and myelography.

DIAGNOSTIC PROCEDURES

CSF analysis—usually normal; mild mixed or neutrophilic pleocytosis can be seen in dogs with acute presentations; elevated protein concentrations can be observed with chronic presentations.

PATHOLOGIC FINDINGS

- Spinal cord white matter tract demyelination at the site of spinal cord compression. Axonal damage can lead to Wallerian degeneration in the ascending and descending white matter tracts.
- Neuronal loss, gliosis, and necrosis can be observed in the gray matter.
- Chronic severe focal spinal cord compression can lead to focal myelomalacia.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient if surgical treatment is elected.
- Outpatient if medical management is chosen.

(CONTINUED) CERVICAL SPONDYLOMYELOPATHY (WOBBLER SYNDROME)

C

NURSING CARE

- Non-ambulatory dogs—keep patients on soft bedding and alternate recumbence side every 4 hours to avoid bed sores.
- Bladder catheterization.
- Physical therapy is essential to avoid muscle atrophy and ankylosis, and to hasten recovery.

ACTIVITY

- Medically treated dogs should have restricted activity for at least 2 months.
- Restriction of activity is also important for the first 2 or 3 months postoperatively to allow bone fusion and prevent implant displacement.

DIET

Avoid excess of protein, calcium, or caloric intake in giant-breed dogs with osseous compression.

CLIENT EDUCATION

Inform that surgery offers the best chance of improvement (approximately 80%) but there is a 1–5% risk of significant complications associated with cervical surgical procedures.

SURGICAL CONSIDERATIONS

- Ventral slot—commonly used and recommended for single ventral compressions; could also be used for two ventral compressions.
- Dorsal laminectomy—primary indication for dorsal or dorsolateral compressions; can also be used for multiple ventral compressions.
- Distraction/stabilization/fusion techniques are recommended primarily for single dynamic ventral compressions, but could be used for multiple compressions.
- Cervical disc arthroplasty—novel technique that appears safe and as effective as the traditional procedures. It can be used for multiple compressions.
- Recurrence rate is approximately 20% with any surgical technique.
- Fenestration provides a very low success rate and is not recommended.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Corticosteroids—Prednisone 1 mg/kg q24h or 0.5 mg/kg q12h progressively decreasing the dosage and frequency. Most dogs can have prednisone discontinued after 4–8 weeks of treatment. Dexamethasone 0.1–0.25 mg/kg q24h can be used as an alternative to prednisone in dogs severely affected.

- Gabapentin—10 mg/kg q8–12h can be used for analgesia in cases of severe pain.

CONTRAINDICATIONS

N/A

PRECAUTIONS

Monitor for signs of gastroenteritis, gastric hemorrhage, and cystitis. A proton pump inhibitor may be used to minimize the risk of gastrointestinal bleeding.

POSSIBLE INTERACTIONS

Do not use corticosteroids in combination with NSAIDs.

ALTERNATIVE DRUG(S)

NSAIDs such as meloxicam 0.1 mg/kg q24h can be used in dogs with only cervical hyperesthesia or mild ataxia.

**FOLLOW-UP****PATIENT MONITORING**

Repeat the neurologic evaluation as often as needed to monitor response to treatment.

PREVENTION/AVOIDANCE

- Excessive activity, jumping, and running should be avoided.
- Avoid use of neck collars; use a body harness instead.

POSSIBLE COMPLICATIONS

Recurrence of clinical signs can occur in dogs treated medically or surgically.

EXPECTED COURSE AND PROGNOSIS

- About 80% of patients improve with surgery.
- Approximately 50% patients improve with medical treatment (restricted activity ± corticosteroids) and 25% remain stable.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Dilated cardiomyopathy, hypothyroidism, and von Willebrand's disease are common in Doberman pinscher dogs. These diseases can affect diagnostic and treatment options.

Doberman pinschers suspected of having CSM should be routinely evaluated for these conditions.

AGE-RELATED FACTORS

- Young giant- or large-breed dogs—vertebral malformation and compression.
- Older dogs—disc-associated compression.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

CHAGAS DISEASE (AMERICAN TRYPARASITIASIS)

BASICS

OVERVIEW

- Caused by the zoonotic hemoflagellate protozoan parasite *Trypanosoma cruzi*.
- Infection—transmission occurs after infected feces of a vector (Triatominae) are deposited in a wound (bite site of vector) or mucous membrane; dog eats an infected vector, or by contaminated blood transfusion.
- After local multiplication at entry site (5 days post-infection), hematogenous spread occurs to most organs but mainly the heart and brain. • Organisms become intracellular, multiply, then rupture out into circulation to produce maximal parasitemias, associated particularly with acute myocarditis and less commonly with diffuse encephalitis (14 days post-infection). • Parasitemias wane (subpatent 30 days post-infection).
- Antibody titers rise (detectable by 16 days post-infection). • Dog enters a protracted asymptomatic period (can last for months to years); progressive and insidious development of myocardial degeneration; eventual dilative cardiomyopathy. • South and Central America—endemic (in both humans and pets). • United States—mostly in Texas but other southern states also, where infected vectors and reservoir hosts live, with raccoons, opossums, and armadillos the main reservoirs in the southeast and mice, rats, and squirrel species in the southwest.

SIGNALMENT

- Young dogs—most common • Acute—dogs usually < 2 years • Chronic—old dogs
- Hunting breeds—likely to contact vectors or reservoir hosts • More often males
- Cats—no cases reported in North America.

SIGNS

General Comments

Two syndromes—acute (myocarditis or encephalitis in young dogs) and chronic (dilated cardiomyopathy in old dogs).

Historical Findings

Acute

- Sudden death • Lethargy • Depression
- Anorexia • Diarrhea • Weakness • Exercise intolerance • Mild to severe CNS dysfunction (such as distemper) • Ataxia, seizures

Chronic

- Weakness • Exercise intolerance • Syncope
- Sudden death

Physical Examination Findings

Acute

- Generalized lymphadenopathy • Heart failure • Tachycardia and arrhythmias
- Neurologic—weakness; ataxia; chorea; seizures (indistinguishable from distemper)

Chronic

- Tachycardia—sustained or paroxysmal

CAUSES & RISK FACTORS

T. cruzi

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cardiomyopathy • Congenital cardiac defects • Traumatic myocarditis • Distemper
- Toxoplasmosis • Neosporosis

CBC/BIOCHEMISTRY/URINALYSIS

Generally normal

OTHER LABORATORY TESTS

- Serology—positive titer confirms diagnosis available from the CDC's parasitology unit.
- On-site immunochromatographic antibody tests have high sensitivity and specificity when used in dogs—excellent tool for survey work not only in dogs but also wildlife. • Antibody titers very sensitive and specific but most cross-react with *Leishmania*. • Organism isolation—LIT culture; collect 50 mL heparinized blood. • Examination above the buffy coat in a microhematocrit tube (spun down to read PCV) using 40× microscope objective—organisms during period of high parasitemia. • PCR—very useful during indeterminate and chronic stages when blood trypomastigotes are very difficult to demonstrate. Has high specificity but low sensitivity unless samples from multiple tissues are examined. Not yet commercially available. • Elevated troponin I—acute disease.

IMAGING

- Radiography—acute: cardiomegaly, pulmonary edema, and (rarely) mild pleural effusion; chronic: cardiomegaly.
- Echocardiography—acute: rarely shows chamber or wall abnormalities; chronic: reduced ejection fraction, fractional shortening, and thinning of right and left ventricular free wall.

DIAGNOSTIC PROCEDURES

Electrocardiography

- Acute—atrioventricular block; depression of QRS amplitude; right bundle branch block.
- Chronic—low QRS amplitude; right bundle branch block; ventricular arrhythmias (initially unifocal VPC, becomes multifocal, then degenerates into various forms of ventricular tachycardia).

TREATMENT

- Medical therapy does not produce clinical cure. • With poor prognosis and zoonotic potential, euthanasia is an option. • The bradyarrhythmias which some dogs develop may respond to pacemaker therapy.

CLIENT EDUCATION

- Alert owner to possible zoonotic risk and potential for sudden death. • Acute—usually develops into the chronic form, which is often fatal. • Infected intact female—can transfer infection to offspring.

MEDICATIONS

DRUG(S)

- Several drugs have limited efficacy during the acute stage; none produces a clinical cure; even treated animals may progress to chronic disease.
- Benzimidazole (Ragonil) 5 mg/kg PO q12h for 60 days; preferred drug for use in dogs; markedly improves acute disease in humans and probably dogs also. Available from CDC.
- Cythioate (Proban)—3.3 mg/kg PO q48h; effective in reducing vector populations; Fipronil Spot-on (Frontline Top Spot, Merial) has been shown to be ineffective in preventing reduviidae from feeding on dogs.
- Supportive treatment of dilated cardiomyopathy (right and left cardiac failure) and ventricular arrhythmias.

FOLLOW-UP

- Cardiac disease—prognosis always guarded
- Chronic—prognosis guarded to hopeless

MISCELLANEOUS

ZOONOTIC POTENTIAL

Exists; essentially incurable in humans, thus euthanasia of infected dogs is an option.

ABBREVIATIONS

- CNS = central nervous system • LIT = liver infusion tryptose • PCR = polymerase chain reaction • PCV = packed cell volume • VPC = ventricular premature complex

CHEDIAK-HIGASHI SYNDROME

BASICS

OVERVIEW

- Autosomal recessive inherited disorder of Persian cats characterized by abnormalities in cellular morphology and pigment formation.
- Large intracytoplasmic granules in circulating leukocytes and melanocytes formed by fusion of preexisting granules.
- Storage pool deficiency of ADP, ATP, magnesium, and serotonin results from lack of platelet-dense granules.
- Prolonged bleeding from trauma, venipuncture, or minor surgery occurs because of impaired platelet aggregation and release reaction.
- Normal coagulation times.
- Depressed chemotaxis.
- No change in rates of infection.
- Mildly depressed neutrophil count but within reference range.

SIGNALMENT

- Persian cats with dilute smoke-blue coat color and yellow-green irises (and white tigers).
- Not reported in dogs.
- Some Arctic foxes with blue or pearl hair coat color.

SIGNS

Historical Findings

Prolonged bleeding from trauma, venipuncture, or minor surgery.

Physical Examination Findings

- Red fundic reflex (lack of choroidal pigment).
- Dilute smoke-blue coat color and yellow-green irises.
- Photophobia (blepharospasm and epiphora) in bright light.

CAUSES & RISK FACTORS

Genetic disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dilute hair coat color

CBC/BIOCHEMISTRY/URINALYSIS

Romanowsky-stained blood smear—leukocytes, especially neutrophils, contain

pink to magenta cytoplasmic inclusions 2 μm in diameter.

OTHER LABORATORY TESTS

None

IMAGING

N/A

DIAGNOSTIC PROCEDURES

None

TREATMENT

- Provide ascorbic acid (vitamin C) to increase cGMP concentration and to improve cell and platelet function (no controlled studies in cats).
- Transfusion of platelet-rich plasma from healthy cats will temporarily normalize bleeding time in affected individuals.
- Experimentally, bone marrow transplantation has restored neutrophil and platelet function in cats, but is impractical for general clinical use.

MEDICATIONS

DRUG(S)

Ascorbic acid (100 mg PO q8h)

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None

FOLLOW-UP

PATIENT MONITORING

None

PREVENTION/AVOIDANCE

- Advise owner of potential for prolonged bleeding after trauma, venipuncture, or minor surgery.
- Provide genetic counseling to eliminate Chediak-Higashi syndrome from animals used for breeding.

- Neuter affected and carrier animals or advise owner not to breed.

POSSIBLE COMPLICATIONS

Prolonged bleeding time

EXPECTED COURSE AND PROGNOSIS

Normal lifespan

MISCELLANEOUS

ABBREVIATIONS

- ADP = adenosine diphosphate
- ATP = adenosine triphosphate

Suggested Reading

CHEMOLECTOMA

BASICS

OVERVIEW

- Chemodectomas are tumors arising from the chemoreceptor cells (such as in the aortic body and the carotid body).
- Other names—*aortic body tumors, cardiac paraganglioma, APUDoma (amine precursor uptake decarboxylase), and glomus body tumor.*
- Aortic body tumors more common (80–90%) in dogs than carotid body tumors (10–20%).

SIGNALMENT

- Rare in cats.
- Dogs age 6–15 years.
- Any breeds—but brachycephalic breeds predisposed—especially boxers, Boston terriers, English bulldogs, and German shepherd dogs.
- Males predisposed for aortic body tumors, no sex predilection for carotid body tumors.

SIGNS

- Nonspecific and dependent upon tumor size and anatomic localization, and can include lethargy, anorexia, weakness, collapse, coughing, respiratory distress, exercise intolerance, distended abdomen, vomiting, sudden death.
- Carotid body tumor—may notice neck mass, regurgitation, dyspnea, Horner's syndrome, laryngeal paralysis.
- May be associated with pericardial effusion and cardiac tamponade—muffled heart sounds, poor pulses, tachycardia, tachypnea, weak pulses, slow capillary refill time, ascites.
- May be associated with cranial vena cava syndrome (edema of head, neck and forelimbs), and in long-standing cases peritoneal effusion might develop consequent to right-sided heart deficits.
- May be associated with pleural effusion—decreased lung sounds ventrally, cyanosis.
- Cardiac arrhythmias with pulse deficits.

CAUSES & RISK FACTORS

Chronic hypoxia may play a role in the development of this disease in brachycephalic breeds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other masses located at the heart base (i.e., hemangiosarcoma, thymoma, ectopic thyroid carcinoma, mesothelioma, abscess, and granuloma).
- Idiopathic pericardial effusion.
- Pericarditis.
- Cardiomyopathy.
- Valvular insufficiency.

CBC/BIOCHEMISTRY/URINALYSIS

Typically normal, but 36% of patients can have nucleated red blood cells without anemia.

OTHER LABORATORY TESTS

N/A

IMAGING

- Thoracic radiography—to evaluate for mass in the region of the heart base, pericardial effusion, metastatic lesions in the lungs.
- Cervical ultrasound, CT or MRI—to evaluate for masses arising in the neck.
- Echocardiography—to image mass and aorta/pulmonary arteries/veins.

DIAGNOSTIC PROCEDURES

- Biopsy of mass.
- ECG—if evidence of arrhythmia, may see low-amplitude QRS complexes with pericardial or pleural effusion, or electrical alternans with pericardial effusion.

TREATMENT

AORTIC BODY TUMORS

- Surgical removal of mass—if possible.
- Subphrenic pericardectomy has been shown to prolong survival.
- Symptomatic pericardiocentesis or thoracocentesis.
- Conformal radiation therapy.
- Palliative thoracoscopic-guided pericardial window.

CAROTID BODY TUMORS

Surgical removal if possible—discuss with owners possibility of postoperative Horner's syndrome and laryngeal paralysis.

BOTH

Possible role of chemotherapy (doxorubicin) and radiation therapy; however, definitive studies are lacking.

MEDICATIONS

DRUG(S)

- The role of chemotherapy in this disease has not been published.
- Pharmacologic intervention for cardiac insufficiency.

FOLLOW-UP

PATIENT MONITORING

Serial thoracic radiography or advanced imaging for monitoring tumor progression and metastasis.

EXPECTED COURSE AND PROGNOSIS

- Carotid body tumors treated with surgery—median survival time 25.5 months.
- Aortic body tumors—animals treated with pericardectomy MST 730 days versus animals that did not have pericardectomy MST 42 days. Larger tumors (as determined by tumor weight to body weight ratio) more likely associated with metastasis.
- Conformal radiation therapy in 1 dog—survival > 42 months.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

It is not recommended to breed animals with cancer. Chemotherapy is teratogenic—do not give to pregnant animals.

SEE ALSO

Pericardial Effusion

ABBREVIATIONS

- ECG = electrocardiogram
- MST = median survival time

CHEYLETIELLOSIS

C

BASICS

OVERVIEW

- A contagious parasitic skin disease of dogs and cats, caused by surface-living *Cheyletiella* spp. mites (*C. yasguri*, *C. blakei*, *C. parsitovorax*). • Signs of mild pruritus and scaling resemble other more common dermatoses. • Potential for lesions in human beings (zoonotic).

SYSTEMS AFFECTED

- Skin/Exocrine

SIGNALMENT

- Dogs and cats. • More severe in young animals. • Cocker spaniels, poodles, and longhaired cats may be inapparent carriers.

SIGNS

Historical Findings

- Cats may exhibit bizarre behavior, head shaking, or excessive grooming. • Pruritus—usually absent to mild, but can be severe depending on individual immune status and response to infestation. • Infestation often suspected only after lesions in human beings develop (pseudo-scabies).

Physical Examination Findings

- Scaling—most important clinical sign; diffuse or plaque-like; more severe in chronically infested or debilitated animals.
- Often referred to as “walking dandruff,” because of the large mite size and excessive scaling. • Prevalence varies by geographic region owing to mite susceptibility to common flea-control insecticides and differences in climate. • Some locations may have low or no incidence of the mite.
- Lesions—dorsal orientation is commonly noted; head can be affected in cats.
- Underlying skin irritation may be minimal.
- Cats may exhibit bilaterally symmetrical alopecia.

CAUSES & RISK FACTORS

- *Cheyletiella* mites are considered partially host-specific for the following species:
 - Dogs—*C. yasguri*. ◦ Cats—*C. blakei*.
 - Rabbits—*C. parsitovorax* (mites are not highly host-specific). • Cheyletiellosis should be considered in every animal that shows scaling, with or without pruritus, especially in young animals or animals living in communities. • Contagion is by direct contact or by fomites. • Common sources of infestation—animal shelters, breeders, and grooming facilities. • Adult female mites may transiently survive in the environment up to 10 days. • Eggs can be found on shed hair.
 - In specific individuals, hypersensitivity to mite allergens may develop, producing clinical signs of pruritus (similar to infestations with *Sarcoptes* or *Notoedres* mites).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Keratinization disorders • Flea allergic dermatitis • *Sarcoptes* and *Notoedres* spp. mite infestation; other fur mites • Atopy • Food hypersensitivity • Endocrinopathy
- Dermatophytosis • Lice infestation

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

DIAGNOSTIC PROCEDURES

- Examination of epidermal debris with a lens or microscope (10X objective)—effective in diagnosing infestation. • Mite numbers may be low; concentration of debris for examination increases the likelihood of diagnosis. • Collection of debris—flea combing (most effective), skin scraping, hair plucking, acetate tape preparation, scale collection, and fecal flotation. • *Cheyletiella* mites are large and can be visualized with a simple handheld magnifying lens; scales and hair may be examined under low magnification; staining is not necessary; finding mite eggs is diagnostic. • Response to insecticide treatment may be required to definitively diagnose suspicious cases in which mites cannot be identified.

TREATMENT

- All animals in the same household must be treated at the same time. • Clip long coats to facilitate treatment if topical treatment is chosen. • Mainstay—six to eight weekly baths to remove scale, followed by rinses with an insecticide. • Lime-sulfur rinses—cats, kittens, dogs, and puppies. • Routine flea sprays and powders—not always effective. Treat all animals in the home before introducing a new pet. • Environmental treatment with frequent cleanings and insecticide sprays—reduces possibility of reinfestation. • Treatment—continue for at least 6–8 weeks to prevent reinfestation from shed eggs. • Combs, brushes, and grooming tools—discard or thoroughly disinfect before reuse.

MEDICATIONS

DRUG(S)

- Amitraz rinses—dogs only; 2-week intervals for four applications.
- Fipronil spray or spot-on—2-week intervals for one to four applications.
- Ivermectin—highly effective (300 µg/kg PO or SC three times at 2-week intervals);

dogs and cats > 3 months old; pour-on forms have shown efficacy in cats (500 µg/kg two times at 2-week intervals) (non-FDA-approved usage).

- Selamectin (Revolution)—apply every 2–4 weeks for three applications (non-FDA-approved usage).
- Imidacloprid/Moxidectin (Advantage-Multi) spot-on at 2-week intervals for three applications (non-FDA-approved usage).
- Milbemycin oxime (Interceptor)—2 mg/kg PO once weekly for 4 weeks.
- Moxidectin (Cydectin)—subcutaneous injection every 2 weeks for three treatments (non-FDA-approved usage—dogs).
- Doramectin (Dectomax)—subcutaneous injection every week for three treatments (non-FDA-approved usage—dogs).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Ivermectin—several dog breeds (e.g., collie, sheltie, Australian shepherd) have shown increased sensitivity and should not be treated with ivermectin. • Selamectin can be safely used in the above-mentioned dog breeds.
- Prevent ingestion of avermectins in sensitive dogs (*MDR1/ABCB1* gene mutation).

FOLLOW-UP

- Treatment failure requires a thorough reevaluation for other causes of pruritus and scaling. • Reinfestation may indicate contact with an asymptomatic carrier or the presence of an unidentified source of mites (e.g., untreated bedding, boarding, wild animals).

MISCELLANEOUS

ZOONOTIC POTENTIAL

A pruritic papular rash may develop in human beings, in areas of contact with the pet.

CHLAMYDIOSIS—CATS

BASICS

DEFINITION

A chronic respiratory infection of cats caused by an intracellular bacterium, characterized by mild to severe conjunctivitis, mild upper respiratory signs, and mild pneumonitis.

PATHOPHYSIOLOGY

- Chlamydophila felis* (previously *Chlamydia psittaci* var. *felis*)—an obligate intracellular bacterium; replicates on the mucosa of the upper and lower respiratory epithelium; produces a persistent commensal flora that causes a local irritation with resulting mild upper and lower respiratory signs; can also colonize the mucosa of the gastrointestinal and reproductive tracts.
- Incubation period—7–10 days; longer than that for other common respiratory pathogens of the cat.

SYSTEMS AFFECTED

- Gastrointestinal—cat: infection without clinical disease; other species: may have clinical gastroenteritis.
- Ophthalmic—chronic conjunctivitis, often unilateral but may be bilateral.
- Reproductive—infection without clinical disease.
- Respiratory—mild rhinitis, bronchitis, and bronchiolitis.

INCIDENCE/PREVALENCE

- Incidence of clinical disease—sporadic; outbreaks of respiratory disease may occur, especially in multi-cat facilities.
- Prevalence of *C. felis* in the feline population—not uncommon, 5–10% chronically infected.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

- Cat
- Human

Mean Age and Range

Usually cats < 1 year of age; any age cat possible.

SIGNS

General Comments

- Infection often subclinical.
- Clinical disease—commonly as a co-infection with other organisms.

Historical Findings

- Upper respiratory infection, with some sneezing, watery eyes, and coughing.
- Sometimes difficult breathing.
- Varying degrees of anorexia.

Physical Examination Findings

- Conjunctivitis—often granular; initially unilateral, usually progresses to become bilateral.

- Lacrimation, photophobia, and blepharospasm.
- Rhinitis with nasal discharge—usually mild.
- Pneumonitis—with the inflammatory process in the alveoli; bronchiolar tubes and airways give audible rales.

CAUSES & RISK FACTORS

- Concurrent infections with other respiratory pathogens.
- Lack of vaccination.
- Multi-cat facilities, especially adoption shelters and breeding catteries.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Feline viral rhinotracheitis—short incubation period (4–5 days), rapid bilateral conjunctivitis, severe sneezing, and ulcerative keratitis.
- Feline calicivirus infection—short incubation period (3–5 days), ulcerative stomatitis, and severe pneumonia.
- Feline reovirus infection—very mild upper respiratory infection; short incubation and duration.
- Bronchial pneumonia caused by bacteria such as *Bordetella bronchiseptica*—localized areas of density within the lungs on radiographs.

CBC/BIOCHEMISTRY/URINALYSIS

Leukocytosis

IMAGING

Radiographs of lungs—helpful with pneumonitis.

DIAGNOSTIC PROCEDURES

- PCR assay for *C. felis*—preferred; conjunctival swab sample.
- Serum antibody assay—unvaccinated cats; indicates infection.
- Conjunctival scrapings stained with Giemsa stain—characteristic intracytoplasmic inclusions.
- Swab samples taken from conjunctiva—isolation of the causative organism in cell cultures.

PATHOLOGIC FINDINGS

- Gross—evidence of chronic conjunctivitis with mucopurulent ocular discharge; minor rhinitis with nasal discharge; sometimes lung changes indicative of pneumonitis.
- Histopathologic (conjunctiva)—an early intense infiltration of neutrophils; inflammatory response changes to lymphocytes and plasma cells; inclusions detected with special stains; inclusions invisible with routine H&E stains.

TREATMENT

APPROPRIATE HEALTH CARE

Generally as outpatient

NURSING CARE

- Keep nostrils and eyes clean of discharge.
- Generally does not require other supportive therapy (e.g., fluids), unless complicated by concurrent infections.

ACTIVITY

- Quarantine affected cats from contact with other cats.
- Do not allow affected cats to go outside.

DIET

Normal

CLIENT EDUCATION

Inform clients of the causative organism, the anticipated chronic course of disease, and the need to vaccinate other cats before exposure.

MEDICATIONS

DRUG(S) OF CHOICE

- Systemic—tetracycline antibiotic of choice (22 mg/kg PO q8h for 3–4 weeks); doxycycline (10 mg/kg q24h PO daily for 4 weeks to prevent recrudescence).
- Ocular—ophthalmic ointments containing tetracycline (q8h).

CONTRAINdicATIONS

Tetracycline—may affect growing teeth of young kittens.

PRECAUTIONS

Colonies/shelters/breeding catteries—all cats may have to be treated; treatment may have to be continued for as long as 4 weeks.

FOLLOW-UP

PATIENT MONITORING

Monitor for improved health as treatment proceeds.

PREVENTION/AVOIDANCE

Vaccines

- Both inactivated and modified live vaccines are available to reduce the severity of infection.
- Vaccines do not prevent infection; rather, they reduce severity and duration of clinical disease.
- American Association of Feline Practitioners—classifies as non-core; for at-risk cats, give a single vaccination at initial visit as early as 9 weeks of age, repeat in 3–4 weeks; revaccinate annually where *C. felis* is endemic.

(CONTINUED)

POSSIBLE COMPLICATIONS

Adverse vaccine reactions—mild clinical disease with modified live vaccines; small percentage of vaccinated cats.

EXPECTED COURSE AND PROGNOSIS

- Tends to be chronic, lasting for several weeks or months, unless successful antibiotic treatment is given.
- Prognosis good.

**MISCELLANEOUS****AGE-RELATED FACTORS**

Primarily a disease of young cats

ZOONOTIC POTENTIAL

C. felis can infect humans, especially immunocompromised individuals; limited number of reports of mild conjunctivitis in humans transmitted from infected cats.

PREGNANCY/FERTILITY/BREEDING

- Endemic breeding catteries—treat all cats with doxycycline for at least 4 weeks; then vaccinate.

- Role of *C. felis* as a pathogen during pregnancy—unclear; can colonize the reproductive mucosa; severe conjunctivitis neonatorum can occur in neonatal kittens infected at or shortly after birth.

SYNONYM

Feline pneumonitis

ABBREVIATIONS

- H&E = hematoxylin and eosin
- PCR = polymerase chain reaction

CHOCOLATE (METHYLXANTHINE) TOXICOSIS

BASICS

DEFINITION

Acute gastroenteric, neurologic, and cardiac toxicosis is caused by excessive intake of methylxanthine alkaloids present in chocolate. Theobromine is the largest fraction of methylxanthines in chocolate products and in cacao bean mulch. A lower concentration of caffeine is also present. Other sources include diet pills, over-the-counter stimulants, and herbal medications.

PATOPHYSIOLOGY

- Methylxanthines are variably absorbed (caffeine < 1 hour; theobromine 10 hours), metabolized by liver; excreted in bile and reabsorbed (enterohepatic cycling).
- Estimated theobromine and caffeine half-life in dogs is 17 hours and 4.5 hours respectively.
- They cross placenta and blood-brain barrier; may be resorbed via urinary bladder.
- Inhibition of phosphodiesterase increases cAMP, potentiating catecholamines and increasing cellular calcium.
- Cause vasoconstriction, increased force of cardiac and skeletal muscle contraction, CNS stimulation, seizures, bronchodilation, and tachycardia.
- Toxic dosages:
 - Theobromine LD₅₀ (dog) 250–500 mg/kg; LD₅₀ (cat) 200 mg/kg
 - Caffeine LD₅₀ (dog) 140 mg/kg; LD₅₀ (cat) 80–150 mg/kg.
 - **Caution:** one-tenth of the LD₅₀ may still be a lethal dosage for some animals.

SYSTEMS AFFECTED

- Cardiovascular—increased myocardial contractility and tachyarrhythmias; tachycardia, hypertension, ventricular premature contractions (VPC).
- Gastrointestinal—early vomiting and diarrhea; may result even from parenteral administration of methylxanthine alkaloids.
- Metabolic—hypokalemia, hyperthermia.
- Nervous—stimulation; enhanced alertness and reflex hyperactivity; tremors; tonic-clonic seizures.
- Renal/Urologic—polyuria, polydipsia.
- Respiratory—tachypnea, hypoxia, cyanosis, respiratory failure.

INCIDENCE/PREVALENCE

- Dogs—among 20 most common poisonings in recent literature, reported by small animal practices, and animal and human poison control centers.
- More common at holiday times—chocolate products and candies readily available.
- Caffeine-containing stimulant tablets, as much as 200 mg/tablet—occasional source.
- Cacao bean hull mulch for landscaping—increasing risk for dogs.

GEOGRAPHIC DISTRIBUTION

Urban and indoor dogs—may be more at risk owing to close proximity to chocolate products or cacao landscape mulch.

SIGNALMENT

Species

- Dogs frequently poisoned based on proximity to methylxanthine products, consuming large doses, and longer half-life of theobromine in dogs (theobromine 17.5 hours vs. caffeine 4.5 hours).
- Cats rarely affected.
- Other species likely have more limited access to chocolate; cacao bean hulls are an increasing source in dogs, horses, and poultry.

Breed Predilections

Small dogs—may be more at risk (amount of chocolate relative to body weight).

Mean Age and Range

- Puppies and young dogs—likely to ingest large amounts of unusual foods.
- Young animals are typically more compromised in metabolism and excretion.

SIGNS

Historical Findings

- Recent confirmed chocolate or cacao hull ingestion.
- Evidence of chewed containers or remnants of packaging from chocolate products.
- Vomiting and diarrhea—often first reported sign, 2–4 hours after ingestion.
- Early restlessness and increased activity or nervousness.
- Polyuria—may result from diuretic action.
- Hematuria occasionally.
- Advanced signs—stiffness; excitement; seizures; hyperreflexia.

Physical Examination Findings

- Vomiting and diarrhea followed by combination of CNS excitation and tachycardia (often extreme) is characteristic.
- Hyperthermia.
- Hyperactivity
- Hyperreflexia.
- Muscle rigidity.
- Tonic-clonic seizures.
- Mydriasis.
- Tachypnea.
- Tachycardia (> 200/min).
- Hypertension.
- Premature ventricular contractions.
- Advanced signs—cardiac failure, weakness, cyanosis, coma, and death.
- Polyuria/polydipsia.
- Death—12–48 hours after ingestion.

CAUSES

- Usually processed chocolate (used for candies and baking).
- Minimum lethal dosage for caffeine and theobromine (dogs)—100–200 mg/kg.
- Potentially lethal exposure (dogs):
 - 5 g baking chocolate provides 20 mg caffeine and 80 mg theobromine (total 100 mg).

◦ A 20 kg dog could be poisoned at 100 g/kg by consuming 5 g chocolate/kg × 20 kg = 100 g chocolate (3.5 oz).

◦ Milk chocolate provides only 2 mg of alkaloids per gram (50 g chocolate/kg bw) or nearly 2 oz/kg, which would be 40 oz (2.5 lb) for a 20 kg dog (unlikely amount).

• Dogs are poisoned by cacao bean hulls (contains both alkaloids) used as landscaping mulch. Several aids to canine risk from chocolate can be found online. See “Internet Resources.”

RISK FACTORS

Chocolate—palatable and attractive; often readily available and unprotected in homes and kitchens.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Convulsant or excitatory alkaloids—strychnine; amphetamine; nicotine; 4-aminopyridine; cocaine; tricyclic antidepressants; serotonin syndrome.
- Metaldehyde snail and slug bait.
- Acute bromethalin poisoning.
- Zinc phosphide poisoning.
- Convulsant pesticides—organochlorines (e.g., chlordane, lindane) and pyrethrins.
- Tremorgenic mycotoxins—penitrem A; aflatrem; roquefortine.
- Acute psychogenic drugs—LSD; cocaine; morning glory.
- Medications (phenylpropanolamine, phenylephrine, pseudoephedrine).
- Cardioactive glycosides—*Digitalis* spp.; *Nerium oleander*.
- Hypomagnesemia and hypocalcemia.

CBC/BIOCHEMISTRY/URINALYSIS

- Hyperglycemia or hypoglycemia—both have been noted and hence not a reliable indicator.
- Hypokalemia.
- Low urine specific gravity and proteinuria.

OTHER LABORATORY TESTS

Methylxanthine Assay

- Stomach contents, plasma, urine.
- Detectable plasma or serum concentration should persist 3–4 days.
- Stable in serum samples for 7 days (room temperature), 2 weeks refrigerated.
- Theobromine in serum of poisoned dogs may range from 100 to 300 mg/L.

DIAGNOSTIC PROCEDURES

ECG—sinus tachycardia, premature ventricular contractions, and ventricular tachyarrhythmia.

PATHOLOGIC FINDINGS

- Small or large amounts of chocolate in stomach or intestine.
- Gastroenteritis—non-specific.
- No distinctive microscopic lesions.

(CONTINUED)

CHOCOLATE (METHYLXANTHINE) TOXICOSIS

C

Table 1

Comparative concentrations of caffeine and theobromine.		
Caffeine Source	Amount (mg/g)	Amount (mg/oz)*
Coffee beans	10–20	284–570
Drip coffee	90–100 mg/6 oz. cup	Ca. 15
Cola drinks	60–90 mg/12 oz. can	5–8
Baking chocolate	Up to 4	Up to 112
Dark chocolate	4–5	135
Milk chocolate	0.2	6
Cocoa	Up to 1.5	46
Cacao bean hulls	5–8.5	142–240
Guarana	30–50	850–1,400
Stimulant tablets	200 mg/tablet	
OTC pain control	60 mg/tablet	
Theobromine Source	Amount (mg/g)	Amount (mg/oz)
Cacao beans	10–50	280–1,400
Baking chocolate	14–16	398–454
Milk chocolate	1.5–2	46–57
Cacao bean hulls	5–9	142–256
Cacao bean mulch	2–30	57–852
Cacao powder	14–29	398–832

* To convert mg/g to mg/oz, multiply by 28.4 g/oz.

- Microscopic renal lesions not consistent; characterized by hyaline droplet degeneration, pyknosis, and karyorrhexis, potentially from impaired renal perfusion.

TREATMENT

APPROPRIATE HEALTH CARE

- By phone—attempt to determine type and amount of exposure; if not possible, refer to hospital as a potential toxicologic emergency.
- Control seizures.
- Detoxification (if seizures controlled) using emesis early, or gastric lavage, and activated charcoal; most effective within 2–4 h post exposure, longer if chocolate remaining in stomach.
- Give activated charcoal daily up to 3 days to reduce enterohepatic recycling of the alkaloids. Only the first dose of charcoal should contain a cathartic.
- Control hyperthermia.
- Treat tachycardia (see “Medications”).
- Urinary catheterization or frequent urine voiding may reduce urinary bladder resorption.
- Provide IV fluid therapy to prevent dehydration, promote diuresis, and avoid hypernatremia.
- Control tremors with methocarbamol or diazepam (see “Medications”). Seizure control may require treatment with diazepam; if not controlled, use either pentobarbital or other general anesthetics (see “Medications”).

NURSING CARE

Fluid therapy—correct electrolyte disturbances caused by vomiting.

ACTIVITY

Avoid stress and excitement—could precipitate hyperreflexia or seizures.

DIET

- Acutely affected patient—no food.
- Convalescence—bland diet for several days to allow recovery from gastroenteritis.

CLIENT EDUCATION

Warn client of the hazards of chocolate ingestion.

SURGICAL CONSIDERATIONS

Rarely, a mass or concretion of chocolate could form that must be removed surgically.

MEDICATIONS

DRUG(S) OF CHOICE

- Induce emesis**—only if patient is not seizing; apomorphine (0.03 mg/kg IV); hydrogen peroxide 3% (1–3 mL/kg PO).
- Gastric lavage—only before onset of vomiting and other clinical signs, if emetics are not effective, seizures controlled, and endotracheal tube in place.
- Once vomiting is controlled—activated charcoal (0.5–1 g/kg PO) adsorbs remaining alkaloids in the gastrointestinal tract—repeated at 4- to 8-hour intervals for 1–2 days to prevent enterohepatic recycling.

- Osmotic cathartic—sodium sulfate (0.25 g/kg PO) or sorbitol 70% at 1–3 mL/kg PO; promotes gastrointestinal elimination of chocolate.

- Hyperactivity and seizures**—control with diazepam (0.5–1 mg/kg IV q10–20min up to 2 times or diazepam CRI at 0.5–1 mg/kg/h).

- Ventricular tachycardia** (dogs)—lidocaine (without epinephrine), 2–4 mg/kg IV followed by 0.03–0.05 mg/kg/min IV drip. Lidocaine NOT RECOMMENDED in cats.
- Serious refractory arrhythmias—metoprolol or propranolol (0.02–0.06 mg/kg IV; rate not > 1 mg/minute); metoprolol preferred but may be difficult to obtain; use oral therapy once patient is stable (metoprolol at 0.2–0.4 mg/kg PO q12h; propranolol at 0.1–0.2 mg/kg PO q8h); monitor the ECG and watch for hypotension as a sequel to this treatment.

- In the rare instance of bradycardia, use atropine at 0.02–0.04 mg/kg IV, IM or SC.

CONTRAINdicATIONS

- Do not use epinephrine concurrent with lidocaine.
- Avoid erythromycin and corticosteroids—these reduce the excretion of methylxanthines.
- Do not use lidocaine in affected cats.

PRECAUTIONS

- Effects may persist longer than the effective life of therapeutic drugs.
- Keep patient under observation until drug administration is no longer needed.
- Methylxanthines—cross the placenta; excreted in milk.

CHOCOLATE (METHYLXANTHINE) TOXICOSIS

(CONTINUED)

ALTERNATIVE DRUG(S)

- Control of hyperreflexia and muscle rigidity may be obtained with methocarbamol (50–220 mg/kg slowly IV).
- If response to diazepam inadequate—consider phenobarbital (5–8 mg/kg IV administered over 5–10 minutes q4–6h) or propofol titrated to effect.
- Refractory seizures—pentobarbital coma or mask down with general anesthetic.

FOLLOW-UP

PATIENT MONITORING

- ECG—arrhythmias.
- Watch for mild to moderate nephrosis in convalescent patients.

PREVENTION/AVOIDANCE

Warn owners about toxicologic hazards of chocolate.

POSSIBLE COMPLICATIONS

Pregnant or nursing animals—risk for teratogenesis of newborns or stimulation of nursing neonates.

EXPECTED COURSE AND PROGNOSIS

- Expected course—12–36 hours, depending on dosage and effectiveness of decontamination and treatment.
- Successfully treated patients—usually recover completely.
- Prognosis—good if oral decontamination occurs within 2–4 hours of ingestion; guarded with advanced signs of seizures and arrhythmias.

MISCELLANEOUS

AGE-RELATED FACTORS

Young animals are typically more compromised in metabolism and excretion.

ZOONOTIC POTENTIAL

Not transmissible, but humans and dogs may access similar sources.

PREGNANCY/FERTILITY/BREEDING

Methylxanthines are teratogens in laboratory animals.

SEE ALSO

- Antidepressant Toxicosis—SSRIs and SNRIs.
- Antidepressant Toxicosis—Tricyclic
- Metaldehyde Toxicosis
- Poisoning (Intoxication) Therapy

ABBREVIATIONS

- CNS = central nervous system
- CRI = continuous rate infusion
- ECG = electrocardiogram.

CHOLANGITIS/CHOLANGIOHEPATITIS SYNDROME

BASICS

DEFINITION

- Cholangitis—bile duct inflammation.
- Cholangiohepatitis—inflammation of bile ducts and surrounding liver parenchyma.
- CCHS—more common in cats; histologically classified as suppurative, nonsuppurative (lymphoplasmacytic, lymphocytic), lymphoproliferative (transition to lymphosarcoma); or granulomatous.

PATOPHYSIOLOGY

- Antecedent or coexisting conditions— inflammation or obstruction involving the extrahepatic bile duct (EHBDO) or pancreatic duct (cat), pancreatitis or IBD (dog, cat); CIN (cat).
- Bacterial infection may be primary or secondary; cholestasis is permissive to bacterial infection.
- Acute or chronic cholangitis—associates with bile duct hyperplasia, biliary epithelial hyperplasia, and a ductular reaction.
- Chronic inflammation—may cause bile duct dystrophic mineralization or choleliths.
- Suppurative disease—usually associated with positive bacterial culture or bacteria are observed cytologically (tissue or bile).
- Nonsuppurative disease—immune mediated.
- Sclerosing or destructive cholangitis— inflammation causing bile duct involution/destruction, immune-mediated or infectious—leads to ductopenia of small- and medium-sized bile ducts; a severe lesion.
- Pyogranulomatous CCHS—infectious or immune mechanisms (dog or cat).
- Lymphoproliferative disease—speculated transition stage of inflammation to neoplasia.

SYSTEMS AFFECTED

- Hepatobiliary—liver and biliary system
- Gastrointestinal—pancreas and intestines

INCIDENCE/PREVALENCE

Nonsuppurative CCHS—most common chronic liver disorder of the cat

SIGNALMENT

Species

Cat (common) and dog (uncommon)

Breed Predilections

Possibly Himalayan, Persian, Siamese cats

Mean Age and Range

- Suppurative CCHS—range 0.4–16 years; but mostly young to middle-aged cats.
- Nonsuppurative CCHS—range, 2–17 years; mostly middle-aged cats.

Predominant Sex

- Suppurative CCHS—male cats predisposed
- Nonsuppurative CCHS—none

SIGNS

General Comments

- Suppurative CCHS—most severe clinical illness, acute onset often < 5 days; abdominal pain, pyrexia; associated with EHBDO.
- Nonsuppurative—ill > 3 week (mo to yrs).

Historical Findings

CCHS—cyclic illness; chronic vague signs: lethargy, vomiting, anorexia, and weight loss; ductopenia (cats) if destructive cholangitis—polyphagic (reduced bile flow compromises nutrient assimilation, causing acholic stool, steatorrhea, and reduced uptake of fat-soluble substances, e.g. vitamin K₁, essential fatty acids, vitamin E).

Physical Examination Findings

- Suppurative CCHS—fever; painful abdomen; anicteric to jaundiced; dehydrated; shock.
- Nonsuppurative CCHS—few physical abnormalities other than hepatomegaly; thickened intestines with IBD; variable jaundice, rare abdominal effusion.
- Ductopenia (cats)—unkempt coat, variable lateral thoracoabdominal alopecia; acholic feces may vacillate with cyclic disease.

CAUSES

Suppurative CCHS

- Bacterial infection—more common in cats: *E coli*, *Enterobacter*, *Enterococcus*, β-hemolytic *Streptococcus*, *Klebsiella*, *Actinomyces*, *Clostridia*, *Bacteroides*; rare toxoplasmosis; dogs: usually enteric opportunists; rare *Campylobacter*, *Salmonella*, *Leptospirosis*, others.
- May represent sequela to EHBDO or other cause of mechanical cholestasis.

Nonsuppurative CCHS

Concurrent disorders—cholecystitis, cholelithiasis, pancreatitis, EHBDO, and IBD (dogs, cats); and CIN (cats).

RISK FACTORS

- Suppurative CCHS—EHBDO; cholelithiasis; cholestasis; infections elsewhere.
- Feline nonsuppurative CCHS—IBD, pancreatitis, EHBDO, cholelithiasis, CIN.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

- Feline hepatic lipidosis (FHL)—may coexist; similar enzyme abnormalities and jaundice but low GGT unless concurrent biliary or pancreatic inflammation.
- EHBDO and obstructive cholelithiasis; variable jaundice, increased ALP, GGT, and transaminase activities; increased cholesterol; US evidence of EHBDO.

- Pancreatitis—may reflect cholelithiasis initiated CCHS in cats; lipemia, high cholesterol, and hyperbilirubinemia; inconsistent high fPLI, lipase, and amylase, and ultrasound features; high fPLI implicates pancreatic inflammation but also may reflect IBD and duct inflammation.

- Lymphoproliferative disease and lymphosarcoma—may involve any enteric segment (thick wall), mesenteric lymphadenopathy; dense portal infiltrates spilling across the limiting plate; shares clinical features with CCHS; multisystemic lymphoma or lymphocytic leukemia may cause circulating “blast” cells; hepatic infiltrates may require immunohistochemical characterization.

- Jaundice of septicemia—hyperbilirubinemia dominates clinical biochemical features, usually disproportionate to magnitude of liver enzyme activity.
- Ductal plate malformations (DPM)—polycystic disease, (dogs, cats), especially Persian and Himalayan cats—normal or modestly increased liver enzymes; progressive peribiliary fibrosis in some DPM phenotypes (see Ductal Plate Malformations); variable mild suppurative or nonsuppurative portal aggregates, cholangitis, or CCHS.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Poikilocytes: common in cats with severe liver disease; non-regenerative anemia: anemia of chronic disease; Heinz body hemolysis: severely ill cats with low RBC GSH.
- Suppurative CCHS—neutrophilic leukocytosis, left shift, toxic neutrophils. Nonsuppurative CCHS—may be normal, lymphoproliferative disorder or lymphoma may have lymphocytosis ± abnormal cell morphology.

Serum Biochemistry

- Consistent findings—high ALT, AST, ALP, variable GGT; in cats higher enzymes in non-suppurative disease.
- Variable findings—high total serum bile acids, bilirubin, and cholesterol: depends on severity and extent of cholestasis, coexistent illness, liver dysfunction.

OTHER LABORATORY TESTS

- Species-specific PLI—may be high with pancreatitis and enteritis.
- Vitamin B₁₂—in cats low values indicate small bowel malabsorption (infiltrative disorders: IBD, lymphoma), pancreatic dysfunction, chronic oral antimicrobials causing bowel bacterial overgrowth.
- Coagulation tests—variable; PT and PIVKA most sensitive for vitamin K₁-induced coagulopathy.
- T₄—rules out hyperthyroidism as cause of liver enzyme activity in cats.

CHOLANGITIS/CHOLANGIOHEPATITIS SYNDROME

(CONTINUED)

IMAGING

- Thoracic radiography—sternal lymphadenopathy suggests abdominal inflammation, general lymphadenopathy suggests lymphoma. Abdominal radiography—normal to large liver in nonsuppurative CCHS; rare mineralized choleliths or biliary structures in suppurative or nonsuppurative CCHS.
- Abdominal ultrasonography—normal to large liver; thick bile duct or GB wall (inflammation, edema, infiltrates, fibrosis); echogenic intraluminal debris; choleliths; focal parenchymal lesions (abscess, inflammation, neoplasia); lymphadenopathy (peripancreatic, perihilar hepatic, or mesenteric) suggests pancreatic, liver, intestinal inflammation or enteric neoplasia; hepatic parenchymal hyperechogenicity (concurrent FHL, inflammation, fibrosis); cysts (DPM, polycystic disease, cystadenoma); **Note:** no US lesions in some animals with severe CCHS.

OTHER DIAGNOSTIC PROCEDURES

Fine-Needle Aspiration Cytology

- Hepatic aspiration—for culture, identify FHL; cytology may reveal bacteria not visualized by light microscopy evaluation of biopsy. **Note:** cytology rules in FHL but is unreliable for diagnosis of nonsuppurative CCHS. Hepatocellular vacuolation is common in ill cats, may be misdiagnosed as FHL.

- Cholecystocentesis—may reveal suppuration, bacteria, trematode eggs, or neoplasia. Normal bile is devoid of cells, blue amorphous appearance with Wright's Giemsa stain.

Percutaneous Biopsy

- US-guided core-needle biopsy—may misdiagnose CCHS due to small sample size; need a minimum of 15 portal triads for accurate diagnosis; if 18-G core needle used, collect a minimum of 4 samples.
- Inaccuracy with needle biopsy methods and biopsy of only a single liver lobe reflects differential lobe involvement and sample size.
- Post-biopsy complications esp. cats: collapse, vasovagal due to biliary trauma, unintentional sampling of non-hepatic tissues with US needle sampling in cats.

Laparoscopy

- Permits direct visualization of GB, porta hepatis, pancreas, and perihepatic and peripancreatic lymph nodes; permits biopsy of multiple liver lobes, as well as pancreas and bile collection (cholecystocentesis).
- In EHBDO—avoid laparoscopy.

Laparotomy

- Esp. if suspected EHBDO—recommended. Permits inspection of biliary structures; biliary

decompression and biliary enteric anastomosis; biopsy of: liver, biliary structures, pancreas, intestines, lymph nodes, and cholecystocentesis.

TISSUE SAMPLING

If nonsuppurative CCHS suspected, also biopsy bowel and pancreas.

BILE AND TISSUE CULTURES

Aerobic and anaerobic bacterial cultures—of liver tissue and bile.

MOLECULAR GENETICS

Genetic test for feline polycystic disease may be appropriate.

PATHOLOGIC FINDINGS

- Suppurative CCHS—swollen liver, blunt edges, focal discolorations; may note erythematous, necrotic, or thick-walled GB (cholecystitis); peripancreatic steatonecrosis or fat saponification (pancreatitis); perihepatic and peripancreatic lymphadenopathy; EHBDO, may observe choleliths or cystic lesions (DPM).
- Nonsuppurative CCHS—large to normal size firm liver (small in very chronic disease); blunt margins; variable surface irregularity, may observe choleliths or cystic lesions (DPM).
- If concurrent FHL: yellow or pale friable parenchyma, samples float in formalin.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient Management

- *Suppurative CCHS with acute febrile illness*, painful abdomen, left-shifted leukogram—hydration support, “best guess” bactericidal antimicrobials: initially based on cytology and Gram stain; start antibiotics if EHBDO or cholecystitis *before* surgery; continue antibiotics ≥ 4 weeks with choleretic therapy (ursodeoxycholic acid, SAMe) until enzymes normalize or signs resolve.

- *Nonsuppurative symptomatic cats*—fluid therapy as necessary; if jaundiced: give vitamin K₁ (0.5–1.5 mg/kg IM q12h for 3 doses) before invasive diagnostics and liver biopsy. Cats with CCHS—may need blood transfusion consequent to surgery or biopsy.
- Polyionic fluids—supplement with B-soluble vitamins (2 mL/L), KCl, and K phosphate as needed; avoid dextrose supplements (see Hepatic Lipidoses).

Outpatient Management

- Suppurative—after acute crisis managed.
- Nonsuppurative—after resolution of acute crisis, provide life-long immunomodulation (if no bacteria observed or cultured), antioxidants, and hepatoprotectants.

ACTIVITY

Restricted while symptomatic.

DIET

Nutritional support—avoid FHL by feeding a balanced high-protein, high-calorie feline diet; supplement water-soluble vitamins; antigen-restricted diet if concurrent IBD; fat-restricted diet if severe ductopenia causing fat malabsorption, or chronic pancreatitis causing maldigestion; may require feeding tubes (esophagostomy preferred, jejunal feeding if symptomatic pancreatitis); rarely require parenteral nutrition (provoke FHL).

CLIENT EDUCATION

Emphasize chronic nature of nonsuppurative CCHS and requirement for life-long therapy.

SURGICAL CONSIDERATIONS

- Cholecystectomy—if cholecystitis.
- Cholecystoenterostomy—may be necessary in patients with EHBDO which increases life-long risk for septic cholangitis. Cholelith removal.

MEDICATIONS

DRUG(S)

Antibiotics for Suppurative CCHS

- Bactericidal—against enteric opportunists; initially use combination of: ticarcillin or clavamox, enrofloxacin, combined with metronidazole (7.5–15 mg/kg PO q12h; low dose if jaundiced).
- Modify initial or empiric antimicrobials based on culture and sensitivity reports. Resistant enterococcus—vancomycin (10 mg/kg q12h IV slow infusion for 7–10 days).

Immunomodulation: Nonsuppurative CCHS

- Glucocorticoids—prednisolone (dogs: 2 mg/kg/day; cats: 4 mg/kg/day) for 14–21 days, taper to lowest effective alternate-day dose; chronic therapy usually needed; ensure prednisolone used in cats as prednisone is not bioavailable in this species; beware of development of diabetes mellitus in cats.
- Metronidazole—combination with prednisolone, for cell-mediated immunomodulation, antiendotoxin effect, and antibacterial, especially if IBD. Recent work implicates chronic bacterial involvement in nonsuppurative feline CCHS that may be attenuated by metronidazole.
- Cats with confirmed ductopenia—require more aggressive immunomodulation; *do not use azathioprine in cat*; clinical experience suggests combination of prednisolone, metronidazole with pulsed methotrexate (see

(CONTINUED)

CHOLANGITIS/CHOLANGIOHEPATITIS SYNDROME

C

below) OR chlorambucil 1–2 mg per cat, load q24h for 3 days then every 3 days.

- *Methotrexate protocol feline nonsuppurative destructive or sclerosing CCHS:* 0.4 mg total dose given in 3 divided doses on 1 day [0.13 mg total at 0, 12, and 24h] and repeated at 7–10 day intervals); may be given PO, IV, IM (parenteral routes require 50% dose reduction); concurrently provide folate (folic acid) at 0.25 mg/kg daily. If lymphoproliferative or neoplastic infiltrates, use chemotherapy protocols developed for enteric lymphoma.

Antioxidants

- Vitamin E (α -tocopherol acetate)—10–30 IU/kg, high dose if chronic EHBDO or ductopenia PO because of fat malabsorption (see EHBDO for alternative form of Vitamin E that is water soluble).
- S-adenosylmethionine (SAMe, use form with proven bioavailability and efficacy as a GSH donor)—20 mg/kg/day enteric-coated tablet PO 2h before feeding; many beneficial effects including anti-inflammatory influence that achieved remission in cats with mild nonsuppurative CCHS (without duct destruction).

Other

- Ursodeoxycholic acid (UDCA)—10–15 mg/kg/day PO divided with food for best bioavailability; can formulate aqueous suspension (refrigerate); provides immunomodulatory, hepatoprotectant, choleretic, antifibrotic, and antioxidant effects. Recent information (humans with destructive cholangitis and knockout mouse models of such) indicate that UDCA may hasten small duct injury in destructive/sclerosing cholangitis. Thus, liver biopsy recommended before prescribing UDCA for cats with “suspected” chronic CCHS. Chronic UDCA in cats should be accompanied by taurine supplementation (250 mg/day) as all bile acids are obligatorily conjugated with taurine in cats.
- B vitamin supplementation with thiamine (B_1) and B_{12} —thiamine 50–100 mg PO q24h for 3 days, then in water-soluble vitamin supplements; B_{12} (0.25–1.0 mg SC) if suspect gut malabsorption (use initial and

sequential plasma B_{12} concentrations to verify need and efficacy of treatment; (some cats require weekly injections, then monthly).

CONTRAINDICATIONS

Adjust drug dosages with regard to liver function and cholestasis. Caution with metronidazole to avoid neurotoxicity: if jaundiced use 7.5 mg/kg PO BID.

FOLLOW-UP

PATIENT MONITORING

Nonsuppurative CCHS—initially monitor enzymes and bilirubin q7–14 days; after remission, assess quarterly; serum bile acid measurements complicated by ursodeoxycholic acid administration (detected by assay).

PREVENTION/AVOIDANCE

Control IBD

POSSIBLE COMPLICATIONS

- Suppurative CCHS may transform to nonsuppurative CCHS or sclerosing CCHS.
- Diabetes mellitus in 30% of cats with sclerosing CCHS treated with prednisolone.
- FHL may develop if inadequate nutritional intake or is induced by glucocorticoids.

EXPECTED COURSE AND PROGNOSIS

- Suppurative CCHS—may be cured.
- Nonsuppurative CCHS—chronic, long-term remission possible (> 8 years documented).

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Pancreatitis
- Hepatic lipidosis
- Polycystic liver disease
- Lymphosarcoma
- Lymphoproliferative disease
- Cholangiocarcinoma—may develop in some cats with chronic nonsuppurative CCHS

CHOLECYSTITIS AND CHOLEDOCHITIS

BASICS

OVERVIEW

- Cholecystitis = gallbladder (GB) inflammation.
- Choledochitis = large bile duct inflammation.
- Associate with cholelithiasis; GB mucocele (GBM); extrahepatic bile duct obstruction (EHBDO); or inflammation involving intrahepatic biliary structures.
- Severe GB inflammation can lead to rupture and subsequent bile peritonitis, necessitating combined surgical and medical treatments.
- Bile duct obstruction increases risk for biliary infection: enteric bacteria transmigrating the bowel wall, pass into the portal circulation, enter the liver, GB, and bile, dispersing endotoxins and bacteria initiating sepsis, and in some cases, bile and/or septic peritonitis.

SIGNALMENT

- Dog and cat
- No breed or sex predilection
- Necrotizing cholecystitis (dogs)—usually middle-aged or older animals.
- GBM: predisposition for dogs with hyper-lipidemia (e.g., endocrinopathies [hyperadreno-corticism, hypothyroidism, diabetes mellitus], pancreatitis, glucocorticoid administration, nephrotic syndrome, idiopathic hyperlipidemia (e.g., Shetland sheepdogs, miniature Schnauzer)—leads to cholestasis and cholecystitis; (see Gallbladder Mucocele).

SIGNS

- Choledochitis: vague signs, variable icterus.
- Sudden onset: inappetence, lethargy, vomiting, vague abdominal pain (may be postprandial with cholecystitis or GBM).
- Mild to moderate jaundice and fever common.
- Chronic postprandial discomfort/distress.
- Severe disease—shock due to endotoxemia, bacteremia, and hypovolemia.
- Soft tissue mass in right cranial abdomen palpable in small dogs and cats reflecting inflammation and adhesions of GB and pericholecystic tissues.

CAUSES & RISK FACTORS

- Impaired bile flow at cystic duct or GB, GB dysmotility, or ischemic insult to the GB wall may precede cholecystitis.
- Irritants in sludged bile (e.g., lyssolecithin, prostaglandins, choleliths, liver flukes) or retrograde flow of pancreatic enzymes (cats) may initiate/augment GB or duct inflammation.
- Previous enteric disorders, trauma, abdominal surgery—may be contributing factors.
- Anomalous GB or duct development: choledochal cyst (rare, cats > dogs).

• Bacterial infection—common; retrograde invasion via ducts from intestine or hemato-genous dispersal from splanchnic circulation.

- Toxoplasmosis and biliary coccidioides—rare.
- Necrotizing cholecystitis (dogs)—ruptured GB (common) and complicating cholelithiasis; *E. coli* and *Enterococcus* spp—common isolates.
- Emphysematous cholecystitis/choledochitis—rare, associates with diabetes mellitus, traumatic GB ischemia, acute cholecystitis (with or without cholelithiasis); common gas-forming organisms—*Clostridia* spp. and *E. coli* often cultured.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pancreatitis
- Focal or diffuse peritonitis
- Bile peritonitis
- Gastroenteritis causing biliary involvement
- Cholelithiasis
- Cholangiohepatitis
- Hepatic necrosis or abscessation
- EHBDO
- GBM
- Septicemia

CBC/BIOCHEMISTRY/URINALYSIS

- Variable leukocytosis with toxic neutrophils and inconsistent left shift
- High bilirubin; bilirubinuria
- High ALT, AST, ALP, and GGT activity
- Low albumin with peritonitis
- High cholesterol and bilirubin if EHBDO
- Hypercholesterolemia and/or hyperlipidemia (triglycerides): breed-related, endocrine, pancreatitis, nephrotic syndrome.

OTHER LABORATORY TESTS

- Abdominocentesis—inflammatory effusion; (see Bile Peritonitis)
- Bile culture (dogs)—*E. coli*, *Enterococcus* spp., *Klebsiella* spp., *Pseudomonas* spp., *Clostridium* spp., others
- Coagulation tests—abnormal if chronic EHBDO (vitamin K deficiency) or DIC in severe conditions with sepsis.

IMAGING

- Abdominal radiography—may reveal loss of cranial abdominal detail with focal or diffuse peritonitis or effusion; ileus; radiodense choleliths; gas in biliary structures; radiodense GB (dystrophic mineralization due to chronic inflammation, porcelain GB, rare).
- Ultrasonography—fluid interface surrounding GB enhances wall image; diffusely thick GB wall, segmental hyperechogenicity and /or laminated wall in necrotizing cholecystitis; double-rimmed GB wall: acute cholecystitis, hepatitis, cholangiohepatitis, third-space fluid dispersal (hypoproteinemia, right heart failure, renal

failure, pyelonephritis, abdominal effusion, iatrogenic fluid overload); GB lumen filled with amorphous echogenic stellate or finely striated pattern, resembling sliced kiwi fruit (“kiwi sign”) if GBM; GB rupture implicated by discontinuous GB wall, pericholecystic fluid or generalized effusion, and hyperechogenicity of surrounding tissue; failure to image GB: may implicate rupture or agenesis; mineralized GB wall may indicate dystrophic mineralization (Limey GB, sacculated GB or ducts due to malformation—Caroli's malformation); intrahepatic bile ducts difficult to visualize or prominent: ascending cholangitis (thick walls), or EHBDO (dilated ducts); pericholecystic fluid: necrotizing cholecystitis and surgical emergency.

- Choledochitis involving CBD: thick wall, intraluminal debris, extends into hepatic ducts.

PATHOLOGIC FINDINGS

Gross appearance—erythematous GB; may appear green-black if necrotizing lesion; tenacious “inspissated” biliary material common with GBM; pigmented choleliths if infection; blood with hemobilia; CBD with thick wall, variable intraductal debris (e.g., biliary particulates, suppurative inflammation).

TREATMENT

- Inpatient—required for critical care during diagnostic/presurgical evaluation or if septic.
- Place intravenous catheter in peripheral vein for polyionic fluids, and blood component therapy as needed.
- Restore fluid and electrolyte balance; monitor electrolytes frequently.
- Plasma—preferred colloid; indicated if hypoalbuminemia and coagulopathy.
- Whole blood or fresh frozen plasma—for surgical cases with bleeding tendencies. If septic, artificial colloids may delay recovery.
- Monitor urine output.
- Remain vigilant for vasovagal reflex (abrupt pathologic bradycardia, hypotension, cardiac arrest) when biliary structures manipulated or during cholecystostomy; be prepared with anticholinergics (atropine).
- GB resection advised for cholecystitis, best based on evaluation at surgery.

MEDICATIONS

DRUG(S)

- Antibiotics—before surgery; broad spectrum; surgical manipulations may initiate bacteremia; select antibiotics for enteric Gram-negative and anaerobic flora; refine treatment using culture and sensitivity results; good initial choice: triad combination

(CONTINUED)

CHOLECYSTITIS AND CHOLEDOCHITIS

C

of: metronidazole, ticarcillin (or clavamox) and a fluorinated quinolone. Reduce standard dose for metronidazole by 50% if cholestatic jaundice.

- Ursodeoxycholic acid—10–15 mg/kg PO daily divided BID with food, tablet form provides best bioavailability; requires decompression of EHBDO prior to treatment.
- Antioxidants: *vitamin E* (α -tocopherol acetate)—10 IU/kg (see Bile Duct Obstruction (Extrahepatic)); *S-adenosylmethionine* (SAMe) use enteric-coated bioavailable product; on empty stomach)—GSH donor (20 mg/kg PO q24h), 2h before feeding; non-bile acid dependent (GSH) choleresis (40 mg/kg PO q24h).
- Vitamin K₁—0.5–1.5 mg/kg SC or IM q12h for 3 doses; **caution:** never administer IV (anaphylactoid reaction); treat early to allow response before surgical manipulations.

CONTRAINDICATIONS

Ursodeoxycholic acid—contraindicated in uncorrected EHBDO or bile peritonitis.

**FOLLOW-UP****PATIENT MONITORING**

- Physical examination and pertinent diagnostic testing—repeat every 2–4 weeks until abnormalities resolve.
- If septic—continue antibiotics until enzymes resolve.

POSSIBLE COMPLICATIONS

Anticipate a protracted clinical course with ruptured biliary tract or peritonitis.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Cholelithiasis
- Ductal plate malformation
- EHBDO
- Gallbladder mucocele
- Bile peritonitis

AGE-RELATED FACTORS

Congenital malformations of biliary structures do not predispose patients to cholecystitis but predispose to choledochitis.

ZOONOTIC POTENTIAL

Campylobacter and *Salmonella* may cause cholecystitis in dogs; advise owner if diagnosed

ABBREVIATIONS

- ALP = alkaline phosphatase

CHOLELITHIASIS

BASICS

OVERVIEW

- Radiopaque or radiolucent calculi in the bile ducts, gallbladder (GB), or rarely bile ductules within the liver (hepatolithiasis). Gallbladder mucocele (GBM) is considered a form of cholelithiasis (see Gallbladder Mucocele).
- May be asymptomatic.
- Symptomatic—signs reflect sludged bile, EHBDO, cholecystitis, cholangiohepatitis, or bile peritonitis.
- Primary constituents of choleliths—mucin, glycoprotein, calcium carbonate, and bilirubin pigments; while dog bile is less lithogenic than human bile (lower cholesterol saturation); dog bile forms bilirubinate sludge with fasting; and provoked by a low-protein low-methionine diet.
- 50% feline choleliths mineralized; may be radiographically visible (calcium carbonate).
- Surgical/medical treatment—not recommended without clinical signs or clinico-pathologic abnormalities (current or historical).

SIGNALMENT

- Cat and dog
- Small-breed dogs may be predisposed
- Hyperlipidemic dogs—predisposed to GBM (see Gallbladder Mucocele)

SIGNS

- May be asymptomatic.
- When accompanied by infection or causing intermittent or complete EHBDO (with or without peritonitis)—vomiting; meal-related discomfort, abdominal pain; fever; ± jaundice.
- Episodic vague peri- or postprandial abdominal pain.

CAUSES & RISK FACTORS

- Predisposing factors—stasis of bile flow (GB dysmotility, choledochal cysts [cats]; lith nidus formation (inflammatory debris, infection, tumor, epithelial exfoliation, residual suture material); bile supersaturation (heme-bilirubin pigments, hemobilia, calcium, enhanced mucin production [inflammation, prostaglandins], cholesterol); fused feline pancreatic and bile duct (ampulla) predisposes to concurrent biliary /pancreatic cholelithiasis, choledochitis, and bile stasis progressing to EHBDO, and pancreatitis.
- Bile sludge and/or GB distention—enhances mucin production and coalescence of bile particulates.
- Inflammatory mediators and bacterial enzymes associated with cholecystitis—aggravate stone precipitation (mucin production, deconjugation, and dehydroxylation of bilirubin-yielding insoluble bili-pigments).
- Low-protein, low-taurine, and low-methionine diet in dogs—lithogenic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- EHBDO—inflammatory, infectious, or neoplastic conditions involving liver or extrahepatic tissues adjacent to porta hepatis; suggested by marked increases in: ALP, GGT, bilirubin and cholesterol.
- Cholangiohepatitis.
- Cholecystitis/Choledochitis.
- Pancreatitis.
- Bile peritonitis.
- GBM.

CBC/BIOCHEMISTRY/URINALYSIS

- May have no clinicopathologic abnormalities.
- CBC—may be normal; abnormalities reflect bacterial infection, endotoxemia, biliary obstruction, or underlying causal factors; inflammatory leukogram in some cases.
- Biochemistry—if symptomatic: variable hyperbilirubinemia, increases in serum ALP, GGT, ALT, and AST activities.

OTHER LABORATORY TESTS

- Bacterial culture—bile: aerobic and anaerobic bacteria often confirmed in symptomatic patients.
- Cholelith nidus—culture may identify bacterial infection.
- Coagulation profile—bleeding may develop with chronic EHBDO (see Bile Duct Obstruction (Extrahepatic)) associated with prolonged clotting times (especially PIVKA and PT); responsive to parenteral vitamin K₁.
- Cholelith analysis: submit to laboratory equipped for cholelith analysis; usual composition—calcium carbonate complexed with mucin and bilirubinate pigments.

IMAGING

- Abdominal radiography—limited value in delineating GB structure/content; choleliths often small, may be radiolucent; rarely mistaken for dystrophic biliary mineralization in animals with chronic cholangitis.
- Ultrasonography—can detect: choleliths ≥ 2 mm diameter, thickened GB wall, distended biliary tract, increased hepatic parenchymal echogenicity (inflammation, lipid, glycogen, or fibrosis), and extrahepatic ductal involvement; may facilitate specimen collection for culture, cytology, and histopathology; may detect evidence of EHBDO within 72hr; **caution:** a distended GB with bile “sludge” is common in anorectic or fasted patients: do not mistake for GB obstruction. Hepatolithiasis casts acoustic shadow in parenchyma. Imaging of choleliths in extrahepatic ducts may be difficult owing to enteric gas obstructing imaging “window.”

DIAGNOSTIC PROCEDURES

Histopathologic evaluation of liver is necessary in patients undergoing surgical

cholelith removal to detect comorbid conditions influencing treatment and prognosis.

TREATMENT

- Controversial whether choleresis with ursodeoxycholate are indicated in animals lacking clinical or clinicopathologic signs.
- Supportive fluids—if hospitalized, according to hydration, electrolyte and acid-base status.
- If hyperlipidemia a predisposing factor—prescribe fat-restricted diet, identify endocrinopathies and treat.
- Control predisposing conditions, especially biliary tree infection (with antimicrobials) and GB dysmotility (by GB removal).
- Exploratory surgery, choledochotomy, cholecystotomy, and possibly cholecystectomy or biliary-enteric anastomosis—indicated in symptomatic cases according to circumstances.
- Warn client that cholelithiasis is a chronic problem and that stones may reform even after surgical removal despite chronic medical treatment.

MEDICATIONS

DRUG(S)

- Antibiotics—based on cultures of bile, tissue, and cholelith nidus or directed against enteric microbial opportunists; initial treatment with Timentin, metronidazole, combined with a fluoroquinolone is usually successful.
- Ursodeoxycholic acid—10–15 mg/kg/day PO, divided BID given with food; provides choleretic, hepatoprotectant, anti-endotoxic, antifibrotic effects, and may facilitate stone dissolution; therapy continued life-long if no cause for cholelithiasis identified.
- Vitamin K₁—parenterally; 0.5–1.5 mg/kg to a maximum of 3 doses in 36h in jaundiced patients; do not administer IV (anaphylaxis).

Antioxidants

- Vitamin E (α -tocopherol acetate)—10 IU/kg per day for patients with high liver enzymes or confirmed hepatobiliary inflammation.
- S-Adenosylmethionine (SAMe, use form with proven bioavailability and efficacy)—GSH donor (important hepatobiliary antioxidant, GSH provides a driving force for non-bile acid dependent choleresis) and is a potential choleretic for patients with high liver enzymes or confirmed hepatobiliary inflammation; (20–40 mg/kg enteric-coated tablet PO q24h, administer 2h before feeding; higher dose recommended for choleresis); also

(CONTINUED)

CHOLELITHIASIS

C

provides antifibrotic and antiinflammatory benefits.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Ursodeoxycholic acid—contraindicated with EHBDO before biliary decompression.

**FOLLOW-UP****PATIENT MONITORING**

- Postoperatively: physical examination and pertinent diagnostic testing—every 2–4 weeks postoperatively until clinical signs and clinicopathologic abnormalities resolve.
- Periodic ultrasonography—assess cholelith status, integrity of biliary tract, hepatic parenchymal changes.

POSSIBLE COMPLICATIONS

Sudden onset of fever, abdominal pain, and malaise—may signify bile peritonitis and/or

sepsis from a breakdown in bile containment, or recurrent cholelith lodged in sphincter of Oddi.

EXPECTED COURSE AND PROGNOSIS

- May be asymptomatic
- Symptomatic disease—reflects existing infection, EHBDO, cholecystitis, or bile peritonitis.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Bile Duct Obstruction (Extrahepatic)
- Cholecystitis
- Choledochitis
- Gallbladder Mucocele

ABBREVIATIONS

- ALP = alkaline phosphatase
- ALT = alanine aminotransferase
- AST = aspartate aminotransferase
- GBM = gallbladder mucocele
- GGT = γ -glutamyltransferase
- GSH = glutathione
- EHBDO = extrahepatic bile duct obstruction
- PIVKA = proteins invoked by vitamin K absence or antagonism
- PT = prothrombin time

CHONDROSARCOMA, BONE

BASICS

OVERVIEW

• Chondrosarcoma (CSA) is a malignant mesenchymal tumor that produces chondroid and fibrillar matrix, but not osteoid. • CSA is the second most common primary bone tumor in dogs, accounting for 5–10% of all primary bone tumors. In cats, primary bone tumors are uncommon, and CSA is third in incidence behind osteosarcoma and fibrosarcoma. • The majority of CSAs arise from flat bones (axial skeleton).

Approximately 30% occur in the nasal cavity, accounting for 15% of all nasal tumors; 20% of CSAs arise from the ribs, accounting for 30–40% of all primary rib tumors. • 20% of CSAs arise from the appendicular skeleton, often but not always at the typical sites where osteosarcoma occurs. CSA accounts for only 3–5% of all primary bone tumors in the appendicular skeleton. • Other reported sites include facial bones, skull, vertebrae, pelvis, digits, and os penis. • Rarely, CSA can arise in soft tissue (extraskeletal) sites. In cats, CSA can arise at sites of previous injection (injection-site sarcoma).

SIGNALMENT

• Dogs: medium- to large-breed dogs weighing between 20 and 40 kg are affected most commonly. Mixed-breed dogs, golden retrievers, boxers, and German shepherd dogs are overrepresented. • Median age is 8 years (reported range 1–15 years) for dogs. • Cats are rarely affected with no obvious predilections.

SIGNS

Historical Findings

• Patients often present with a visible mass at the affected site. • Appendicular CSA usually is associated with lameness if involvement of weight-bearing bone. • Rarely, rib tumors can be associated with respiratory signs or visible body wall anomaly. • Additional clinical signs vary with the site of involvement.

Physical Examination Findings

• Findings depend on the anatomic location. • Often, but not always, a firm to hard mass will be palpable. The mass often is painful, but not always. • Rib CSA occurs most commonly at the costochondral junction. Any rib can be affected and dyspnea is rare and associated with space-occupying effect.

CAUSES & RISK FACTORS

- Etiology largely unknown.
- Osteochondromatosis (multiple cartilaginous exostosis) lesions can transform into CSA.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other primary bone tumors (osteosarcoma, fibrosarcoma, hemangiosarcoma).
- Metastatic bone tumors (transitional cell, prostatic, mammary, thyroid, apocrine gland anal sac carcinomas). • Tumors that locally invade adjacent bone (especially oral, nasal, digital, and joint tumors). • Bacterial or fungal osteomyelitis.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

IMAGING

• Radiographs of the primary lesion show features of an aggressive bone lesion (bone lysis, cortical destruction, non-homogenous bone formation, ill-defined zone of transition). • Thoracic radiographs are recommended to screen for pulmonary metastasis. • CT is recommended for axial tumors to more accurately stage local disease and plan for surgery and/or radiation therapy. • If patient is undergoing CT, concurrent imaging of the thorax is recommended as a more sensitive way to screen for pulmonary metastasis.

DIAGNOSTIC PROCEDURES

- Histopathology is needed for definitive diagnosis. • Fine-needle aspirate bone cytology may provide a supportive diagnosis.

TREATMENT

• Amputation is recommended for appendicular tumors. • For axial tumors, wide surgical excision is recommended whenever possible. • Stereotactic radiation therapy provides effective local control for canine osteosarcoma and might be an alternative to surgery for patients with CSA. • Palliative therapy is recommended for patients with nonresectable local disease or gross metastasis, or when definitive therapy is declined. Palliative care focuses on pain control.

MEDICATIONS

DRUG(S)

Pain Management

- Nonsteroidal anti-inflammatory drugs.
- Tramadol.
- Gabapentin.
- Intravenous aminobisphosphonates (e.g. pamidronate, zoledronate) might alleviate bone pain and slow pathologic bone resorption.

Chemotherapy

The role of chemotherapy has not been defined in veterinary oncology, but it does not improve outcome in humans.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Use NSAIDs cautiously in all cats and in dogs with renal insufficiency. • Do not combine NSAIDs with corticosteroids.

FOLLOW-UP

PATIENT MONITORING

Physical examination every 2–3 months and thoracic radiographs every 3–4 months to monitor for local tumor control and distant metastases, respectively.

EXPECTED COURSE AND PROGNOSIS

• Overall, 15–30% will develop metastatic disease, with the lungs being the most commonly affected site. Metastatic rates approach 50% for high-grade tumors. • With aggressive surgery, median survival is > 3 years and many dogs will enjoy long-term local control. However, depending on tumor location and completeness of excision, up to 40% will develop local recurrence. • With palliative care alone, survival times of > 1 year are still possible.

CHONDROSARCOMA, LARYNX AND TRACHEA

BASICS

OVERVIEW

- Chondrosarcoma is a malignant mesenchymal tumor that produces chondroid and fibrillar matrix, but not osteoid.
- Osteochondroma is a benign tumor with an apical margin of hyaline cartilage and a base of cancellous bone.
- Laryngeal and tracheal tumors are rare in dogs and cats.

SIGNALMENT

- CSA arises in both the larynx and trachea in dogs with no obvious breed or gender predilections with an age range of 1–10 years.
- Osteochondroma typically occurs in the trachea of young dogs (< 1 year of age) with no obvious breed or gender predilections.
- CSA and osteochondroma have not been reported in the larynx or trachea of cats.

SIGNS

Historical Findings

- Voice change
- Loud or stertorous breathing
- Coughing or dyspnea
- Exercise intolerance
- Severe respiratory distress, cyanosis, collapse
- Dysphagia

Physical Examination Findings

- Inspiratory stertor.
- Respiratory stridor.
- Dyspnea, cyanosis.
- A laryngeal mass might be visible on unsedated oral examination.
- A laryngeal or tracheal mass rarely is externally palpable; however, widening of the laryngeal box might be digitally detectable.

CAUSES & RISK FACTORS

None known

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Laryngeal paralysis.
- Elongated soft palate (brachycephalic breeds).
- Laryngeal collapse.
- Collapsing trachea.
- Reverse sneezing.
- Pharyngeal or laryngeal foreign body.
- Laryngeal trauma and secondary inflammation.
- Other laryngeal tumors: rhabdomyoma, oncocytoma, squamous cell carcinoma, adenocarcinoma, mast cell tumor, osteosarcoma, fibrosarcoma, plasma cell tumor, lymphoma.

- Other tracheal tumors: squamous cell carcinoma, lymphoma, mast cell tumor, leiomyoma, adenocarcinoma, osteosarcoma.
- Thyroid adenocarcinoma.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

Pulse oximetry and/or arterial blood gas

IMAGING

- Cervical radiographs are of limited benefit. Laryngeal tumors typically are visualized radiographically only when very large.
- Cervical ultrasound can help identify a laryngeal mass and guide percutaneous fine-needle aspiration or needle core biopsy.
- Thoracic radiography recommended for evaluating the trachea and screening for pulmonary metastasis.
- Computed tomography can identify the origin of neoplastic growth, as well as the extent of disease.

DIAGNOSTIC PROCEDURES

- Sedated laryngeal exam—sedation and anesthesia are not without risk, be prepared to intubate the patient and/or perform an emergency tracheostomy.
- Laryngoscopy and tracheoscopy—be prepared to perform an emergency tracheostomy.
- Cytology of samples collected via fine-needle aspiration or ultrasound-guided fine-needle aspiration.
- Tissue biopsy and histopathology are needed to reach a definitive diagnosis.

TREATMENT

- Management of respiratory distress—keep patient calm, provide oxygen support and anti-inflammatory medications. In cases of severe respiratory distress, be prepared to intubate or perform an emergency tracheostomy.
- Small, benign laryngeal tumors can be removed surgically by submucosal resection or partial laryngectomy.
- Large, invasive laryngeal cancers are best treated with total laryngectomy and permanent tracheostomy. Owners must be aware of the extensive long-term postoperative care required and high complication rate which include aspiration pneumonia.
- Small, benign tracheal tumors can be debulked via tracheoscopy and electrocautery; however, local recurrence can occur.
- Larger and malignant tracheal tumors should be treated with resection—full-thickness removal with end-to-end anastomosis can be performed on 20–60% of the trachea, usually up to 4–8 tracheal rings.

- Radiation therapy has rarely been used. Because of the chondroid and mineral matrix produced by CSAs and osteochondromas, radiation therapy likely will stabilize tumor size at best and not cause substantial shrinkage.

MEDICATIONS

DRUG(S)

- Dexamethasone sodium phosphate (0.1–0.2 mg/kg IV) to help alleviate secondary inflammation contributing to acute respiratory distress.
- Chemotherapy has not been systemically evaluated, but is not thought to be effective.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Every effort should be made to rule out lymphoma before administering corticosteroids.

FOLLOW-UP

PATIENT MONITORING

- Monthly physical examinations are recommended.
- For laryngeal tumors, a sedated laryngeal exam should be performed every 2–3 months.
- For tracheal tumors, radiographs of the trachea and/or tracheoscopy should be performed every 2–3 months.
- Thoracic radiographs should be taken every 3–4 months to screen for possible pulmonary metastasis.

EXPECTED COURSE AND PROGNOSIS

- Prognosis for CSA is guarded because most dogs have advanced infiltrative disease at the time of diagnosis. Even when tumors can be removed, excision usually is incomplete and local recurrence is common.
- Long-term prognosis for tracheal osteochondroma is good if the lesion can be completely resected.

MISCELLANEOUS

ABBREVIATION

- CSA = chondrosarcoma

CHONDROSARCOMA, NASAL AND PARANASAL SINUS

BASICS

OVERVIEW

- Chondrosarcoma is a malignant mesenchymal tumor that produces chondroid and fibrillar matrix, but not osteoid.
- Nasal CSA arises most commonly from the nasal turbinates.
- In dogs, approximately 30% of all CSA occur in the nasal cavity; this accounts for 15% of all nasal tumors.

SIGNALMENT

- For CSA in general, mixed-breed dogs, golden retrievers, boxers, and German shepherd dogs are overrepresented.
- Median age is 8 years (range, 1–15 years).
- CSA tends to develop at a younger age than other nasal tumors.
- Rare in cats—no obvious breed or sex predilections.

SIGNS

Historical Findings

- Unilateral or bilateral epistaxis and/or mucopurulent discharge.
- Sneezing, stertorous breathing, and/or facial deformity.
- Decreased appetite and/or halitosis secondary to oral cavity invasion.
- Seizures, behavior changes, and/or obtundation secondary to cranial invasion.

Physical Examination Findings

- Epistaxis and/or nasal discharge (unilateral or bilateral).
- Decreased nasal air flow (unilateral or bilateral).
- Pain on nasal or paranasal sinus palpation or percussion.
- Facial deformity, decreased retropulsion of the eyes or exophthalmia, and epiphora.
- Visible mass effect protruding through the palate into the oral cavity.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other nasal tumors—adenocarcinoma, squamous cell carcinoma, osteosarcoma, fibrosarcoma, lymphoma, transmissible venereal tumor (dogs), nasopharyngeal polyp (cats).

- Fungal rhinitis—aspergillosis and penicilliosis (dogs), cryptococcis (cats), sporotrichosis (both).
- Rhinosporidiosis (dogs).
- Foreign body
- Thrombocytopenia or other coagulopathy.
- Tooth root abscess.
- Oronasal fistula.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal—evaluate for thrombocytopenia if signs of epistaxis.

OTHER LABORATORY TESTS

- Nasal flush for cytology and culture—rarely helpful.
- Coagulation profile.
- Buccal mucosal bleeding time.

IMAGING

- Skull radiographs—soft tissue opacity in the nasal cavity and/or frontal sinuses.
- Thoracic radiographs to screen for pulmonary metastasis.
- CT for detecting soft tissue opacity within the nasal cavity and surrounding sinuses, bony destruction, and extension through the cribriform plate into the brain.

DIAGNOSTIC PROCEDURES

- Mandibular lymph node cytology to screen for possible metastasis.
- Rhinoscopy can sometimes be helpful for visualizing a mass or fungal plaque and guiding a subsequent biopsy.
- Tissue biopsy and histopathology is needed for definitive diagnosis. The biopsy instrument should not pass caudal to the level of the medial canthus of the eye to avoid penetrating the cribriform plate.

TREATMENT

- Radiation therapy is the treatment of choice.
- Conventional linear accelerator is used most commonly. However, if available, stereotactic radiation therapy can reduce the number of radiation treatments and reduce adverse effects.
- Palliative radiation protocols (fewer treatments and lower total radiation dose) might be preferable for dogs with very advanced disease.

MEDICATIONS

DRUG(S)

- Prednisone (0.5–1 mg/kg PO q24h) to help relieve nasal congestion.

- Phenylephrine nasal spray can be used intermittently to help with epistaxis.
- Empiric antibiotic therapy can be considered for secondary bacterial infections.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None

FOLLOW-UP

PATIENT MONITORING

- Physical examinations every 2–3 months and thoracic radiographs every 3–4 months.
- CT of the skull can be considered when clinical signs recur or progress.

EXPECTED COURSE AND PROGNOSIS

- < 10% develop metastasis (lungs affected most commonly).
- Median survival with palliative care alone is 3 months.
- With definitive radiation therapy, median survival is around 15 months, and 2-year survival rate is around 30%.
- Brain involvement is a poor prognostic sign.
- Unilateral versus bilateral involvement is not a significant prognostic factor.

MISCELLANEOUS

SEE ALSO

- Adenocarcinoma, Nasal

CHONDROSARCOMA, ORAL

C

BASICS

OVERVIEW

- Chondrosarcoma is a malignant mesenchymal tumor that produces chondroid and fibrillar matrix, but not osteoid.
- CSA accounts for 5–10% of all primary bone tumors. Mandibular and maxillary CSA has been reported in dogs, but these are not common locations for this tumor. (See Chondrosarcoma, Bone, and Chondrosarcoma, Nasal and Paranasal Sinus.)
- In patients with CSA involving the maxilla, thorough evaluation is needed to ensure this is not a primary nasal tumor secondarily invading into the maxilla.

SIGNALMENT

- Most common in medium to large-breed dogs. Mixed-breed dogs, golden retrievers, boxers, and German shepherd dogs are overrepresented.
- Median age is 8 years (reported range 1–15 years).
- Cats are rarely affected; no obvious breed or sex predilections.

SIGNS

Historical Findings

- Visible mass involving the mandible or maxilla.
- Halitosis, dysphagia, and/or hypersalivation.
- Bloody oral discharge and oral pain.
- Weight loss secondary to a prolonged decrease in food intake.

Physical Examination Findings

- A firm to hard mass centered on the maxilla or mandible is seen most commonly.
- The overlying gingival mucosa usually is intact, although trauma and ulceration from the occlusal teeth is common with larger tumors.
- Loose or missing teeth.
- Difficulty or pain when opening the mouth (especially caudal tumors).
- Facial deformity.
- Ipsilateral mandibular lymphadenopathy.
- Nasal discharge, epistaxis, or decreased air flow through the nares (maxillary tumors).

CAUSES & RISK FACTORS

None identified

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other primary oral tumors including melanoma, fibrosarcoma, squamous cell carcinoma, and epulis (ameloblastoma or periodontoma)
- Craniomandibular osteopathy
- Dentigerous cyst, tooth root abscess, or osteomyelitis

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

IMAGING

- Skull or dental radiographs will show features of an aggressive bone lesion (bone lysis, cortical destruction, non-homogenous bone formation, ill-defined zone of transition).
- High detail dental radiographs may be appropriate for imaging smaller lesions.
- CT imaging can more accurately stage local disease and is useful for planning surgery and/or radiation therapy.

DIAGNOSTIC PROCEDURES

- Histopathology is required to reach a definitive diagnosis. All tissue removed should be submitted to the pathologist. This allows for the most accurate diagnosis, and allows for margin evaluation to assess completeness of excision.
- Fine-needle aspiration and cytology of ipsilateral mandibular lymph node recommended, especially if it is enlarged.

TREATMENT

- Surgical excision—removal of the affected segment of bone (maxillectomy or mandibulectomy) with a margin of at least 2–3 cm is recommended whenever possible.
- If excision is incomplete, adjuvant radiation therapy might help improve local control, although there is little information regarding efficacy.
- Radiation therapy can be considered as a sole local treatment modality but, because of the chondroid matrix produced by CSAs, radiation therapy likely will stabilize tumor size and not necessarily cause substantial shrinkage.
- Chemotherapy has not been evaluated but is not thought to be effective.
- Palliative care focuses on pain control.

MEDICATIONS

DRUG(S)

- Nonsteroidal anti-inflammatory drugs.
- Tramadol.
- Gabapentin.
- Intravenous aminobisphosphonates (pamidronate or zoledronate) might alleviate bone pain and attenuate bone resorption.
- Empiric antibiotic therapy can be considered for secondary bacterial infections.

FOLLOW-UP

PATIENT MONITORING

Physical examination every 2–3 months and thoracic radiographs every 3–4 months.

EXPECTED COURSE AND PROGNOSIS

- Most patients die or are euthanized due to local disease progression.
- Overall metastatic rate is 15–30%, with the lungs being affected most commonly.
- Metastatic rates approach 50% for high-grade tumors.
- Prognosis depends on tumor size and location, and surgical resectability.
- With complete excision, long-term control is possible; however, with incomplete excision, local recurrence within 6–12 months is likely.

CHORIORETINITIS

BASICS

DEFINITION

- Inflammation of the choroid and retina.
- Choroid is also called posterior uvea.
- Diffuse inflammation may result in frank retinal detachment (see Retinal Detachment).

PATHOPHYSIOLOGY

• Caused by infectious agents, neoplastic cells, or immune complexes (immune-mediated diseases); hematogenous pathogenic factors inducing choroidal inflammation is most common. • Choroid and retina—closely apposed; physiologically interdependent; inflammation of one usually results in inflammation of the other. • May also occur as a retinochoroiditis—retinal inflammation preceding and inducing choroidal inflammation.

SYSTEMS AFFECTED

- Nervous.
- Ophthalmic.
- Other systems if underlying disease is systemic.

INCIDENCE/PREVALENCE

- Fairly common
- Exact incidence unknown

GEOGRAPHIC DISTRIBUTION

Depends on the prevalence of infectious cause (e.g., systemic mycoses, rickettsial disease).

SIGNALMENT

Species

Dog and cat

Breed Predilections

• Systemic mycoses—more common in large hunting breed dogs. • Uveodermatologic syndrome—Akita, chow, and Siberian husky are predisposed. • Borzoi, border collie, beagle: chorioretinopathy. • Bernese mountain dog, golden retriever: systemic histiocytosis.

Mean Age and Range

Depends on underlying cause

Predominant Sex

Uveodermatologic syndrome—more common in young male dogs.

SIGNS

• Not usually painful, except when anterior uvea is affected. • Vitreous abnormalities—may note exudates, hemorrhage, or syneresis (liquefaction). • Interruption or alteration of the course of retinal blood vessels—due to retinal elevation. • Ophthalmomyiasis (cats)—curvilinear tracts from migrating larvae. • Others—related to underlying systemic disease.

Lesions

- Active—indistinct margins; tapetal hyporeflectivity; white-gray color; alter course of retinal blood vessels. • Few or small lesions—may note no apparent visual deficits.
- Extensive lesions involving larger areas of the retina—blindness or reduced vision.

• Inactive (scars)—discrete margins; hyperreflective in the tapetum, sometimes with hyperpigmented central areas; depigmented in the non-tapetum and may have some surrounding or central hyperpigmentation.

CAUSES

Dogs

- Septicemia or bacteremia—discospondylitis; endocarditis.
- Viral—canine distemper; herpesvirus (rare, usually neonates); rabies.
- Bacterial or rickettsial—septicemia or bacteremia; leptospirosis; brucellosis; pyometra (toxic uveitis); *Borrelia*; ehrlichiosis; Rocky Mountain spotted fever; bartonellosis.
- Fungal—aspergillosis; blastomycosis; coccidioidomycosis; histoplasmosis; cryptococcosis; acremoniosis; Pseudallescheriasis (single case report), Candida (single case report); geotrichosis.
- Algal—protothecosis.
- Protozoal—toxoplasmosis; leishmaniasis; *Neospora*.
- Parasitic—ocular larval migrans (*Strongyles*, *Ascarids*, *Baylisascaris*); *Sarcocystis neurona* (one report in dog) and ophthalmomyiasis interna (Diptera larval migrans) can occur in dogs but is more common in cats

Cats

- Viral—FeLV; FIV; FIP.
- Bacterial—septicemia or bacteremia; bartonellosis.
- Fungal—*cryptococcosis*, histoplasmosis, *blastomycosis*, others.
- Parasitic—toxoplasmosis; ophthalmomyiasis interna (Diptera, Cuterebra); ocular larval migrans; leishmaniasis (one report).
- Protozoal—toxoplasmosis,

Idiopathic

• Common.

- Multifocal chorioretinitis or chorioretinopathy in borzoi, border collie, and beagle—an acquired syndrome in which affected dogs have multifocal retinal edema or chorioretinal atrophy.
- Bernese mountain dog and other breeds—systemic or malignant histiocytosis.

Immune

- Any immune-mediated disease may cause vasculitis or inflammation, resulting in exudative retinal detachment or chorioretinitis; exact cause often undetermined; with thrombocytopenia, may see small multifocal or large retinal and/or vitreal hemorrhages with associated inflammation.
- Septicemia or bacteremia with associated immune complex disease.
- Dogs—Vogt-Koyanagi-Harada-like (uveodermatologic) syndrome; target is melanin pigment granule (abundant in uveal tissue), leading to severe anterior and posterior inflammation (affected dogs may also exhibit depigmentation of the skin, especially at mucocutaneous junctions); target of SLE is nuclear antigen.
- Cats—periarteritis nodosa; SLE.

Metabolic

Early hypertensive retinopathy may have multifocal localized lesions.

Neoplastic

Multiple myeloma, lymphoma, malignant histiocytosis, and neoplasia can metastasize to the eye.

Toxic

- Ethylene glycol; idiosyncratic drug reactions (e.g., trimethoprim-sulfa); ivermectin especially in predisposed breeds with multiple drug resistance gene.
- Photic injury: exposure to bright light can burn the retina; i.e., operating microscope lights, welding light exposure.

Trauma

- Exogenous infection—trauma (perforating wound or migrating foreign body).

RISK FACTORS

- FeLV or FIV infection—may predispose cat to ocular toxoplasmosis and/or other infectious causes of chorioretinitis/uveitis.
- Dogs or cats on immunosuppressive therapy for other problems.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ophthalmic examination—usually sufficient for diagnosis; may note a slow pupillary light reflex if large areas of the retina are affected.
- Blindness or impaired vision—optic neuritis; CNS disease; diffuse retinal inflammation.
- See “Causes.”
- Retinal dysplasia—bilateral, symmetrical folds or geographic clumps of pigment or altered fundus reflectivity; no associated signs of inflammation in the eye; Labrador retrievers and springer spaniels predisposed but occurs in many breeds.

CBC/BIOCHEMISTRY/URINALYSIS

- Normal—if problem confined to the eye.
- Abnormal—depend on underlying systemic disease.

OTHER LABORATORY TESTS

- Depends on suspected systemic problem.
- ANA for suspected SLE.
- Protein electrophoresis for myeloma.
- Documentation of Bence-Jones protein in urine.
- Skin biopsy—SLE; uveodermatologic syndrome.
- Coagulation profile.
- Bacterial culture of ocular or body fluids.
- Serologic or PCR testing—*infectious disease* (see “Causes”).
- Cytology of lymph node aspirates.
- Histopathology of enucleated eyes.

IMAGING

- Thoracic radiography—lymphadenopathy; metastatic disease; infiltrates consistent with infectious agents.
- Spinal radiography—bony changes consistent with discospondylitis or multiple myeloma.
- Ocular ultrasound—

(CONTINUED)

retinal detachments; intraocular masses; especially helpful if the ocular media are not clear. • Abdominal ultrasound—screen for primary neoplasia, organ disease.

DIAGNOSTIC PROCEDURES

- Indirect ophthalmoscopy—screens a large area of the retina.
- Direct ophthalmoscopy—facilitates examination of suspicious areas.
- CSF tap—indicated for signs of CNS disease or optic neuritis.
- Vitreocentesis or subretinal fluid aspirate—may perform if other diagnostic tests fail to yield a causal agent or for suspected infectious agent or neoplasia; vitreocentesis may aggravate inflammation or induce hemorrhage, or retinal detachment, lessening the chance for restoration of vision.
- Measurement of blood pressure.

PATHOLOGIC FINDINGS

- Masses or retinal or choroidal exudates.
- Fungal organisms—in exudates and inflammatory cells.
- Perivascular inflammation—vasculitis; FIP.
- Inactive lesions—retinal and choroidal atrophy (thinning); may note RPE hyperpigmentation and tapetal destruction.

TREATMENT

APPROPRIATE HEALTH CARE

- Depends on physical condition of patient.
- Usually outpatient.

NURSING CARE

Fluid or other therapy for systemic disease.

CLIENT EDUCATION

- Inform client that chorioretinitis may be a sign of systemic disease, so diagnostic testing is important.
- Warn client that immune-mediated disease requires life-long therapy for controlling inflammation.
- Inform client that dogs with uveodermatologic syndrome may also have anterior uveitis and secondary glaucoma, which require treatment.
- Dermatitis may also require management.

MEDICATIONS

DRUG(S) OF CHOICE

- Identify and treat any underlying systemic disease (e.g., itraconazole or fluconazole for systemic mycosis, doxycycline for *Rickettsia*, azithromycin or doxycycline for *Bartonella*).
- Topical medications—not effective in dogs with intact lenses, treat any associated anterior

uveitis, e.g., topical corticosteroids (1% prednisolone acetate or 0.1% dexamethasone given q6–8h) and parasympatholytics (1% atropine given at a frequency that dilates the pupil and reduces pain). Treat any secondary glaucoma with appropriate antiglaucoma drugs (timolol maleate 0.5%, dorzolamide 2%).

- Systemic therapy—required.
- Feline toxoplasmosis—clindamycin 12.5 mg/kg PO q12h for 14–21 days.
- Systemic prednisone at anti-inflammatory doses—0.5 mg/kg PO, then taper; when systemic mycosis has been ruled out or is being treated with appropriate systemic antifungal therapy; avoid use unless large areas of the retina are affected and vision is severely threatened.
- Prednisone at immunosuppressive doses—2 mg/kg divided q12 for 3–10 days (ideal), then taper very slowly over months; for immune-mediated disease; may facilitate retinal reattachment.

CONTRAINICATION

Systemically administered corticosteroids—do not use unless systemic mycosis is ruled out or is being definitively treated.

PRECAUTIONS

With prednisone treatment consider concurrent oral antacids such as ranitidine or famotidine.

ALTERNATIVE DRUG(S)

- Neoplastic conditions (lymphoma, GME, or multiple myeloma)—chemotherapeutic agents.
- Uveodermatologic syndrome or autoimmune etiology—may require azathioprine, cyclosporine, leflunomide or mycophenylate (see Retinal Detachment) and steroids to control inflammation.

FOLLOW-UP

PATIENT MONITORING

- As appropriate for underlying cause and type of medical treatment.
- CBC platelet count and liver enzymes—monitor for side effects of systemic immunosuppressive drugs.
- IOP—for anterior uveitis.

PREVENTION/AVOIDANCE

Tick and flea control measures

POSSIBLE COMPLICATIONS

- Permanent blindness
- Cataracts
- Glaucoma
- Chronic ocular pain
- Death—secondary to systemic disease

CHORIORETINITIS

C

EXPECTED COURSE AND PROGNOSIS

- Prognosis for vision—guarded to good, depending on amount of retina affected; visual deficits or blindness if large areas of the retina were destroyed; focal and multifocal disease do not markedly impair vision but do leave scars.
- Prognosis for life—guarded to good, depending on underlying cause.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Several systemic diseases

ZOONOTIC POTENTIAL

- Toxoplasmosis—may be transmitted to humans if patient is shedding oocysts in feces.
- Vector-borne diseases—infected animals may act as reservoirs, i.e., *Bartonella*, *Rickettsia*, others.

SYNONYMS

Retinochoroiditis

SEE ALSO

- Retinal Degeneration
- Retinal Detachment
- Uveodermatologic Syndrome

ABBREVIATIONS

- ANA = antinuclear antibody
- CNS = central nervous system
- CSF = cerebrospinal fluid
- FeLV = feline leukemia virus
- FIP = feline infectious peritonitis
- FIV = feline immunodeficiency virus
- GME = granulomatous meningoencephalitis
- IOP = intraocular pressure
- RPE = retinal pigment epithelium
- SLE = systemic lupus erythematosus

CHYLOTHORAX

BASICS

DEFINITION

- Accumulation of chyle in the pleural space.
- Chyle—triglyceride-rich fluid from the intestinal lymphatics that empties into the venous system in the thorax.
- Pseudochylous effusion—effusion that contains less triglycerides and more cholesterol compared to serum.
- Thoracic lymphangiectasia—tortuous, dilated lymphatics found in many animals with chylothorax.
- Fibrosing pleuritis—condition in which pleural thickening leads to constriction of the lung lobes; when severe, results in marked restriction of ventilation; can be caused by any chronic pleural exudate but is most commonly associated with chylothorax and pyothorax.

PATOPHYSIOLOGY

- Alteration of flow through the thoracic duct leading to leakage of chyle—can be related to increased pressure or permeability in the thoracic duct or venous obstruction downstream.
- Can be caused by any disease or process that increases systemic venous pressure at the entrance of the thoracic duct to the venous system.
- Cardiac causes—pericardial disease, cardiomyopathy, heartworm disease, other causes of right-sided heart failure.
- Non-cardiac causes—neoplasia (especially mediastinal lymphoma in cats), lung lobe torsion, diaphragmatic hernia, venous granuloma, venous thrombus.
- Less commonly thoracic duct rupture/trauma—surgical (thoracotomy), non-surgical (e.g., hit by car).
- Idiopathic most common.

SYSTEMS AFFECTED

- Respiratory—due to reduced lung expansion.
- Systemic signs can be present secondary to the respiratory distress (e.g., decreased appetite, weight loss).

GENETICS

Unknown

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dogs—Afghan hounds and Shiba Inus
- Cats—Oriental breeds (e.g., Siamese and Himalayan)

Mean Age and Range

- Any age affected.
- Cats—more common in older cats; could indicate an association with neoplasia.
- Afghan hounds—develop when

middle-aged.

- Shiba Inus—develop when young (< 1–2 years of age).

Predominant Sex

None identified

SIGNS

General Comments

- Signs will depend on the rate of fluid accumulation and volume of pleural effusion.
- Usually not exhibited until there is marked impairment of ventilation.
- Many patients appear to have the condition for prolonged periods before diagnosis.

Historical Findings

- Tachypnea and respiratory difficulty.
- Coughing—can be present for months before examination, likely due to lung compression associated with pleural effusion.
- Lethargy.
- Anorexia and weight loss.
- Exercise intolerance.

Physical Examination Findings

- Vary with cause of effusion.
- Muffled heart and lung sounds ventrally.
- Increased bronchovesicular sounds, particularly in the dorsal lung fields.
- Pale mucous membranes or cyanosis.
- Arrhythmia.
- Heart murmur.
- Signs of right-sided heart failure (e.g., jugular pulses, ascites, hepatomegaly).
- Decreased compressibility of the anterior chest—common in cats with a cranial mediastinal mass.

CAUSES

- Cranial mediastinal masses—lymphoma, thymoma.
- Cardiac disease—heartworm, cardiomyopathy, pericardial disease, congenital diseases.
- Lung lobe torsion.
- Venous obstruction—granuloma, thrombi.
- Congenital abnormality of thoracic duct.
- Cardiac or thoracic surgery.
- Idiopathic—most common cause.

RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of pleural effusion—neoplasia, pyothorax, heart failure, FIP.

CBC/BIOCHEMISTRY/URINALYSIS

- Often normal.
- Lymphopenia and hypoalbuminemia—can be found.
- Hyponatremia and hyperkalemia sometimes noted due to fluid shifts with repeat thoracocentesis.

OTHER LABORATORY TESTS

Heartworm testing

Fluid Analysis

- Classified as an exudate.
- Color will depend on fat content from diet and presence of concurrent hemorrhage—usually milky white and opaque but can appear serosanguinous and range from yellow to pink.
- Protein content varies, and high lipid-content will make refractive index inaccurate.

- Total nucleated cell count—usually < 10,000 cells/ μL .
- Fluid triglycerides—higher compared to serum.
- Fluid cholesterol—lower compared to serum.

Cytology

- Place sample in an EDTA tube to allow cell count to be performed.
- Initially, cytology is comprised of primarily small lymphocytes, neutrophils, and macrophages containing lipid.
- Chronic effusions contain less lymphocytes due to continued loss and more non-degenerate neutrophils due to inflammation from multiple thoracocenteses or irritation of pleural lining by chyle.
- Atypical lymphocytes—suggestive of underlying neoplasia.

IMAGING

Thoracic Radiography

- Two to four views if patient is stable—pleural effusion.
- Dorsoventral view associated with less stress than ventrodorsal view in an animal with respiratory difficulty.
- Repeat radiographs after thoracocentesis to assess for underlying causes of effusion or evidence of fibrosing pleuritis; if collapsed lung lobes do not appear to re-expand after pleural fluid is removed or if respiratory distress persists with only minimal fluid present, suspect underlying pulmonary parenchymal or pleural disease (e.g., fibrosing pleuritis).

Ultrasonography/Echocardiography

- Should be performed before thoracocentesis if patient is stable—fluid acts as an acoustic window, enhancing visualization of thoracic structures.
- Assess for underlying causes—detect abnormal cardiac structure and function, pericardial disease, and mediastinal masses.

CT Lymphangiography

- Can quantify TD branches more accurately than standard radiographic lymphangiography.
- In dogs, percutaneously inject 1–2 mL of non-ionic contrast material into mesenteric lymph nodes using ultrasound or CT guidance.
- Acquire helical thoracic CT images before and after injection of contrast media.
- Can document location and character of the thoracic duct and its tributary lymphatics; likely useful for surgical planning.

PATHOLOGIC FINDINGS

- Lymphatics (including the thoracic duct)—difficult to identify at necropsy.
- Fibrosing pleuritis—lungs appear shrunken; pleural layers (visceral and parietal) are diffusely thickened.
- Fibrosing pleuritis—characterized histologically by diffuse, moderate-to-marked thickening of the pleura by fibrous connective tissue with moderate

(CONTINUED)

infiltrates of lymphocytes, macrophages, and plasma cells.

TREATMENT

APPROPRIATE HEALTH CARE

- Dyspneic animal—immediate thoracocentesis; removal of even small amounts of pleural effusion can markedly improve ventilation.
- Identify and treat the underlying cause, if possible.
- Medical management—usually treated on an outpatient basis with intermittent thoracocentesis as needed based on clinical signs (see “Medications”).
- Chest tubes—place *only* in patients with suspected chylothorax secondary to trauma (very rare), in cases with rapid fluid accumulation, or after surgery.
- Surgery if medical management does not resolve the problem in 2–3 months (see “Surgical Considerations”).

NURSING CARE

- Patients undergoing multiple thoracocenteses can rarely develop electrolyte abnormalities (hyponatremia, hyperkalemia) that may need to be corrected with fluid therapy.
- Thoracocentesis—perform under aseptic conditions to reduce the risk of iatrogenic infection; antibiotic prophylaxis generally unnecessary if proper technique is used.

ACTIVITY

Patients will usually restrict their own exercise as pleural fluid volume increases or if they develop fibrosing pleuritis.

DIET

- Low-fat—potentially decreases the amount of fat in the effusion, which would improve the patient’s ability to resorb fluid from the thoracic cavity; not a cure; may help in management by facilitating reabsorption.
- Medium-chain triglycerides are transported via the thoracic duct in dogs and are no longer recommended.

CLIENT EDUCATION

- Inform client that no specific treatment will stop the effusion in all patients with the idiopathic form of the disease.
- Inform client that the condition can spontaneously resolve in some patients after several weeks or months.

SURGICAL CONSIDERATIONS

Thoracic Duct Ligation and Pericardectomy

- Recommended in patients that do not respond to medical management.
- The duct usually has multiple branches in the caudal thorax where ligation is performed; failure to occlude all branches results in continued pleural effusion.
- Always perform in conjunction with lymphangiography; methylene blue injected in the mesenteric

lymph node greatly facilitates visualization and complete occlusion of all branches.

- Thickening of the pericardium can prevent formation of lymphaticovenous communications—perform pericardectomy simultaneously with TD ligation; reports of up to 100% success rate when both techniques are performed; a second surgery can be necessary if all branches are not occluded.
- Video-assisted thorascopic surgery for thoracic duct ligation and pericardectomy is reported to have similar success rates to thoracotomy (86%).

Other

- Success rates of 83–88% reported for cisterna chyli ablation in combination with thoracic duct ligation.
- Salvage procedures for recurrence after thoracic duct ligation include cisterna chyli and thoracic duct glue embolization, pleuroperitoneal or pleurovenous shunts or placement of a PleuralPort.

MEDICATIONS

DRUG(S) OF CHOICE

- Rutin 50–100 mg/kg PO q8h; believed to increase macrophage removal of proteins, which promotes absorption of fluid; complete resolution of effusion appears to occur in some patients; further study is required to determine whether resolution occurs spontaneously or in response to this therapy.
- Somatostatin analog (octreotide)—a naturally occurring substance that inhibits gastric, pancreatic, and biliary secretions and prolongs gastrointestinal transit time, decreases jejunal secretion, and stimulates gastrointestinal water absorption; in traumatic chylothorax, reduction of gastrointestinal secretions may aid healing of the TD by decreasing TD lymphatic flows; resolution of pleural fluid has occurred in dogs and cats with idiopathic chylothorax in which octreotide has been administered but the mechanism is unknown; octreotide (Sandostatin; 10 µg/kg SC q8h for 2–3 weeks) is a synthetic analog of somatostatin that has a prolonged half-life and minimal side effects.

CONTRAINdications

Cardiac disease or neoplasia—treat the underlying disease rather than the effusion (other than heartworm disease in cats where TD ligation may be beneficial while the heartworm infection clears).

FOLLOW-UP

PATIENT MONITORING

- Monitor for signs of recurrence of pleural effusion (tachypnea, labored breathing,

respiratory distress)—perform thoracentesis as needed.

- Periodically reevaluate for several years to detect recurrence.

POSSIBLE COMPLICATIONS

- Fibrosing pleuritis.
- Iatrogenic infection with repeated thoracocentesis—important to use aseptic technique.

EXPECTED COURSE AND PROGNOSIS

- Can resolve spontaneously or after surgery.
- Untreated or chronic disease—can result in severe fibrosing pleuritis and persistent dyspnea.
- Euthanasia—frequently performed in patients that do not respond to surgery or medical management.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Diffuse lymphatic abnormalities (e.g., intestinal lymphangiectasia, hepatic lymphangiectasia, pulmonary lymphangiectasia, and chylous ascites)—may be noted; may worsen the prognosis.

AGE-RELATED FACTORS

Young patients may have a better prognosis than old animals because of the association of neoplasia with advanced age.

ABBREVIATIONS

- CT = computed tomography
- EDTA = ethylene diamine tetra-acetate
- FIP = feline infectious peritonitis
- TD = thoracic duct

CIRRHOSIS AND FIBROSIS OF THE LIVER

BASICS

DEFINITION

• Hepatic fibrosis—replacement/effacement of hepatic parenchyma, intrasinusoidal, variable zonal, deposition of extracellular matrix (ECM). • Cirrhosis—regenerative nodules with dissecting fibrotic partitions and regions of parenchymal extinction, deranging hepatic architecture; usually reflects chronic necro-inflammatory liver injury.

PATOPHYSIOLOGY

• Fibrosis—usually reflects injury associated release of cytokines / mediators stimulating production and accumulation of ECM; exception: ductal plate malformation (DPM)-with congenital hepatic fibrosis [CHF] phenotype (severe portal-to-portal bridging fibrosis without chronic inflammation). • Cirrhosis—consequence of chronic hepatic injury, fibrogenesis, and hepatic regeneration; typified by: regenerative nodules, reduced functional hepatic mass, collagen deposition in sinusoids (space of Disse) or portal tracts, compromising parenchymal perfusion. • Cirrhosis/fibrosis—lead to hepatic dysfunction, capillarization of hepatic sinusoids, collagenization of the space of Disse, development of sinusoidal hypertension, intrahepatic shunting through collagenized sinusoids and recanalized vascular pathways in fibrotic partitions between regenerative nodules. These microcirculatory disturbances impair exchanges between blood and hepatocytes. • Sinusoidal hypertension—leads to (1) hepatofugal portal flow (away from liver), (2) splanchnic hypertension, (3) APSS formation, (4) episodic HE, (5) splanchnic pooling of blood, decreased effective systemic blood volume, stimulation of renal sodium and water retention, with ascites formation, (6) hypertensive splanchnic vasculopathy predisposing to enteric bleeding.

SYSTEMS AFFECTED

• GI—splanchnic portal hypertension leads to ascites and propensity for enteric bleeding. • Neurologic—HE. • Hemic—RBC microcytosis reflect APSS; bleeding tendencies: failed factor synthesis or activation, thrombocytopenia; reduced anticoagulants increase risk for thrombosis. • Renal/urologic—ammonium biurate crystalluria; isosthenuria: PU/PD; hepatorenal syndrome (rare) may follow therapeutic paracentesis of large volume ascites (Postcentesis Hypotension Syndrome [PHS]). • Endocrine/metabolic—hypoglycemia if end-stage liver failure, usually provoked by prolonged inappetence. • Respiratory—tachypnea if tense ascites; biventricular effusion (rare, leakage across diaphragm (rare), pulmonary edema (rare). • Skin—superficial

necrolytic dermatitis (see Diabetic Hepatopathy), unkempt coat.

GENETICS

Familial predisposition for chronic hepatitis—Doberman pinscher, cocker spaniel, Labrador retriever, Maltese, Bedlington terrier (copper related), others.

INCIDENCE/PREVALENCE

High in dogs with chronic necroinflammatory liver disease, animals with chronic EHBDO, dogs with severe hepatic copper accumulation.

SIGNALMENT

Species

• Cirrhosis: dogs with chronic hepatitis; cats with chronic cholangitis/cholangiohepatitis; dogs and cats with chronic EHBDO. • Severe fibrosis: dogs and cats with severe DPM-CHF phenotype.

Breed Predilection

- Many breeds and mixed breed dogs.
- Copper-associated hepatopathy (Cu-AH—genetics proven only in Bedlington terriers; Labrador retrievers, Doberman pinschers and Dalmatians appear predisposed, but all breeds at risk for Cu-AH due to dietary Cu intake.
- DPM-CHF phenotype; boxers may be predisposed, many breeds of dogs and cats; cats with polycystic malformations at risk.

Mean Age and Range

- Cirrhosis (dogs)—any age; more common in middle to older dogs; Cu-AH any age.
- Biliary cirrhosis (cats)—with chronic cholangiohepatitis often > 7 years old.
- Fibrosis—DPM-CHF phenotype (dogs, cats): ECM accumulates with aging (suspected), genetic cause (see Ductal Plate Malformations).

Predominant Gender

- Cocker spaniels—may be higher in males.
- Doberman pinschers and Labrador retrievers—no sex predilection. • DPM: no gender predilections.

SIGNS

General Comments

- Initially—vague and nonspecific. • Later—relate to complications of portal hypertension (e.g., HE, ascites, gastroduodenal bleeding), and impaired hepatic function.

Historical Findings

• Chronic intermittent lethargy, anorexia, reduced body condition • GI signs: vomiting, diarrhea or constipation • Melena: late stage or as develop APSS • PU/PD • Late onset—ascites, bleeding, HE • Jaundice: acquired necroinflammatory disease often jaundiced. DPM usually anicteric • Cats—ascites uncommon with acquired necroinflammatory disease, more common with DPM; ptalism, aggression, seizures with HE.

Physical Examination Findings

- Lethargy • Poor body condition/coat
- ± Variable jaundice • ± Ascites • ± HE

- Obstructive uropathy: ammonium biurates
- Anasarca—rare; may develop with overzealous fluid therapy • Liver size—dogs microhepatia, cats variable • Coagulopathy: variable, uncommon in DPM • Cutaneous lesions: superficial necrolytic dermatitis (severe degenerative vacuolar hepatopathy; see Diabetic Hepatopathy).

CAUSES

- Chronic necroinflammatory, oxidant, or immune-mediated liver injury has many causes. May develop subsequent to chronic inflammatory bowel disease or pancreatitis.
- Cu-AH. • Drug- or toxin-induced liver injury—anticonvulsants; azole antifungals; NSAIDs oxibendazole; trimethoprim-sulfamethoxazole; chronic food-borne toxins (aflatoxins), others. • Infections—leptospirosis, canine adenovirus I. • Chronic cholangiohepatitis (cats). • Chronic EHBDO (> 6 weeks, dogs and cats). • Single episode of massive hepatic necrosis; sago palm (cycad toxicity), xylitol, NSAIDs in dogs with substantial Cu accumulation.

RISK FACTORS

- Breed predisposition: Cu-AH or other causes yet ill-defined (see above) • Dietary Cu intake > patient tolerance • Hepatic iron accumulation: supplementation • Chronic hepatobiliary inflammation • Chronic EHBDO • Chronic phenobarbital administration (dogs) • NSAIDS: (dogs), especially carprofen

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Chronic hepatitis—common in dogs
- Cholangiohepatitis—common in cats
- Noncirrhotic portal hypertension: dogs
- Chronic EHBDO—dogs, cats • Chronic IBD or pancreatitis—dogs, cats • Hepatic neoplasia • Metastatic neoplasia or carcinomatosis • Congenital portosystemic vascular anomaly (PSVA, shunt) • Congenital portal atresia: intrahepatic or extrahepatic
- Right-sided heart failure, pericardial disease
- Cats—hepatic lipidosis; FIP; toxoplasmosis
- Hemolytic anemia (jaundice differential)

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Microcytic RBCs: APSS; mild anemia: small RBCs with normal cell count; anemia of chronic disease; microangiopathic shearing: sinusoidal fibrosis, APSS. • Mild thrombocytopenia, variable. • Leukogram: variable.

Biochemistry

- Bilirubin variable. • Liver enzyme activities—high (ALT > ALP) noted before clinical signs or liver dysfunction; at end-stage enzymes may decline. • Normal to hypoalbuminemia. • Normal to

(CONTINUED)

CIRRHOSIS AND FIBROSIS OF THE LIVER

C

hyperglobulinemia. • Hypocholesterolemia—reflects APSS. • Low BUN—reduced urea cycle activity, APSS, protein-restricted diet, PU/PD. • Hypoglycemia—rare in dogs, rare in cats. • Hypokalemia—may predispose to HE. • Hyponatremia—fluid imbalance with ascites.

Urinalysis

- Isosthenuria—with PU/PD
- Ammonium biurate crystalluria
- Bilirubinuria, bilirubin crystalluria

OTHER LABORATORY TESTS

- Ascitic fluid—pure or modified transudate
- Coagulation tests—inconsistently prolonged PT, APTT, buccal mucosal bleeding time
- Low protein C and antithrombin activity—reflects APSS, synthetic failure, or DIC
- Serum bile acids—high; reflects APSS or cholestasis in cirrhosis
- Hyperammonemia: inferred from ammonium biurate crystalluria

IMAGING***Radiography***

Abdominal—small to normal sized liver; ascites may obscure details; urate calculi radiolucent unless calcium complexed.

Ultrasonography

- Abdominal—hyperechoic or mixed echogenic parenchyma; ± nodularity; abdominal effusion (ascites); APSS (color flow Doppler); or no parenchymal change in some cases.
- Doppler interrogation of portal vasculature—may confirm hepatofugal flow or nests of APSS especially near left kidney or splenic vessels.

DIAGNOSTIC PROCEDURES

- Fine-needle aspiration cytology—helps rule out neoplasia; rule-in bacterial infection; *cannot define fibrosis or nonsuppurative inflammation*.
- Liver biopsy—for definitive diagnosis; 18G needle core too small for accuracy; use 14–16G.
- Laparoscopy—best biopsy method; permits gross visualization, documents APSS, biopsy access to multiple liver lobes and focal lesions.

PATHOLOGIC FINDINGS***Gross***

- Fibrosis—small, firm irregular to finely nodular liver; DPM-CHF may not be small; fibrotic liver may display APSS, ± ascites.
- Cirrhosis—firm irregular liver; prominent micro- or macro-nodules, APSS, ± ascites.

Histopathology

- Immune-mediated hepatitis—periportal, lobular, or centrilobular lymphoplasmacytic infiltrates, hepatic cord disorganization, sinusoidal fibrosis (space of Disse), biliary hyperplasia (ductular reaction).
- Cu-AH—initially centrilobular, may evolve immune-mediated hepatitis; single necrotic hepatocytes.
- DPM—bridging partitions with proliferative nonfunctional embryonic bile ducts embedded in ECM interconnecting

portal regions.

- Post-necrotic fibrosis—fibrosis marks regenerative repair, disorganized wide hepatic cords, engorged lymphatics reflect sinusoidal hypertension.
- Cirrhosis—diffuse lesion; fibrosis, nodular regeneration distorting lobular architecture (double-wide hepatic cord, 1 cell width = normal), periportal or sinusoidal fibrosis depending on zone of chronic injury, engorged lymphatics reflect sinusoidal hypertension; single hepatocyte necrosis if active disease.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Outpatient—minimally symptomatic patients.
- Inpatient—diagnostic tests; treatment for dehydration, severe HE, enteric bleeding (hypertensive vasculopathy), tense ascites.

NURSING CARE

- Fluids—avoid lactate if hepatic failure; avoid sodium loading if ascites.
- B complex vitamins (esp. cats)—2 mL/L fluid advised.
- Vitamin K₁—0.5–1.5 mg/kg SC q12h for 3 doses initially; titrate with PIVKA or PT.
- Glucose—if hypoglycemia; 2.5–5% dextrose in polyionic solution; titrate to response.
- Potassium chloride—in fluids, as needed.
- Avoid alkalosis—worsens HE.
- Therapeutic large volume abdominocentesis if tense ascites is non-responsive to medical treatment; **caution:** PH_S-hypotensive crisis and acute renal failure (IV volume shifts).

ACTIVITY

Limit

DIET

- Withhold oral food in acute severe HE if stupor, coma, or vomiting associated with enteric bleeding or pancreatitis.
- Consider PPN or TPN.
- If HE: restrict protein intake, use soy or dairy protein sources (dogs) combined with medical interventions to increase nitrogen tolerance; individualize protein intake to maintain body condition, muscle mass, albumin (see Hepatic Encephalopathy).
- Sodium restriction if ascites.
- Fat restriction rarely needed.
- Supplement water-soluble vitamins.

CLIENT EDUCATION

- Treatment is palliative and symptomatic.
- Antifibrotics may reduce fibrosis but limited evidence; fibrosis diminished by control of inflammation and provocative diseases.
- Attenuate factors provoking HE—azotemia, dehydration; infection; catabolism; high protein meals, hypokalemia; alkalemia; constipation, endoparasitism; enteric bleeding; certain drugs.

SURGICAL CONSIDERATIONS

- Cirrhosis—high anesthetic risk; gas anesthesia preferred—isoflurane or

sevoflurane.

- Coagulopathy—predisposes to bleeding with minor invasive procedures/surgeries; BMBT may better assess risk for bleeding.
- Postoperative intensive care—avoid HE, maintain hydration, euglycemia, electrolytes, acid-base balance (avoid alkalemia).
- Predisposed to enteric bacterial translocation—judiciously administer antibiotics esp. if surgical procedures involve alimentary canal or biliary structures.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Treatments for specific etiologies: chelate Cu if Cu-AH; withdraw potentially hepatotoxic drugs, herbal or natural remedies.
- No clinical trials prove efficacy of specific regimens in animals.

Immune Modulation—see Hepatitis, Chronic

- Prednisolone/prednisone—1–4 mg/kg q24h PO; taper to lowest effective dose (e.g., 0.25–0.5 mg/kg PO q48h); reduce dose with polypharmacy; survival effect see reference.
- Azathioprine—dogs: 1–2 mg/kg PO q48h; use 3-day loading SID dose; contraindicated in cats (toxic); dogs: combined with prednisone, antioxidants, antifibrotics PPC, or cyclosporine.

Antifibrotics—see Hepatitis, Chronic

- Immunomodulation, SAMe, silybinin, Vit. E: also considered antifibrotics—interfere in signaling processes that promote fibrogenesis.
- Ursodiol—7.5 mg/kg/day PO q12h with food: use indefinitely; provides hepatoprotectant, antiinflammatory, choleric, antioxidant, and other benefits.
- Polyunsaturated phosphatidylcholine with dilinolylphosphatidylcholine (PhosChol)—25 mg/kg/q24h, mix with food. No side effects.
- Colchicine—0.025–0.03 mg/kg q24–48h: no evidence supporting chronic benefit; side effects complicate use: inhibits mitosis-cell replication, may cause GI, bone marrow, neurologic adverse effects, avoid concurrent p450 cytochrome inhibition (e.g., ketoconazole).
- Losartan and telmisartan—losartan: 0.5 mg/kg/q24h or telmisartan: 0.5–1 mg/kg q24h for initial dosing, closely monitor blood pressure, renal function, and potassium, reducing dose if hypotension or hyperkalemia. These are angiotensin receptor blockers (ARB), selectively antagonizing angiotensin-1 receptor, bypassing intermediary activation steps within the RAAS cascade. Angiotensin-2 acting via angiotensin-1 (AT1) receptors on hepatic stellate cells (HSC) is a key mediator of hepatic sinusoidal fibrosis, increasing HSC proliferation and HSC synthesis of growth factors, cytokines, and additional bioactive molecules. Evidence suggests that AT1

CIRRHOSIS AND FIBROSIS OF THE LIVER

(CONTINUED)

C receptor blockade reduces HSC activation, and attenuates liver fibrosis, but may impose a suppressive influence on hepatic regeneration (evidence supports HSC activation is highly connected to hepatocyte proliferation and differentiation). These drugs also increase PPAR γ expression associated with induced HSC quiescence. ARBs are used in humans as antihypertensives with partial PPAR- γ agonist activity; and shown have nephroprotective (diabetes, renal injury models), to protect against some forms of drug-induced hepatotoxicity, and to limit hepatic fibrosis in various chronic models of liver disease (e.g., chronic EHBDO, Schistosomiasis induced fibrosis, CCl₄ induced injury, others).

Antioxidants

- Necroinflammatory disorders.
- S-adenosylmethionine (SAMe, use bioavailable product as proven GSH donor)—20 mg/kg q24h PO, empty stomach. Vitamin E mixed tocopherols—10 U/kg q24h PO with food.

Hepatoprotectants

- Necroinflammatory disorders.
- Ursodeoxycholate, Vitamin E, SAMe also provide hepatoprotectant effects.
- Silibinin—efficacy unclear, use PPC complexed form (bioavailable), 2–5 mg/kg q24h PO.
- Elemental zinc: 1.5–3 mg PO q24h (if low liver zinc confirmed); adjust dose with plasma zinc measurements; avoid $\geq 800 \mu\text{g/dL}$.

Gastroprotectants

Gastric acid inhibitors—if enteric bleeding (see Hepatitis, Chronic).

- Eliminate endoparasitism.

Specific Conditions

Ascites

- Restrict activity and sodium intake combined with diuretic therapy.
- Dietary sodium restriction (0.2% dry matter basis or $< 100 \text{ mg}/100 \text{ kcal}$).
- Diuretics (see Hypertension, Portal; Hepatitis, Chronic); slowly mobilize effusion: furosemide (0.5–2 mg/kg IV, SC, PO q12h) combined with spironolactone (0.5–2 mg/kg PO q12h); adjust dose to response (4–7 day recheck observation); individualize chronic treatment to response; diuretics may be intermittently used to mobilize recurrent ascites.
- Therapeutic large volume abdominocentesis if nonresponsive ascites mobilization after 7–14 days of diuretics and sodium restriction; may require fluid support as a result of intravascular to abdominal fluid shift causing PHS and ARF.

- Consider vasopressin V₂ antagonists with low dose diuretics for treatment resistant ascites (no published data for dogs or cats); tolvaptan at 10 mg/kg used in dogs with experimentally modeled congestive heart failure.

Coagulopathy

See Coagulopathy of Liver Disease

HE

See Hepatic Encephalopathy

CONTRAINDICATIONS

NSAIDs—avoid; potentiate enteric bleeding; may worsen ascites; potentiates centrilobular hepatic necrosis-hepatotoxic metabolites and Cu-AH.

PRECAUTIONS

- Diuretics—dehydration, hypokalemia, alkalemia worsen HE. • Glucocorticoids—increase susceptibility to infection, enteric bleeding, sodium and water retention and ascites, protein catabolism, HE. • Avoid drugs or reduce dose if first-pass hepatic extraction, if require hepatic conjugation or biotransformation (e.g., metronidazole—reduce conventional dose to 7.5 mg/kg PO q12h, as used for HE).

ALTERNATIVE DRUG(S)

- Dexamethasone—if ascites, replace prednisone/prednisolone to avoid mineralocorticoid effect); divide pred. dose by 7–10, administer q3–4 days; taper dose to efficacy.
- Mycophenolate: alternative for azathioprine.

FOLLOW-UP

PATIENT MONITORING

- Liver enzymes, albumin, BUN, cholesterol, bilirubin—monthly to quarterly, as needed.
- Serial monitoring of TSBA—does not add prognostic or diagnostic information. • Body condition score, weight, muscle mass—reflects nutritional adequacy/nitrogen balance.
- Abdominal girth: reflects ascites volume.
- Azathioprine, mycophenolate, colchicine—monitor for possible bone marrow toxicity (serial CBCs) and other side effects.

POSSIBLE COMPLICATIONS

HE, septicemia, bleeding—may be life-threatening; DIC—may be a terminal event.

EXPECTED COURSE AND PROGNOSIS

- Occasional flare-ups of HE and ascites may require hospitalizations for adjustment of nutritional and medical interventions.

- Sodium restriction and diuretics may require titration to achieve optimal control of ascites. • Natural history of fibrotic/cirrhotic hepatic disease in dogs is poorly characterized.
- Presence of ascites indicates severe disease.
- DPM—survival up to 12 years after diagnosis. • Cirrhosis—survival > 5 years with careful interventional management.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Dogs with leptospirosis-associated chronic liver disease (rare) may shed organisms.

CLOSTRIDIAL ENTEROTOXICOSIS

BASICS

DEFINITION

- A complex and poorly understood disorder characterized by diarrhea in dogs and cats associated with *Clostridium perfringens* toxins.
- The presence of CP enterotoxin and enterotoxigenic fecal isolates appears to provide the best evidence of CP-associated diarrhea.
- CP is considered to be associated with antibiotic responsive diarrhea.

PATHOPHYSIOLOGY

- *Clostridium perfringens* is a normal commensal found in the intestinal tract of humans and animals. The organism is found in a vegetative form living in a symbiotic relationship with the host.
- Certain strains of CP (generally type A based on PCR analysis) produce an alpha toxin and are capable of producing a more virulent enterotoxin (CPE) that binds to the enteric mucosa, alters cell permeability, and results in cell damage and/or subsequent cell death.
- CPE production is co-regulated with sporulation of the organism. Conditions that precipitate sporulation in animals include a sudden change in diet, dietary indiscretion, injudicious use of antibiotics causing a severe dysbiosis, and underlying intestinal disease.
- There appear to be a number of intrinsic host-related factors that influence CPE production and pathogenicity of CP.

SYSTEMS AFFECTED

Gastrointestinal

INCIDENCE/PREVALENCE

- Incidence is unknown, but it is suspected that up to 34% of cases of diarrhea in dogs are CP-related. The infection is far less common in cats.
- May also be associated as a nosocomial diarrhea.

SIGNALMENT

Species

Dog and cat

Mean Age and Range

- Disease may occur in any age animal.
- Most animals that develop chronic clinical signs tend to be middle-aged or older.

SIGNS

General Comments

- Clinical signs are associated with either an acquired acute self-limiting diarrhea lasting 5–7 days, chronic intermittent diarrhea, or signs associated with other gastrointestinal or non-gastrointestinal disease.
- Chronic signs are often characterized by intermittent episodes recurring every 4–6 weeks that may persist for months to years. The syndrome may result as a

nosocomial (hospital-acquired) disease with signs precipitated during or shortly following hospitalization or boarding at a kennel.

- CP has also been associated with acute hemorrhagic gastroenteritis (HGE), and frequently observed concurrently with cases having parvovirus.

Historical Findings

- Most common sign is large bowel diarrhea having fecal mucus, small amounts of fresh blood, small scant stools, tenesmus with an increased frequency of stools.
- Dogs may also have signs of small bowel diarrhea characterized by a large volume of watery stool.
- Other signs include vomiting, flatulence, hematochezia, abdominal discomfort, or a generalized unthriftiness in chronic cases.

Physical Examination Findings

- Evidence of systemic illness or debilitation is rare.
- Abdominal discomfort may be detected on palpation.
- There may be evidence of blood or mucus in the feces.
- Fever is uncommon.

CAUSES

- It is unknown if enterotoxigenic CP is a true acquired infection or is an opportunistic pathogen. There are only certain biotypes of CP genetically capable of producing CPE, and only certain animals are affected clinically. The disease may be associated with small intestinal bacterial overgrowth.
- Diarrhea may be associated with dietary indiscretions or diet change.

RISK FACTORS

- Stress factors to the gastrointestinal tract, dietary change, antibiotic administration, concurrent disease, or hospitalization may precipitate signs.
- The pathogenicity of CP may depend on the metabolic, mucosal, and immunologic integrity of the gastrointestinal tract.
- Possibly IgA deficiency.
- An alkaline intestinal luminal environment promotes CP sporulation and CPE production.
- Primary intestinal bacterial overgrowth.

DIAGNOSIS

- Cases having acute or chronic intermittent clinical signs should be suspected of having CP.
- Diagnostic testing should always be evaluated during the onset of clinical episodes.
- Late in the course of disease evidence of CP or CPE may be absent.
- CP is usually an antibiotic-responsive diarrhea; however, a response to empiric antibiotic therapy in a dog with nonspecific

diarrhea does not infer a diagnosis of *C. perfringens*.

DIFFERENTIAL DIAGNOSIS

- All causes of diarrhea, including systemic or metabolic disease as well as specific intestinal disorders, should be considered.
- Gastrointestinal parasites, inflammatory bowel disease, chronic idiopathic colitis, and irritable bowel syndrome may resemble CP enterotoxicosis.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC may show evidence of hemoconcentration secondary to dehydration.
- Dogs with HGE commonly show a discordant PCV or Hct relative to the total protein on CBC. It is not uncommon to observe a Hct of 60% or higher in dogs with severe HGE in conjunction with a normal or low-normal total protein of 6.5 mg/dL. This is due to a combination of hemoconcentration secondary to dehydration and splenic contraction together with intestinal protein loss.
- Biochemical alterations may reflect underlying dehydration.

OTHER LABORATORY TESTS

There is no gold standard diagnostic test for confirming *C. perfringens*-associated diarrhea.

Microbiology

- Fecal culture alone should not be used to diagnose *C. perfringens* because the organism is a normal commensal. *C. perfringens* can be isolated from the feces of approximately 90% of healthy dogs.
- Specific fecal spore cultures will detect high concentrations of clostridial spores ($> 10^6$ spores/gram of feces) in affected animals and correlate well with clinical disease, but are rarely performed.

Enterotoxin Assay

- Detection of CPE via ELISA can be helpful for diagnosing *C. perfringens*-associated diarrhea; however, CPE is detected in approximately 10–14% of healthy dogs and up to 34% of diarrheic dogs, decreasing the utility of this test alone.
- There are many other virulence genes and toxins that appear to play a role in *C. perfringens*-associated diarrhea in dogs, including the necrotizing toxin gene, *netF*.
- RT-PCR for detection of CPE gene (*cpe*) and alpha toxin gene is commercially available; however, many healthy dogs have detectable alpha toxin gene, decreasing the diagnostic utility of this assay as a stand-alone test.
- Detection of *cpe* and CPE concurrently in a dog displaying clinical signs consistent with *C. perfringens* is the most accurate means for making a diagnosis.

Fecal Cytology

- Cytology involves making a thin fecal smear on a microscope slide, air-drying or

CLOSTRIDIAL ENTEROTOXICOSIS

(CONTINUED)

heat-fixing, and staining with Diff-Quik, Wright's stain, or New Methylene Blue.

- CP spores have a "safety-pin" appearance with an oval structure and a dense body at one end of the spore wall.
- Identification of high numbers of CP endospores on fecal cytology correlates poorly with clinical disease or fecal CPE activity.
- High numbers of fecal endospores can be found in the feces of healthy dogs, decreasing the diagnostic utility of fecal cytology in these animals.

DIAGNOSTIC PROCEDURES

Colonoscopy will help rule out concurrent intestinal disease.

PATHOLOGIC FINDINGS

- Colon biopsies taken during asymptomatic periods are usually unremarkable.
- Patients with CP enterotoxicosis may have colonoscopic evidence of hyperemic or ulcerated mucosa.
- Histology may show catarrhal or suppurative colitis.
- Occasionally a mild lymphocytic and plasmacytic enteritis is present.

TREATMENT

APPROPRIATE HEALTH CARE

- Most treated as outpatients.
- When diarrhea or vomiting is severe, and resulting in dehydration and electrolyte imbalance, hospitalization may be required.

NURSING CARE

Fluid and electrolyte therapy may be required to replace losses occurring from diarrhea, particularly in dogs with HGE.

ACTIVITY

Restricted during acute disease

DIET

- Dietary manipulation plays a role in the treatment and management of cases with chronic recurring disease. Diets high in fiber, either soluble (fermentable) or insoluble fiber, often result in clinical improvement by reducing enteric clostridial numbers. This may be due to acidification of the distal intestine, potentially limiting CP sporulation and enterotoxin production.
- Commercial high-fiber diets can be supplemented with psyllium (1/2–2 tsp/day) as a source of soluble fiber.
- Diets low in fiber should be supplemented with fiber (coarse bran 1–3 tbs/day) as a source of insoluble fiber or psyllium added as a source of soluble fiber.

- Probiotics may be beneficial for preventing recurrences of *C. perfringens*-associated diarrhea by altering the intestinal microbiota.

CLIENT EDUCATION

Acute disease is often self-limiting. There have been no documented reports of zoonotic transmission of *C. perfringens* from animals to humans.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics

- Antibiotics should be avoided in dogs with mild disease because the infection typically has a brief, self-limiting nature.
- In dogs with severe diarrhea or evidence of systemic disease, antibiotics can be administered for 5 days.
- Antibiotics of choice for treatment of *C. perfringens* in dogs include ampicillin (20 mg/kg q8h) or amoxicillin (20 mg/kg q8h), metronidazole (10 mg/kg q12h), or tylosin (5–10 mg/kg q24h). Tetracyclines should be avoided due to the high incidence of induction of resistance genes.

ALTERNATIVE DRUGS(S)

- Probiotics (such as lactobacillus or others) may alter the intestinal microbiota, reducing the likelihood of recurrences.
- Chronic cases may respond well to high-fiber diets (see "Diet"), and dietary manipulation may be attempted as the sole therapy following resolution of signs.

FOLLOW-UP

PATIENT MONITORING

The patient's response to antibiotic therapy does not confirm a diagnosis of *C. perfringens*-associated diarrhea. Monitoring for hydration status and electrolyte imbalances is warranted in dogs with moderate to severe disease.

PREVENTION/AVOIDANCE

Feeding high-fiber diets or probiotics may decrease the incidence of *C. perfringens*-associated diarrhea.

EXPECTED COURSE AND PROGNOSIS

- Most animals respond well to therapy. Chronic cases may require long-term therapy to control clinical signs.
- A lack of response to therapy suggests concurrent disease, and further diagnostic evaluation is warranted.

MISCELLANEOUS

ASSOCIATED CONDITIONS

CP enterotoxicosis is frequently associated with other enteric disease such as parvovirus, acute hemorrhagic gastroenteritis, or inflammatory bowel disease.

ZOONOTIC POTENTIAL

Unknown

PREGNANCY/FERTILITY/BREEDING

Antibiotic therapy may be contraindicated

COAGULATION FACTOR DEFICIENCY

BASICS

DEFINITION

Hemostatic defects characterized by a lack of one or more procoagulant proteins (coagulation factors).

PATHOPHYSIOLOGY

- Coagulation involves a complex series of enzymatic reactions that generate a burst of thrombin (factor IIa) at sites of blood vessel injury. Thrombin then cleaves plasma fibrinogen into fibrin monomers that are subsequently polymerized and cross-linked to form an insoluble fibrin clot.
- Functional and/or quantitative coagulation factor deficiencies cause a failure of fibrin clot formation.
- The liver is the sole or primary site of synthesis of most coagulation factors. After synthesis, factors II, VII, IX, and X require a vitamin K-dependent modification to become fully active.

SYSTEMS AFFECTED

- Coagulation factor deficiency can cause spontaneous hemorrhage, prolonged post-traumatic hemorrhage, and ultimately blood loss anemia.
- Spontaneous hemorrhage—often develops in body cavities or potential spaces (i.e., hemothorax, hemoperitoneum, hemarthrosis, subcutaneous or intramuscular hematoma).

SIGNALMENT

- Acquired factor deficiencies—depends on underlying disease process.
- Heredity factor deficiencies—severe defects manifest by 3–6 months of age, milder hemostatic defects manifest after surgery or trauma.
- Hemophilia A and B (factor VIII and IX deficiencies)—X-linked recessive traits (males express the bleeding tendency, female carriers are clinically normal).
- Hemophilia A is a common hereditary factor deficiency and is seen in all breeds and mixed-breed dogs and cats.
- All other factor deficiencies—autosomal traits; males and females express signs with equal frequency. Specific defects are more likely to be propagated within a single breed, but all breeds are at risk for developing new mutations.
- Factor XII deficiency is common in cats but does not cause a clinical bleeding tendency.

SIGNS

- Hematoma formation
- Intracavitary hemorrhage
- Prolonged hemorrhage post-surgery, trauma
- Blood loss anemia

CAUSES

- Acquired—synthetic failure (liver disease); vitamin K deficiency (cholestasis, anticoagulant rodenticide toxicity, malabsorption, long-term antibiotics, coumadin); factor inhibition (heparin

overdose, envenomation); factor consumption and depletion (DIC); factor dilution (high-volume transfusion, plasma expanders); hyperfibrinolysis (secondary fibrinogen depletion).

- Heredity—distinct mutations in coagulation factor genes.

RISK FACTORS

See acquired causes above.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Thrombocytopenia should be the first rule-out for any patient with abnormal hemorrhage.
- Acquired coagulopathies often develop because of liver disease, anticoagulant rodenticide ingestion, and DIC.
- Liver disease is accompanied by changes in CBC and chemistry profiles (see Coagulopathy of Liver Disease).
- Anticoagulant rodenticide toxicity prolongs the APTT and PT screening tests but does not affect TCT or fibrinogen.
- DIC always develops secondary to systemic disease (especially sepsis or neoplasia) and is often accompanied by low or falling platelet count.
- Massive transfusion (>1 blood volume) with stored blood products may dilute functional factors, fibrinogen, and platelets below hemostatic levels.
- Hyperfibrinolysis may develop after hypovolemic shock and traumatic blood loss but generally does not cause prolongation of APTT and PT screening tests.
- Heredity coagulation factor deficiencies cause prolongation of coagulation screening tests, whereas vWD does not.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

Therapeutic dosages of unfractionated heparin, coumadin, and plasma expanders (dextran, hetastarch) prolong coagulation screening tests.

Disorders That May Alter Laboratory Results

- Improper sample collection will invalidate coagulation test results (poor venipuncture technique, partially filled citrate collection tubes, use of heparin or clot activator tubes).
- Extreme lipemia, hemoglobinemia, or icterus may interfere with clot detection by photo-optical coagulation analyzers.
- Because of factor lability, samples should be assayed on site or plasma separated and sent on ice to the laboratory.

Valid if Run in Human Laboratory?

- Interpretation of coagulation assay results requires same-species reference ranges and controls. For example, human APTT values are generally twice those of dogs and cats.
- The laboratory should confirm cross-reactivity

of antigenic assays and optimization of functional tests for animal plasmas.

CBC/BIOCHEMISTRY/URINALYSIS

- Regenerative anemia develops after blood loss.
- Platelet count is normal unless the patient has DIC or massive bleeding.
- Resorption of blood from large hematoma may cause high bilirubin.

OTHER LABORATORY TESTS

- Coagulation screening tests (ACT, APTT, PT, TCT) are functional tests that measure the time for in vitro clot formation.
- Coagulation factor and fibrinogen deficiencies prolong clotting time (see algorithm, Figure 1).
- ACT is a point-of-care screening test that detects severe deficiencies of all factors (except factor VII). The ACT may be influenced by anemia, thrombocytopenia, and changes in blood viscosity.
- APTT is a screening test of the contact pathway (prekallikrein, high molecular weight kininogen, factor XII) intrinsic system (factors XI, IX, VIII), common system (factors X, V, II), and severe fibrinogen deficiency.
- PT is a screening test of factor VII, common system, and severe fibrinogen deficiency.
- The TCT is a screening test of functional fibrinogen and is sensitive to the presence of fibrinogen inhibitors.
- Acquired coagulation factor deficiencies generally cause prolongation of more than one screening test.
- The most common hereditary factor deficiencies (hemophilia and factor XII deficiency) specifically prolong APTT.
- Individual factor assays can be performed for definitive diagnosis of hereditary or complex coagulopathies.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

The buccal mucosa bleeding time is prolonged in patients with severe thrombocytopenia, platelet dysfunction, von Willebrand disease, and fibrinogen deficiency, but BMBT is insensitive to coagulation factor deficiencies.

TREATMENT

- Transfusion of fresh whole blood, fresh plasma, and fresh frozen plasma will supply all coagulation factors.
- Cryoprecipitate is a specific source of factor VIII, fibrinogen, and vWF. Cryo-supernatant plasma supplies all other factors.
- Component therapy is preferred for surgical prophylaxis and non-anemic patients to prevent red cell sensitization and volume overload.
- Patients with severe acquired or hereditary factor deficiencies may require repeated transfusion (q8–12h) to control or prevent hemorrhage.

COAGULATION FACTOR DEFICIENCY

(CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE

Vitamin K₁ is an effective treatment for patients with anticoagulant rodenticide poisoning and other causes of vitamin K deficiency.

CONTRAINDICATIONS

NSAIDs, anticoagulants, and plasma expanders should be avoided to prevent further compromise of hemostasis.

PRECAUTIONS

- Intramuscular injections and jugular catheter placement should be avoided because of the risk of inducing additional bleeding.
- Intravenous administration of vitamin K is not recommended because of the risk of anaphylaxis.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

Alternatives such as antifibrinolytic drugs (EACA and tranexamic acid) may prove useful to reduce or eliminate transfusion requirements, but have not yet been evaluated in veterinary clinical trials.

FOLLOW-UP

PATIENT MONITORING

- PT or factor VII assays can be used to monitor effectiveness of vitamin K

administration in animals with anticoagulant toxicity. Test results should normalize after 24–48 hours of initiating therapy. • ACT is a less specific but reasonable substitute for monitoring response to vitamin K.

- Hereditary defects can be monitored by clinical arrest of bleeding, stabilization of Hct, resolution of hematoma, and, if needed, specific factor analyses.

POSSIBLE COMPLICATIONS

Transfusion poses a risk of immune reactions (e.g., RBC sensitization, urticaria) and non-immune reactions (disease transmission, volume overload).

MISCELLANEOUS

ASSOCIATED CONDITIONS

None

AGE-RELATED FACTORS

None

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

Patients with hereditary factor deficiencies should not be bred.

COAGULATION SCREENING TESTS: APTT, PT, TCT

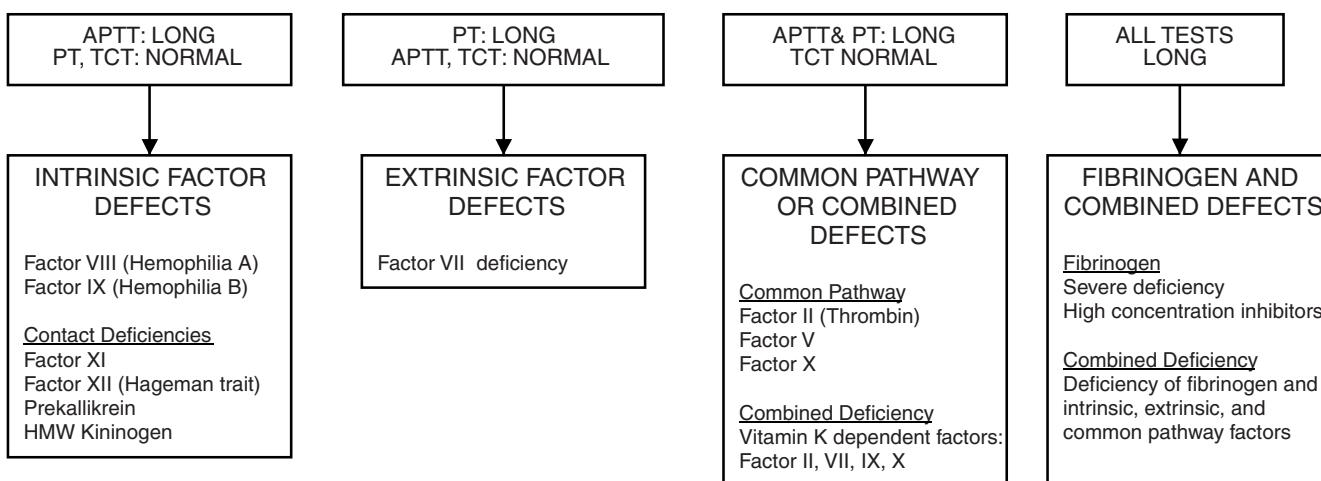

Figure 1.

Diagnostic algorithm for coagulation factor deficiencies.

COAGULOPATHY OF LIVER DISEASE

BASICS

OVERVIEW

- Liver is the sole/primary site of synthesis of coagulation, anticoagulant, and fibrinolytic proteins with few exceptions (e.g. Factors V, VIII, vWF, tPA).
- Despite abnormal clotting time test results, few patients exhibit spontaneous bleeding.
- Causes of hemostatic imbalance:
 - (1) reduced synthesis or activation of procoagulant proteins; vitamin K deficiency,
 - (2) dysfibrinogenemia due to abnormal fibrin polymerization,
 - (3) reduced clearance of FDP,
 - (4) thrombocytopenia or thrombocytopathy,
 - (5) enhanced fibrinolysis.
- Vitamin K deficiency—linked to severe intra- or extrahepatic cholestasis or steatorrhea or prolonged oral antibiotic administration.

SIGNALMENT

Dog and cat of any age, breed, or sex

SIGNS

- Often minor or no bleeding.
- Melena; hematemesis; hematochezia; hematuria.
- Prolonged bleeding if provoked: venipuncture, cystocentesis, biopsy, surgical wounds.
- Spontaneous bruising/hematomas—rare unless severe vitamin K deficiency or fulminant DIC.

CAUSES & RISK FACTORS

- Severe hepatic failure of any etiology
- Acute viral liver disease
- EHBDO
- Chronic liver disease—especially cirrhosis
- Concurrent small bowel disease (e.g., cats with cholangiohepatitis or hepatic lipidosis) predisposing to vitamin K deficiency
- High CVP and portal hypertension
- PSVA: asymptomatic factor deficiency and prolonged APTT common; overt bleeding uncommon.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Toxicities—anticoagulant rodenticides, NSAIDs (GI lesions), causes of acute liver failure (e.g., ingestion of aflatoxin or cycad)
- Hereditary hemostatic defects
- Thrombocytopenia
- DIC—any cause GI infiltrative disorders
- Hepatic amyloidosis (factor deficiency, spontaneous liver lobe fractures)
- Abdominal trauma

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—normal or regenerative anemia; severe bleeding (2–5 days); microcytosis; portosystemic shunting; thrombocytopenia

- Biochemistry—high liver enzymes; bilirubinemia; low albumin; hypoglobulinemia; low cholesterol
- Urinalysis—hematuria; bilirubinuria

OTHER LABORATORY TESTS

Hemostatic tests—thrombocytopenia; prolonged APTT (ACT), PT, TCT, and PIVKA; low fibrinogen and coagulation factors; low anticoagulant factors (AT, protein C); high FDP and D-dimer.

IMAGING

Abdominal Ultrasonography

- Effusion (ascites, hemorrhage)
- Liver changes vary with disorders
- Abnormal enteric motility, thickening in area of bleeding (portal hypertensive vasculopathy)

TREATMENT

- Not necessary unless invasive procedures planned or spontaneous hemorrhage noted.
- Fresh whole blood—provides replacement of red cells, coagulation factors, functional platelets.
- Fresh frozen plasma—provides coagulation factors, other hemostatic proteins and reduces risk of red cell sensitization or volume overload.
- Cryoprecipitate—for severe hypofibrinogenemia or bleeding with coexistent vWD.
- Platelet-rich plasma—rarely indicated.
- Avoid synthetic colloids if bleeding tendencies observed.

BIOPSY

- High risk for bleeding—PIVKA, PT, APTT, or ACT prolonged by > 50%; thrombocytopenia < 50,000/ μ L; prolonged mucosal bleeding time.
- Iatrogenic hemorrhage—grave prognosis if spontaneous bleeding with undetermined cause.
- Hemostasis support—post-procedure bleeding.
- Ultrasound-guided needle core—highest risk; observe biopsy site within 15 minutes, then sequentially over several hours post-procedure.
- Laparoscopy—affords visibility and allows hemostasis (cautery, Gelfoam pack biopsy site).
- Laparotomy—wedge biopsy; ill-advised in patients with overt bleeding.

MEDICATIONS

DRUG(S)

- Based on cause of hepatic abnormality.
- Vitamin K deficiency—parenteral vitamin K₁ (0.5–1.5 mg/kg q12h SC up to 3 doses in

24-hour interval one time); vitamin K₁ PO (Mephyton, 1 mg/kg q24h) if normal enteric bile acid uptake.

• DIC—correct primary disease; consider heparin for overt thrombosis (unfractionated heparin [UFH]: 200 U/kg q6–12h; or low molecular weight heparin [enoxaparin]: 1 mg/kg q12–24h), dose titration based on clinical status and laboratory monitoring (ACT, aPTT [UFH], heparin anti-Xa activity [all heparins]).

- Blood products—fresh whole blood: 12–20 mL/kg q24h; fresh frozen plasma: 10–20 mL/kg q12h; plasma cryosupernatant (albumin, vitamin K-dependent factors): 10–20 mL/kg q12h; cryoprecipitate (fibrinogen, vWF, factor VIII): 1 U/10 kg or dose to effect.
- DDAVP—0.5–1 μ g/kg IV in saline; may increase coagulation factors, shortens bleeding times, reduces bleeding tendencies; empirically used for biopsy-induced bleeding.
- Antifibrinolytics—EACA: 100 mg/kg loading, 30 mg/kg/h; tranexamic acid: 25 mg/kg q8h; if hyperfibrinolysis.

CONTRAINdicATIONS

- Stored whole blood—may provoke HE.
- Vitamin K₁ (cats)—too much causes Heinz body hemolysis and oxidant liver injury.
- Aspirin or other NSAIDs—may predispose to renal failure, worsen ascites, provoke emesis and spontaneous bleeding.
- High-volume transfusion in citrate-based anticoagulants (especially in animals < 5 kg) may induce symptomatic hypocalcemia.
- Avoid provocative procedures—e.g., jugular venipuncture or catheter placement, cystocentesis if recognized bleeding tendencies.

FOLLOW-UP

PATIENT MONITORING

- Optimized PT test, PIVKA, factor VII—most sensitive to vitamin K deficiency; if no improvement after 48 hours of vitamin K₁ injection, unlikely benefit from further dosing.
- Heart rate, blood pressure, mucous membrane color and refill, PCV, and total solids to monitor response if active bleeding.
- Biopsy site—observe immediately and sequentially (ultrasonography) for hemorrhage.
- Sample abdominal effusion to determine if hemorrhage or ascites.

PREVENTION/AVOIDANCE

- Well-balanced diet replete with vitamins.
- Consider impaired vitamin K availability or synthesis from chronic oral antimicrobials.
- Invasive procedures—anticipate bleeding; pretreat with vitamin K₁; give DDAVP within 20 minutes of anticipated biopsy or if

COAGULOPATHY OF LIVER DISEASE

(CONTINUED)

bleeding tendencies persist despite vitamin K₁ therapy (repeated DDAVP of no use); fresh frozen plasma for factor/fibrinogen replacement and active bleeding; avoid volume overload and increased CVP.

- Eliminate enteric parasitism.

POSSIBLE COMPLICATIONS

Hemorrhage, anemia, hypovolemia, HE

EXPECTED COURSE AND PROGNOSIS

Spontaneous hemorrhage, refractory coagulopathy, and DIC—poor prognosis.

**MISCELLANEOUS****ABBREVIATIONS**

COBALAMIN DEFICIENCY

C

BASICS

OVERVIEW

- Cobalamin deficiency occurs in patients with cobalamin malabsorption when all body stores of cobalamin have been utilized and cobalamin is deficient on a cellular level.
- Cobalamin is required by virtually all cells in the body and plays a major role in β -oxidation, conversion of certain amino acids, and the formation of tetrahydrofolate, and is thus crucial for energy production, amino acid metabolism, and DNA and RNA synthesis.
- Cobalamin deficiency is associated with gastrointestinal signs and systemic complications, such as immunodeficiencies, central neuropathies, and peripheral neuropathies.
- Cobalamin is absorbed exclusively in the ileum of dogs and cats via a receptor-mediated mechanism.
- The main causes of cobalamin deficiency in dogs and cats include chronic gastrointestinal disease involving the ileum (e.g., inflammatory bowel disease, small intestinal dysbiosis, intestinal lymphoma), exocrine pancreatic insufficiency, short bowel syndrome, and, in rare cases, inherited cobalamin malabsorption or dietary deficiencies.

SIGNALMENT

- In the US, Chinese Shar Pei have a high prevalence of cobalamin deficiency. Isolated families of other breeds, such as the giant schnauzer, beagle, border collie, and Australian shepherd dog, have also been described as having cobalamin deficiency.
- Exocrine pancreatic insufficiency is particularly common in German shepherd dogs. These patients are usually young adults at the time of presentation.
- No other breed, sex, or age predilections are known for canine or feline patients with cobalamin deficiency.

SIGNS

- Clinical signs attributable to the underlying disease process:
 - Chronic enteropathy: diarrhea, weight loss, vomiting, poor appetite, or others.
 - EPI: weight loss, failure to thrive, loose stools, steatorrhea, polyphagia or even pica, borborygmus, flatulence.
- Clinical signs attributable to cobalamin deficiency: weight loss, failure to thrive, poor hair coat, lethargy, anorexia; rarely stupor and encephalopathy.

CAUSES & RISK FACTORS

- Intestinal disease involving the distal small intestine (i.e., the ileum): inflammatory bowel disease, food responsive enteropathy, lymphoma, others.

- Exocrine pancreatic insufficiency.
- Short bowel syndrome.
- Hereditary (Chinese Shar Pei, giant schnauzer).
- Dietary; being fed an exclusively vegan or vegetarian diet without concurrent supplementation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other diseases causing chronic gastrointestinal disease, immunosuppression, central neuropathies, or peripheral neuropathies.

CBC/BIOCHEMISTRY/URINALYSIS

- May be within normal limits.
- May show changes associated with an underlying disease process (e.g., hypoalbuminemia in patients with severe inflammatory bowel disease).
- May show anemia, neutrophilia with left shift, or neutropenia. Rubricytes have been documented in cobalamin-deficient dogs and have been interpreted as evidence of ineffective erythropoiesis. Hypersegmented neutrophils can also be observed.

OTHER LABORATORY TESTS

- Serum and urine methylmalonic acid concentration are increased in patients with cobalamin deficiency. However, analysis (by GC/MS) is time-consuming and expensive and is not available for routine clinical use.
- Decreased or low normal serum cobalamin concentrations. Studies measuring methylmalonic acid in serum from dogs and cats have shown that patients with low normal serum cobalamin concentrations may be cobalamin-deficient on a cellular level. Note that all assays used for the measurement of serum cobalamin concentration in dogs and cats have been developed for use in humans and thus must be analytically validated for dogs and cats before routine clinical use. In addition, each lab should develop specific reference intervals.

IMAGING

Not useful

DIAGNOSTIC PROCEDURES

None for the diagnosis of cobalamin deficiency. However, intestinal biopsies may be useful to confirm and characterize chronic enteropathies.

TREATMENT

Treatment of the underlying disease process if identified (e.g., inflammatory bowel disease, EPI, lymphoma, small intestinal dysbiosis).

MEDICATIONS

DRUG(S)

- Cobalamin supplements:
 - cyanocobalamin (usually at 1,000 μ g/mL; for parenteral use or 1 mg tablet for oral use)
 - hydroxocobalamin (usually at 1,000 μ g/mL; for parenteral use)
 - methylcobalamin (usually 1 mg capsule; mainly for oral use).
- Traditionally, cobalamin supplementation in cobalamin-deficient patients has been administered parenterally (usually subcutaneously) using most commonly cyanocobalamin or rarely hydroxocobalamin.
- Cats receive 250 μ g/injection; dogs receive between 250 μ g (small dog) and 1,500 μ g (giant dog) per injection.
- In either species there are 6 weekly injections, one more injection a month later, and reevaluation of serum cobalamin concentration a month later.
- Continue therapy weekly or bi-weekly if serum cobalamin is still low; continue monthly or bi-monthly if cobalamin is in the mid-normal range; discontinue if serum cobalamin is in the high end of the normal range.
- Recently, two reports have suggested that oral supplementation may be effective as well at 1 mg q24h for 2–3 months. Re-evaluation suggested as above.

FOLLOW-UP

Depending on the severity of the underlying disease process, the complications from cobalamin deficiency, and treatment response.

PATIENT MONITORING

- See above; re-evaluation of serum cobalamin concentration 1 month after either the last cobalamin injection or the last oral dose of cobalamin.
- Additional monitoring as required for the underlying disease process.

MISCELLANEOUS

ABBREVIATION

- EPI = exocrine pancreatic insufficiency

Coccidioidomycosis

C

BASICS

DEFINITION

A systemic mycosis caused by the inhalation of infective arthroconidia of the soil-borne fungus *Coccidioides immitis*.

PATHOPHYSIOLOGY

- Grows in soil in the mycelial state.
- Inhalation of infective arthroconidia is the primary route of infection; at body temperature, all but one nucleus is shed and an immature spherule is produced within 2–3 days.
- Spherule matures and ruptures releasing 200–300 endospores which can produce new spherules.
- Neutrophils cannot penetrate the spherule wall but can phagocytize the endospores.
- Fewer than 10 inhaled arthrospores are sufficient to cause disease in susceptible animals.
- Respiratory signs are often noted 1–3 weeks after exposure; signs of dissemination may not be evident for several months.
- Most infections are mild or subclinical although dogs appear more susceptible to the development of disseminated disease.
- Fever, lethargy, inappetence, coughing, and joint pain or stiffness may be noticed. Dissemination may occur within 10 days, resulting in signs related to the organ system involved; skin lesions are usually associated with dissemination, but penetrating wounds have rarely been associated with skin lesions.

SYSTEMS AFFECTED

- Respiratory—the site of initial infection.
- Extrapulmonary spread may occur to long bones and joints, eyes, pericardium and myocardium, skin, CNS, testes, and visceral organs.

INCIDENCE/PREVALENCE

Not an uncommon disease in endemic areas, rare in non-endemic areas. It occurs more commonly in dogs and rarely in cats.

GEOGRAPHIC DISTRIBUTION

- *C. immitis* is found in the southwestern United States in the geographic Lower Sonoran life zone.
- More common in Southern California, Arizona, and southwest Texas and is less prevalent in New Mexico, Nevada, and Utah.

SIGNALMENT

Species

Dog and cat

Breed Predilections

None

Mean Age and Range

Though most commonly diagnosed in young animals (< 4 years of age), it is seen in animals of all ages.

Predominant Sex

None

SIGNS

Historical Findings

- Coughing (ranges from dry/harsh to wet/productive)
- Fever unresponsive to antibiotics
- Anorexia, weight loss
- Weakness, lameness
- Seizures, paraparesis, back and neck pain
- Visual changes

Physical Examination Findings

Dogs

- Signs with pulmonary involvement:
- Coughing and dyspnea
- Fever, lethargy
- Signs with disseminated disease:
- Bone swelling, joint enlargement, and lameness.
- Lymphadenomegaly, skin lesions, and draining tracts.
- Neurologic dysfunction can include seizures, ataxia, and behavioral changes.
- Uveitis, keratitis, and iritis.

Cats

- Similar to dogs although skin lesions are most common type of infection in cats.
- Dyspnea
- Lameness caused by bone involvement
- Uveitis

CAUSES

C. immitis grows several inches deep in the soil, where it survives high ambient temperatures and low moisture. After a period of rainfall, the organism returns to the soil surface where it sporulates, releasing many arthroconidia that are disseminated by wind and dust storms.

RISK FACTORS

- Aggressive nosing in contaminated soil and underbrush may expose susceptible animals to large numbers of arthroconidia.
- Dust storms after the rainy season; increased incidence noted after earthquakes.
- Land development with earth disruption may lead to increased exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pulmonary lesions may resemble those of other systemic mycoses (e.g., histoplasmosis, blastomycosis).
- Lymphadenomegaly may be seen in lymphoma, other systemic mycoses, and localized bacterial infections.
- Bone lesions may resemble those caused by primary or metastatic bone tumors or bacterial osteomyelitis.
- Skin lesions must be differentiated from routine abscesses or other infective processes.
- For seizures and ataxia, consider inflammatory and oncologic etiologies.

CBC/BIOCHEMISTRY/URINALYSIS

- Hemogram—mild nonregenerative anemia, neutrophilic leukocytosis, monocytosis.
- Serum chemistry profile—hyperglobulinemia, hypoalbuminemia, other changes may be consistent with organ of involvement.

- Urinalysis—proteinuria with inflammatory glomerulonephritis.

OTHER LABORATORY TESTS

Serologic tests (generally by AGID or ELISA) for antibody to *C. immitis* may provide a presumptive diagnosis; may aid in monitoring response to therapy.

IMAGING

- Radiography of lung (interstitial infiltrates) and bone lesions (osteolysis) may aid in diagnosis.
- MRI may help in diagnosing granulomas in the CNS.

DIAGNOSTIC PROCEDURES

- Serologic testing; repeat serology titers in 4–6 weeks when low titers are accompanied by clinical signs.
- Microscopic identification of the large spherule form of *C. immitis* in lesion or biopsy material is the definitive method of diagnosis (large 10–80 μm round, double-walled structure containing endospores).
- Lymph node aspirates and impression smears of skin lesions or draining exudate may yield organisms.
- Cultures should be performed by trained laboratory personnel using protective hoods.
- Biopsy of infected tissue often is preferred to avoid false-negative results.
- Tissues involved, however, may not be readily accessible and finding the organism can be challenging; therefore, serologic testing can be a more logical approach.

PATHOLOGIC FINDINGS

- Granulomatous, suppurative, or pyogranulomatous inflammation present in many tissues.
- Presence of the characteristic spherule forms in affected tissues.

TREATMENT

APPROPRIATE HEALTH CARE

- Generally treated as outpatient.
- Concurrent clinical symptoms (e.g., seizures, pain, coughing) should be treated appropriately.

ACTIVITY

Restrict activity until clinical signs begin to subside.

DIET

Feed a high-quality palatable diet to maintain body weight.

CLIENT EDUCATION

- Treatment is potentially long (> 6 months) and expensive.
- Relapse (especially with disseminated disease) is common.
- Reassure client that the infection is not zoonotic.

SURGICAL CONSIDERATIONS

In cases of focal granulomatous organ involvement (e.g., consolidated pulmonary lung lobe, eye, kidney), surgical removal of the affected organ may be indicated.

Coccidioidomycosis

(CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE

Coccidioidomycosis is considered one of the most severe and life threatening of the systemic mycoses. Treatment of disseminated disease often requires at least 1 year of aggressive antifungal therapy.

Dogs

- Ketoconazole—5–10 mg/kg PO q12h; ideally given with food; treatment typically requires at least 1 year of therapy; if titers rise or clinical signs deteriorate over the first 4–6 weeks of treatment, alternative therapy should be considered.
- Fluconazole—5 mg/kg PO q12h; noted to greatly increase the success of treatment; neurologists recommend 10 mg/kg to increase penetration in neurologic infections; cost of the drug has significantly decreased with the availability of a medical-grade generic compound; treatment failures have been noted with the use of chemical-grade compounded formulations.
- Itraconazole—5 mg/kg PO q12h; administered similarly as KTZ it has been reported to have a higher penetration rate than ketoconazole; some suggest greater efficacy of itraconazole over fluconazole.
- Amphotericin B is rarely recommended because of the risk of renal damage and the availability of effective oral medications; AMB can be administered at a dosage of 0.5 mg/kg IV 3 times per week, for a total cumulative dosage of 8–10 mg/kg; given IV either as a slow infusion (in dogs that are gravely ill) or as a rapid bolus (in fairly healthy dogs); for slow infusion, add AMB to 250–500 mL of 5% dextrose solution and administer as a drip over a period of 4–6 hours; for a rapid bolus, add AMB to 30 mL of 5% dextrose solution and administer over a period of 5 minutes through a butterfly catheter; to lessen the adverse renal effects of AMB, consider 0.9% NaCl (2 mL/kg/h) for several hours before initiating AMB therapy.

Cats

- Any of the following azoles may be used in cats:
 - Ketoconazole 50 mg total dose PO q12h
 - Fluconazole 25–50 mg total dose PO q12h
 - Itraconazole 25–50 mg total dose PO q12h

CONTRAINdications

- Drugs metabolized primarily by the liver should be used with caution alongside any azole drugs. • Drugs metabolized primarily by the kidneys should be used with caution along with AMB.

PRECAUTIONS

- Side effects of azoles include inappetence, vomiting, and hepatotoxicity (typically ALT > ALP); liver values should be monitored; drugs may be stopped until signs abate and restarted at a lower dose, which may be slowly increased to the recommended dose if the animal is able to tolerate the drug; newer azoles (ITZ and FCZ) have fewer side effects.
- Side effects of AMB therapy can be severe, especially renal dysfunction, fever; use with caution if patient is azotemic but not an absolute contraindication if the infection is life-threatening.

FOLLOW-UP

PATIENT MONITORING

- Serologic titers should be monitored every 3–4 months; animals should be treated until their titers fall to less than 1:4; consider itraconazole levels (2–4 hour post-pill) in patients showing a poor response to itraconazole therapy, especially if using a generic or compounded formulation.
- Creatinine and urinalysis should be monitored in all animals treated with AMB; treatment should be temporarily discontinued if the creatinine rises above the reference range or greater than 20% above baseline or if granular casts are noted in the urine.

PREVENTION/AVOIDANCE

- No vaccine is available for dogs or cats.
- Contaminated soil in endemic areas should be avoided, particularly during dust storms after the rainy season.

POSSIBLE COMPLICATIONS

Pulmonary disease resulting in severe coughing may temporarily worsen after therapy is begun owing to inflammation in the lungs. Low-dose short-term oral prednisone and cough suppressants may be required to alleviate the respiratory signs.

EXPECTED COURSE AND PROGNOSIS

- The prognosis for localized respiratory disease is good. • The prognosis for disseminated disease is more guarded; many dogs will improve following oral therapy with resolution of signs reported in up to 90% cases; however, relapses may be common, especially if therapy is shortened; overall recovery rate has been estimated at 60%.
- The prognosis with CNS involvement may be guarded to poor. • The prognosis for cats is not well documented, but long-term therapy should be anticipated and relapses are common. • Serologic testing every 3–4 months after completion of therapy is recommended to monitor the possibility of relapse. • Spontaneous recovery from disseminated coccidioidomycosis without treatment is extremely rare.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- The spherule form of the fungus, as found in animal tissues, is not directly transmissible to humans or to other animals. • Under certain rare circumstances, however, there could be reversion to growth of the infective mold form of the fungus on or within bandages placed over a draining lesion or in contaminated bedding; draining lesions can lead to contamination of the environment with arthrospores; care should be exercised whenever handling an infected draining lesion. • Special precautions should be recommended to households in which the owners may be immunosuppressed.

PREGNANCY/FERTILITY/BREEDING

Azole drugs can be teratogenic and should be used in pregnant animals only if the potential benefit justifies the potential risk to offspring.

SYNONYMS

- Desert rheumatism (in humans) • San Joaquin Valley fever • Valley fever

ABBREVIATIONS

- AGID = agar gel immunodiffusion • AMB = amphotericin B • CNS = central nervous system • ELISA = enzyme-linked immunosorbent assay • FCZ = fluconazole
- ITZ = itraconazole • KTZ = ketoconazole
- MRI = magnetic resonance imaging

Coccidiosis

C

BASICS

OVERVIEW

- An enteric infection, traditionally associated with *Cystoisospora canis* (dogs) and *Cystoisospora felis* (cats) as potential pathogens; other species of *Cystoisospora* may be present.
- Strictly host-specific (i.e., no cross-transmission).
- Eimeria* spp. are not parasitic for dogs or cats.
- Toxoplasma gondii* in cats and *Cryptosporidium parvum* in neonatal pups and kittens are coccidians in a non-traditional sense.
- Toxoplasma* infection in cats may cause clinical signs similar to those with *Cystoisospora* infections; oocysts shed in the environment may potentially cause a public health problem.
- Cryptosporidium* is still being assessed as an acute, life-threatening coccidiosis (cryptosporidiosis) of neonatal pups and kittens, but can also cause non-life-threatening small bowel diarrhea in dogs and cats, particularly those housed in crowded environments.
- Voluminous watery diarrhea is characteristic; auto-infection and continuing recycling within the intestinal tract result in a rapid loss of mucosal lining with cryptosporidiosis.

SIGNALMENT

Dog and cat (especially puppies and kittens)

SIGNS

- Watery-to-mucoid, sometimes blood-tinged, diarrhea; vomiting; abdominal discomfort; inappetance
- Weak puppies and kittens
- Immunocompromised animals

CAUSES & RISK FACTORS

- Infected dogs or cats contaminating environment with oocysts of *Cystoisospora* spp. or *Cryptosporidium* spp.
- Stress
- Immunocompromise

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Enteric viral infections and other intestinal parasites

CBC/BIOCHEMISTRY/URINALYSIS

Usually unremarkable; may be hemoconcentrated if dehydrated

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Fecal flotation (preferably centrifugation flotation technique) for oocysts (distinguish from pseudoparasitic *Eimeria* sp.); use sucrose solution (s.g., 1.27); zinc sulfate (s.g., 1.18). Acid-fast stains should be considered for detection of *Cryptosporidium* spp.
- Direct fluorescent antibody (DFA) assay is a sensitive dual assay (can detect *Giardia* cysts and *Cryptosporidium* oocysts very well) and can be performed at reference laboratories or university parasitology laboratories.
- Cystoisospora* oocysts should be 40 μm long; cysts of *Cryptosporidium* are approximately 5 μm diameter.

TREATMENT

- Usually treated as an outpatient
- Inpatient if debilitated
- Fluid therapy if dehydrated

MEDICATIONS

DRUG(S)

- Sulfadimethoxine—55 mg/kg PO on the first day, then 25–50 mg/kg once daily for up to 10–14 days or until dog is asymptomatic for *Cystoisospora* and fecal examination is negative for oocysts.
- Sulfadiazine/trimethoprim 15–30 mg/kg sulfadiazine PO daily up to 10 days; for toxoplasmosis in cats 15 mg/kg sulfadiazine PO q12h for 28 days.
- Amprolium (extra-label) for prevention: dogs, 30 mL of 9.6% solution in 1 gallon of drinking water or 1.25 grams of 20% powder in food to feed four puppies daily. Give as a sole source of food or water for 7 days prior to shipping; bitches can be given 9.6% solution as the sole source of water 10 days prior to whelping; or treatment: dogs, 100 mg q24h PO for 7 days; cats with *Cystoisospora* 60–100 mg total dose PO once daily for 7 days.
- No effective or approved treatment for *Cryptosporidium*; paromomycin 165 mg/kg q12h for 5 days has been suggested (extra-label); however, the drug is potentially nephrotoxic and ototoxic in cats and should not be used. Azithromycin has been used at a dosage of 7–10 mg/kg PO q12h for 7 days for eradication of *Cryptosporidium* spp. in dogs and cats; however, efficacy is unknown.
- Efficacy of tylosin at a dosage of 10–20 mg/kg PO q12h for 2–4 weeks is questionable.

- Clindamycin at 10 mg/kg PO q12h for 2–4 weeks recommended for toxoplasmosis.
- Ponazuril at 30–50 mg/kg for 3 consecutive days. Treatment can be repeated after 3- to 5-day break to increase efficacy. Single dosages of the drug are generally ineffective.

PRECAUTIONS

- As with most antibiotics, mild gastrointestinal upset can be seen with the antibiotics presented here.
- Amprolium—not recommended to be used over 12 days in puppies, exogenous thiamine in high doses may decrease efficacy; neurologic signs have been reported in some dogs—if observed, discontinue medication and begin thiamine supplementation.
- Sulfadimethoxine—diminished hepatic or renal function or urinary obstruction.
- Sulfadiazine/trimethoprim—potentially teratogenic; dog: irreversible KCS, Type 1 or Type 3 hypersensitivity (especially in larger breed dogs); cat: anorexia, leukopenia, anemia, hematuria.

CONTRAINdications/POSSIBLE INTERACTIONS

Sulfa medications—preexisting renal or hepatic disease.

FOLLOW-UP

Fecal flotation (for *Cystoisospora* spp. oocysts) or DFA (for *Cryptosporidium* spp. oocysts) 1–2 weeks following treatment.

COGNITIVE DYSFUNCTION SYNDROME

BASICS

DEFINITION

Syndrome associated with brain aging. Leads to alterations in awareness, decreased responsiveness to stimuli, deficits in learning and memory and agitation and anxiety. Subtle signs seen in early stages, referred to as cognitive decline may include alterations in activity and play and increasing anxiety.

PATHOPHYSIOLOGY

- Unclear which changes are associated with the clinical signs. • Decline in neurons, decrease in frontal lobe volume, increase in ventricular volume and neurotoxic deposits including lipofuscin, ubiquitin, and beta-amyloid. • Toxic free radicals (reactive oxygen species) increase with age because of chronic illness and stressors, age-related decline in mitochondrial efficiency, and decreased clearance mechanisms. • Possible correlation between cognitive decline and amount of beta-amyloid in the cerebral cortex and with increases in toxic free radicals.
- Compromised cerebral vascular blood flow and infarcts may be contributory.
- Neurotransmission is compromised. May be a decline in catecholamine and cholinergic transmission.

SYSTEMS AFFECTED

- Behavioral • Nervous

GENETICS

May be genetic correlation with respect to the distribution of beta-amyloid and the age at which it begins to accumulate.

INCIDENCE/PREVALENCE

- Clinical signs of cognitive dysfunction have been reported to arise in 41% of dogs over 14.
- Prevalence in dogs over 10 estimated at 14.2%. • Clinical signs reported to arise in 50% of cat over 15. • Prevalence in cats over 10 estimated at 35%. • Progressive—pets with existing signs more likely to develop additional signs over next 12 months.

SIGNALMENT

Species

Dogs and cats

Mean Age and Range

- Increased prevalence with increasing age.
- Neuropsychological testing in dogs and cats can identify a decline in memory and learning as early as 6 to 8 years of age. • Clinical signs may not be noticed by pet owners until several years after initial decline except in dogs trained to perform more specialized tasks (e.g., hearing ear, seeing eye, drug detection, agility).

SIGNS

Historical Findings

- Clinical signs have been categorized using the acronym DISHA. • Disorientation,

including getting lost in familiar environments, confusion, or inability to navigate through familiar routes (e.g., goes to the wrong side of door). • Interactions with humans or other animals may be altered (increased irritability, decreased interest in play/affection or increased attention seeking). • Sleep-wake cycle alterations (temporal disorientation), including night waking, vocalization and/or increased sleep during the day. • Housetraining and other previously learned behaviors might deteriorate. • Activity may be altered—including a decline in activity level, exploration, self-care, or even eating. However, as the condition progresses, activity levels may increase with signs of restlessness, pacing, aimless wandering, or compulsive activity disorders such as excessive licking. • Anxiety and agitation – signs may increase in pets with cognitive dysfunction.

Physical Examination

- No specific abnormalities associated with cognitive dysfunction. • Other age-related medical disorders might be noted.

CAUSES

- Exact cause is unknown and animals are variably affected. • Environmental factors may contribute to age related degeneration
- May also be predisposing genetic factors
- Diet, enrichment, and stress management may be in part preventive.
- See "Pathophysiology."

RISK FACTORS

- Chronic or recurrent illness or stress might lead to increased accumulation of reactive oxygen species. • Conditions that affect the cerebral vascular blood supply (e.g., systemic hypertension, anemia).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Any medical condition or disease process that affects the pet's mental attitude or behavior must be ruled out. • Pain (e.g., arthritis, dental disease) can lead to increased irritability, anxiety, and altered response to stimuli • If mobility is affected, the pet may become increasingly aggressive rather than retreat and may be less able to access its elimination area. • Impaired sight or hearing might lead to a decreased responsiveness or increased reactivity to stimuli. • Diseases of the urinary tract can cause inappropriate urination. • Organ failure, tumors, and immune diseases can also affect behavior.
- Endocrinopathies such as hypothyroidism can lead to behavior changes ranging from lethargy to aggression, while hyperadrenocorticism may be associated with altered sleep-wake cycles, housesoiling, panting, and polyphagia. Hyperthyroidism in cats can lead to increased irritability and

increased activity. • Diseases that affect the central nervous system or its circulation can affect behavior.

CBC/BIOCHEMICAL/URINALYSIS

Normal with CDS but concurrent disease processes common in aged dogs.

OTHER LABORATORY TESTS

Normal with CDS

IMAGING

- Used to rule out primary organic/structural cause. • Most important when there are abnormalities on the neurologic examination or when the onset is sudden; less likely to be of diagnostic value if signs are slowly progressive in the absence of other neurologic findings. • Pets with cognitive dysfunction may have increased ventricular volume and an overall decline in brain mass, but these findings alone are not diagnostic.

DIAGNOSTIC PROCEDURES

- Endoscopy, radiography, ultrasound, and other specialized diagnostic procedures may be necessary to rule out other causes of the clinical signs. • BAER testing or ophthalmologic referral might be indicated if sensory dysfunction is a suspected cause of the signs. • A therapeutic trial might be a useful diagnostic aid, for example, to determine the effects of pain management on the resolution of clinical signs.

PATHOLOGIC FINDINGS

Evaluation for brain pathology and staining for β -amyloid deposition might be indicative of the degree of cognitive dysfunction. This type of assessment is available only on postmortem samples.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient care

NURSING CARE

Depends on the type and severity of the clinical signs of cognitive dysfunction.

ACTIVITY AND TRAINING

- Maintain as much exercise, play, training, work, and other daily routines as is practical for the pet's age and health. • Maintaining mental and physical stimulation has been shown to reduce or slow progression of cognitive decline.

DIET AND NEUTRACEUTICALS

- Selected based on the pet's health assessment. • If the pet's health does not require the need for a special therapeutic diet, then a senior diet that has demonstrated efficacy in improving cognitive function should be used. • Hill's Prescription Diet b/d has been shown to improve memory, learning ability, and clinical signs of cognitive dysfunction syndrome. The diet is

(CONTINUED)

COGNITIVE DYSFUNCTION SYNDROME

supplemented with antioxidants such as vitamins E and C, selenium, beta carotene, and flavonoids and carotenoids, omega-3 fatty acids EPA and DHA, and carnitine and alpha lipoic acid, which may improve mitochondrial health. • A canine diet (Purina ProPlan Bright Minds 7+), which is supplemented with medium-chain triglycerides to provide ketones to aging neurons as an alternative energy source has also been shown to improve signs of cognitive function in older dogs. • Some natural supplements may help to improve the signs or slow the decline of cognitive dysfunction. ° Supplements containing phosphatidylserine (Senilife, CEVA Animal Health and Activait, VetPlus), apoaequorin (Neutricks, LLC), and SAMe (Novifit, Virbac Animal Health) have demonstrated some evidence of efficacy. ° For cats, SAMe and a diet containing fish oil, arginine, and antioxidants (not presently available commercially) has demonstrated a beneficial effect.

CLIENT EDUCATION

- Lifelong therapy is required, and concurrent medications may be necessary if the pet has multiple problems. • Any changes in the pet's health or behavior should be reported immediately, as this may be due to cognitive dysfunction or new health problems.
- Considering the pet's health and cognitive status, the owner must be advised on any limitations on what might be achieved.
- Signs are generally progressive; treatment is aimed at slowing the progression of the disease, not cure.

**MEDICATIONS****DRUG(S) OF CHOICE****Selegiline**

- Licensed for use in dogs in North America.
- Monoamine oxidase B inhibitor, in dogs, may contribute to improved catecholamine transmission, a decrease in free radicals, and a neuroprotective effect.
- Dog dose: 0.5–1 mg/kg PO q24h in the morning and maintained if effective.
- Reevaluate clinical signs for improvement after 1–2 months.
- Side effects might include occasional gastrointestinal upset and restlessness, and repetitive behavior at higher doses.

Propentofylline

- Not licensed in North America but is licensed in other countries.
- Methylxanthine.
- Purported to inhibit platelet aggregation and thrombus formation, make the red cells more pliable, and increase blood flow.
- For use in the treatment of dullness and lethargy in old dogs.

- May increase oxygen supply to the CNS without increasing glucose demand.
- Dog: 3 mg/kg PO q12h.

Nicergoline

- Alpha-adrenergic antagonist that may improve cognitive function through vasodilatory effects on cerebral circulation
- Dog: 0.25–0.5 mg/kg PO q12h.

Cats

- No therapeutic agents licensed for treatment of CDS.
- Selegiline (0.5–1 mg/kg PO q24h), propentofylline (1/4 of 50 mg tablet PO q24h) and nicergoline (0.25–0.5 mg/kg PO q24h) have been used off label in cats with anecdotal evidence of effect

CONTRAINdicATIONS

- Selegiline should not be used concurrently with MAO inhibitors such as amitraz, narcotics, alpha-adrenergic agents such as phenylpropanolamine or ephedrine, or selective serotonin reuptake inhibitors (e.g., fluoxetine) or tricyclic antidepressants (e.g., clomipramine). • A 2-week washout is suggested following most tricyclic antidepressants and up to 5 weeks following fluoxetine before starting selegiline.

PRECAUTIONS

- Choose medications that are least sedating and least anticholinergic. • Potential drug interactions must be considered with concurrent use of drugs and over-the-counter medications.

POSSIBLE INTERACTIONS

See "Contraindications."

ALTERNATIVE DRUG(S)

- Enhancement of the noradrenergic system with drugs such as adrafinil and modafinil to improve alertness and exploration.
- Anti-inflammatory medication, and natural supplements such as gingko biloba and curcumin might be considered based on preliminary work in other species.
- Medication used in humans for Alzheimer's disease to enhance cholinergic transmission might be useful, but doses and pharmacokinetics in dogs have not been determined. Potential side effects include nausea, vomiting, diarrhea, and sleep-wake disturbances. • Anxiolytics such as buspirone, drugs to help induce sleep such as benzodiazepines, or antidepressants such as fluoxetine (not in conjunction with selegiline) might be considered to treat anxiety and apathy. • Natural supplements might help to normalize sleep-wake cycles or reduce anxiety (e.g. melatonin, valerian, L-theanine, alpha-casozepine, Harmonease [VPL], Adaptil and Feliway [CEVA]).

**FOLLOW-UP****PATIENT MONITORING**

- If a drug or diet is dispensed, then therapeutic response should be evaluated after 30–60 days and the dose adjusted or treatment changed if there is insufficient improvement. • If the pet is stable, twice-yearly checkups are recommended for senior pets unless new problems arise before a reassessment is due.

PREVENTION/AVOIDANCE

- Providing an enriched environment and as much physical activity as is practical for the pet's age and health may help to prevent or delay the onset of cognitive decline. • Early intervention is the best way to slow the progress or prevent complications.

EXPECTED COURSE AND PROGNOSIS

- Diet and medication should control the clinical signs and slow progression in a majority of cases. • Because of the pet's increasing age, cognitive decline may advance and other concurrent health problems are likely to arise.

**MISCELLANEOUS****SYNOMYMS**

- Age-related cognitive and affective disorders, involutive depression, dysthymia
- Dementia • Senility

ABBREVIATIONS

- BAER = brainstem auditory evoked response • CDS = cognitive dysfunction syndrome • CNS = central nervous system
- MAO = monoamine oxidase • SAMe = S-adenosyl-L-methionine-tosylate disulfate

COLD AGGLUTININ DISEASE

BASICS

OVERVIEW

- A rare Type II autoimmune disorder in which antierythrocyte antibodies have enhanced activity at temperatures < 99°F (37.2°C) and usually < 88°F (31.1°C).
- Cold agglutinins are typically IgM, although IgG and IgG-IgM mixed have been reported. • Cold agglutinins with low thermal amplitude usually associated with direct erythrocyte agglutination at low body temperatures in the peripheral microvasculature and with acro-cyanotic disease or other peripheral vaso-occlusive phenomena, all initiated or intensified by cold exposure.
- Fixation of complement and hemolysis is a warm reactive process occurring at higher body temperatures; at those temperatures cold agglutinins have eluted off the RBC, lowering the rate of complement binding. Therefore, acute hemolytic anemias are uncommon.
- Most cold agglutinins cause little or no shortening of erythrocyte lifespan.
- High thermal amplitude cold agglutinins (rare)—may cause chronic hemolysis; the resulting anemia is often mild and stable, but exposure to cold may greatly augment binding of cold agglutinins and complement-mediated intravascular hemolysis.

SIGNALMENT

- Rare disorder in dogs and cats.
- Low titer of naturally occurring cold agglutinins (usually 1:32 or less) may be found in healthy dogs and cats; this is without clinical significance.
- Genetic basis, mean age and range, breed, and sex predilections unknown.
- More likely to occur in colder climates.

SIGNS

- Often a history of cold exposure.
- Acrocyanosis associated with sludging of erythrocyte agglutinates in cutaneous microvasculature.
- Erythema.
- Skin ulceration with secondary crusting.
- Dry, gangrenous necrosis of ear tips, tail tip, nose, and feet.
- Affected areas may be painful.
- Anemia may or may not be an important feature; clinical signs include pallor, weakness, tachycardia, tachypnea, icterus, pigmenturia, mild splenomegaly, and soft heart murmur.

CAUSES & RISK FACTORS

- Primary disease—idiopathic.
- Secondary disease—associated with upper respiratory infection (cats), neonatal isoerythrolysis, lead intoxication (dogs), and neoplasia.
- Cold exposure a risk factor.
- In humans, cold agglutinin disease has been described in liver transplant cases after tacrolimus administration.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diagnosis made by historical findings (cold exposure), results of physical examination, demonstrating cold agglutination in vitro.
- Skin lesions—cutaneous vasculitis, hepatocutaneous syndrome, erythema multiforme, toxic epidermic necrolysis, dermatomyositis, DIC, SLE, lymphoreticular neoplasms, frostbite, lead poisoning, and pemphigus.
- Anemia—warm antibody hemolytic anemia; other causes of anemia.
- Macroscopic hemagglutination in vitro—dysproteinemias may lead to rouleaux formation, mimicking erythrocyte agglutination on a glass slide.

CBC/BIOCHEMISTRY/URINALYSIS

- Autoagglutination at room temperature.
- Laboratory abnormalities secondary to hemolysis.

OTHER LABORATORY TESTS

- Cold agglutinins should be suspected when blood in heparin or EDTA on a glass slide agglutinates spontaneously at room temperature with enhancement at 39°F (3.9°C), and the erythrocytes disperse again upon warming to 99°F (37.2°C).
- If no agglutination can be induced in vitro, it is inconceivable for it to occur in vivo in extremities.
- Doubtful cases can be confirmed by Coombs' test at 39°F and 99°F.
- Coombs' test at 99°F—cold agglutinins usually not detected because they may be eluted off the erythrocytes during washing; thus test requires the use of anti-complement factor serum.
- Coombs' test at 39°F—incidence of a positive result in healthy dogs has been reported to be > 50%, which may be caused by unspecific binding of the reagent itself or by binding of naturally occurring non-pathogenic low-titer cold agglutinins.
- The globulin class can be established by immunolectrophoresis of a concentrated eluate of the patient's erythrocytes, which may be important for prognosis and treatment.

PATHOLOGIC FINDINGS

- Dermal necrosis.
- Ulceration with secondary features of opportunistic infections.
- Vascular thrombosis with evidence of ischemic necrosis.

TREATMENT

- The patient should be hospitalized in a warm environment until the disease is non-progressive.
- Supportive care and

wound management depend on clinical signs; if necrosis involving the tail tip or feet is severe, amputation may be required.

- Splenectomy is of little assistance in patients with IgM-mediated hemolytic disorders but may be helpful in those with therapy-resistant IgG-mediated hemolytic anemia.
- Inform the client to keep the patient in a warm environment at all times to prevent relapse.
- Exercise restriction.
- In humans, therapy is often ineffective. Plasmapheresis, intravenous gamma globulins, and rituximab ± fludarabine have been beneficial in some patients.

MEDICATIONS

DRUG(S)

IgM Cold Agglutinins

- Immunosuppressive therapy is not very effective against IgM-mediated disorders but can be tried (i.e., corticosteroids, leflunomide, cyclosporine).
- Plasmapheresis.
- Folic acid supplementation.

IgG Cold Agglutinins

Immunosuppressive therapy

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Monitor patient for signs of infection secondary to immunosuppressive therapy.
- Do not use cold IV fluids.

FOLLOW-UP

- A patient with known cold agglutinin disease should be kept in warm environments at all times.
- Cold agglutinin disease usually characterized by acute onset and rapid progression.
- Prognosis is guarded to fair.
- Recovery may take weeks.

COLIBACILLOSIS

BASICS

DEFINITION

- *Escherichia coli*—Gram-negative member of the *Enterobacteriaceae*; normal inhabitant of the intestine of most mammals; along with other infectious agents, may increase the severity of parvovirus infections.
- Acute infection of puppies and kittens in the first week of life; characterized by septicemia and multiple organ involvement.
- Isolation from stool of young animals— inconclusive evidence of pathogenic potential because it is normal flora; need to assess virulence potential using molecular methods.
- Isolation from blood cultures or internal organs—constitutes better evidence of causality.
- Infection of older dogs and cats— documented; individual strains poorly characterized in regard to virulence attributes.

PATHOPHYSIOLOGY

- Virulence factors—not well defined; likely *E. coli* as a cause of septicemia in neonatal dogs and cats reflects a balance between immunologic immaturity and intestinal barrier function of the host and resident enteric *E. coli* rather than a single virulent strain.
- ETEC, AEEC, UPEC, and CNF+ *E. coli* strains—recovered from dogs.
- Similar *E. colis* isolated from cats (strains poorly characterized).
- Intestinal strains colonize and multiply in the small intestine; ETEC then elaborates uncharacterized adhesins and enterotoxins (STa); the attaching and effacing factor of AEEC (EAE+).
- Many strains of *E. coli* from dogs and cats are hemolytic.
- A new type of *E. coli* has been found in boxer dogs with IBD (granulomatous colitis) characterized by ability to adhere, to invade, and to replicate in macrophages, resulting in a tremendous inflammatory response within the intestinal wall.

SYSTEMS AFFECTED

- Neonates—small intestine (enteritis); multiple body systems (septicemia).
- Puppies/kittens and adults—small intestine (enteritis); urogenital (cystitis, endometritis, pyelonephritis, prostatitis); mammary gland (mastitis); large intestine (colitis).

GENETICS

Boxer dogs may be predisposed to large bowel colitis.

INCIDENCE/PREVALENCE

- Few statistics available.
- More common in neonatal puppies and kittens < 1 week old that have not received any or adequate amounts of colostrum.

- Problem in overpopulated kennels and catteries.
- Sporadic accounts in older dogs and cats (mainly diarrhea and urogenital problems).
- Purulent skin disease and otitis and meningoencephalomyelitis.

Dogs

- ETEC—2.7–29.5% of diarrheic dogs; strains: STa/STb+/-, and CNF+ isolated from diarrheic dogs along with hemolysin.
- AEEC/EPEC—diarrheic cats; strains: EAE+, hemolysin.
- *E. coli* (usually β -hemolytic)—major cause of septicemia in newborn puppies exposed *in utero*, during birth, or from mastitic milk.

Cats

- AEEC/EPEC—diarrheic cats; strains: EAE+, hemolytic.
- ExPEC—acute necrotizing and hemorrhagic pneumonia and pleuritis; strains: CNF-1 plus other adhesions.
- UPEC—cystitis; strains: CNF-1+, P-fimbria, hemolysin.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat

Breed Predilections

Boxer dogs may be predisposed to large bowel colitis.

Mean Age and Range

- Neonatal infections common (diarrhea, septicemia) up to 2 weeks of age.
- Puppies/kittens and adult animals—sporadic disease often associated with other infectious agents.

Predominant Sex

None

SIGNS

General Comments

E. coli—one of the most common causes of septicemia and death in puppies and kittens.

Historical Findings

- Neonates—sudden-onset vomiting, weakness/lethargy, diarrhea, cold skin; one or more animals affected in a litter.
- Puppies/kittens and adults—vomiting and diarrhea.

Physical Examination Findings

- Neonates—acute depression, anorexia, vomiting, tachycardia, weakness, hypothermia, cyanosis, watery diarrhea.
- Puppies/kittens and adults—ETEC associated with acute vomiting, diarrhea, anorexia, rapid dehydration, fever.

CAUSES

- *E. coli*—member of the endogenous microbial flora of the adult's gastrointestinal tract, prepuce, and vagina.
- Many strains isolated from case material are poorly characterized in regard to virulence

factors; strains need to be evaluated by molecular methods to assess virulence potential.

- Often found in older dogs and cats concurrently with other infectious agents.

RISK FACTORS

Neonates

- Bitch/queen in poor health and nutritional status—unable to provide good care and colostrum to offspring.
- Lack of colostrum or insufficient colostrum.
- Dirty birthing environment.
- Difficult or prolonged labor and birth.
- Crowded facilities—buildup of feces in environment, greater chance for fecal-oral spread of infection.

Puppies/Kittens and Adults

- Concurrent disease—parvovirus; heavy parasitism
- Antimicrobial drugs—upset microbial flora of gastrointestinal tract
- Immunosuppression
- Post-parturient mastitis
- Venous catheterization

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious enteritis—viral: feline panleukopenia, FeLV, FIV, enteric coronavirus, canine parvovirus, rotavirus, canine distemper; bacterial: *Salmonella*, *E. coli*, *Campylobacter jejuni*, *Yersinia enterocolitica*, bacterial overgrowth syndrome, *Clostridium difficile*, *Clostridium perfringens*; parasitic: hookworms, ascarids, whipworms, *Strongyloides*, *Giardia*, coccidia, cryptosporidia, rickettsiae (salmon poisoning).
- Dietary-induced enteritis—overeating; abrupt changes; starvation; thirst; food intolerance or allergy; indiscretions (e.g., foreign material or garbage).
- Drug- or toxin-induced enteritis—antimicrobial agents; antineoplastic agents; anthelmintics; heavy metals; organophosphates.
- Extra-intestinal disorders or metabolic diseases—acute pancreatitis; hypoadrenocorticism; liver or kidney disease; pyometra; peritonitis.
- Functional or mechanical ileus—gastric-dilatation volvulus; intussusception; electrolyte disorder; gastrointestinal foreign body.
- Neurologic disorders—vestibular disease; psychogenic such as fear, excitement, pain.
- Fading neonates.

CBC/BIOCHEMISTRY/URINALYSIS

- Few abnormalities noted, owing to rapidity of death in puppies.

COLIBACILLOSIS

C

- Adults with enteritis may show chemistry abnormality, depending on the state of dehydration.

DIAGNOSTIC PROCEDURES

- Antimicrobials—produce false-negative results if used before obtaining bacterial cultures.
- Routine bacterial culture and identification of *E. coli* from blood (antemortem) or necropsy tissue (bone marrow, heart blood, liver/spleen, brain, mesenteric lymph node) required.
- Appropriate testing of strains—identify adhesins and toxins (by DNA colony hybridization, PCR) in ETEC and VTEC strains.

PATHOLOGIC FINDINGS

- Acute enteritis
- Mucosal inflammation of small intestine
- Petechiae and hemorrhagic lesions on serosal surface of gastrointestinal mucosae and all body cavities
- Fibrin on abdominal wall
- Necrosis of liver/spleen

TREATMENT

APPROPRIATE HEALTH CARE

Acutely ill puppies/kittens—inpatients; good nursing care.

NURSING CARE

- Balanced parenteral polyionic isotonic solution (lactated Ringer's)—restore fluid balance.
- Oral hypertonic glucose solution—for secretory diarrhea, as required.

ACTIVITY

Acutely ill immature puppies/kittens (bacteremic/septicemic)—restricted activity, cage rest, monitoring, and warmth.

DIET

Puppies—likely to still be nursing when affected; good nursing care needed with bottle-feeding and/or IV nutrients.

CLIENT EDUCATION

Neonates—life-threatening with poor prognosis.

MEDICATIONS

DRUG(S) OF CHOICE

- Antimicrobial therapy—*septicemia*.
- Guided by culture and susceptibility (MIC) testing of *E. coli*; empiric therapy until results available.
- Amikacin: dog and cat, 20 mg/kg IV q24h.
- Cefazolin: dog and cat, 5–15 mg/kg IV q6–8h.
- Cefoxitin: dog and cat, 30 mg/kg once, then 15 mg/kg IV q4h.

- Enrofloxacin: dog, 10 mg/kg IV q24h; cat, 5 mg/kg IV q24h; avoid use in pregnant, neonatal, or growing animals (medium-sized dogs < 8 months of age; large or giant breeds < 12–18 months of age) because of cartilage lesions.
- Ticarcillin-clavulanate: dogs and cats, 50 mg/kg PO q6h.

CONTRAINdications

- Fluoroquinolones—enrofloxacin: avoid use in pregnant, neonatal, or growing animals (medium-sized dogs < 8 months of age; large or giant breeds < 12–18 months of age) because of cartilage lesions.
- Chloramphenicol and trimethoprim-sulfa are likely ineffective for *E. coli* septicemia.

PRECAUTIONS

Ensure adequate hydration and perfusion when using aminoglycosides.

FOLLOW-UP

PATIENT MONITORING

- Blood culture—puppies/kittens with fever and/or diarrhea.
- Monitor temperature—with signs of lethargy and/or depression.
- Monitor behavior—eating, drinking, and/or nursing; adequate weight gain.

PREVENTION/AVOIDANCE

- Bitch/queen—good health; vaccinated; good nutritional status.
- Clean and disinfect parturition environment (1:32 dilution of bleach); clean bedding after birth frequently.
- Ensure adequate colostrum intake of all littermates.
- Separate mother with nursing litter from other cats or dogs.
- Keep the density low in kennel or cattery rooms.
- Wash hands and change clothes and shoes after handling other cats/dogs and before dealing with neonates.

EXPECTED COURSE AND PROGNOSIS

- Neonates—life-threatening; prognosis often poor; neonate may rapidly succumb; quick treatment with supportive care essential for survival.
- Adults—self-limiting with supportive care, depending on the degree of dehydration and existence of other diseases.

MISCELLANEOUS

AGE-RELATED FACTORS

Neonates—greatest risk of infection and subsequent septicemia.

ZOONOTIC POTENTIAL

- Little documented information of the virulence potential of *E. coli* strains from dogs or cats for humans, although recently, similarities have been found between canine fecal and UTI *E. coli* and human *E. coli* associated with UTI, sepsis, and meningitis; growing concern for the presence of multidrug resistance determinants in *E. coli* strains from companion animals.
- Always wash hands after handling animals (especially patients with diarrhea) because of the risk of acquiring other infectious agents (e.g., salmonellae, *Giardia*).
- Caution: keep children and immunosuppressed persons away from pets with diarrhea.

SYNONYMS

- *E. coli* septicemia
- Neonatal enteritis

ABBREVIATIONS

- AEEC = attaching and effacing *E. coli*
- CNF = cytotoxic necrotizing factor
- EAE = experimental autoimmune encephalomyelitis
- EPEC = enteropathogenic *E. coli*
- ETEC = enterotoxigenic *E. coli*
- ExPEC = extraintestinal pathogenic *E. coli*
- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus
- IBD = inflammatory bowel disease
- MIC = minimal inhibitory concentration
- PCR = polymerase chain reaction
- UPEC = uropathogenic *E. coli*
- UTI = urinary tract infection
- VTEC = verotoxigenic *E. coli*

COLITIS AND PROCTITIS

C

BASICS

DEFINITION

- Colitis—inflammation of the colon (large intestine). Colitis may be acute and self-limiting or chronic.
- Colitis does not infer causality, and an underlying cause of the colitis should be investigated, particularly in chronic cases.
- Proctitis—inflammation of the rectum.

PATHOPHYSIOLOGY

- Inflammation of the colon causes accumulation of inflammatory cytokines, disrupts tight junctions between epithelial cells, stimulates colonic secretion, stimulates goblet cell secretion of mucus, and disrupts motility.
- These mechanisms reduce the ability of the colon to absorb water and electrolytes, and store feces, which causes frequent diarrhea, often with mucus and/or frank blood.

SYSTEMS AFFECTED

Gastrointestinal

GENETICS

- Breeds predisposed to histiocytic ulcerative colitis (granulomatous colitis) include boxers, French bulldogs, and perhaps border collies.
- German shepherd dogs are predisposed to perianal fistulae that can be associated with colitis.

INCIDENCE/PREVALENCE

- Approximately 30% of dogs with chronic diarrhea examined at one university hospital.
- 75% of dogs with a food-responsive enteropathy had clinical signs of colitis.
- Prevalence of colitis is probably higher than perceived, because many diarrheic dogs and cats can have mixed bowel diarrhea (component of small and large bowel diarrhea).

GEOGRAPHIC DISTRIBUTION

N/A except for certain infectious diseases (pythiosis: predominantly Gulf Coast and southeast United States although becoming more widespread; histoplasmosis: Midwest, eastern United States).

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Boxer dogs, French bulldogs, border collies (granulomatous colitis).
- German shepherd dogs: perianal fistulas and concurrent colitis.

Mean Age and Range

Any age; boxers, French bulldogs usually younger (< 2 years of age).

SIGNS

Historical Findings

- Fecal consistency can be variable from semiformed to liquid.

- Marked increase in frequency of defecation (6–15 times per day) with small fecal volume.
- Tenesmus.
- Increased fecal mucus.
- Hematochezia; cats may have formed feces with hematochezia.
- Occasional dyschezia (painful defecation).
- Vomiting in approximately 30% dogs.
- Weight loss is less common, but can be seen with colonic lymphoma, histoplasmosis, and pythiosis.

Physical Examination Findings

- Usually unremarkable.
- Rectal examination may reveal a thickened and irregular colorectal mucosa.
- Dogs with GC may show systemic signs of weight loss and anorexia.

CAUSES

- Dietary: food-responsive enteropathy is a common and important cause of colitis; dietary indiscretion; food intolerance.
- Drug administration (antibiotics, NSAIDs).
- Infectious—*Trichuris vulpis*, *Entamoeba histolytica*, *Balantidium coli*, *Tritrichomonas foetus*, *Clostridium perfringens* and *Clostridium difficile*, *Campylobacter jejuni* and *Campylobacter coli*, *Yersinia enterocolitica*, *Prototheca*, *Histoplasma capsulatum*, and pythiosis/phycomycosis.
- Traumatic—foreign body, abrasive material.
- Inflammatory—secondary to pancreatitis (transverse colitis).
- Inflammatory/immune—IBD (lymphoplasmacytic, eosinophilic, granulomatous) colitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Neoplasia—colonic lymphoma, adenocarcinoma, sarcomas.
- Irritable bowel syndrome.
- Colorectal polyps do not typically cause signs of colitis, but instead cause hematochezia in association with formed stool that is defecated at normal frequency.
- Cecal inversion.
- Ileoceccocolic intussusception.

CBC/BIOCHEMISTRY/URINALYSIS

- Results usually unremarkable; neutrophilia with a left shift can be seen with severe inflammatory causes; eosinophilia secondary to eosinophilic colitis, parasitism, histoplasmosis, and pythiosis/phycomycosis.
- Mild microcytic, hypochromic anemia may occur secondary to chronic intestinal bleeding and iron deficiency.
- Hyperglobulinemia in some patients (especially cats) with chronic disease.

OTHER LABORATORY TESTS

- Examination of fecal centrifugation flotation, direct fecal smear (only on fresh diarrheic feces), fecal bacterial toxin

immunoassays (*C. perfringens* enterotoxin and *C. difficile* toxins A and B), and PCR for bacteria and toxin genes when indicated, serum ELISA test for *Pythium* when indicated.

- Rectal scraping for cytology for *Histoplasma* organisms.
- Fecal PCR or In Pouch TF medium for culture of *Tritrichomonas foetus*.

IMAGING

- Abdominal radiographs—usually unremarkable.
- Abdominal ultrasonography—may reveal masses, diffuse thickening or altered architecture of the colon, or enlarged associated lymph nodes.
- Contrast studies—barium may be administered transcolonically to evaluate the colorectal mucosa for irregularities or filling defects and colorectal strictures; however, the procedure is rarely indicated in dogs and cats with colitis and is of low sensitivity in general.

OTHER DIAGNOSTIC PROCEDURES

- Colonoscopy with biopsy—procedure of choice for diagnosis of chronic or refractory cases. Animals must be adequately prepared for colonoscopy by being fasted and administered osmotic cathartics such as Osmoprep or Golytely; mucosal changes visible grossly in animals with colitis include disappearance of submucosal blood vessels, granular appearance of mucosa, hyperemia, excessive mucus, ulceration, pinpoint hemorrhage (small ulcerations), or mass(es).
- One should always obtain multiple biopsy specimens from multiple locations (ascending colon, transverse colon, descending colon, and rectum) because the extent of mucosal change assessed histologically does not necessarily reflect the severity of the colitis or proctitis.

PATHOLOGIC FINDINGS

Histopathologic findings depend on the histologic type of colitis—lymphoplasmacytic, eosinophilic, or histiocytic represent the most common subtypes; hyperplastic mucosa may be seen with irritable bowel syndrome; various infectious agents may be seen with special stains.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient medical management unless diarrhea is severe enough to cause dehydration and warrant hospitalization.

NURSING CARE

Give dehydrated patients balanced electrolyte solution with potassium IV or SC.

DIET

- There is no inherent benefit to fasting patients with diarrhea, unless the cause of the diarrhea has an osmotic component.

COLITIS AND PROCTITIS

(CONTINUED)

- Animals that do not have severe clinical signs can be managed with an elimination diet or hypoallergenic diet for 2 weeks. The response to dietary therapy is typically seen within the first 5–7 days following dietary implementation. Obtain a comprehensive dietary history to optimize selection of a novel, single protein source diet. Strict dietary compliance is pivotal during this trial period to optimize interpretation of response.
- Fiber supplementation with poorly fermented fiber (e.g., bran and alpha-cellulose) is recommended to increase fecal bulk, improve colonic muscle contractility, and bind fecal water to produce formed feces.
 - Some fermentable fiber sources (e.g., psyllium or a diet containing beet pulp or fructooligosaccharides) may be beneficial—short-chain fatty acids produced by fermentation may be beneficial for colonocyte function.

CLIENT EDUCATION

Treatment may be intermittent and long-term in patients with inflammatory/immune-mediated colitis. Recurrences can be seen, particularly when drug therapy is being tapered.

SURGICAL CONSIDERATIONS

Segments of colon severely affected by fibrosis from chronic inflammation and subsequent stricture formation may need surgical excision, especially in patients with the granulomatous form of the disease; cecal inversion and ileoceccocolic intussusception require surgical intervention; pythiosis/phymomycosis often requires surgical excision or debulking.

MEDICATIONS

DRUG(S) OF CHOICE

Antimicrobial Drugs

- *Trichuris*—fenbendazole (50 mg/kg PO q24h for 5 consecutive days, repeat in 3 months).
- *Entamoeba, Balantidium*—metronidazole (25 mg/kg PO q12h for 5–7 days).
- *Tritrichomonas foetus*—Ronidazole (30 mg/kg q24h for 14 days).
- *Clostridium perfringens*—metronidazole (10 mg/kg PO q12h for 5 days), tylosin (5–10 mg/kg PO q24h for 5 days), ampicillin or amoxicillin (20 mg/kg PO q8h for 5 days).
- *Clostridium difficile*—metronidazole (10 mg/kg PO q12h for 5 days),
- *Campylobacter* spp.—Erythromycin (10–15 mg/kg PO q8h), or azithromycin (5–10 mg/kg PO q24h) can be given for 7–10 days. Azithromycin is better tolerated than erythromycin,
- *Yersinia* spp.—select the drug on the basis of bacterial culture and sensitivity testing.
- *Prototheca*—no known treatment.

- *Histoplasma*—itraconazole (dogs, 10 mg/kg PO q24h; cats, 5 mg/kg PO q12h; several months of therapy is necessary); amphotericin B (0.25–0.5 mg/kg slow IV q48h up to cumulative dose of 4–8 mg/kg) in advanced cases.
- Pythiosis—itraconazole (10 mg/kg PO q24h) and terbinafine (10 mg/kg PO q24h) are the drugs of choice following surgical debridement of affected portions of bowel. Antifungal therapy is often administered for 3–4 months or longer in affected animals.

Anti-inflammatory and Immunosuppressive Drugs for Inflammatory/Immune Colitis

- Sulfasalazine (dogs, 25–40 mg/kg PO q8h for 3–6 weeks with a progressive tapering of the dose throughout the course of drug therapy; cats, 20 mg/kg PO q12h for 3 weeks). Use with caution, particularly in cats, in which adverse effects on the gastrointestinal tract and kidneys can be observed. Sulfasalazine has been associated with irreversible KCS.
- Corticosteroids—prednisone for dogs and prednisolone for cats: 1–2 mg/kg PO q12h for 5–7 weeks with gradual, progressive tapering of dose. Most cats can be started off on 5 mg (per cat) q12h with gradual taper. Never use more than 50 mg total of prednisone (per day) for any animal, regardless of size.
- Azathioprine (dogs) 1–2 mg/kg PO q24h for 10–14 days followed by a taper to 1–2 mg/kg q48h for 4–6 weeks. The drug is markedly myelosuppressive in cats and should be avoided even though a lower dose (0.3 mg/kg PO q48h) for this species has been published.

- Chlorambucil is an effective immunomodulator in both dogs and cats and is usually administered in conjunction with prednisone or prednisolone. Several dosing regimes have been published: cats, 2 mg per cat q3–4 days for 2–3 months (or longer if managing lymphoma) or 15 mg/m² given for 4 consecutive days every 3 weeks for 2–3 months; dogs, 0.1–0.2 mg/kg PO q24h for 8–12 weeks for immune disease, with gradual tapering of dose over the course of therapy.
- Cyclosporine (5 mg/kg PO q12–24h for 6 weeks for immune disease).
- Sulfasalazine or other 5-ASA drugs—may be a reasonable consideration following assessment to dietary therapy for 2 weeks, and is typically reserved for cases with mild colitis before considering prednisone therapy.
- Granulomatous colitis is managed with fluoroquinolones such as enrofloxacin at 10 mg/kg q 24h for 6–8 weeks.
- Reconsider the diagnosis carefully in dogs that do not respond to dietary therapy, fenbendazole administration, and tylosin therapy.

Motility Modifiers (Indicated for symptomatic relief only in animals with intractable diarrhea and must be avoided in all animals with a suspected infectious enteropathy)

- Loperamide (0.1 mg/kg PO q8–12h).
- Diphenoxylate (0.1–0.2 mg/kg PO q8h).
- Propantheline bromide (0.25–0.5 mg/kg PO q8h) if colonic spasm is contributing to clinical signs.

Anthelmintics

- Broad-spectrum anthelmintics such as fenbendazole (50 mg/kg q24h for 5 consecutive days) in conjunction with dietary therapy (elimination diet) for the first 2 weeks is the mainstay of therapy for most patients with chronic colitis, unless the animal is a boxer breed that should have endoscopy and biopsy to confirm the granulomatous colitis that has a different therapy and prognosis.
- Tylosin is a highly effective antimicrobial that can be administered following assessment of response to dietary and anthelmintic therapy.

CONTRAINDICATIONS

Anticholinergics

PRECAUTIONS

- Monitor patients on sulfasalazine for signs of keratoconjunctivitis sicca. Measure tear production (Schirmer tear test) at baseline and every 2 weeks throughout the course of therapy. Discontinue drug if tear production decreases.
- Monitor patients on azathioprine for bone marrow suppression—CBC every 2–3 weeks; stop treatment or go to alternate day if WBC count falls below 3,000 cells/ μ L.
- Azathioprine can also increase the risk of pancreatitis and should be used extremely cautiously in any dog at increased risk for pancreatitis. Azathioprine can also cause a hepatopathy.
- Chlorambucil can cause a progressive neutropenia and a CBC should be repeated q2–3 weeks in all animals receiving this drug.
- Cyclosporine can cause hepatotoxicity and a chemistry panel should be performed as baseline before starting the drug and repeated q2–3 months.
- Amphotericin B is nephrotoxic and requires close assessment of renal function via urinalyses and serum biochemistry panels.
- Enrofloxacin-resistant cases of granulomatous colitis are increasing in prevalence due to antimicrobial resistance, necessitating alternative antimicrobial therapy in select cases.

FOLLOW-UP

PATIENT MONITORING

Infrequent recheck examinations or client communication by phone. Recheck of CBC is

(CONTINUED)

COLITIS AND PROCTITIS

C

important for animals on immunomodulatory therapy.

PREVENTION/AVOIDANCE

- Avoid exposure to infectious agents (e.g., other dogs, contaminated foods, moist environments).
- Avoid abrupt dietary changes.

POSSIBLE COMPLICATIONS

Recurrence of signs without treatment, when treatment is tapered, and with progression of disease.

EXPECTED COURSE AND PROGNOSIS

- Most bacterial and parasitic infectious causes have an excellent prognosis with a high likelihood of cure following therapy.
- *Protorheca*—grave; no known treatment except excision.
- *Histoplasma* spp.—poor in advanced or disseminated disease; mild-to-moderate cases generally respond to therapy.
- Pythiosis/phycomycosis—poor long-term prognosis in most animals, despite surgical intervention, given advanced stage of disease at diagnosis.
- Cecal inversion, ileoceccolic intussusception—good with surgical resection if diagnosed in a timely fashion.
- Inflammatory—fair to good with treatment in patients with lymphoplasmacytic, eosinophilic, and granulomatous colitis.

- Most dogs with mild to moderate nonspecific colitis respond favorable to a combination of fenbendazole, feeding of an elimination or hypoallergenic diet, and tylosin therapy.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Inflammatory/immune disease and infectious agents may also affect the small intestine concurrently.

ZOONOTIC POTENTIAL

Entamoeba, *Balantidium*, *Campylobacter jejuni*, *Yersinia* in immunosuppressed individuals.

PREGNANCY/FERTILITY/BREEDING

Caution with drug use—corticosteroids, azathioprine, cyclosporine, antifungals, and antibiotics.

SYNOMYS

- Inflammatory bowel disease (IBD)
- Large bowel diarrhea

COLITIS, HISTIOCYTIC ULCERATIVE

BASICS

OVERVIEW

- Relatively common cause of colitis in boxer breeds and infrequently seen in French bulldogs and border collies.
- Boxer colitis is also referred to as granulomatous colitis (GC) in light of the granulomatous inflammation (macrophages) in the colon.
- Etiology of GC is an adherent-invasive *E. coli* (AIEC) strain.

SIGNALMENT

- Dogs; primarily affects young boxers, usually less than 3 years of age.
- Reported in French bulldogs and border collies less frequently.

SIGNS

- Bloody, mucoid diarrhea with marked increase in the frequency of defecation.
- Tenesmus.
- Weight loss and anorexia can occur and debilitation may develop.

CAUSES & RISK FACTORS

- GC appears to be a genetic disorder in boxer breeds associated with reduced macrophage phagocytic function and an inability to kill adherent-invasive *E. coli*.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of colitis—non-histiocytic IBD (lymphocytic plasmacytic, eosinophilic colitis), other infectious causes of colitis (pythiosis), parasitic colitis (whipworms), food-responsive diarrhea.
- Cecal inversion.
- Ileocolic intussusception.
- Neoplasia—lymphoma, adenocarcinoma.
- Foreign body.
- Colorectal polyps. Dogs with colorectal polyps do not have diarrhea or increased mucus in their stools, and instead have a normal defecation frequency with formed stools coated with frank blood.
- Irritable bowel syndrome.
- Differentiate by clarifying the history (colitis vs. colorectal neoplasia), fecal floatations, abdominal imaging, and colonoscopy or proctoscopy and biopsy.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually unremarkable; microcytic anemia may be present in boxer dogs with GC secondary to intestinal bleeding.
- Chemistry panel may reveal hypoalbuminemia, electrolyte abnormalities, and prerenal azotemia in dogs with severe diarrhea and anorexia.

OTHER LABORATORY TESTS

N/A

IMAGING

Abdominal ultrasound in boxer dogs with GC often reveals mild or moderate mesenteric or sublumbar lymphadenomegaly, and the colonic wall can appear thickened.

DIAGNOSTIC PROCEDURES

- Proctoscopy or colonoscopy to obtain colonic biopsies.
- Most boxer dogs with GC have involvement of the descending colon, underscoring the diagnostic utility of proctoscopy.
- Common changes in appearance to the colonic wall include erythema, irregularity, and ulceration of the colonic and rectal wall.

MICROBIOLOGIC TESTING

E. coli is commonly isolated on routine bacteriologic media from feces of both healthy dogs and dogs with diarrhea. However, attempts to isolate *E. coli* from colonic biopsies is recommended for sensitivity testing and optimization of antimicrobial therapy.

PATHOLOGIC FINDINGS

- Histopathologic lesions include neutrophilic inflammation, epithelial ulceration, crypt hyperplasia and distortion, decreased numbers of goblet cells, and large numbers of macrophages that stain positive with periodic acid-Schiff (PAS) stain.
- The presence of *E. coli* within macrophages can be confirmed using fluorescent in-situ hybridization (FISH).

TREATMENT

- Outpatient medical management following confirmation of the diagnosis.
- Antimicrobial therapy utilizing fluoroquinolones is the mainstay of therapy.
- Diet change to include a moderately fermentable fiber source can be used in cases that do not show complete resolution of diarrhea.

MEDICATIONS

DRUG(S)

Antimicrobials—First-Line Therapy

- Enrofloxacin (10 mg/kg q24h), for a minimum duration of 6–8 weeks is typically associated with rapid resolution of clinical signs and resolution of histopathologic abnormalities.
- Because enrofloxacin resistance has been documented in some isolates from dogs with GC, attempts to isolate *E. coli* from colonic biopsies before treatment is recommended such that antimicrobial susceptibility testing can be performed.
- Antimicrobials that penetrate intracellularly, such as fluoroquinolones, chloramphenicol, rifampin, or trimethoprim-sulfonamides, should be preferentially chosen for treatment based on the results of antimicrobial susceptibility testing.
- Chloramphenicol and trimethoprim-sulfonamide should be considered for cases resistant to fluoroquinolones.

Anti-inflammatory/Immunosuppressive Drugs

- Rarely indicated in dogs with GC, and used at anti-inflammatory dose in conjunction with appropriate antimicrobial therapy.
- Diagnosis must be reconsidered if there is no dramatic improvement in clinical signs following administration of fluoroquinolone therapy because not all boxers with signs of colitis have GC.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Avoid anticholinergics or other motility modifiers such as Imodium in dogs with an infectious cause of their diarrhea.

FOLLOW-UP

PATIENT MONITORING

- Monitor clinical signs, stool consistency and frequency, and body weight.
- Dogs showing a favorable response should improve within 3–5 days of starting fluoroquinolone therapy.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Colonic stricture if inflammation is uncontrolled for long periods.

EXPECTED COURSE AND PROGNOSIS

- Generally good prognosis following appropriate antimicrobial therapy.
- Increasing injudicious administration of fluoroquinolones to dogs is increasing the resistance of *E. coli* to this class of antimicrobials, necessitating the use of alternative antimicrobials in a subset of dogs.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- Boxers, French bulldogs and border collies with GC should not be bred.

COMPULSIVE DISORDERS—CATS

BASICS

DEFINITION

- Compulsive disorders are relatively invariant exaggerated behavior patterns, often derived from normal behaviors but out of context and repetitive, without apparent function. May be performed to the exclusion of other normal behaviors or to the detriment of the animal.
- May be a heterogeneous group of conditions with differing pathologies including compulsive, stereotypic and neurologic; therefore abnormal repetitive behaviors might be used to describe the clinical presentation until a diagnosis is made.
- Considered here are psychogenic dermatitis/alopecia, compulsive fabric chewing, and hyperesthesia syndrome.

PATOPHYSIOLOGY

- Diagnosis of exclusion; must rule out pathophysiologic causes, including psychomotor seizures, before a presumptive diagnosis is made.
- Can be a behavioral response to confinement, specific anxiety-producing event, or undefined environmental conditions (e.g., conflict, stress, anxiety, frustration); over time, can become fixed and independent of the environment.
- Behaviors may be self-reinforcing—allowing some animals to cope with conditions that do not meet their species-specific needs.

SYSTEMS AFFECTED

- Behavioral
- Gastrointestinal—fabric chewing
- Musculoskeletal—feline hyperesthesia (involves cutaneous trunci muscle), tail attack/mutilation
- Skin/Exocrine—psychogenic dermatitis/alopecia
- Nervous—feline hyperesthesia syndrome

GENETICS

None identified, although the association of compulsive fabric chewing with Asian breeds suggests a heritable component.

INCIDENCE/PREVALENCE

Unknown, uncommon

GEOGRAPHIC DISTRIBUTION

None identified

SIGNALMENT*Species*

Cat

Breed Predispositions

Siamese, Burmese, other Asian breeds and crosses overrepresented for fabric chewing and sucking.

Mean Age and Range

- Compulsive disorders can develop at any time, generally not seen in kittens.
- Psychogenic dermatitis/alopecia: 6 months to 12 years.
- Fabric chewing: 12 to 49 months; generally around 24 months.
- Hyperesthesia syndrome: 1 to 5 years.

Predominant Sex

None

SIGNS*General Comments*

- Behaviors may quickly increase in frequency if reinforced with attention by owner.
- Scolding or punishment may increase cat anxiety and worsen expression of behavior.

Historical Findings

- Onset may be coincident with an environmental change (e.g., move or new household member) suggesting stress effect, cat may hide to avoid punishment.
- Psychogenic dermatitis/alopecia—may be associated with excessive grooming to the exclusion of other activities; may be history of flea exposure or diet change.
- Compulsive fabric chewing—some patients show preference for a specific fabric type such as wool or may have general texture preference. Grind fabric with molars; may ingest fabric leading to foreign body obstruction.
- Hyperesthesia syndrome—may be triggered by tactile contact (petting along the dorsum and rump), may be episodic; flea exposure.

Physical Examination Findings

- Psychogenic dermatitis/alopecia—focal, partial, and bilateral dermatitis or alopecia; most common locations: groin, ventrum, and medial or caudal thigh regions; appearance of the skin variable (normal or abnormal; erythematous to abraded).
- Fabric chewing—often normal; secondary gastrointestinal inflammation or obstruction may occur if cat ingests material.
- Hyperesthesia syndrome—may be normal. Episode may be prompted by petting or scratching dorsum; signs may include dilated pupils, salivation, alarming vocalization, “rippling skin” (hyperresponsive cutaneous trunci muscle), inappropriate urination or defecation, tail twitching, frantic grooming, self-directed (especially to tail) or owner-directed aggression, escape behavior.

CAUSES

Unidentified

RISK FACTORS

- Changes in surroundings might predispose cat to compulsive disorder.
- More commonly reported in indoor cats.

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

Rule out medical differentials, including psychomotor seizures, before a behavioral diagnosis is made.

Psychogenic Dermatitis/Alopecia

- Skin conditions—especially those associated with pruritis.
- External parasites, especially fleas.
- Fungal or bacterial dermatitis.
- Food hypersensitivity, atopy.
- Cutaneous neoplasia.

- Eosinophilic granuloma complex
- Nervous system disorders
- Disk rupture and associated neuritis
- Feline hyperesthesia syndrome
- Pain/neuropathy

Fabric Chewing

- Lead intoxication
- Hyperthyroidism
- Thiamin deficiency

Hyperesthesia Syndrome

- Seizure disorder
- Skin disorders (external parasites)
- Food hypersensitivity
- Flea bite hypersensitivity
- Spinal disorder/neuropathy
- Myositis, myopathy

CBC/BIOCHEMISTRY/URINALYSIS

Minimum database to rule out metabolic abnormalities. No consistent clinicopathologies are associated with compulsive disorders.

OTHER LABORATORY TESTS*Psychogenic Alopecia*

Microscopic examination of hairs (trichogram), skin scraping, skin biopsy, fungal culture, bacterial culture, examination for external parasites, intradermal allergy testing—rule out dermatologic condition

Fabric Chewing

- Serum lead level—if indicated for pica
- Serum T4

Hyperesthesia Syndrome

Rule out dermatologic condition as above

IMAGING

CT or MRI—if indicated by abnormalities on the neurologic examination. Fabric chewing—imaging GIT if obstruction or foreign body suspected.

DIAGNOSTIC PROCEDURES*Psychogenic Alopecia*

Complete dermatologic evaluation (see “Other Laboratory Tests”)

Hyperesthesia Syndrome

Skin and/or muscle biopsy (as necessary)

PATHOLOGIC FINDINGS*Psychogenic Alopecia*

- Microscopic examination of hairs—typically shafts are cleanly broken off at variable length as a result of trauma from the tongue.
- If primarily behavioral, results of other dermatologic testing will be generally normal.

**TREATMENT****APPROPRIATE HEALTH CARE**

Supportive care

NURSING CARE*Fabric Chewing*

Create a “safe place” for when the cat is left alone, devoid of fabric of the sort favored for chewing.

ACTIVITY

Increase opportunities for play and social interactions by providing outlets favored by the affected cat.

COMPULSIVE DISORDERS—CATS

(CONTINUED)

Table 1

Drugs and dosages used to manage feline compulsive disorder.				
Drug	Drug Class	Oral Dosage in Cats	Frequency	Side Effects (Usually Transient)
Fluoxetine	SSRI	0.5–1.0 mg/kg	q24h	Decreased appetite, sleepiness
Paroxetine	SSRI	0.25–0.50 mg/kg	q24h	Constipation
Clomipramine	TCA	0.25–0.50 mg/kg	q24h	Sleepiness, urine retention
Amitriptyline	TCA	0.25–1.0 mg/kg	q24h	Sleepiness, urine retention
Gabapentin	Anticonvulsant	3–10 mg/kg	q12h	Sleepiness, sedation

DIET

- *Fabric chewing*: increasing fiber in the diet has been suggested
- *Presumptive psychogenic alopecia*: Exclusion diet

CLIENT EDUCATION

- Identify and remove triggers for the behavior, if applicable.
- Do not reward the behavior.
- Ignore the behavior as much as possible; distract the cat and initiate an acceptable behavior.
- Note details of the time, place, and social milieu so that an alternative behavior (play or feeding or food-dispensing toy) may be scheduled prior to initiation of the compulsive behavior.
- Punishment is contraindicated and can increase the unpredictability of the patient's environment, increase the patient's fear or aggressive behavior, and disrupt the human-animal bond.
- Reduce environmental stress—increase the predictability of household events (feeding, play, exercise, and social time with the client); eliminate unpredictable events as much as possible.

SURGICAL CONSIDERATIONS

N/A

**MEDICATIONS****DRUG(S) OF CHOICE**

- If a specific etiology cannot be identified, drugs may be helpful (Table 1).
- Goal—use the drugs until control is achieved for 2 months; attempt gradual withdrawal by decreasing dosage at 2-week intervals. Treatment should be resumed at the last effective dose at the first sign of relapse; may be life-long.
- Drugs are listed with dosage used to manage behavior and common side effects.
- Hyperesthesia syndrome: gabapentin has been reported anecdotally to reduce the frequency and intensity of bouts.

CONTRAINdications

- SSRIs—depending on agent: poor appetite, constipation, sedation.
- TCAs—cardiovascular abnormalities (cardiac conduction disturbances), glaucoma, urinary and fecal retention.
- Transdermal route does not produce satisfactory drug levels.

PRECAUTIONS

- Start behavioral drugs at low dose to avoid side effects. May give at bedtime to reduce complaints of sedation, may be given with food.
- No drugs are approved by the FDA for the treatment of these disorders in cats; inform client of the extra-label use and the risks involved; document the discussion in the medical record or with a release form.

POSSIBLE INTERACTIONS

Do not use TCAs or SSRIs with monoamine oxidase inhibitors, including selegiline.

ALTERNATIVE DRUG(S)

Phenobarbital if seizure disorder suspected. Selegiline if cognitive dysfunction. *Presumptive psychogenic alopecia*: exclusion diet, parasiticide trial course of steroids.

**FOLLOW-UP****PATIENT MONITORING**

- Before initiating treatment, record the frequency of compulsive behavior so that progress can be monitored.
- Successful treatment requires a schedule of follow-up examinations; a recommended schedule is a phone check 1 week after the initial consultation and an office recheck 4–6 weeks later. If improvement is evident, the treatment regime should be continued. If there is no improvement, differential diagnoses should be considered or an alternative drug should be considered.
- If a medication is not effective after dosage adjustment, select an agent from another drug class.

PREVENTION/AVOIDANCE

Create an enriched environment with distributed resources, safe and accessible elevated resting sites, exercise and play opportunities, and predictable social interactions with people.

POSSIBLE COMPLICATIONS

- Treatment failure.
- Realistic expectations must be made; immediate control of a long-standing problem is unlikely.

EXPECTED COURSE AND PROGNOSIS

With treatment, prognosis for improvement is good; treatment can be life-long.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Avoidance behavior or aggression toward the owner—if the owner punishes the patient when it exhibits a compulsive behavior.

AGE-RELATED FACTORS

None

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

- Do not breed animals that display compulsive behavior.
- Tricyclic antidepressants—contraindicated in pregnant animals.

SYNOMYS

Hyperesthesia syndrome: rippling skin disease, neurodermatitis

SEE ALSO

Compulsive Disorders—Dogs

ABBREVIATIONS

- GIT = gastrointestinal tract
- OCD = obsessive-compulsive disorder
- SSRI = selective serotonin reuptake inhibitor
- TCA = tricyclic antidepressant

COMPULSIVE DISORDERS—DOGS

BASICS

DEFINITION

- Heterogeneous group of conditions with differing pathologies including compulsive, stereotypic, and neurologic; therefore “abnormal repetitive behaviors” might be used to describe the clinical presentation until a diagnosis is made.
- Can be categorized as locomotor (spinning, tail chasing, circling, fence running, pacing, light/shadow chasing); oral (licking, sucking/mouthing an object/body part [e.g., flank, tail, limb], pica, excessive drinking, “fly biting”); or hallucinatory (“fly biting,” hind end checking, freezing, staring), with or without vocal and affective responses.
- Compulsive disorders are abnormal, repetitive, exaggerated and/or sustained, variable in form and fixated on a goal. They are derived from normal maintenance behaviors such as grooming, predation, and ingestion. Motivational conflict or frustration appears to trigger the behaviors in specific contexts often associated with high arousal; over time, with repeated/sustained conflict, the behavior becomes emancipated from the original trigger stimuli and is displayed in diverse contexts.
- Stereotypes are repetitive behaviors that are unvaried in sequence and have no obvious function or purpose. They may arise in situations of conflict or frustration related to confinement or husbandry practices, when the environment lacks sufficient outlets for the normal behavior repertoire, and with maternal deprivation.

PATOPHYSIOLOGY

- Likely associated with alterations in brain neurotransmitter functions: primarily serotonin; also dopamine, endorphins. Different CDs may preferentially involve different brain regions.
- Abnormal serotonin transmission has been identified as a primary mechanism by which compulsive disorders are induced; stereotypes might be induced by dopaminergic stimulation.

SYSTEMS AFFECTED

- Behavioral—fear, anxiety, aggression.
- Cardiovascular—tachycardia.
- Endocrine/Metabolic—HPA axis upregulation.
- Gastrointestinal—inappetence, gastroenteritis, foreign body obstruction
- Hemic/Lymphatic/Immune—stress leukogram
- Musculoskeletal—weight loss, self-injury.
- Respiratory—tachypnea.
- Skin/Exocrine—abrasions/lacerations/; wounds/infections secondary to self-trauma.

GENETICS

- Likely genetic predisposition/susceptibility: higher than expected occurrence among first-generation relatives (though manifestations may differ).
- Certain breeds overrepresented for specific CDs.

INCIDENCE/PREVALENCE

Generally uncommon; more common in certain breeds/families.

SIGNALMENT

Species

Dog

Breed Predispositions

Bull terrier—spinning, freezing; German shepherd—spinning, tail chasing; Great Dane, German shorthaired pointer—self-directed oral behaviors, fence running, hallucinations; Doberman—flank/blanket sucking; miniature schnauzer—hind end checking; border collie—light/shadow chasing.

Mean Age and Range

May be presented at any age; usually develops from onset of sexual (6 months) to social (12–24 months) maturity; earlier onset (3–6 months) reported for some CDs.

Predominant Sex

Some CDs may be more common in males.

SIGNS

General Comments

- Wide variety of manifestations: behaviors may be repetitive or static (e.g., freezing).
- Signs may or may not be observed during examination. Descriptions may be unclear; videotape aids diagnosis and treatment planning.

Historical Findings

- May be other signs of anxiety/concurrent behavioral diagnoses (e.g., separation anxiety, fears, aggression) and/or a history of stress (e.g., inadequate stimulation, punishment, schedule/routine/household change).
- Behavior may first be displayed as part of play or in situations of high arousal or stress; eventually may occur in multiple contexts independent of identifiable triggers.
- Certain repetitive behaviors are expressed in situations with little to no external stimulation or evidence of arousal (e.g., blanket sucking).
- Occurs whether or not the owner is present. If punished, pet may avoid detection.
- Hallmarks—behavior is ritualized, often exaggerated in form, and with time increases in frequency, intensity, and duration.
- Behavior may be difficult or impossible to interrupt (even with physical restraint).
- Behavior may interfere with normal functioning (e.g., eating, sleeping, social interactions).

Physical Examination Findings

- May be unremarkable.
- May see skin lesions and injuries related to self-trauma (especially to tail, forelimbs, distal extremities); excessive tooth wear/damage; lameness or loss of/poor body condition.

CAUSES

No direct cause

RISK FACTORS

- Environmental stress (e.g., kenneling—spinning), management, illness, other.
- Owner/environmental reinforcement of the behavior.
- Medical disease, pain, or neuropathy—may increase anxiety or may be primary cause of behavior.
- Sensory abnormalities (e.g., visual deficits) may contribute.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dermatologic disease (e.g., atopy)
- Gastrointestinal disease (e.g., IBD)
- Metabolic/endocrine disease (e.g., Cushing's)
- Neurologic disease (e.g., seizure focus, forebrain neoplasia)
- Orthopedic disease (e.g., DJD)
- Any disorder causing abnormalities of sensation such as dysesthesia, paresthesia, (sensory neuropathy)
- Other problem behaviors: displacement or conflict behaviors, play and attention seeking, and behaviors occurring secondary to lack of stimulation or due to resource restriction (e.g., water restriction—excessive drinking),
- Diagnostics needed to rule out physical causes of behavior, especially self-mutilation.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually within the laboratory's reference range—use for general health screening; prior to drug use.
- Hematocrit, cholesterol, triglyceride increases have been reported.

OTHER LABORATORY TESTS

Various; specific to differential diagnoses.

IMAGING

- For neurologic differentials, CT and MRI to rule out structural brain disease; altered brain/gray matter volume/density reported in CD.
- Radiography, ultrasound if needed to rule out underlying physical causes.

DIAGNOSTIC PROCEDURES

- None specific for CD.
- Indications based on other differentials (e.g., endoscopy, biopsy, echocardiography).

TREATMENT

Not all repetitive behavior is abnormal; it may represent a coping mechanism. If not harmful nor interfering with normal functioning, health, or human-animal bond, intervention may be unnecessary or contraindicated.

APPROPRIATE HEALTH CARE

- Outpatient unless severe self-mutilation/self-injury; hospitalization may exacerbate CD.
- Sedation—stop-gap measure; if needed to stop serious self-mutilation, increases suspicion of underlying physical abnormality.
- Treat associated physical conditions (primary or

COMPULSIVE DISORDERS—DOGS

(CONTINUED)

C

secondary). • Combination of environmental modification, behavior modification, and pharmacologic treatment. • Pharmacologic intervention—implement early; reduction of anxiety facilitates behavioral therapy.

- Environmental modification—reduce stress and anxiety; identify and remove sources (e.g., triggers) and/or begin desensitization and counter-conditioning exercises.
- Punishment—contraindicated; increases anxiety, may worsen behavior and increase patient secrecy. • Provide structured, consistent interactions, routine, and sufficient exercise, enrichment/mental stimulation appropriate to the species and individual; includes interactive play and reward-based training.
- Behavior modification—teach the patient to relax in a variety of settings; also teach a calm, desirable behavior incompatible with the stereotypic one, coupled to a verbal cue (e.g., for circling, teach to lie down with head and neck outstretched in response to “Head down”). In some cases, a head collar (e.g., Gentle Leader, Halti) left on the dog (when the owner is home) in the problem contexts may allow the owner to use gentle physical guidance along with verbal encouragement/cues to interrupt the behavior and redirect it more effectively. Monitor for situation in which behavior occurs and pre-empt it by engaging the pet in an incompatible activity; if behavior occurs, disrupt immediately, redirect the animal to alternative incompatible activity and reward (food, play, other reinforcer).
- Have clients monitor behaviors via videos and written logs for objective assessment of response to therapy. Improvement may be seen in frequency and/or intensity of bouts.

Discussion of a rating scale and how to judge changes may help in assessing response to therapy.

- Bandages, collars, braces, and crates increase distress, do not address the behavioral condition, and may worsen it. If needed to ensure healing, use as briefly as possible.

ACTIVITY

Environmental enrichment

DIET

N/A

CLIENT EDUCATION

• Cure is unlikely; usually requires life-long management.

- Teach client to recognize all body language/behaviors reflecting anxiety.

SURGICAL CONSIDERATIONS

Tail/limb mutilation: avoid amputation; it is unlikely to resolve the CD.

MEDICATIONS

DRUG(S) OF CHOICE

- SSRIs and TCAs—effects are via CNS serotonin effects.
- Generally treat at low end of dose range for 4–6 weeks; gradually

increase dosage if ineffective and no adverse events.

- SSRIs: fluoxetine 1–2 mg/kg q24h; sertraline 1–3 mg/kg q24h; paroxetine 1–2 mg/kg q24h.
- TCAs: clomipramine is most serotonergic (most effective, fewest side effects)—2–3 mg/kg q12h.
- If symptoms resolve, continue medication for >1 month, then reduce dose no faster than 25% every two weeks. Recurrence common.

CONTRAINDICATIONS

- Hepatic or renal compromise—medications metabolized by these organs.
- Cardiac conduction anomalies—TCAs.
- Use extreme care combining serotonergic drugs (e.g., SSRI with tramadol); risk of serotonin syndrome (potentially fatal).
- Do not use SSRIs or TCAs within 2 weeks of MAOIs (e.g., selegiline, amitriptyline).

PRECAUTIONS

- Use of listed medications for CD is extra- or off-label.
- TCA overdose—cardiac conduction disturbances.
- TCA/SSRI overdose—serotonin syndrome.
- Most common side effects of SSRIs and TCAs: lethargy, appetite change; less common: increased anxiety/reactivity, vomiting/diarrhea; severe side effects may necessitate drug discontinuation.

POSSIBLE INTERACTIONS

SSRIs competitively inhibit CYP450 enzymes: may increase warfarin, many TCAs, some benzodiazepines and anticonvulsants, other medications; check compatibility and adjust dosage if necessary.

ALTERNATIVE DRUG(S)

- Synthetic pheromones (Adaptil), l-theanine or alpha-casozepine may reduce anxiety (see label for dosing).
- Second-line TCAs, e.g., amitriptyline 1–6 mg/kg q12h.
- Selegiline (MAOI) 0.5–1 mg/kg q24h: may be effective in some cases.
- Memantine (NMDA receptor antagonist) 0.3–1 mg/kg q12h.
- Narcotic antagonists (e.g., naltrexone, naloxone) may be effective but not a practical therapeutic option. Antipsychotics (e.g., thioridazine, haloperidol) not recommended due to risk of adverse effects, efficacy undocumented.

FOLLOW-UP

PATIENT MONITORING

- CBC, biochemistry, T₄ (TCAs may artificially lower) and urinalysis—semiannually to yearly if chronic treatment; adjust dosages accordingly.
- Medications may take 8–12 weeks or longer to affect CDs; first sign of efficacy may be change in bout duration/frequency.
- Relapses common during stressful situations; manage with increased intensity of behavior modification, addition of short-term, shorter-acting anxiolytics (e.g., benzodiazepines).

PREVENTION/AVOIDANCE

Monitor animals with affected relatives; early recognition and intervention.

POSSIBLE COMPLICATIONS

Dermatologic/musculoskeletal injury; gastrointestinal disorders.

EXPECTED COURSE AND PROGNOSIS

- Untreated CDs almost always progress.
- > 50% reduction in CD in approximately two-thirds of cases with appropriate medication and behavioral and environmental modification.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Various; specific to type of CD.

PREGNANCY/FERTILITY/BREEDING

- Listed medications not evaluated/contraindicated in pregnant animals; avoid use.
- Do not breed affected animals.

SYNOMYMS

Obsessive-compulsive disorder

SEE ALSO

Acral Lick Dermatitis

ABBREVIATIONS

- CD = compulsive disorder
- CNS = central nervous system
- CT = computed tomography
- CYP450 = cytochrome P450

CONGENITAL AND DEVELOPMENTAL RENAL DISEASES

BASICS

DEFINITION

- Functional or morphologic abnormalities resulting from heritable (genetic) or acquired disease processes affecting differentiation and growth of the developing kidney before or shortly after birth.
- Renal agenesis—complete absence of one or both kidneys.
- Renal dysplasia—disorganized renal parenchymal development.
- Renal ectopia—congenital malposition of one or both kidneys; ectopic kidneys may be fused.
- Glomerulopathy—glomerular disease of any type.
- Tubulointerstitial nephropathy—a non-inflammatory disorder of renal tubules and interstitium.
- Polycystic renal disease—formation of multiple, variable-sized cysts throughout the renal medulla and cortex.
- Renal telangiectasia—multifocal vascular malformations involving the kidneys and other organs.
- Renal amyloidosis—extracellular deposition of amyloid in glomerular capillaries, glomeruli, and interstitium.
- Nephroblastoma—a congenital renal neoplasm arising from the pluripotent metanephric blastema.
- Multifocal renal cystadenocarcinoma—a hereditary renal neoplasm in dogs.
- Fanconi syndrome—a generalized renal tubular functional anomaly characterized by impaired reabsorption of glucose, phosphate, electrolytes, amino acids, and uric acid.
- Primary renal glucosuria—an isolated functional defect in renal tubular reabsorption of glucose.
- Cystinuria—excessive urinary excretion of cystine because of an isolated functional defect in renal tubular reabsorption of cystine and other dibasic amino acids.
- Xanthinuria—excessive urinary excretion of xanthine caused by a deficiency in xanthine oxidase.
- Hyperuricuria—excessive urinary excretion of uric acid, sodium urate, or ammonium urate.
- Primary hyperoxaluria—intermittent hyperoxaluria, l-glyceric aciduria, oxalate nephropathy, and acute renal failure.
- Congenital nephrogenic diabetes insipidus—polyuria caused by diminished renal responsiveness to antidiuretic hormone.

PATHOPHYSIOLOGY

- Many congenital and developmental renal disorders are caused by genetic abnormalities that disrupt the normal sequential and coordinated development and interaction of multiple embryonic tissues involved in formation of the mature kidney.
- Congenital and developmental renal disorders may also be caused by non-genetic factors affecting the developing kidney before or shortly after birth.

SYSTEMS AFFECTED

Renal/Urologic

GENETICS

- Familial renal disorders have been reported in the following breeds of dogs and cats:
- Renal agenesis in beagle and Doberman pinscher
- Renal dysplasia in Alaskan malamute, border terrier, boxer, chow chow, Dutch kooiker, golden retriever, keeshond, Lhasa apso, miniature schnauzer, Rhodesian ridgeback, shih tzu, soft-coated Wheaten terrier, and standard poodle dogs
- Glomerulopathy in beagle, Belgian shepherd, Bernese mountain dog, Brittany spaniel, bull terrier, bullmastiff, Dalmatian, Doberman pinscher, English cocker spaniel, Newfoundland, Pembroke Welsh corgi, rottweiler, Samoyed, and soft-coated Wheaten terrier dogs
- Tubulointerstitial nephropathy in Norwegian elkhound dogs
- Polycystic renal disease in beagle, bull terrier, cairn terrier, and West Highland white terrier dogs, and in Persian, exotic shorthair, and Himalayan cats
- Renal telangiectasia in Pembroke Welsh corgi
- Renal amyloidosis in Abyssinian, Oriental shorthair, and Siamese cats, and in beagle, English foxhound, and shar-pei dogs
- Renal cystadenocarcinoma in German shepherds
- Fanconi syndrome in basenji and border terrier dogs
- Primary renal glucosuria in Norwegian elkhound, Scottish terrier, and basenji dogs
- Cystinuria in Australian cattle, Australian shepherd, basenji, basset hound, bullmastiff, Chihuahua, English bulldog, dachshund, French bulldog, Irish terrier, mastiff, Newfoundland, Scottish deer hound, Staffordshire bull terrier, and Welsh corgi dogs and in domestic cats
- Xanthinuria in Cavalier King Charles spaniel and wirehaired dachshund dogs, and in domestic shorthair cats
- Hyperuricuria in Dalmatians, black Russian terriers, and English bulldogs
- Primary hyperoxaluria in domestic shorthair cats and in Tibetan spaniels.

INCIDENCE/PREVALENCE

Uncommonly recognized, but occur more frequently in related animals from more than one generation than in the general population.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Sporadic cases can occur without an apparent familial predisposition in any breed of dog or cat.

Mean Age and Range

Most patients are < 5 years old at time of diagnosis.

Predominant Sex

- Familial cystinuria occurs primarily in male dogs.
- Samoyed hereditary glomerulopathy more common in males than females.
- Familial glomerulonephropathy of Bernese mountain dogs is more common in females.

SIGNS

General Comments

Most congenital and developmental disorders cannot be distinguished from acquired renal diseases on the basis of history or physical examination.

Historical Findings

- Indicate chronic renal failure.
- Some glomerulopathies associated with abdominal distension, edema, or other signs of the nephrotic syndrome.
- Abdominal distension in some patients with polycystic kidneys or renal neoplasms.
- Hematuria or abdominal pain in some patients with renal telangiectasia or renal neoplasms.
- Patients with unilateral renal agenesis, ectopic kidneys, and isolated renal tubular transport defects are frequently asymptomatic.

Physical Examination Findings

- Signs associated with chronic renal failure.
- Ascites or pitting edema in some patients with protein-losing glomerulopathies or amyloidosis.
- Renomegaly or abdominal mass lesions in some patients with polycystic kidneys, renal neoplasms, or fused ectopic kidneys.

CAUSES

Non-hereditary

- Infectious agents—feline panleukopenia virus and canine herpesvirus infection associated with renal dysplasia.
- Drugs—corticosteroids, diphenylamine, and biphenyls associated with polycystic kidneys; chlorambucil and sodium arsenite associated with renal agenesis.
- Dietary factors—hypovitaminosis A associated with renal ectopia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rule out acquired and non-developmental causes of primary renal disease.
- Rule out non-renal causes of hematuria, proteinuria, glucosuria, abdominal distention, or ascites.

CBC/BIOCHEMISTRY/URINALYSIS

- Nonregenerative anemia in patients with chronic renal failure.
- Azotemia and urine specific gravity < 1.030 observed in dogs and < 1.035 observed in cats if renal failure develops.
- Proteinuria, hypoalbuminemia, and hypercholesterolemia in patients with the nephrotic syndrome.
- Normoglycemic glucosuria in animals with Fanconi syndrome or primary renal glucosuria.
- Hematuria in patients with congenital renal neoplasia or renal telangiectasia.
- Cystine crystalluria in patients with cystinuria.
- Xanthine crystalluria in patients with xanthinuria.
- Urine crystalluria in patients with hyperuricuria.

CONGENITAL AND DEVELOPMENTAL RENAL DISEASES

(CONTINUED)

OTHER LABORATORY TESTS

Direct genetic tests are available for detection of specific genetic mutations associated with familial nephropathy in English cocker spaniel dogs, familial cystinuria in Newfoundland dogs, and familial polycystic renal disease in Persian and Persian-derived breeds of cats.

IMAGING

Survey abdominal radiography, renal ultrasonography, and excretory urography are important means of identifying and characterizing congenital and developmental renal disorders and their associated sequelae.

DIAGNOSTIC PROCEDURES

Consider light microscopic evaluation of kidney biopsy specimens from patients with morphologic or functional abnormalities of the kidney for which a definitive diagnosis has not been established by other, less invasive means.

PATHOLOGIC FINDINGS

- Renal dysplasia—end-stage kidneys; primary lesions include immature (“fetal”) glomeruli, persistent mesenchyme, persistent metanephric ducts, atypical tubular epithelium, and dysontogenic metaplasia; primary lesions usually associated with, and may be obscured by, secondary degenerative, inflammatory, and compensatory lesions.
- Glomerulopathies—usually normal-to-small kidneys; most are characterized by a primary membranoproliferative glomerulonephritis with variable degrees of tubulointerstitial disease, but cystic atrophic membranous glomerulopathy is the characteristic lesion in affected rottweilers.
- Tubulointerstitial nephropathy—end-stage kidneys; renal lesions include periglomerular fibrosis, parietal epithelial cell hyperplasia and hypertrophy, interstitial fibrosis, and interstitial mononuclear cell infiltrate.
- Polycystic renal disease—see specific chapter.
- Renal amyloidosis—see specific chapter.
- Renal telangiectasia—lesions include multiple, variable-sized, red-black, blood-filled nodules and clots in the renal cortex and medulla, interstitial fibrosis, interstitial mononuclear cell infiltrate, and hydronephrosis.
- Nephroblastoma—unilateral renal mass; microscopically characterized by both embryonic mesenchymal and epithelial tissue components.
- Multifocal renal cystadenocarcinoma—bilaterally enlarged kidneys with irregular protruding cystic structures or multifocal neoplastic renal tubular epithelial cell proliferations.
- Renal ectopia—kidneys abnormally located in the retroperitoneal space or abdomen; horseshoe

kidneys are symmetrically fused along the medial border of either pole.

- Fanconi syndrome—inconsistent microscopic findings of tubular atrophy, interstitial fibrosis, and acute papillary necrosis.
- Primary hyperoxaluria—large, irregularly shaped kidneys; microscopic lesions include renal tubular deposition of calcium oxalate crystals and variable interstitial and periglomerular fibrosis.

TREATMENT

- The nature of congenital and developmental renal disorders often precludes specific treatment.
- Supportive or symptomatic treatment may improve quality of life and minimize progression in patients with renal dysfunction.
- Refer to chapters describing specific renal diseases or clinical syndromes.

MEDICATIONS

DRUG(S) OF CHOICE

Refer to chapters describing specific renal diseases or clinical syndromes.

CONTRAINDICATIONS

Avoid potentially nephrotoxic drugs (e.g., gentamicin, nonsteroidal anti-inflammatory drugs) or anesthetic agents that decrease renal function when possible.

PRECAUTIONS

Avoid drugs requiring renal excretion in patients with renal failure; if necessary, modify dosage regimens to compensate for decreased renal clearance of drugs and other metabolites.

FOLLOW-UP

PATIENT MONITORING

Refer to chapters describing specific renal diseases or clinical syndromes.

PREVENTION/AVOIDANCE

Congenital and developmental renal disorders are irreversible, so control lies in preventing breeding of affected animals. Always consider early identification and correction of predisposing factors (genetic and non-genetic) that may affect future offspring.

POSSIBLE COMPLICATIONS

- Acute or chronic renal failure
- Nephrotic syndrome
- Urolithiasis
- Hydronephrosis
- Urinary tract infection

EXPECTED COURSE AND PROGNOSIS

- Highly variable; depends on the specific disorder, the extent of primary lesions, and the severity of renal dysfunction.
- Most congenital and developmental disorders are irreversible and may result in advanced chronic renal failure, but some patients with mild-to-moderate renal dysfunction may remain stable for long periods.
- Patients with some disorders (e.g., unilateral renal agenesis, renal ectopia, cystinuria, hyperuricuria, primary renal glucosuria) may remain asymptomatic unless the disorder is complicated by urolithiasis, urinary tract infection, or other disease processes that promote progressive renal dysfunction.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Polycystic renal disease associated with hepatic biliary cysts.
- Cystinuria, xanthinuria, and hyperuricuria associated with formation of uroliths.
- Amyloidosis in Chinese shar-pei dogs associated with intermittent pyrexia or swelling of the hocks.
- Renal neoplasms associated with hypertrophic osteoarthropathy, polycythemia, or other paraneoplastic syndromes.

SYNOMYMS

Familial renal disease, juvenile renal disease

CONGENITAL OCULAR ANOMALIES

C

BASICS

DEFINITION

Solitary or multiple abnormalities that affect the globe or its adnexa; observed in young dogs and cats at birth or within the first 6–8 weeks of life.

PATHOPHYSIOLOGY

- Breed-related inherited defects.
- Spontaneous malformations. • *In utero* systemic infections and inflammations, exposure to toxic compounds, and lack of specific nutrients in pregnant dams or bitches.

SYSTEMS AFFECTED

Ophthalmic—entire eye or any part; unilateral or bilateral.

GENETICS

- Known, suspected, or unknown mode of inheritance. • PPM in basenjis—dominant trait. • PHTVL and PHPV in Doberman pinschers—dominant allele with variable expression. • Multifocal retinal dysplasia in English springer spaniels—recessive trait.
- CEA—recessive trait. • MOD in Australian shepherds—autosomal recessive trait with incomplete penetrance. • Retinal dystrophy in briards—recessive trait. • Rod cone dysplasia in collies, Irish setters, Cardigan Welsh corgi and Sloughi dogs—recessive traits; non-allelic disease. • Cone rod dystrophy in pit bull terriers and in long- and shorthaired dachshund breeds; recessive traits; non-allelic disease. • Photoreceptor dysplasia in Abyssinians, Persian, and domestic shorthair cats—dominant trait in Abyssinians and in domestic shorthair cats, recessive in Persians.

INCIDENCE/PREVALENCE

- Incidence—low; dogs > cats.
- CEA—> 50% in collies, lower in other breeds.

SIGNALMENT

Species

Dog and cat

Breed Predilections

See “Genetics”

Mean Age and Range

See “Definition”

SIGNS

General Comments

- Depends on defect. • May cause no signs of disease; often incidental finding. • May be congenitally blinding disease.

Historical Findings

Ranges from none to severe visual impairment to blindness.

Physical Examination Findings

- Anophthalmos—congenital lack of the globe; exceedingly rare. • Microphthalmos—congenitally small eye; often associated with other hereditary defects. • Eyelid agenesis or

colobomas of the eyelids—may result in congenitally open eyelids; affects the temporal portion of the upper eyelid; may cause blepharospasm and epiphora.

- Dermoids—islands of aberrant skin tissue involving either eyelids, conjunctiva, or cornea; blepharospasm and epiphora.
- Atresia and imperforate puncta of the lacrimal system—common in dog breeds; results in a tear streak at the nasal canthus; usually not associated with other ocular findings.
- Congenital KCS—sporadically in any dog or cat breed; usually unilateral; affected eye appears smaller than the normal eye; thick mucous discharge from a red and irritated eye.
- PPM—remnants of the pupillary membrane spanning from the iris collarette to another portion of the iris, lens or cornea; may coexist with other defects; numerous dog breeds, especially basenjis.
- Iris cysts—pigmented or non-pigmented ball-like structures may float freely in the anterior chamber or be attached to the posterior iris, ciliary body or corneal endothelium.
- Congenital glaucoma—in dogs and cats; rare; note enlarged, red, and typically painful eye.
- Pupillary abnormalities—polycoria, acorea, aniridia, or dyscoria.
- Congenital cataracts—primary, often inherited or secondary to other developmental defects; associated with other anomalies of the lens, including microphakia, lenticonus or lentiglobus, and coloboma.
- PHTVL and PHPV—persistence of parts of the hyaloid vasculature; developmental aberrations of the vitreous, lens, and lens capsule; may show cataract, leukocoria, and/or a reddish sheen from the pupillary area with intralenticular bleeding.
- Retinal dysplasia—in several dog breeds; sporadically in cats; effect on retinal structure depends on severity; ranges from focal folds to geographic focal detachment to complete retinal detachment.
- CEA—bilateral area of choroidal hypoplasia temporal to optic nerve; visual impairment or blindness can be caused by optic nerve coloboma and retinal detachment.
- MOD—microphthalmia, microcornea, heterochromia irides, pupillary abnormalities, cataract, fundus coloboma, retinal detachment, intraocular hemorrhage.
- Coloboma of the posterior segment—primary or in conjunction with CEA or MOD; typically seen in optic nerve head in CEA, usually at the 6 o'clock position, or in the fundus periphery in MOD; may be in other locations of the fundus near the optic nerve head.
- Rod and cone dysplasia in Irish setters, and collie dogs, Persian and Abyssinians cats; rod dysplasia and early rod degeneration in Norwegian elkhounds; cone degeneration or hemeralopia in Alaskan malamutes and cone rod dystrophies in dogs; often show pupillary abnormalities and visual impairment in the first few months of life.
- Retinal dystrophy in briards; RPE65 null

mutation; congenital night blindness; nystagmus, dilated pupils; but normal fundus until middle age. • Retinal detachment—often seen in conjunction with other hereditary ocular diseases (e.g., retinal dysplasia, CEA, MOD); found in Labrador retrievers, Bedlington terriers, Sealyham terriers, and collies with CEA; signs include widely dilated pupils, weak to absent pupillary light reflexes; blindness with complete detachment.

CAUSES

- Genetic. • Spontaneous malformations.
- Infections and inflammations during pregnancy. • Toxicity during pregnancy.
- Nutritional deficiencies.

RISK FACTORS

Breeding dogs or cats that are homozygous or heterozygous for a hereditary disease with recessive inheritance or affected animals where the disease has a dominant inheritance.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious and inflammatory processes in adnexa—may mimic and mask congenital abnormalities.
- Cataracts induced at an early age and especially those that progress quickly may seem to be congenital.
- Post-inflammatory ophthalmic lesions with synechia—easily confused with PPM.
- Tumors of the anterior segment—may be confused with iris cysts.
- Generalized retinopathy of inflammatory origin—may appear to be photoreceptor dysplasia with retinal atrophy; usually unilateral.
- Retinal detachment as a result of trauma or uveitis in young dogs—may appear to be a congenital abnormality of neural retina.
- Optic nerve atrophy due to inflammatory process—may be difficult to differentiate from congenital optic nerve hypoplasia.

IMAGING

Ultrasound—diagnosis of abnormalities of the lens and the posterior segment.

DIAGNOSTIC PROCEDURES

- Examination with diffuse illumination—permits for diagnosis of adnexal and anterior and posterior segment anomalies.
- Evaluation of tear production (Schirmer tear strips)—performed routinely with chronic adnexal inflammatory and infectious processes.
- Tonometry when glaucoma is suspected.
- Direct and/or indirect ophthalmoscopy and biomicroscopy—necessary to diagnose abnormalities of the internal structures; examination after pupil dilation; difficult to perform in patients

CONGENITAL OCULAR ANOMALIES

(CONTINUED)

younger than 5 weeks. • ERG—objective evaluation of retinal function.

C PATHOLOGIC FINDINGS

- Congenital KCS—usually keratitis with corneal neovascularization, scarring, and pigmentation; inflammatory changes of conjunctiva; abnormally developed or atrophied lacrimal glands.
- Congenital glaucoma—buphthalmos common, sometimes secondary lens luxation and neuroretinal thinning; abnormally developed iridocorneal filtration angle.
- PHTVL and PHPV—range of defects; retrorenal pigmented dots and plaques, strands of vascular tissue from the optic nerve head to the posterior lens capsule; often posterior lens capsule defects with cataracts.
- Retinal dysplasia—abnormal folding of the neuroretina; multifocal defects often along the major blood vessels in central tapetal fundus; with geographic defects—usually large, abnormal area with elevated retina and surrounding area of hyperpigmentation and scarring; sometimes completely detached retina.
- Rod cone dysplasia—abnormalities in rod and/or cone outer and inner segments; degeneration of photoreceptor nuclei.
- Retinal dystrophy in briards—large lipoid-like inclusions in the retinal pigment epithelium and disorganization and degeneration of photoreceptors with time.
- Coloboma—notch in affected tissue; thinning of the neural retina in region of the optic nerve head or near its border with posterior segment defects.
- Retinal detachment—neural retina detached from the retinal pigment epithelium; neural retina often atrophic.
- Optic nerve hypoplasia—avascular, dark, abnormally small, circular optic nerve head.

TREATMENT

APPROPRIATE HEALTH CARE

- Patients usually referred to an ophthalmologist.
- No medical treatment for most congenital abnormalities, except symptomatic treatment or surgery.

NURSING CARE

- In KCS—removing of discharge and flushing with saline.
- Accommodate handicap of blind animals: leash walking, supervision.

ACTIVITY

Visually impaired or blind animals need adequate exercise.

DIET

Provide a diet adequate in vitamins, antioxidants, and omega-3 fatty acids, especially in photoreceptor degenerations.

CLIENT EDUCATION

- Depends on abnormality.
- Discuss visual capacity, possible progression, and sequelae.

SURGICAL CONSIDERATIONS

- Depends on abnormality.
- Adnexal abnormalities—surgery as soon as possible.
- Congenital KCS—parotid duct transposition.
- Cataract extraction—congenital cataract may be associated with other anomalies, decreasing the chances for visual rehabilitation or causing surgical complications; careful presurgical evaluation needed: imaging, ERG.
- Congenital glaucoma—enucleation or intrascleral prosthesis treatments of choice; consider euthanasia if bilateral.

MEDICATIONS

DRUG(S) OF CHOICE

- Congenital KCS—tear substitutes, frequent application, antibiotics may be added; cyclosporin ophthalmic ointment q12h.
- Congenital cataracts—if only in nuclear region of the lens, mydriatics used to increase visual capability.

PRECAUTIONS

Cats are sensitive to systemic administration of enrofloxacin, shown to cause retinal degeneration and blindness in cats when exceeding normal dose.

FOLLOW-UP

PATIENT MONITORING

- Depends on defect.
- Congenital KCS—repeated monitoring of tear production and status of external eye.
- Congenital cataracts and severe PHTVL and PHPV—regular checkups, usually on a 6-month basis; monitor progression.
- Large colobomatous defects of the fundus and geographic retinal dysplasia—regular checkups to monitor possible retinal detachment.

PREVENTION/AVOIDANCE

Restrict breeding of affected animals and of known carriers of documented hereditary defects; note that DNA-based tests are available for various diseases (see list of diagnostic facilities offering genetic testing below).

POSSIBLE COMPLICATIONS

- In congenital KCS with parotid duct transposition, keratitis and dermatitis may occur due to excessive deposition of minerals from saliva.
- Cataract surgery can result in glaucoma, retinal detachment, and corneal scarring in puppies and kittens; surgery seldom recommended before age 8–12 weeks.

EXPECTED COURSE AND PROGNOSIS

- Most abnormalities affecting adnexa can be corrected in young dogs and cats.
- In congenital KCS with parotid duct transposition prognosis is good.
- Prognosis for most anterior segment abnormalities is good to fair.
- Prognosis in glaucoma is poor.
- For photoreceptor abnormalities the prognosis for vision is poor, but the eyes should remain comfortable.
- For most other abnormalities the prognosis depends on the severity of the condition.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Retinal dysplasia—described with chondrodysplastic skeletal abnormalities in field-trial Labradors and Samoyeds.

PREGNANCY/FERTILITY/BREEDING

- Depends on defect.
- Dogs and cats affected with congenital ocular anomalies with blindness and/or pain should not be used for breeding.
- Many congenital ocular anomalies are hereditary and the use of affected animals in breeding should be prohibited or severely restricted. Breeding advice should be sought from a kennel club and breed associations.

ABBREVIATIONS

- CEA = collie eye anomaly
- ERG = electroretinography
- KCS = keratoconjunctivitis sicca
- MOD = merle ocular dysgenesis
- PHPV = persistent hyperplastic primary vitreous
- PHTVL = persistent hyperplastic tunica vasculosa lentis
- PPM = persistent pupillary membranes

CONGENITAL SPINAL AND VERTEBRAL MALFORMATIONS

BASICS

DEFINITION

Anomalous development of spinal structures, which are apparent at birth or within the first weeks of life.

PATHOPHYSIOLOGY

- Malformation of the occipital bones, atlas, and axis; malformation of the odontoid process; occipitoatlantoaxial malformation; and occipital dysplasia—may cause atlantoaxial subluxation with secondary compression and trauma to the first segments of the cervical spinal cord.
- Other embryonic or developmental anomalies of the vertebrae such as hemivertebra, transitional vertebra, block vertebra, and butterfly vertebra—these defects cause deformity and instability of the vertebral canal and, in rare occasions, compression of the associated spinal cord or nerve roots.
- Sacrococcygeal dysgenesis—characterized by absence or partial development of the sacrocaudal spinal cord segments; often associated with additional malformations (e.g., spina bifida).
- Spina bifida—caused by failure of fusion of the vertebral arches; may be associated with protrusion of the spinal cord and meninges; other malformations often linked to this syndrome include spinal dysplasia, dysraphism, syringomyelia/hydromyelia, and myelodysplasia.
- Congenital spinal stenosis—can occur when vertebral malformations cause segmental or diffuse narrowing of the spinal cord; inborn errors in skeletal growth, hypertrophy of ligamentum flavum, and bony proliferation may also contribute to the stenosis.

SYSTEMS AFFECTED

Nervous—spinal cord; spinal nerve roots; and vertebral column.

GENETICS

- A genetic background, with unknown mode of inheritance, is suspected in most congenital spinal diseases.
- Sacrococcygeal dysgenesis—autosomal dominant.
- Thoracic hemivertebra of German shorthaired pointers—autosomal recessive.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species and Breed Predilections

- Malformation of the occipital bones, atlas, and axis—most common in small-breed dogs.
- Hemivertebra, transitional vertebra, block vertebra, and butterfly vertebra—most common in brachycephalic, “screw-tailed” breeds (e.g., French and English bulldog, pug, Boston terrier).
- Sacrococcygeal dysgenesis—Manx cat.

- Spina bifida—bulldog, Manx cat, and other screw-tailed breeds.
- Spinal dysraphism—Weimaraner.
- Congenital spinal stenosis—Doberman pinscher; chondrodystrophic breeds.

Mean Age and Range

- Often silent, vertebral malformation may cause clinical disease during the rapid growth of the animal (e.g., 5–9 months of age).
- Spinal cord anomalies cause clinical disease from birth on.

SIGNS

- Distortion of the spinal column—lordosis; kyphosis; and scoliosis in cases of vertebral malformations.
- Ataxia and paresis associated with spinal cord compression and trauma.
- Signs vary with spinal cord segment(s) involved.

CAUSES

Breed-related inherited defects are suspected for most congenital spinal abnormalities, although interactions between several genes and environmental factors (e.g., teratogenic compounds, nutritional deficiencies) are likely involved and would explain some of these complex pathologic changes.

RISK FACTORS

- Teratogenic compounds
- Toxins
- Nutritional deficiencies
- Stress

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Metabolic disease (e.g., storage diseases).
- Nutritional disease (e.g., hypovitaminosis and hypervitaminosis A, thiamine deficiency).
- Early onset inflammatory or infectious processes (e.g., viral, protozoal, and rarely bacterial).
- Toxin exposure (e.g., lead, organophosphates, hexachlorophene, organochlorine).
- Trauma.

CBC/BIOCHEMISTRY/URINALYSIS

Usually within normal limits.

OTHER LABORATORY TESTS

N/A

IMAGING

- Survey radiography—reveal vertebral malformation(s) and deviation of the spinal column.
- Myelography—to determine the level(s) of spinal cord compression; flexed and extended views may cause neurologic deterioration if instability present.
- CT myelography, and 3-D reconstructed imaging—to characterize bony abnormalities and associated spinal cord compression.

- MRI—sensitive modality to visualize abnormalities of spinal cord parenchyma, cauda equina, nerve roots and surroundings soft tissues.

DIAGNOSTIC PROCEDURES

Cerebrospinal fluid analysis to rule out infectious/inflammatory conditions.

PATHOLOGIC FINDINGS

- Multiple congenital malformations—often present concomitantly; pathologic changes reflect several disease processes.
- Acute compression of the spinal cord secondary to congenital malformation(s)—may result in spinal cord ischemia, hemorrhage, ballooning of the myelin sheath at the point of compression or trauma, and axonal swelling or loss; in chronic spinal cord compression, myelin degeneration, astrocytosis, and fibrosis are more prominent; at spinal sites, cranial and caudal to the primary injury, Wallerian degeneration can be observed in ascending or descending pathways, respectively.
- Chronic changes—may result from vertebral malformations secondary to bony proliferation, thickening of the joint capsule, hypertrophy of articular processes, and thickening of the ligaments surrounding the spinal cord.
- Atlantoaxial subluxation—congenital aplasia or hypoplasia of the odontoid process and surrounding ligaments.
- Occipitoatlantoaxial malformations—fusion of the atlas to the occipital bone (cats) and dorsal angulation of the dens (dogs).
- Occipital dysplasia—anomaly of the foramen magnum in which the occipital bone is incompletely formed and fibrous tissue membrane covers the caudal cerebellum.
- Sacrococcygeal dysgenesis—caudal vertebral aplasia or hypoplasia.
- Spina bifida—incomplete fusion of the dorsal vertebral arches where the meninges or spinal cord can protrude; most commonly seen in the caudal lumbar or sacral area; a dimple can be observed in few cases secondary to the lack of separation between the neuroectoderm and other ectodermal structures, leaving a small attachment between the spinal cord or meninges and the skin; often seen with myelodysplasia, central canal defects, syringomyelia or hydromyelia, and abnormal gray-matter differentiation.
- Spinal stenosis—pathologic changes observed within the spinal cord are most commonly chronic and are caused by focal or diffuse narrowing of the spinal canal.

TREATMENT

APPROPRIATE HEALTH CARE

- Depends on severity of neurologic deficits.
- Outpatient—if animal is ambulatory.

CONGENITAL SPINAL AND VERTEBRAL MALFORMATIONS (CONTINUED)

- Inpatient—if animal is non-ambulatory or requires emergency surgical treatment (e.g., for atlantoaxial subluxation).

NURSING CARE

- Restricted activity combined with physical therapy—may help neurologically disabled patients in the postoperative period; a cart may be necessary for severely affected patients.
- Management of urination—essential for cases in which disorders of micturition accompany the spinal injury.

ACTIVITY

Restricted, especially if vertebral subluxation is present.

DIET

Maintaining a lean body weight limits stress on the spinal column.

CLIENT EDUCATION

- Many congenital vertebral malformations are clinically silent.
- Perform a thorough workup when a congenital malformation results in neurologic abnormalities.
- Heritability is suspected and breeding must be performed only with serious consideration.
- Many neurologically affected dogs and cats left untreated are euthanized.
- Early surgical intervention often necessary to alleviate compression of the spinal cord and prevent further damage.

SURGICAL CONSIDERATIONS

- In general, surgical decompression is required when congenital malformation(s) cause narrowing of the spinal canal and compression of the spinal cord. In cases of chronic or diffuse spinal cord compression, improvement following surgery is minimal.
- Atlantoaxial subluxation—surgical ventral decompression combined with stabilization of the atlantoaxial joint with pins or screws is the treatment of choice.
- Spina bifida—meningoceles can be closed surgically to prevent leakage of cerebrospinal fluid and infections; surgery usually not attempted when the spinal cord parenchyma is involved.

MEDICATIONS

DRUG(S) OF CHOICE

Corticosteroids may be used in some cases, with questionable results.

CONTRAINDICATIONS

Avoid steroids with concomitant infections.

PRECAUTIONS

Steroids may cause ulcerations of the gastrointestinal tract and inhibit bone growth.

POSSIBLE INTERACTIONS

Steroids reduce immune response following vaccination.

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Frequent neurologic examinations—to monitor the progression of clinical signs in developing animals (e.g., every 4–6 weeks).
- Neuroimaging—repeat as needed.

PREVENTION/AVOIDANCE

Avoid breeding affected animals.

POSSIBLE COMPLICATIONS

- Depend on the type and severity of neurologic signs. In cases of subluxation of the atlantoaxial joint, acute death may occur.
- Acute paralysis can also be seen with vertebral subluxation, with further trauma and spinal cord compression.
- Implant failure may be observed after surgical decompression/stabilization.

EXPECTED COURSE AND PROGNOSIS

- Prognosis varies depending on the type of malformation, degree of spinal cord compression or injury, and surgical decompression or stabilization techniques.
- Vertebral malformation without compression of the spinal cord—prognosis is good.
- Atlantoaxial subluxation following surgical decompression or stabilization—prognosis is fair to good.
- Spinal cord compression treated surgically—prognosis is fair.
- Spina bifida associated with spinal cord malformation, chronic neurologic disease despite surgical treatment, and lower motor neuron incontinence—prognosis is poor.

- Medical treatment usually is insufficient to alleviate moderate to severe neurologic signs caused by spinal cord compression secondary to congenital vertebral malformation(s).

CONGESTIVE HEART FAILURE, LEFT-SIDED

BASICS

DEFINITION

Failure of the left side of the heart to advance blood at a sufficient rate to meet the metabolic needs of the patient or to prevent blood from pooling within the pulmonary venous circulation.

PATHOPHYSIOLOGY

- Low cardiac output causes lethargy, exercise intolerance, syncope, and prerenal azotemia.
- High hydrostatic pulmonary venous pressure causes leakage of fluid from pulmonary venous circulation into pulmonary interstitium and alveoli. When fluid leakage exceeds ability of lymphatics to drain the affected areas, pulmonary edema develops.

SYSTEMS Affected

- All organ systems can be affected by poor perfusion. • Respiratory increased rate and effort because of edema. • Cardiovascular.

GENETICS

Some congenital heart defects, cardiomyopathies, and valvular heart disease have a genetic basis in some breeds.

INCIDENCE/PREVALENCE

Common

GEOGRAPHIC DISTRIBUTION

Seen everywhere, but prevalence of causes varies with location.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Varies with cause

Mean Age and Range

Varies with cause

Predominant Sex

Varies with cause

SIGNS

General Comments

Signs vary with underlying cause and species.

Historical Findings

- Weakness, lethargy, exercise intolerance.
- Coughing (dogs) and dyspnea (increased respiratory rate and effort); respiratory signs often worsen at night and can be partially relieved by assuming a standing, sternal, or “elbows abducted” position (orthopnea).
- Cats rarely cough from heart failure, and a client complaint of coughing should prompt a search for primary airway disease.

Physical Examination Findings

- Tachypnea. • Coughing, often soft in conjunction with tachypnea (dogs).
- Dyspnea and tachypnea. • Pulmonary crackles and wheezes. • Pale/gray/cyanotic mucous membranes. • Prolonged capillary refill time. • Possible murmur or gallop.
- Weak femoral pulses.

CAUSES

Pump (Muscle) Failure of Left Ventricle

- DCM • Trypanosomiasis (rare)
- Doxorubicin cardiotoxicity (dogs)
- Hypothyroidism (rare) • Hyperthyroidism (rarely causes pump failure; more commonly causes high output failure) • Pacing-induced cardiomyopathy (muscle failure caused by persistent pathologic supraventricular or ventricular tachyarrhythmia)

Pressure Overload of Left Heart

- Systemic hypertension (uncommon cause of heart failure in animals) • Subaortic stenosis
- Coarctation of the aorta (rare; Airedales predisposed) • Left ventricular tumors (rare)

Volume Overload of Left Heart

- Mitral valve endocardiosis (dogs) • Mitral valve dysplasia (cats and dogs) • PDA (dogs)
- Ventricular septal defect • Aortic valve insufficiency secondary to endocarditis (dogs)

Impediment to Filling of Left Heart

- Pericardial effusion with tamponade
- Restrictive pericarditis • Restrictive cardiomyopathy • Hypertrophic cardiomyopathy • Left atrial masses (e.g., tumors and thrombus) • Pulmonary thromboembolism • Mitral stenosis (rare)
- Cor triatriatum sinister (cats, rare)

Rhythm Disturbances

- Bradycardia (high-grade AV block)
- Tachycardia (e.g., atrial fibrillation, sustained supraventricular tachycardia, and ventricular tachycardia; see pacing-induced cardiomyopathy under pump failure)

RISK FACTORS

Conditions causing chronic high cardiac output (e.g., hyperthyroidism and anemia).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Must differentiate from other causes of coughing, dyspnea, and weakness.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC usually normal; maybe stress leukogram. • Mild-to-moderate liver enzyme elevation; bilirubin generally normal.
- Prerenal azotemia in some animals.

OTHER LABORATORY TESTS

- Thyroid disorders may be detected. • Serum NT-proBNP and troponin I concentrations are higher in animals with L-CHF than in normal animals.

IMAGING

Radiographic Findings

- Left heart and pulmonary veins enlarged.
- Pulmonary edema, often hilar, especially involving the right caudal lung lobe in acute edema of dog, but may be patchy, especially in cats; acute pulmonary edema may begin in right caudal lung lobe.

Echocardiography

- Findings vary markedly with cause, but left atrial enlargement a relatively consistent finding in cardiogenic pulmonary edema.
- Diagnostic test of choice for documenting congenital defects, cardiac masses, and pericardial effusion.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

- Atrial or ventricular arrhythmias.
- Evidence of left heart enlargement (e.g., wide P waves, tall and wide QRS complexes, and left axis orientation). • May be normal.

PATHOLOGIC FINDINGS

Cardiac findings vary with disease.

TREATMENT

APPROPRIATE HEALTH CARE

- Usually treat as outpatient unless animal is dyspneic or severely hypotensive. • Identify and correct underlying cause whenever possible. • Minimize handling of critically dyspneic animals. Stress can kill!

NURSING CARE

Oxygen in dyspneic patients.

ACTIVITY

Restrict activity when dyspneic or tachypneic.

DIET

Initiate moderately sodium-restricted diet. Severe sodium restriction is indicated in animals with advanced disease.

CLIENT EDUCATION

With few exceptions (e.g., animals with thyroid disorders, arrhythmias, nutritionally responsive heart disease), left congestive heart failure is not curable.

SURGICAL CONSIDERATIONS

- Surgical intervention, coil embolization, Amplatz occluder placement or balloon valvuloplasty may benefit selected patients with some forms of congenital and acquired valvular heart disease. Response to these interventions varies. • Pericardiocentesis in animals with pericardial effusion.

MEDICATIONS

DRUG(S) OF CHOICE

Diuretics

- Furosemide (1–2 mg/kg q8–24h) or other loop diuretic is the initial diuretic of choice; diuretics are indicated to reduce preload and remove pulmonary edema. Critically dyspneic animals often require high doses (4–8 mg/kg) given IV to stabilize; this dose can be repeated in 1 hour if animal is still severely dyspneic. An IV bolus of 0.66 mg/kg followed by a CRI of 0.66–1 mg/kg/h for 1–4 hours causes

CONGESTIVE HEART FAILURE, LEFT-SIDED

(CONTINUED)

greater diuresis than an equal dose divided into two IV boluses given 4 hours apart. Once edema resolves, taper to the lowest effective dosage. • Spironolactone (0.5–2 mg/kg PO q12–24h) increases survival in humans with CHF and is in current clinical trials in dogs. Use in combination with furosemide.

- Thiazide diuretics can be added to furosemide and spironolactone in refractory heart failure cases. • Torsemide may be useful as a substitute for furosemide in animals requiring chronic furosemide dosing in excess of 12 mg/kg (total daily dose).

ACE Inhibitors

- ACE inhibitor such as enalapril (0.5 mg/kg q12–24h) or benazepril (0.25–0.5 mg/kg q24h) indicated in most animals with L-CHF.
- ACE inhibitors improve survival and quality of life in dogs with L-CHF secondary to degenerative valve disease and DCM.

Positive Inotropes

- Pimobendan (0.25–0.3 mg/kg PO q12h) is a calcium channel sensitizer that dilates arteries and increases myocardial contractility. First-line agent in treating DCM or CHF due to chronic valve disease. Efficacy in cats with CHF is not known, but possibly beneficial.
- Dobutamine (dogs, 2.5–10 µg/kg/minute; cats, 0.5–5 µg/kg/minute) is a potent positive inotropic agent that may provide valuable short-term support of a heart failure patient with poor cardiac contractility. • Positive inotropes in general are potentially arrhythmogenic, monitor carefully.

Venodilators

- Nitroglycerin ointment (one-fourth inch/5 kg q6–8h) causes venodilation, lowering left atrial filling pressures. • Used for acute stabilization of patients with severe pulmonary edema and dyspnea. • May be useful in animals with chronic L-CHF; to avoid tolerance, use intermittently and with 12-hour dose-free interval between the last dose of 1 day and the first dose of the next.

Antiarrhythmic Agents

Treat arrhythmias if clinically indicated.

CONTRAINDICATIONS

Avoid vasodilators in patients with pericardial effusion or fixed outflow obstruction.

PRECAUTIONS

- ACE inhibitor and arterial dilators must be used with caution in patients with possible outflow obstruction. • Pulmonary hypertension, hypothyroidism and hypoxia increase risk for digoxin toxicity; hyperthyroidism diminishes effects of digoxin. • ACE inhibitor and digoxin—use cautiously in patients with renal disease. • Dobutamine—use cautiously in cats. • Spironolactone—may cause facial pruritis in cats.

POSSIBLE INTERACTIONS

- Combination of high-dose diuretics and ACE inhibitor may cause azotemia, especially in animals with severe sodium restriction.

- Combination diuretic therapy adds to risk of dehydration and electrolyte disturbances.
- Combination vasodilator therapy predisposes animal to hypotension.

ALTERNATIVE DRUG(S)

Arterial Dilators

- Hydralazine (0.5–2 mg/kg PO q12h; 0.5 mg/kg PO to start when added to ACEI) or amlodipine (0.05–0.2 mg/kg PO q24h) can be substituted for an ACE inhibitor in patients that do not tolerate the drug or have advanced renal failure. Monitor for hypotension and tachycardia; can be cautiously added to an ACE inhibitor in animals with refractory L-CHF.
- Nitroprusside (1–10 µg/kg/minute) is a potent arterial dilator that is usually reserved for short-term support of patients with life-threatening edema.

Digoxin

- Digoxin (dogs, 0.22 mg/m² q12h; cats, 0.01 mg/kg q48h) is used in animals with atrial fibrillation and myocardial failure (e.g., dilated cardiomyopathy). Commonly used in combination with diltiazem to control the rate of atrial fibrillation. • Digoxin is also indicated to treat dogs with refractory heart failure from either myocardial failure or volume loads. However, its use as a primary agent in myocardial failure has been replaced by pimobendan. • In humans, digoxin has no effect on mortality but decreases hospitalization due to heart failure.

Calcium Channel Blockers

- Diltiazem (0.5–1.5 mg/kg PO q8h) is frequently used in L-CHF patients for rate control in animals with supraventricular arrhythmias not controlled by digoxin and in cats with hypertrophic cardiomyopathy.

Beta-Blockers

- Atenolol and metoprolol are used for rate control in animals with supraventricular tachycardia, hypertrophic cardiomyopathy, and hyperthyroidism. • Used alone or with a class 1 antiarrhythmic drug for control of ventricular arrhythmias; these drugs depress contractility (negative inotropes), so use cautiously in patients with myocardial failure or active signs of CHF. • On basis of human studies, may enhance survival in animals with idiopathic DCM; treatment is best initiated under the guidance of a cardiologist, starting with very low dosage and gradually increasing the dosage. Carvedilol is sometimes used for this purpose, starting at 0.1 mg/kg q24h and titrating to 0.5 mg/kg q12h.

Nutritional Supplements

- Potassium and magnesium supplementation if deficiency is documented; use potassium supplements cautiously in animals receiving an ACE inhibitor or spironolactone.
- Taurine supplementation in cats with DCM and dogs with DCM and taurine deficiency (e.g., American cocker spaniels) • L-carnitine supplementation may help some dogs with

DCM. • Coenzyme Q₁₀ is of potential value based on the results in humans with DCM.

FOLLOW-UP

PATIENT MONITORING

- Monitor renal status, electrolytes, hydration, respiratory rate and effort, heart rate, body weight, and abdominal girth (dogs). • If azotemia develops, reduce the dosage of diuretic. If azotemia persists and the animal is also on an ACE inhibitor, reduce or discontinue the ACE inhibitor. Use digoxin with caution if azotemia develops. • Monitor ECG if arrhythmias are suspected. • Check digoxin concentration periodically. Recommended range is 0.5–1.5 ng/mL, 8–10 hours after a dose.

PREVENTION/AVOIDANCE

- Minimize stress, exercise, and sodium intake in patients with heart disease. • Prescribing an ACE inhibitor early in the course of heart disease in patients with DCM may slow the progression of heart disease and delay onset of CHF. Their role in asymptomatic animals with mitral valve disease remains controversial. Pimobendan delays the onset of CHF in Doberman pinschers, and in dogs with hemodynamically significant mitral valve regurgitation.

POSSIBLE COMPLICATIONS

- Syncope • Aortic thromboembolism (cats)
- Arrhythmias • Electrolyte imbalances
- Digoxin toxicity • Azotemia and renal failure

EXPECTED COURSE AND PROGNOSIS

Prognosis varies with underlying cause; cats and dogs that survive their initial episode of pulmonary edema and can be reliably medicated often survive months to more than a year with a good quality of life.

MISCELLANEOUS

AGE-RELATED FACTORS

- Congenital causes seen in young animals.
- Degenerative heart conditions and neoplasia generally seen in old animals.

CONGESTIVE HEART FAILURE, RIGHT-SIDED

BASICS

DEFINITION

Failure of the right side of the heart to advance blood at a sufficient rate to meet the metabolic needs of the patient or to prevent blood from pooling within the systemic venous circulation.

PATOPHYSIOLOGY

- High hydrostatic pressure leads to leakage of fluid from venous circulation into the pleural and peritoneal space and potentially into the pericardium and interstitium of peripheral tissue.
- When fluid leakage exceeds ability of lymphatics to drain the affected areas, pleural effusion, ascites, pericardial effusion, and peripheral edema develop.

SYSTEMS AFFECTED

All organ systems can be affected by either poor delivery of blood or the effects of passive congestion from backup of venous blood.

GENETICS

- Some congenital cardiac defects have a genetic basis in certain breeds.
- Arrhythmogenic right ventricular cardiomyopathy appears to have a genetic basis in boxer dogs.

INCIDENCE/PREVALENCE

Common

GEOGRAPHIC DISTRIBUTION

Syndrome seen everywhere, but prevalence of various causes varies with location.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Varies with cause

Mean Age and Range

Varies with cause

Predominant Sex

Varies with cause

SIGNS

General Comments

- Signs vary with underlying cause and between species.
- Pleural effusion without ascites and hepatomegaly is rare in dogs with R-CHF.
- Ascites without pleural effusion is rare in cats with R-CHF.
- Small volume pericardial effusion without tamponade is relatively common in cats with R-CHF.
- Interstitial peripheral edema is a rare manifestation of R-CHF in both species.

Historical Findings

- Weakness
- Lethargy
- Exercise intolerance
- Abdominal distension
- Dyspnea, tachypnea

Physical Examination Findings

- Jugular venous distention
- Hepatojugular reflex
- Jugular pulse in some animals

- Hepatomegaly
- Ascites common in dogs and rare in cats with R-CHF
- Possible regurgitant murmur in tricuspid valve region or ejection murmur at left heart base (pulmonic stenosis)
- Muffled heart sounds if animal has pleural or pericardial effusion
- Weak femoral pulses
- Rapid, shallow respiration if animal has pleural effusion or severe ascites
- Peripheral edema (infrequent)

CAUSES

Pump (Myocardial) Failure of Right Ventricle

- Idiopathic dilated cardiomyopathy
- ARVC
- Hypertrophic cardiomyopathy (cats)
- Restrictive cardiomyopathy (cats)
- Trypanosomiasis
- Doxorubicin cardiotoxicity
- Chronic hyperthyroidism

Volume Overload of Right Ventricle

- Chronic AV valve (mitral \pm tricuspid) insufficiency caused by endocardiosis
- Tricuspid valve dysplasia

Pressure Overload of Right Ventricle

- Heartworm disease
- Chronic obstructive pulmonary disease with pulmonary hypertension
- Pulmonary thromboembolism
- Pulmonic stenosis
- Tetralogy of Fallot
- Right ventricular tumors
- Primary pulmonary hypertension

Impediment to Right Ventricular Filling

- Pericardial effusion (tamponade)
- Constrictive/restrictive pericarditis
- Right atrial or caval masses
- Tricuspid stenosis
- Cor triatriatum dexter

Rhythm Disturbances

- Bradycardia, generally complete atrioventricular block
- Tachyarrhythmias, generally sustained supraventricular tachycardia

RISK FACTORS

- No heartworm prophylaxis
- Offspring of animal with right-sided congenital cardiac defect
- Conditions that augment demand for cardiac output (e.g., hyperthyroidism, anemia, pregnancy)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Must differentiate from other causes of pleural effusion and ascites; generally requires a complete diagnostic work-up that includes CBC, biochemistry profile, heartworm test, thoracentesis or abdominocentesis with fluid analysis and cytologic examination, and, sometimes, thoracic and abdominal ultrasound.
- Animals with ascites or pleural effusion due to heart failure should have jugular venous distension.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC usually normal; animals with heartworm disease may have eosinophilia.

- Mild to moderately high ALT, AST, and ALP because of passive congestion of the liver; bilirubin generally normal.
- Prerenal azotemia in some animals.

OTHER LABORATORY TESTS

Heartworm test may be positive.

IMAGING

Thoracic Radiographic Findings

- Right heart enlargement in some animals
- Dilated caudal vena cava (diameter greater than the length of the vertebra directly above the heart)
- Pleural effusion (especially cats)
- Hepatosplenomegaly and possible ascites (especially dogs)

Echocardiography

- Findings vary with underlying cause.
- Especially useful for documenting congenital defect, cardiac mass, and pericardial effusion.
- Abdominal ultrasound reveals hepatomegaly with hepatic vein dilation, flow reversal in the hepatic veins (Doppler) and, possibly, ascites.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

- Small ($< 1 \text{ mV}$) QRS complexes in all frontal axis leads if animal has pericardial or pleural effusion.
- Electrical alternans or elevated ST segment in animal with pericardial effusion.
- Evidence of right heart enlargement (e.g., tall [$> 0.4 \text{ mV}$] P waves in lead II, deep S waves in leads I, II, aVF, and right axis deviation).
- Atrial or ventricular arrhythmias.
- ECG may be normal.

Abdominocentesis

Analysis of ascitic fluid in patients with R-CHF generally reveals modified transudate with a total protein $> 2.5 \text{ mg/dL}$.

Thoracentesis

- Cats with pleural effusion associated with R-CHF may have transudate, modified transudate, or chylous effusion.
- Dogs with pleural effusion and R-CHF may have transudate or modified transudate.

Central Venous Pressure

Central venous pressure is high ($> 9 \text{ cmH}_2\text{O}$) or rises dramatically to that level and remains elevated for more than an hour following a fluid bolus (e.g., 5–10 mL/kg IV).

PATHOLOGIC FINDINGS

- Cardiac findings vary with disease.
- Hepatomegaly in animals with centrilobular necrosis (chronic condition).

TREATMENT

APPROPRIATE HEALTH CARE

Most animals treated as outpatients unless dyspneic or collapsed (e.g., significant pleural or pericardial effusion).

CONGESTIVE HEART FAILURE, RIGHT-SIDED

(CONTINUED)

NURSING CARE

Thoracentesis and abdominocentesis may be required periodically for patients no longer responsive to medical management or for those with severe dyspnea due to pleural effusion or ascites.

ACTIVITY

Restrict activity

DIET

Restrict sodium moderately; severe sodium restriction is indicated for animals with advanced disease.

CLIENT EDUCATION

- With few exceptions (e.g., in heartworm disease, arrhythmias, hyperthyroidism, and idiopathic pericardial effusion), R-CHF is not curable.
- Most patients improve with initial treatment but often have recurrent failure.

SURGICAL CONSIDERATIONS

- Surgical intervention or balloon valvuloplasty is indicated to treat certain congenital defects such as pulmonic stenosis or cor triatriatum dexter and Amplatz occluder placement for morphologically appropriate atrial septal defects.
- Pericardiocentesis or pericardectomy is done if animal has pericardial effusion.
- Removal of heartworms from the heart via the jugular vein in dogs with caval syndrome.

MEDICATIONS

DRUG(S) OF CHOICE

Drugs should be administered only after a definitive diagnosis is made.

Diuretics

- Furosemide (1–2 mg/kg q8–24h) or another loop diuretic is the initial diuretic of choice. Diuretics are indicated to remove excess fluid accumulation.
- Spironolactone (2 mg/kg PO q12–24h) increases survival in humans with heart failure. Use in combination with furosemide.

Vasodilators

- ACE inhibitors such as enalapril (0.5 mg/kg q12–24h) or benazepril (0.25–0.5 mg/kg q24h) are helpful in DCM and chronic AV valve insufficiency.
- Sildenafil (0.5–1 mg/kg PO q12h up to 2–3 mg/kg q8h) may be beneficial in the setting of pulmonary hypertension.

Pimobendan

- Calcium sensitizer that acts as an inodilator, causing arterial vasodilation and increases myocardial contractility.
- Especially useful in myocardial failure.
- Dose—0.25–0.3 mg/kg PO q12h.

Digoxin

- Digoxin (dogs, 0.22 mg/m² q12h; cats, 0.01 mg/kg q48 h) is used in animals with myocardial failure (e.g., dilated cardiomyopathy) and atrial fibrillation.
- Digoxin is also indicated in animals with refractory CHF that have supraventricular arrhythmias (e.g., sinus tachycardia, atrial fibrillation, and atrial or junctional tachycardia).

CONTRAINDICATIONS

- Avoid diuretics in patients with pericardial effusion/tamponade.
- Avoid vasodilators in patients with pericardial effusion or fixed outflow obstructions.

PRECAUTIONS

- ACE inhibitors and arterial dilators must be used with caution in patients with possible outflow obstructions.
- Pulmonary hypertension, hypothyroidism and hypoxia increase risk for digoxin toxicity; hyperthyroidism diminishes effects of digoxin.
- ACE inhibitor and digoxin—use cautiously in patients with renal disease.
- Dobutamine—use cautiously in cats.
- Spironolactone—may cause facial pruritis in cats.

POSSIBLE INTERACTIONS

- Combination of high-dose diuretics and ACE inhibitor may alter renal perfusion and cause azotemia.
- Combination diuretic therapy promotes risk of dehydration and electrolyte disturbances.

ALTERNATIVE DRUG(S)

- Patients unresponsive to furosemide, spironolactone, vasodilator, pimobendan and digoxin (if indicated) may benefit from triple diuretic therapy by adding a thiazide diuretic, or substitution of torsemide for furosemide, generally at 0.1–0.2 mg of torsemide for each 1 mg of furosemide previously administered.
- Potassium and magnesium supplementation if deficiency documented; use potassium supplements cautiously in animals receiving ACE inhibitor or spironolactone.
- Treat arrhythmias if clinically indicated.
- Taurine supplementation in cats with DCM and dogs with DCM and taurine deficiency.
- Carnitine supplementation may help some dogs with DCM (e.g., cocker spaniels and boxers).

FOLLOW-UP

PATIENT MONITORING

- Monitor renal status, electrolytes, hydration, respiratory rate and effort, body weight, and abdominal girth (dogs).
- If

azotemia develops, reduce the diuretic dosage. If azotemia persists and the animal is also on an ACE inhibitor, reduce or discontinue this drug. If azotemia develops, reduce the digoxin dosage to avoid toxicity.

- Monitor ECG periodically to detect arrhythmias.
- Monitor digoxin concentrations. Normal values are 0.5–1.5 ng/mL for a serum sample obtained 8–10 hours after a dose is administered.

POSSIBLE COMPLICATIONS

- Pulmonary thromboembolism
- Arrhythmias
- Electrolyte imbalances
- Digoxin toxicity
- Azotemia and renal failure

EXPECTED COURSE AND PROGNOSIS

Prognosis varies with underlying cause.

MISCELLANEOUS

AGE-RELATED FACTORS

- Congenital causes seen in young animals.
- Degenerative heart conditions and neoplasia generally seen in old animals.

Breed Predilections

Infectious—purebred cats may be predisposed.

Mean Age and Range

Infectious—commonly affects young animals.

Predominant Sex

N/A

SIGNS

- Blepharospasm • Conjunctival hyperemia
- Ocular discharge—serous, mucoid, or mucopurulent • Chemosis • Conjunctival follicles • Upper respiratory infection—possible with infectious etiologies

CAUSES

Viral

- FHV—most common infectious cause; only one that leads to corneal changes (e.g., dendritic or geographic ulcers).
- Calicivirus—may cause conjunctival ulcerations.

Bacterial

- *Chlamydophila felis*—chemosis is a common clinical sign.
- *Mycoplasma* spp.—may represent overgrowth of normal flora.
- Conjunctivitis neonatorum—accumulation of exudates under closed eyelids prior to natural opening; bacterial or viral component (see Ophthalmia Neonatorum).

Immune-Mediated

- Eosinophilic • Lipogranulomatous
- Allergic • Related to systemic immune-mediated diseases

Trauma or Environmental Causes

- Conjunctival foreign body • Irritation from dust, smoke, chemicals, or ophthalmic medications

Secondary to Adnexal Disease

- May develop KCS as a result of scarring (see Keratoconjunctivitis Sicca).
- Eyelid diseases (e.g., entropion, trichiasis, distichia, or eyelid agenesis)—cause frictional irritation or exposure.
- Dacryocystitis or nasolacrimal system outflow obstruction.

Secondary to Other Ocular Diseases

- Ulcerative keratitis • Corneal sequestrum

RISK FACTORS

Stress or immune system compromise (FHV)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Must distinguish primary conjunctivitis from secondary conjunctival hyperemia (see Red Eye).
- Thorough systematic ophthalmic exam allows rule-out of other potential diseases (e.g., ulcers, uveitis, glaucoma, orbital disease); assess pupil size and symmetry, look for aqueous flare, perform IOP and fluorescein staining.
- Deeper, darker, more linear and immobile blood vessel injection indicates episcleral vasculature congested due to intraocular disease.
- Conjunctival mass biopsy will differentiate neoplasia (lymphoma and squamous cell carcinoma most common).

CBC/BIOCHEMISTRY/URINALYSIS

Normal, except with systemic disease

OTHER LABORATORY TESTS

Infectious—consider serologic tests for FeLV and FIV; rule out underlying immunocompromise.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Thorough adnexal examination—rule out eyelid abnormalities and foreign bodies under eyelids or third eyelid.
- Complete ophthalmic examination—rule out other ocular diseases (e.g., uveitis and glaucoma).
- Fluorescein stain—assess for corneal ulceration or dendritic lesions (FHV) and observe nares for stain passage to indicate nasolacrimal system patency.
- Nasolacrimal flush—considered to rule out dacryocystitis or nasolacrimal system obstruction.
- Bacterial culture if initial treatment is unsuccessful; specimen is taken before anything is placed in the eye (e.g., topical anesthetic, fluorescein, flush) to prevent inhibition or dilution of bacterial growth.
- Schirmer tear test—if ocular surface appears visibly dry; performed before anything is placed in the eye.
- Conjunctival cytology—may reveal a cause (rare); eosinophils diagnose eosinophilic conjunctivitis; may see degenerate neutrophils and intracytoplasmic bacteria, which indicate bacterial infection; may see intracytoplasmic inclusion bodies with chlamydial or mycoplasmal infection; rarely see intranuclear

FHV inclusions.

- Conjunctival biopsy—"snip biopsy" may be useful with mass lesions and immune-mediated disease or chronic disease.
- PCR testing for Chlamydia or FHV.
- Virus isolation or IFA testing for FHV; false-positive result if fluorescein staining is done before IFA testing.
- Serologic test for FHV antibodies—not useful due to widespread exposure and vaccination.

PATHOLOGIC FINDINGS

- Biopsy—typical signs of inflammation (e.g., neutrophils and lymphocytes); possibly infectious agents.
- Histopathology of mass lesions may reveal neoplasia (e.g., squamous cell carcinoma and lymphoma).

TREATMENT

APPROPRIATE HEALTH CARE

- Primary—often outpatient.
- Secondary to other diseases (e.g., ulcerative keratitis, uveitis, glaucoma)—may need hospitalization to address a severe underlying ophthalmic issue.

NURSING CARE

Irritant induced conjunctivitis—flush ocular surfaces and remove foreign body if observed.

ACTIVITY

- No restriction for most patients.
- Suspected contact irritant or acute allergic disease—prevent contact with the offending agent.
- Suspected FHV—minimize stress.
- Do not expose patients with infectious disease to susceptible animals.

DIET

- No change for most patients.
- Suspected underlying skin disease and/or food allergy—food elimination diet recommended.

CLIENT EDUCATION

- When solutions and ointments are prescribed, instruct the client to use the solution(s) before the ointment(s) and wait at least 5 minutes between treatments.
- If copious discharge is noted, instruct the client to clean the eyes before giving medication.
- Instruct the client to call for instructions if the condition fails to improve or worsens, which indicates that the condition may not be responsive, may be progressing, or that the animal may be having an adverse reaction to a prescribed medication.

SURGICAL CONSIDERATIONS

- Lipogranulomatous conjunctivitis—surgical incision and curettage of glandular material and inflammatory infiltrates.
- Entropion, distichia, or other eyelid disease—perform temporary or permanent surgery depending on the findings, signalment and history.
- Nasolacrimal duct obstruction—difficult; treatment often not recommended (see Epiphora).
- Conjunctival neoplasia—depending on tumor type and extent of involvement may involve local excision and

CONJUNCTIVITIS—CATS

(CONTINUED)

adjunctive therapy (β -irradiation, cryotherapy), enucleation, or exenteration.

- Symblepharon—conjunctival adhesions may require surgical resection once active infection is controlled.
- Corneal sequestration—keratectomy often recommended (see Corneal Sequestrum).

MEDICATIONS

DRUG(S) OF CHOICE

Herpetic

- Condition usually mild and self-limiting.
- Antiviral treatment—indicated for severe intractable conjunctivitis, herpetic keratitis, and before keratectomy for corneal sequestra suspected to be related to FHV; for all antivirals treat 2 weeks past the resolution of clinical signs.
- 0.5% cidofovir solution (available from compounding pharmacies)—topical q12h.
- 0.1% idoxuridine solution or 0.5% ointment (available from compounding pharmacies)—topical q4h.
- Vidarabine 3% ointment—topical q4h.
- Trifluridine 1% solution—topical q4h; potentially irritating.
- Oral famciclovir found to be effective and safe for use in cats. Dosage is controversial—most commonly used as famciclovir 250 mg tablet—1/2 tab PO q12h for 2–3 weeks; however, used without complication at doses up to 90 mg/kg PO q8h.
- Lysine 500 mg PO q12h for adult cat (250 mg PO q12h for kitten).

Chlamydial or Mycoplasmal

- Tetracycline, erythromycin or chloramphenicol ophthalmic ointment—topically q6–8h; continue for several days past resolution of all clinical signs; recurrence or reinfection common.
- Topical ciprofloxacin ophthalmic solution q6–8h as an alternative to ophthalmic ointment.
- Doxycycline 10 mg/kg PO q24h for 3–4 weeks may be superior to or used along with topical ophthalmic treatment.
- Based on bacterial culture and sensitivity results.

Neonatal

Carefully open the eyelid margins (medial to temporal), establish drainage, and treat with topical antibiotic ointment q6–8h and an antiviral for suspected FHV.

Eosinophilic

- Topical corticosteroid—0.1% dexamethasone sodium

phosphate q6–8h generally effective; taper gradually to the lowest effective dose or transition to cyclosporine.

- Cyclosporine 0.2% ointment or 1–2% compounded solution,—therapy q8–24h.
- Oral megestrol acetate—may help resistant condition but rarely used given possible systemic side effects.

CONTRAINDICATIONS

- Topical corticosteroids—avoid with known or suspected infectious conjunctivitis; may result in FHV recrudescence and predispose to corneal sequestrum formation; never use if corneal ulceration is noted.
- Valacyclovir should never be used in cats.

PRECAUTIONS

- Topical medications may be irritating.
- Monitor all patients treated with topical corticosteroids for signs of corneal ulceration; discontinue agent immediately if corneal ulceration occurs.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Other corticosteroids—1% prednisolone acetate; betamethasone.

FOLLOW-UP

PATIENT MONITORING

Recheck shortly after beginning treatment (at 5 days); then in 2 weeks or as needed.

PREVENTION/AVOIDANCE

- Treat any underlying disease that may be exacerbating the conjunctivitis.
- Minimize stress for patients with herpetic disease.
- Isolate patients with infectious conjunctivitis to prevent spread.
- Prevent reexposure to infectious sources.
- Vaccination recommended; infection is still possible if the cat was exposed to an infectious agent before being vaccinated (e.g., FHV infection from an infected queen).

POSSIBLE COMPLICATIONS

- Corneal sequestration (black lesion representing necrotic cornea and possibly associated with FHV)—usually requires surgical keratectomy.
- Symblepharon (adhesions between the conjunctival surfaces \pm cornea)—may require surgical intervention.
- KCS—most likely from chronic FHV.

EXPECTED COURSE AND PROGNOSIS

- FHV—most patients become chronic carriers; episodes less common as patient matures; may see repeated exacerbations; tend to note more severe clinical signs at times of stress or immunocompromise.
- Bacterial conjunctivitis—usually resolves with appropriate administration of antibiotic.
- Immune-mediated diseases (e.g., eosinophilic)—control not cure; may require chronic treatment at the lowest level possible.
- If an underlying disease is found (e.g., KCS, entropion), resolution may depend on appropriate treatment and resolution of the disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS

FeLV and FIV—may predispose patient to the chronic carrier state of FHV conjunctivitis.

AGE-RELATED FACTORS

FHV—tends to be more severe in kittens and in old cats with waning immunity.

ZOONOTIC POTENTIAL

Chlamydophila felis—low

PREGNANCY/FERTILITY/BREEDING

- Use topical and systemic medications with caution, if at all, in pregnant animals.

SEE ALSO

- Keratoconjunctivitis Sicca • Red Eye
- Ophthalmia Neonatorum • Corneal Sequestrum

ABBREVIATIONS

- FeLV = feline leukemia virus
- FHV = feline herpesvirus
- FIV = feline immunodeficiency virus
- IFA = immunofluorescent antibody test
- KCS = keratoconjunctivitis sicca
- PCR = polymerase chain reaction

CONJUNCTIVITIS—DOGS

C

BASICS

DEFINITION

Inflammation of the conjunctiva, the vascularized mucous membrane that covers the anterior portion of the sclera (bulbar conjunctiva) and lines the eyelids (palpebral conjunctiva) and third eyelid.

PATHOPHYSIOLOGY

- Primary—allergic; infectious; environmental.
- Secondary to other ocular disease—KCS, entropion, distichiasis.

SYSTEMS AFFECTED

Ophthalmic—ocular with possible eyelid involvement.

GENETICS

N/A

INCIDENCE/PREVALENCE

Common

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog

Breed Predilection

Breeds predisposed to allergic or immune-mediated skin diseases (e.g., atopy) tend to have more problems with allergic conjunctivitis or KCS.

Mean Age and Range

N/A

Predominant Sex

None

SIGNS

- Blepharospasm
- Conjunctival hyperemia
- Ocular discharge—serous, mucoid, or mucopurulent
- Chemosis
- Follicle formation on posterior third eyelid surface
- Enophthalmos and third eyelid elevation

CAUSES

Infectious

- Bacterial—rare as a primary condition, most commonly secondary to KCS; conjunctivitis neonatorum involves accumulation of exudates under closed eyelids prior to natural opening.
- Viral—canine herpes virus-1, canine distemper virus, or canine adenovirus-2.
- Parasitic—Leishmania, Onchocerca, or Thelazia.
- Conjunctival manifestation of systemic infectious disease.

Immune-Mediated

- Allergic—especially in atopic patients.
- Follicular conjunctivitis—especially in dogs younger than 18 months, secondary to chronic antigenic stimulation.
- Lymphocytic/plasmacytic conjunctivitis—especially in German shepherds with or

without chronic superficial keratitis (pannus).

- Related to systemic immune-mediated diseases (e.g., pemphigus).

Trauma or Environmental Causes

- Conjunctival foreign body
- Irritation from dust, smoke, chemicals, or ophthalmic medications

Other

Ligneous conjunctivitis—rare, young female Dobermanns may be predisposed.

Secondary to Adnexal Disease

- Aqueous tear film deficiency (see Keratoconjunctivitis Sicca) or qualitative tear deficiency.
- Eyelid diseases—entropion, ectropion, medial canthal pocket syndrome, eyelid mass.
- Hair or eyelash disorders—trichiasis, distichiasis, ectopic cilia.
- Exposure—facial nerve paralysis, lagophthalmos.
- Dacryocystitis or nasolacrimal system outflow obstruction (e.g., obstructed duct or imperforate punctum).

Referred Inflammation from Other Ocular Diseases

- Ulcerative keratitis
- Nodular episcleritis
- Anterior uveitis
- Glaucoma

RISK FACTORS

Atopy and KCS

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Must distinguish primary conjunctivitis from secondary conjunctival hyperemia or referred inflammation.
- Thorough systematic ophthalmic exam allows rule out of other potential diseases (e.g., KCS, ulcers, uveitis, glaucoma, orbital disease); assess pupil size and symmetry, look for aqueous flare, attempt globe retropulsion, perform Schirmer tear test, IOP and fluorescein staining.
- Deeper, darker, more linear and immobile blood vessel injection indicates episcleral vasculature congested due to episcleritis or intraocular disease.
- Mass biopsy will differentiate conjunctival neoplasia (rare: melanoma, hemangioma, hemangiosarcoma, lymphoma, papilloma, mast cell tumor) or nodular episcleritis.

CBC/BIOCHEMISTRY/URINALYSIS

Normal, except with systemic disease.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Thorough adnexal examination—rule out facial nerve paralysis, lagophthalmos, eyelid abnormalities, hair or eyelash disorders, and foreign bodies in cul-de-sacs or under third

eyelid.

- Schirmer tear test—measures aqueous tears to diagnose or rule out KCS; perform before anything else is placed in the eye.
- Fluorescein stain—no corneal retention rules out ulcerative keratitis; stain flow to nares rules out nasolacrimal disease.
- Tear film breakup time—assesses tear film stability to rule out qualitative tear deficiency.

- Intraocular pressures—rule out glaucoma.
- Globe retropulsion—rule out orbital disease.
- Examine for signs of anterior uveitis (e.g., hypotony, aqueous flare, and miosis) or other intraocular disease (e.g., cataracts, lens luxation).
- Consider a nasolacrimal duct flush—rule out nasolacrimal disease if fluorescein stain did not pass to nares.
- Aerobic bacterial culture and sensitivity—consider with mucopurulent discharge if KCS has been ruled out; ideally, specimens are taken before anything is placed in the eye (e.g., topical anesthetic, fluorescein, and flush) to prevent inhibition or dilution of bacterial growth.
- Conjunctival cytology—may reveal a cause (rare); lymphocytes and plasma cells diagnostic for lymphocytic/plasmacytic conjunctivitis; eosinophils may help diagnose allergic conjunctivitis; may see degenerate neutrophils and intracytoplasmic bacteria indicating bacterial infection; rarely see distemper virus intracytoplasmic inclusion bodies.
- Conjunctival biopsy—may be useful with mass lesions and nodular episcleritis or chronic disease for which a definitive diagnosis has not been made.
- Intradermal skin testing—may be helpful with suspected allergic conjunctivitis.

PATHOLOGIC FINDINGS

- Biopsy—typical signs of inflammation (e.g., neutrophils and lymphocytes); may note infectious agents.
- Histopathology of mass lesions may reveal neoplasia or nodular episcleritis.
- Ligneous conjunctivitis—thick amorphous eosinophilic hyaline-like material.

TREATMENT

APPROPRIATE HEALTH CARE

- Primary—often outpatient.
- Secondary to other diseases (e.g., ulcerative keratitis, uveitis, glaucoma, lens luxation)—may require hospitalization to address a severe underlying ophthalmic issue.

NURSING CARE

- Irritant induced conjunctivitis—flush ocular surfaces and remove foreign body if observed.
- Allergic or follicular conjunctivitis— instruct the client to apply a viscous artificial tear gel to both eyes before the patient is active outdoors (q8–12h) then flush the ocular surface with eye wash when returning indoors to remove “trapped” allergens.

CONJUNCTIVITIS—DOGS

(CONTINUED)

- Secondary to ectropion or medial canthal pocket syndrome— instruct the client to flush the ocular surface with eye wash daily to remove dust, dirt, or other particulate matter that collects ventrally.

ACTIVITY

- No restriction for most patients.
- Suspected contact irritant or acute allergic disease— prevent contact with the offending agent.
- Do not expose patients with infectious viral disease to susceptible animals.

DIET

- No change for most patients.
- Suspected underlying skin disease and/or food allergy— food elimination diet recommended.

CLIENT EDUCATION

- When solutions and ointments are prescribed, instruct the client to use the solution(s) before the ointment(s) and wait at least 5 minutes between treatments.
- If copious discharge is noted, instruct the client to clean the eyes before giving medication.
- Instruct the client to call for instructions if the condition fails to improve or worsens, which indicates that the condition may not be responsive, may be progressing, or that the animal may be having an adverse reaction to a prescribed medication.
- Inform the client that an Elizabethan collar should be placed on the patient if self-trauma occurs.

SURGICAL CONSIDERATIONS

- Follicular conjunctivitis—if follicles are large and unresponsive to medical care, consider follicle debridement.
- Entropion, distichia, or other eyelid disease—perform temporary or permanent surgery depending on the findings, signalment and history.
- Nasolacrimal duct obstruction—if repeated flushing attempts at weekly intervals along with medical therapy is unsuccessful consider contrast study and surgery (see Epiphora).
- Conjunctival neoplasia—depending on tumor type and extent of involvement may involve local excision and adjunctive therapy (β -irradiation, cryotherapy), enucleation, or exenteration.

MEDICATIONS

DRUG(S) OF CHOICE

Bacterial

- Initial treatment— broad-spectrum topical triple antibiotic q6–8h continuing several days past the resolution of clinical signs.
- Based on bacterial culture and sensitivity results if refractory to initial treatment.
- Systemic antibiotic (e.g., cephalosporin)— occasionally indicated, especially for more generalized disease (e.g., pyoderma).

Neonatal

Carefully open the eyelid margins (medial to lateral), establish drainage, and treat with topical antibiotic ointment q6–8h.

Herpetic

- Condition usually mild and self-limiting.
- Antiviral treatment—indicated for severe intractable canine herpes virus-1 conjunctivitis or herpetic keratitis.
- 0.5% cidofovir solution (available from compounding pharmacies) — topical q12h.
- Trifluridine 1% solution—topical q4h.
- 0.1% idoxuridine solution (available from compounding pharmacies)—topical q4h.

Immune-Mediated

- Depends on severity.
- Allergic and follicular conjunctivitis— attempt “Nursing Care” first with viscous artificial tear gel lubricants and ocular flushing q8–12h; if nonresponsive consider antihistamine eye drops (e.g., ketotifen) q8–12h or topical corticosteroid (e.g., dexamethasone) q8–12h.
- Lymphocytic/plasmacytic conjunctivitis— 0.1% dexamethasone q8h then taper gradually to lowest effect dose; could attempt transition to cyclosporine 0.2% ointment or 1–2% compounded solution q12–24h.
- Treatment of any underlying disease (e.g., atopy) often improves clinical signs of allergic conjunctivitis.

Tear Deficiencies

- Aqueous tear film deficiency (see Keratoconjunctivitis Sicca)
- Qualitative tear deficiency—cyclosporine 0.2% ointment or 1–2% compounded solution q12h and viscous artificial tear lubricants q6–12h.

CONTRAINdications

Topical corticosteroids— avoid if corneal ulceration is present, patient is at high risk for ulceration (e.g., entropion, lagophthalmos, severe KCS), and with known or suspected infectious conjunctivitis.

PRECAUTIONS

- Topical medications may be irritating.
- Topical corticosteroids—monitor all patients carefully for signs of corneal ulceration; discontinue agent immediately if corneal ulceration occurs.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Other corticosteroids—1% prednisolone acetate; betamethasone; hydrocortisone.

FOLLOW-UP

PATIENT MONITORING

Recheck shortly after beginning treatment (at 5 days); then recheck in 2 weeks or as needed.

PREVENTION/AVOIDANCE

Treat any underlying disease that may be exacerbating the conjunctivitis (e.g., KCS, allergic or immune-mediated skin disease).

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Good prognosis when underlying cause identified and treated (e.g., KCS, adnexal disease, eyelash disorder).
- Bacterial—usually resolves with appropriate antibiotics; may depend on resolution of underlying disease (e.g., KCS).
- Allergic or follicular—nursing care or medical treatment may be needed during peak allergy times.
- Lymphocytic/plasmacytic—tend to be controlled and not cured; may require chronic treatment at the lowest level possible.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Atopy • Pyoderma

AGE-RELATED FACTORS

N/A

CONSTIPATION AND OBSTIPATION

BASICS

DEFINITION

- Constipation—infrequent, incomplete, or difficult defecation with passage of hard or dry feces.
- Obstipation—intractable constipation caused by prolonged retention of hard, dry feces; defecation is impossible in the obstipated patient.

PATHOPHYSIOLOGY

- Constipation can develop with any disease that impairs the passage of feces through the colon. Potential causes include congenital vertebral malformation, spinal cord disease, pelvic canal narrowing (trauma), rectal mass lesions causing obstruction, and perianal disease causing painful defecation. Often in cats, no underlying etiology can be identified.
- Delayed fecal transit allows removal of additional salt and water, producing drier feces. Clinical signs are attributable to dehydration and potential toxemia resulting from fecal retention.
- Peristaltic contractions may increase during constipation, but eventually motility diminishes because of smooth muscle degeneration secondary to chronic overdistension.

SYSTEMS AFFECTED

Gastrointestinal

GENETICS

N/A

INCIDENCE/PREVALENCE

Common clinical problem in older cats; less common in dogs.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

- Dog and cat
- More common in cat

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

Historical Findings

- Straining to defecate with small or no fecal volume
- Hard, dry feces
- Infrequent defecation
- Small amount of liquid, mucoid stool—sometimes with blood present produced after prolonged tenesmus
- Occasional vomiting, inappetence, and/or lethargy

Physical Examination Findings

- Colon filled with hard feces. Severe impaction may cause abdominal distention.
- Other findings depend on the underlying cause.
- Rectal examination may reveal mass, stricture, perineal hernia, anal sac disease, foreign body or material, prostatic enlargement, or narrowed pelvic canal.

CAUSES

Dietary

- Bones
- Hair
- Foreign material
- Excessive fiber
- Inadequate water intake

Environmental

- Lack of exercise
- Change of environment—hospitalization, dirty litter box
- Inability to ambulate

Drugs

- Anticholinergics
- Antihistamines
- Opioids
- Barium sulfate
- Sucralfate
- Antacids
- Kaopectolin
- Iron supplements
- Diuretics

Painful Defecation (Dyschezia)

- Anorectal disease—anal sacculitis, anal sac abscess, perianal fistula, anal stricture, anal spasm, rectal foreign body, rectal prolapse, proctitis.
- Trauma—fractured pelvis, fractured limb, dislocated hip, perianal bite wound or laceration, perineal abscess.

Mechanical Obstruction

- Extraluminal—healed pelvic fracture with narrowed pelvic canal, prostatic hypertrophy, prostatitis, prostatic neoplasia, intrapelvic neoplasia, sublumbar lymphadenopathy.
- Intraluminal and intramural—colonic or rectal neoplasia or polyp, rectal stricture, rectal foreign body, rectal diverticulum, perineal hernia, rectal prolapse, and congenital defect (atresia ani).

Neuromuscular Disease

- Central nervous system—paraplegia, spinal cord disease, intervertebral disc disease, cerebral disease (lead toxicity, rabies).
- Peripheral nervous system—dysautonomia, sacral nerve disease, sacral nerve trauma (e.g., tail fracture/pull injury).
- Colonic smooth muscle dysfunction—idiopathic megacolon in cats.

Metabolic and Endocrine Disease

- Impaired colonic smooth muscle function—hyperparathyroidism, hypothyroidism, hypokalemia (chronic renal failure), hypercalcemia.

- Debility—general muscle weakness, dehydration, neoplasia.

RISK FACTORS

- Drug therapy—anticholinergics, narcotics, barium sulfate
- Metabolic disease causing dehydration
- Intact male—perineal hernia, prostatic disease
- Perianal fistula
- Pica—foreign material
- Excessive grooming—hair ingestion
- Decreased grooming/inability to groom—longhaired cats, pseudocoprostasis
- Pelvic fracture

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dyschezia and tenesmus (e.g., caused by colitis or proctitis)—unlike constipation, associated with increased frequency of attempts to defecate and frequent production of small amounts of liquid feces containing blood and/or mucus; rectal examination reveals diarrhea and lack of hard stool.
- Stranguria (e.g., caused by cystitis/urethritis)—unlike constipation, can be associated with hematuria and abnormal findings on urinalysis (pyuria, crystalluria, bacteruria).

CBC/BIOCHEMISTRY/URINALYSIS

- Usually unremarkable.
- May detect hypokalemia, hypercalcemia.
- High PCV and total protein in dehydrated patients.
- High WBC in patients with severe obstipation secondary to bacterial or endotoxin translocation, abscess, perianal fistula, prostatic disease.
- Pyuria and hematuria with prostatitis.

OTHER LABORATORY TESTS

- If patient (dog) is hypercholesterolemic, consider a thyroid panel to rule out hypothyroidism.
- If patient is hypercalcemic, consider parathyroid hormone assay.

IMAGING

- Abdominal radiography documents severity of colonic impaction. Other findings may include colonic or rectal foreign body, colonic or rectal mass, prostatic enlargement, fractured pelvis, dislocated hip, or perineal hernias.
- Pneumocolon (after enemas to clean colon) may better define an intraluminal mass or stricture.
- Ultrasonography may help define extraluminal mass and prostatic disease.

DIAGNOSTIC PROCEDURES

Colonoscopy may be needed to identify a mass, stricture, or other colonic or rectal

CONSTIPATION AND OBSTIPATION

(CONTINUED)

lesion; rectal/colonic mucosal biopsy specimens should always be obtained.

C

TREATMENT

APPROPRIATE HEALTH CARE

- Remove or ameliorate any underlying cause if possible.
- Discontinue any medications that may cause constipation.
- May need to treat as inpatient if obstipation and/or dehydration present.

NURSING CARE

Dehydrated patients should receive IV (preferably) or SC balanced electrolyte solutions (with potassium supplementation if indicated).

ACTIVITY

Encourage activity

DIET

Dietary supplementation with a bulk-forming agent (bran, methylcellulose, canned pumpkin, psyllium) is often helpful, though they can sometimes worsen colonic fecal distension; in this case, feed a low-residue-producing diet.

CLIENT EDUCATION

Feed appropriate diet and encourage activity.

SURGICAL CONSIDERATIONS

- Manual removal of feces with the animal under general anesthesia (after rehydration) may be required if enemas and medications are unsuccessful.
- Subtotal colectomy may be required with recurring obstipation that responds poorly to assertive medical therapy.

MEDICATIONS

DRUG(S) OF CHOICE

- Emollient laxatives—docusate sodium or docusate calcium (dogs, 50–100 mg PO q12–24h; cats, 50 mg PO q12–24h).
- Stimulant laxatives—bisacodyl (5 mg/animal PO q8–24h). Ensure that animal is not obstructed prior to use of stimulant laxatives.
- Saline laxatives—isosmotic mixture of polyethylene glycol and poorly absorbed salts; usually administered as a trickle amount via nasoesophageal tube over 6–12 hours.
- Disaccharide laxative—lactulose (1 mL/4.5 kg PO q8–12h to effect).

- Warm water enemas may be needed; a small amount of mild soap or docusate sodium can be added but is usually not needed; sodium phosphate retention enemas (e.g., Fleet; C.B. Fleet Co., Inc.) are contraindicated because of their association with severe hypocalcemia.
- Suppositories can be used as a replacement for enemas; use glycerol, bisacodyl, or docusate sodium products.
- Motility modifiers can be administered—cisapride (dogs, 0.3–0.5 mg/kg PO q8–12h; cats, 2.5–10 mg/cat PO q8–12h) may stimulate colonic motility; indicated with early megacolon.

CONTRAINdications

- Lubricants such as mineral oil and white petrolatum are NOT recommended because of the danger of fatal lipid aspiration pneumonia due to their lack of taste.
- Fleet enemas.
- Anticholinergics.
- Diuretics.

PRECAUTIONS

Cisapride, and cholinergics—can be used with caution; contraindicated in obstructive processes. Avoid the use of metoclopramide because it does not affect the colon.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

- Ranitidine causes contraction of colonic smooth muscle in vitro.
- Newer generation cisapride-like drugs may be available soon.
- Pilot studies in Europe demonstrate improved ease of defecation following the administration of multistrain probiotic bacteria.

FOLLOW-UP

PATIENT MONITORING

Monitor frequency of defecation and stool consistency at least twice a week initially, then weekly or biweekly in response to dietary and/or drug therapy.

PREVENTION/AVOIDANCE

Keep pet active and feed appropriate diet. Subcutaneous fluids to ensure hydration can help reduce the frequency of constipation, particularly in cats.

POSSIBLE COMPLICATIONS

- Chronic constipation or recurrent obstipation can lead to acquired megacolon.
- Overuse of laxatives and enemas can cause diarrhea.
- Colonic mucosa can be damaged by improper enema technique, repeated rough mechanical breakdown of feces, or ischemic necrosis secondary to pressure of hard feces.
- Perineal irritation and ulceration can lead to fecal incontinence.

EXPECTED COURSE AND PROGNOSIS

Varies with underlying cause

MISCELLANEOUS

ASSOCIATED CONDITIONS

Vomiting—with severe/prolonged obstipation

BASICS

OVERVIEW

- Irritant contact dermatitis and allergic contact dermatitis—rare and possibly different pathophysiologic syndromes with similar clinical signs; differentiation may be more conceptual than practical.
- ICD—results from direct damage to keratinocytes by exposure to a particular compound; damaged keratinocytes induce an inflammatory response directed at the skin without prior sensitization.
- ACD—considered a type IV (delayed) hypersensitivity, an immunologic event requiring sensitization and elicitation: Langerhans cells interact with environmental haptens to create antigens, leading to the sensitization of T-lymphocytes and activation following reexposure with release of cytokines (most notably TNF- α and IFN- γ).
- Recent reports blur the distinction between ICD, ACD, and atopic dermatitis.

SIGNALMENT

- Dogs and cats.
- ICD—occurs at any age as a direct result of the irritant nature of the offending compound.
- ACD—rare in young animals; most animals are chronically exposed to the antigen (months to years); extremely rare in cats, except when exposed to d-limonene-containing insecticides.
- Increased risk of ACD—German shepherd dog, poodle, wirehaired fox terrier, Scottish terrier, West Highland white terrier, Labrador and golden retriever.

SIGNS

Lesions

- Location determined by antigen contact; commonly limited to glabrous skin and regions frequently in direct contact with the environment.
- Thick hair coat of dogs is an effective barrier against contactants.
- Extreme erythroderma stops abruptly at the hairline.
- Initial erythema and papules leading to crusts and excoriations; vesicles uncommon.
- Chronic exposure leads to lichenification and hyperpigmentation.

Others

- Reactions to topical medications (e.g., otic preparations, spot-on flea products) usually localized.
- Generalized reactions, resulting from shampoos or insecticide sprays.
- Pruritus—moderate to severe (most common).
- Seasonal incidence may indicate a plant or outdoor antigen (e.g., ice-melting substance).

CAUSES & RISK FACTORS

- Reported offending substances—plants, mulch, cedar chips, fabrics, rugs, carpets, plastics, rubber, leather, nickel, cobalt, concrete, soaps, detergents, floor waxes, epoxy

resin, carpet and litter deodorizers, herbicides, fertilizers, insecticides (including newer topical flea treatments), flea collars, topical preparations especially neomycin.

- Increased incidence of ACD and ICD in the young and in atopic animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Atopy
- Food allergy
- Drug reaction
- Insect bites/hypersensitivity
- Pelodera dermatitis
- Hookworm dermatitis
- Pyoderma
- *Malassezia* dermatitis
- Dermatophytosis
- Demodicosis
- Lupus erythematosus
- Seborrheic dermatitis
- Solar dermatitis
- Thermal injuries
- Trauma from rough surfaces
- Staphylococcal folliculitis

DIAGNOSTIC PROCEDURES

- ACD—closed-patch test sometimes helpful (corticosteroids and NSAIDs must be discontinued 3–6 weeks before testing); use materials taken from the environment or home applied to upper thorax skin under a bandage for 48 hours. Examine for 5 days. Erythema, edema, variable pruritus.
- Best diagnostic test for ICD—eliminate contact irritant or antigen, followed by provocative exposure.
- Open patch test—applying the substance to the inside pinnae causing mild erythema, edema, pruritus. Examine daily for 5 days.
- Skin biopsy.

PATHOLOGIC FINDINGS

- Intraepidermal vesiculation and spongiosis; superficial dermal edema with perivascular mononuclear cell infiltrate in ICD and ACD; polymorphonuclear cell infiltrate in ICD; leukocyte exocytosis common.
- Lymphocytic spongiotic or eosinophilic and lymphocytic spongiotic infiltrate with intraepidermal eosinophilic pustules in canine ACD.

TREATMENT

- Eliminate offending substance(s).
- Bathe with hypoallergenic shampoos to remove antigen from the skin.
- Create mechanical barriers, if possible—socks, shirts, restriction from environment.

MEDICATIONS

DRUG(S)

- Systemic corticosteroids—prednisolone (1 mg/kg PO q24h for 5–7 days then q48h for 2 weeks).

- Topical corticosteroids for focal lesions.
- Pentoxifylline 10–25 mg/kg PO q8-12h initially; may be reduced to q24h to maintain; may cause gastric irritation.
- Cyclosporine 5 mg/kg q24h for ACD.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Pentoxifylline—do not administer with alkylating agents, cisplatin, and amphotericin B; cimetidine may increase serum levels of pentoxifylline.

FOLLOW-UP

PREVENTION/AVOIDANCE

Remove offending substances from the environment.

EXPECTED COURSE AND PROGNOSIS

ICD

- Acute condition—may occur after only one exposure; can be manifested within 24 hours of exposure.
- Corticosteroids rarely helpful.
- Lesions resolve 1–2 days after irritant removal.

ACD

- Requires months to years of exposure for hypersensitivity to develop.
- Reexposure results in development of clinical signs within 1–5 days; signs may persist for several weeks.
- Responds well to corticosteroids; pruritus returns after discontinuation if the antigenic stimulus persists.
- Hypo sensitization not effective.
- Prognosis—good if the allergen is identified and removed; poor if the allergen is not identified; may require life-long treatment.

ABBREVIATIONS

- ACD = allergic contact dermatitis
- ICD = irritant contact dermatitis
- IFN- γ = interferon gamma
- NSAID = nonsteroidal anti-inflammatory drug
- TNF- α = tumor necrosis factor alpha

COONHOUND PARALYSIS (ACUTE POLYRADICULONEURITIS)

BASICS

DEFINITION

- Acute inflammatory disorder involving the axons and myelin of nerve roots, spinal nerves, and peripheral nerves in dogs, with or without a previous history of contact with raccoon saliva, vaccination, or a gastrointestinal or respiratory infection.
- Proposed animal model for Guillain-Barré syndrome in humans.

PATOPHYSIOLOGY

- Etiology uncertain, appears to be immune-mediated.
- Immune-mediated inflammation develops 7–14 days after antecedent event (delayed hypersensitivity reaction?).
- Thought to be the dog's immune system reaction to a cross-reacting antigen (suspect molecular mimicry phenomenon between external antigen and gangliosides from dog's neural tissue, with the development of antiganglioside autoantibodies).
- Coonhound paralysis (CHP)—antecedent event is recent contact with raccoon saliva.
- Acute canine idiopathic polyradiculoneuritis (ACIP)—affected dogs with identical clinical signs than those with CHP but without a history of raccoon exposure; may have history of recent respiratory or gastrointestinal infection.
- Post-vaccinal polyradiculoneuritis—antecedent event is recent vaccination (rare).
- *Toxoplasma gondii* infection—dogs with ACIP more likely to have positive titers than control dogs (possible triggering factor?).

SYSTEMS AFFECTED

- Peripheral nervous system—most severe involvement in the ventral (motor) nerve roots and ventral root components of the spinal nerves; lumbosacral nerve roots affected more severely than cervical and thoracic nerve roots.
- Cranial nerves—nerve VII often affected; nerves IX, X occasionally affected.
- Respiratory failure—secondary to intercostal and/or phrenic nerve involvement in some patients.

GENETICS

No proven basis.

INCIDENCE/PREVALENCE

- Most commonly recognized acute polyneuropathy in dogs.
- Low incidence.

GEOGRAPHIC DISTRIBUTION

- CHP—relative to the distribution of raccoons (e.g., North and Central America; parts of South America).
- ACIP—worldwide.

SIGNALMENT

Species

Dog, very occasionally cat.

Breed Predilections

- CHP—Coonhounds; any breed in contact with raccoons susceptible.
- ACIP, post-vaccinal polyradiculoneuritis—none.

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

Historical Findings

- Appear 7–14 days after contact with raccoon saliva (bite or scratch), receipt of a vaccination, or development of a respiratory or gastrointestinal infection.
- Initial signs—stiff, stilted gait in all limbs, typically starting in the pelvic limbs and eventually progressing to the thoracic limbs.
- Rapid progression (2–4 days) to a flaccid, lower motor neuron tetraparesis to tetraplegia.
- Owners may notice loss or change of voice.
- Appetite and water consumption—usually normal.
- Urination and defecation—normal.
- Progressive phase of the disease—clinical signs can continue to worsen up to 5–10 days after onset.

Neurologic Examination Findings

- Usually symmetrical.
- Stiff, stilted gait that usually progresses rapidly to lower motor neuron tetraparesis or tetraplegia; some dogs may remain ambulatory tetraparetic.
- Generalized hyporeflexia to areflexia, with the exception of a normal perineal reflex.
- Generalized hypotonia to atonia, severe neurogenic muscle atrophy.
- Affected dogs often show inability to hold the head up.
- Aphonia or dysphonia common; no megaesophagus.
- Facial paresis—bilateral incomplete palpebral closure in some patients.
- Respiration—labored in severely affected dogs; occasional progression to respiratory paralysis.
- Pain sensation intact; hyperesthesia common, may reflect variable dorsal nerve root inflammation.
- Motor dysfunction—always predominates; even tetraplegic patient can usually wag its tail.
- Mental status, urination and defecation—unaffected.

CAUSES

- CHP—contact with a raccoon; perhaps more important, contact with raccoon saliva.
- ACIP—none proven; possibly previous respiratory or gastrointestinal viral or bacterial infection.

- Post-vaccinal polyradiculoneuritis—recent vaccination (rare).

RISK FACTORS

- CHP—coonhounds tend to be predisposed primarily because of the nature of their activities; previous disease does not confer immunity and may increase risk of redevelopment; multiple bouts not uncommon.
- ACIP—unknown.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other acute polyneuropathy (i.e., paraneoplastic neuropathy)
- Distal denervating disease
- Botulism
- Tick bite paralysis
- Fulminant myasthenia gravis
- Black widow spider bite envenomation, coral snake envenomation
- Intoxications (lasalocid, blue-green algae)
- Generalized (diffuse) or multifocal myelopathy (involving both cervical and lumbosacral intumescences)

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

OTHER LABORATORY TESTS

- Serum immunoglobulins—high serum IgG but not IgM in some patients.
- Immunologic—serum reaction to raccoon saliva on ELISA; dogs with CHP have a strong positive reaction that decreases in intensity over time; dogs without disease but with raccoon contact have a strong positive reaction; dogs with ACIP but with no raccoon contact have a negative reaction.
- Immunologic—for dogs with ACIP, the identification of anti-GM2 ganglioside antibodies reached a diagnostic sensitivity of 60% and a specificity of 97%.

IMAGING

Thoracic radiographs and abdominal ultrasound—normal

DIAGNOSTIC PROCEDURES

CSF Analysis

- Lumbar—high protein without an increase in leukocytes at all stages of disease.
- Albumin leakage across the disrupted blood-nerve barrier of the affected ventral nerve roots is the primary cause of the protein increase.

Electrodiagnostics

- Electromyography (EMG)—generalized spontaneous activity (fibrillation potentials and positive sharp waves) consistent with denervation; EMG normal in the first 4–5 days.
- Markedly low compound muscle action potential amplitudes after motor nerve stimulation.

(CONTINUED)

COONHOUND PARALYSIS (ACUTE POLYRADICULONEURITIS)

C

- F waves (late waves that indicate proximal motor nerve and ventral nerve root function)—prolonged minimum latencies, increased F ratio, decreased amplitudes.
- Motor nerve conduction velocities—usually normal; severely affected patients may have mildly decreased values.
- Sensory nerve function—usually normal.
- Abnormalities provide evidence of severe peripheral motor axonopathy (more severe in proximal portions of the nerves and ventral nerve roots), along with demyelination in the proximal motor nerves and ventral nerve roots.

PATHOLOGIC FINDINGS

- Ventral nerve roots and the ventral root components of the spinal nerves—most severe lesions, various degrees of axonal degeneration, paranodal and segmental demyelination, and leukocyte infiltration (predominantly monocytes and macrophages).
- Peripheral nerves—affected to a lesser degree; might be normal.
- Dorsal nerve roots—much less severely affected.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Inpatient—closely monitor patients in the progressive phase of the disease (especially during first 5 days) for respiratory problems.
- Severe respiratory compromise—mechanical ventilation as required.
- Intravenous fluid therapy—administer if patient is dehydrated.
- Outpatient—once patient is stable and the progressive phase of the disease is over.

NURSING CARE

- Patients are usually able to eat and drink; hand feed in sternal position until able to reach food and water.
- Intensive physical therapy—important to decrease muscle atrophy; severe neurogenic muscle atrophy is inevitable.
- Frequent turning and excellent padding—essential to prevent pressure sores.

ACTIVITY

- Encourage as much movement as possible.

DIET

- No restrictions.
- Make sure patient is able to reach food and water.
- Cervical weakness—may need to hand feed patient in sternal position.

CLIENT EDUCATION

- Inform client that good nursing care is essential.
- Discuss importance of preventing pressure sores and urine scalding and of limiting the degree of muscle atrophy by frequent daily

physical therapy (passive limb movement, swimming as the patient's strength begins to improve).

- Patient needs soft bedding that must be kept free of urine and feces, frequent turning (every 3–4 hours), frequent bathing, and adequate nutrition.

SURGICAL CONSIDERATIONS

N/A

**MEDICATIONS****DRUG(S) OF CHOICE**

- None proven effective.
- Immunoglobulin—1 g/kg IV daily for 2 consecutive days, 0.5 g/kg IV daily for 3 consecutive days, or 0.4 g/kg IV daily for 5 consecutive days; given early may shorten recovery time in ACIP.

CONTRAINDICATIONS

Corticosteroids—do not improve clinical signs or shorten course of disease; may reduce survival in humans with Guillain-Barré syndrome.

PRECAUTIONS

Monitor for possible adverse reactions (anaphylaxis, hematuria) after IV immunoglobulin administration.

**FOLLOW-UP****PATIENT MONITORING**

- Outpatient—keep in close contact with client regarding complications or changes in the patient's condition.
- Urinalysis—perform periodically to check for cystitis in tetraplegic or severely tetraparetic patients.
- Ideally, reevaluate at least every 2 weeks.

PREVENTION/AVOIDANCE

- CHP—if possible, avoid contact with raccoons.
- Post-vaccinal polyradiculoneuritis—if strong association with a specific vaccination, avoid that particular vaccine in the future.

POSSIBLE COMPLICATIONS

- Respiratory paralysis—in progressive phase of the disease.
- Pressure sores, urine scalding, cystitis—common in chronically recumbent dogs.

EXPECTED COURSE AND PROGNOSIS

- Signs stabilize once the progressive phase of the disease is over.
- Most affected dogs recover fully over 3–6 weeks; severely affected cases may take up to 3–4 months to recover; incomplete recoveries can happen.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

COPPER ASSOCIATED HEPATOPATHY

BASICS

DEFINITION

- Severe hepatic accumulation of copper (Cu) causes acute or chronic hepatitis leading to cirrhosis or death from liver failure.
- Mild to moderate hepatic Cu accumulation augments oxidative injury and increases risk for liver disease by other hepatobiliary insults, notably, hepatotoxicity from NSAIDs.
- *Primary Copper Associated Hepatopathy* (Cu-AH) depicts copper accumulation in the absence of other liver disorders or as the major cause of liver injury.
- *Secondary Cu-AH* depicts Cu accumulation caused by severe chronic cholestasis in cats (not dogs) or fulminant hepatic failure (rare).
- *Genetic-Primary Cu-AH*: only proven in the Bedlington terrier.
- *Acquired-Primary Cu-AH*: Most common canine cause of Cu-AH, reflects dietary Cu availability in commercial dog food that exceeds an individual's ability to maintain a neutral Cu balance.
- *Congenital Primary Cu-AH*: (no gene mutation characterized) is comparatively rare in cats.
- Some animals with primary Cu-AH accumulate Cu without histologic evidence of liver damage despite vacillating liver enzyme activity (ALT most common).

PATOPHYSIOLOGY

- Hepatic Cu homeostasis depends on a complex regulatory system that includes: protein transporters, chaperones, membrane receptors, intracellular binding-proteins, and canalicular egress pumps. Cu is absorbed from the small intestine, stored in the liver, with excess excreted in bile.
- A single gene mutation in dogs (*COMMD1*) is proven to cause genetic-primary Cu-AH in Bedlington terriers.
- More commonly, canine hepatic Cu accumulation reflects Cu intake exceeding capacity to maintain neutral Cu balance; this likely reflects complex transporter differences between individual dogs and may reflect genetic drift associated with development of breed standards.
- Secondary Cu-AH reflects reduced canalicular Cu egress secondary to severe cholestasis (cats only) or severe panlobular liver injury (fulminant hepatic failure, rare).
- In primary Cu-AH: cytosolic hepatocellular Cu first accumulates in zone 3 (centrilobular region).
- In secondary Cu-AH (cats): cytosolic hepatocellular Cu accumulates in zone 1 (periportal) or adjacent to injured regions.
- Hepatic Cu concentrations are widely variable. Primary Cu-AH may range from 500 to > 10,000 µg/g dry weight liver (DWL) whereas secondary Cu-AH rarely exceeds 1,000 µg/g DWL.
- Cu accumulation causes hepatocellular injury due to oxidative membrane and mitochondrial injury.
- Focal

hepatitis progresses to chronic hepatitis and eventually cirrhosis and may initiate an immune-mediated process.

- Rarely, acute severe hepatic necrosis releases Cu into the systemic circulation causing hemolysis and/or an acute-onset acquired Fanconi syndrome (proximal renal tubular injury causing euglycemic glucosuria).

SYSTEMS AFFECTED

- Hepatobiliary—focal hepatitis, chronic hepatitis, eventual cirrhosis.
- Hemic/Lymphatic—hemolytic anemia a rare sequel to acute hepatic necrosis in dogs with high hepatic Cu concentrations (e.g., Bedlington terrier) in which large amounts of Cu are suddenly released into the systemic circulation.
- Renal—rare reversible Fanconi syndrome causing euglycemic glucosuria, granular casts, with or without clinicopathologic evidence of reduced renal function.

GENETICS

- Autosomal recessive *COMMD1* mutation in Bedlington terriers reduces biliary Cu excretion.
- Gene mutations remain unproven in other breeds and in cats.
- Predisposition to Cu-AH is recognized in Labrador retrievers, West Highland white terriers, Doberman pinschers, and other breeds likely reflecting pharmacogenetic differences in Cu regulatory proteins or processes selected during breed development.

INCIDENCE/PREVALENCE

- Bedlington terrier—at one time up to 2/3 of dogs carried the *COMMD1* mutation; incidence significantly declined with genetic testing.
- Prevalence of excess hepatic Cu remains high in West Highland white terriers, Labrador retrievers, Doberman pinschers and other breeds; historical account in Skye terriers.
- Cu-AH is currently the most common cause of chronically increased ALT activity in dogs (since the mid 1990s), likely linked with altered Cu supplements in dog foods.
- Cu-AH currently comprises ≥ 20% of liver biopsy submissions for abnormal enzyme activity in dogs. High hepatic Cu concentration (> 400 µg/g DWB) is not always associated with histologic evidence of liver injury.
- Primary-congenital Cu-AH occurs in cats but is comparatively rare.

GEOGRAPHIC DISTRIBUTION

Reported worldwide

SIGNALMENT

Species

Dog and cat; more common in dogs

Breed Predilections

Bedlington terrier, West Highland white terrier, Labrador retriever, Doberman pinscher, Dalmatian, Welsh Corgi, Keeshond, Staffordshire terrier observed to

have increased incidence of high hepatic Cu concentrations. No canine breed is exempt.

Mean Age and Range

- Bedlington terrier—Cu slowly accumulates to a maximum at ~ 6 years of age; dogs can be clinically affected at any age, most present as middle-aged to older dogs with chronic hepatitis.
- West Highland white terrier—maximum Cu accumulation observed by 12 months of age; clinical disease may occur at any time; some dogs with high hepatic Cu live to old age (15 y) without evidence of liver injury.
- Labrador retrievers, Dalmatians, other breeds with apparent increased risk—young adult to middle-aged at diagnosis for chronic hepatitis.
- Doberman pinschers—may begin to develop hepatitis with ALT increases and Cu accumulation at 1–3 years of age; clinical signs of liver disease often occur after 7 years of age.
- Skye terrier—all ages can be affected.

Predominant Sex

None

SIGNS

Historical Findings

- Primary Cu-AH: 4 categories (1) no clinical signs, (2) subclinical disease, (3) acute disease (uncommon) associated with severe acute hepatic necrosis, or (4) chronic progressive hepatitis (middle-aged to older dogs), progressive to cirrhosis.
- Secondary Cu-AH accompanies feline necroinflammatory cholestatic liver disease (cholangiohepatitis) or rarely, in dogs with fulminant liver necrosis.
- Acute signs—sudden onset lethargy, anorexia, vomiting; may have a rapid course, with dogs succumbing despite intensive supportive care.
- Chronic signs—variable, intermittent lethargy, hyporexia, weight loss, vomiting, diarrhea, polydipsia and polyuria. Later signs may include: abdominal distention (ascites), jaundice, bleeding tendencies, and HE.

Physical Examination Findings

- Acute signs—lethargy, weakness, jaundice, pallor (anemia), vomiting, diarrhea, and dark urine (bilirubinuria; rare hemoglobinuria).
- Chronic signs—weight loss, ascites, jaundice, and nodular microhepatia. Melena and petechial hemorrhage in animals with diffuse panlobular injury.

CAUSES

- Genetic Cu-AH—single gene mutation in Bedlington terriers.
- Primary Cu-AH: either Bedlington mutation or suspected pharmacogenetic differences in other dog breeds involving regulatory pathways influencing Cu homeostasis making them intolerant to current levels of dietary Cu supplementation.
- Secondary Cu-AH—necroinflammatory chronic cholestatic liver disease in cats or diffuse severe panlobular injury in dogs or cats (rare) impairing Cu regulatory pathways.

(CONTINUED)

COPPER ASSOCIATED HEPATOPATHY

C

RISK FACTORS

- Primary—feeding diets or providing water with Cu concentrations exceeding an individual dog's ability to maintain a neutral Cu balance.
- Stress may precipitate acute disease.
- Asymptomatic dogs with primary Cu-AH may become symptomatic when additional disease processes or toxicities (e.g., NSAID administration; CCNU chemotherapy) impose oxidative challenge or another primary liver abnormality develops (e.g., immune-mediated hepatitis, severe glycogen-type vacuolar hepatopathy, cholangiohepatitis).

**DIAGNOSIS****DIFFERENTIAL DIAGNOSES**

- Acute diseases—*infectious diseases* (e.g., infectious canine hepatitis, leptospirosis, septicemia), acute hepatic necrosis, hepatic abscess, drug- or toxin-induced hepatic injury, acute pancreatitis, hepatic lymphoma, autoimmune hemolytic anemia, or zinc toxicity.
- Chronic diseases—chronic hepatitis; cholangiohepatitis of inflammatory or immune-mediated origin, drug- or toxin-induced liver injury, severe diffuse glycogen-type vacuolar hepatopathy (dogs), infectious hepatitis, chronic obstructive biliary disease, chronic fibrosing pancreatitis, congenital portosystemic shunt, hepatic neoplasia, or metastatic neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

- *CBC*—may be normal. Regenerative anemia, leukocytosis, neutrophilia in some animals with acute Cu-associated hemolysis. Microcytic or normocytic, normochromic non-regenerative anemia in some dogs with chronic progressive disease. RBC microcytosis may reflect acquired portosystemic shunting (APSS).
- *Biochemistry*—increased liver enzymes (ALT, AST, GGT and ALP; transaminase increases prominent with fold increase in ALT > ALP; hyperbilirubinemia notable in dogs with severe liver injury. Increased ALT without clinical signs increases suspicion for early or cyclic Cu-AH necrosis.
- As hepatic function deteriorates, hypoalbuminemia, \pm hyperglobulinemia, low BUN, rare hypoglycemia, and hypocholesterolemia develop.
- *Urinalysis*—usually normal or positive for bilirubinuria; later dilute urine, ammonium biurate crystalluria may appear in dogs with APSS which reflect sinusoidal hypertension (remodeling and fibrosis). Rarely, acquired Fanconi syndrome reflects proximal renal tubule Cu toxicity.

OTHER LABORATORY TESTS

- High fasting or postprandial TSBA values.
- Prolonged PT, APTT, ACT, and mucosal

bleeding time in advanced cases. • Rare increase in serum Cu concentrations in dogs with acute severe Cu-AH liver necrosis; otherwise serum Cu does not reflect liver Cu concentrations; a low yield screening test.

- Hepatic Cu measurements must be reconciled with histopathologic findings.
- Genetic marker testing in Bedlington terriers: microsatellite markers or specific *COMMD1* mutation. However, kindreds of Bedlington terriers with Cu-AH have had negative PCR-based gene tests (suspected additional gene mutation).

IMAGING

- Radiography—unremarkable in most dogs; small liver in chronic hepatic injury, poor abdominal detail if ascites.
- Ultrasonography—early: normal hepatic echogenicity; later: hyperechoic to mixed nodular echogenicity; abdominal effusion if ascites.

DIAGNOSTIC PROCEDURES

- *Liver biopsy*—confirms and characterizes liver injury. • Routine H&E staining—can overlook pathologic Cu accumulation.
- Cu-specific staining—rhodanine (preferred) or rubanic acid stains needed to identify and confirm Cu-protein aggregates and detail zonal distribution and association with liver injury.
- Semiquantitative scoring system—estimates severity of Cu accumulation.
- Cu measurements—can be completed on: fresh, frozen, formalin fixed liver, or liver tissue extracted from paraffin blocks.
- Distribution of hepatocytes with cytosolic Cu granules and quantification of Cu should be reconciled—areas of dense fibrosis, parenchymal extinction, regenerative nodules contain lower Cu concentrations than unremodeled liver tissue. This phenomenon causes discordance between measured and assessed Cu accumulation.

Cu Measurement

- *Atomic absorption spectroscopy*—gold standard method of Cu determination. • Cu must be expressed per DWL.
- Hepatic Cu determination (atomic absorption spectroscopy)—requires at least a full needle biopsy (≥ 16 g) sample.
- *Digital scanning of rhodanine-stained biopsy sections*—validated against atomic absorption spectroscopy; accurately measures liver Cu (Cornell University) on biopsy reconciling histologic change with Cu; routine diagnostic assessment (Cornell University).

Hepatic Cu Concentrations (DWL)

- Normal hepatic Cu: $\leq 400 \mu\text{g/g}$.
- Hepatic Cu concentration in dogs with primary Cu-AH ($\mu\text{g/g}$ DWL):
 - Bedlington terriers: 850–12,000
 - West Highland white terriers: up to 3,500
 - Labrador retrievers: 400–9,000
 - Doberman pinschers: 1,000–10,000
 - Dalmatians: 750–8,400
 - Cats: 700–8,000

- Avoid analytic methods “estimating” sample hydration or reporting Cu on a wet weight basis.

PATHOLOGIC FINDINGS

- Cu accumulates in lysosomes in Zone 3 (centrilobular) hepatocytes in dogs.
- Histochemical Cu staining (e.g., rhodanine) confirms affiliation of Cu with histologic injury.
- Histologic features commonly include formation of “copper granulomas” in areas of hepatocellular necrosis.
- Oxidative injury—mechanism of hepatocellular injury.
- In some cases, an apparent immune-mediated hepatitis accompanies the Cu-AH lesions, reflecting response to neopeptope formation.
- Chronic untreated necroinflammatory injury progresses to chronic hepatitis, parenchymal extinction, liver fibrosis, and eventually to cirrhosis with splanchnic hypertension, and formation of APSS.
- Cu-AH causing necroinflammatory liver injury leads to development of microhepatia with nodules reflecting regenerative nodules, and a fibrotic “firm” texture.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Outpatient for most dogs.
- Inpatient evaluation and treatment for dogs with signs of hepatic failure.
- See Hepatitis, Chronic Active and Cirrhosis and Fibrosis of the Liver for detailed management of liver disease.

NURSING CARE

- Animals in liver failure require fluid and electrolyte correction; treatment for HE; may require treatment for coagulopathy; and should be treated with IV N-acetylcysteine (NAC) for oxidative injury, with d-penicillamine chelation started as soon as oral treatment is possible.
- Dogs demonstrating hemolytic anemia may require whole or packed RBC transfusion and IV NAC.
- Dogs demonstrating acquired Fanconi syndrome require IV fluid therapy to protect against acute renal failure and IV NAC.

ACTIVITY

Normal; rest if signs of severe necrosis.

DIET

- Feed Cu-restricted diets to all affected dogs *for their lifetime*.
- Prescription liver diets deliver 2.2–2.5 g protein/kg body weight when fed for maintenance energy requirements.
- Dietary protein content should only be reduced for dogs exhibiting signs of nitrogen intolerance, e.g., HE or developing ammonium biurate crystalluria (reflects hyperammonemia and APSS formation).
- Supplemental protein is added to the base “liver” diet to increase protein

COPPER ASSOCIATED HEPATOPATHY

(CONTINUED)

intake by 0.5 g up to 1.5 g protein/kg body weight using low Cu-containing foods.

- Select supplemental low Cu-containing protein sources using the USDA food tables (available on internet).
- Determine the amount for selected foods to feed using the Nutritional Analysis Tool-2 (free web software, site maintained by the Illinois School of Human Nutrition).
- Balanced homemade diets avoiding Cu-rich foods (e.g., organ meats, nuts, certain grains) may also be formulated, but these should be recommended by a Veterinary Clinical Nutritionist. Such diets are frequently not feasible for large-breed dogs where commercial diets are often the better option as a baseline meal, as described above.
- Prescription type liver diets contain the lowest Cu content (approximately 4 mg/kg of diet) formulated originally to maintain neutral Cu balance in Cu-AH affected Bedlington terriers.
- Chelation therapy in conjunction with commercial diets can successfully manage affected dogs.
- All affected dogs *must* have lifetime dietary/water Cu restriction.
- Measure waterborne Cu and restrict access to water with Cu > 0.2 ppm.
- Avoid mineral supplements containing Cu.
- Supplement water-soluble vitamins but avoid ascorbate (vitamin C supplements during Cu hepatotoxicity: may augment oxidative injury).

CLIENT EDUCATION

- Educate all Bedlington terrier owners about the genetic basis of Cu-AH in this breed and appropriate genetic testing.
- Other breeds should be monitored for increased ALT activity and Cu should be specifically stained for in liver biopsies.
- Dogs receiving NSAIDs with associated increase in ALT activity should be investigated for potential "silent" hepatic Cu accumulation.
- Dietary management and chronic intermittent chelation or zinc administration are needed for life in most dogs.

SURGICAL CONSIDERATIONS

- Animals with hepatic failure are surgical and anesthetic risks.
- Hypoxia encountered during anesthesia or surgery can provoke Cu-driven oxidative injury.

MEDICATIONS

DRUG(S)

See other liver topics for other specific treatments of chronic hepatitis and cirrhosis.

CHELATION

d-penicillamine

- 10–15 mg/kg PO q12h.
- Chelates Cu, promotes urinary excretion of Cu, and suspected to have other Cu-protective effects.
- Initiate treatment in dogs with increased

ALT activity and biopsy confirmed centrilobular Cu accumulation affecting > 25% centrilobular hepatocytes or reconciling with lobular injury/remodeling (reticulin and Masson's trichrome staining assessment).

- Hepatic Cu as low as 600 µg/g DWL may require chelation and chronic management.
- Dogs with hepatic Cu < 1,500 µg/g DWL are usually easily cleared with 6 months of d-penicillamine chelation (biopsy proven).
- Dogs with hepatic Cu > 3,000 µg/g may require > 9–12 months of chelation.
- Administer drug 1 h before feeding.
- Drug-associated vomiting or hyporexia may be abated with low dose prednisone.
- Following a course of therapy (6 months–1 year) re-biopsy to monitor treatment efficacy is optimal, but following ALT is an alternative method of monitoring.
- Expect substantial decline in ALT by 8 weeks of chelation.
- Successful chelation results in remarkable histologic improvement and resolution of ALT activity.

Trentine hydrochloride

- 5–15 mg/kg PO q12h; alternative Cu chelator; as effective as d-penicillamine with similar guidelines.
- Administer 1 h before meals.
- Acute renal failure has been observed in some dogs given higher dosing of trentine.
- Trentine is currently restrictively expensive.
- Trentine is not more effective than d-penicillamine in humans with Wilson's disease; results are interchangeable.

Zinc—Blocking Enteric Cu Uptake

- Zinc therapy may assist in chronic control of Cu-AH. Use of zinc is predicated on study of 6 dogs (see Suggested Reading).
- Zinc reduced intestinal absorption of Cu; study demonstrated reduced hepatic Cu concentrations with 2 years of therapy in a few Bedlington (n=3) and West Highland white terriers (n=3).
- 100 mg of elemental zinc PO q12h as loading dose for 2 months, then 25–50 mg PO q12h for Bedlington-terrier-sized dog; zinc acetate is best tolerated.
- In humans with Wilson's disease, zinc dosing is optimized with Cu-isotope uptake studies.
- In humans, zinc therapy is less effective than chelation for chronic management (see Suggested Reading).
- Administer zinc 1 h before feeding.
- May be beneficial in earlier stages or dogs with lower hepatic Cu concentrations (generally < 1,000 µg/g DW).
- Zinc may lack efficacy in dogs with high Cu concentrations and hepatitis where chelation therapy is preferred.
- Coadministration of zinc and Cu chelators requires careful staggered dosing; direct physical interaction makes treatment ineffective.
- Vomiting, inappetence, gastritis—frequent side effects.
- Low concentrations of zinc given in a low Cu diet in previously chelated Labrador retrievers was found to be no better than feeding a Cu-restricted diet (see Suggested Reading).

ANTIOXIDANTS

- d- α -tocopherol (vitamin E)—10 U/kg q24h PO may protect the liver from oxidative damage imposed by Cu.
- S-Adenosylmethionine (SAMe), use product with proven bioavailability that increases hepatic GSH—20 mg/kg q24h, enteric-coated tablets given on an empty stomach.

HEPATOPROTECTANTS

- Silibinin (milk thistle extract, use form bound to PPC for best bioavailability)—5 mg/kg PO q24h; utility in Cu storage hepatopathy undetermined.
- Ursodeoxycholic acid—10–15 mg/kg PO divided BID given with food for best bioavailability; recommended if chronic hepatitis (see Hepatitis, Chronic Active) and high serum bile acid concentrations.

CONTRAINdications

- Ascorbic acid (vitamin C) may augment Cu hepatotoxicity.
- Avoid treatment with NSAID in affected dogs as these may cause centrilobular toxic adduct-related liver injury.

POSSIBLE INTERACTIONS

Penicillamine or trentine may not be effective if given concurrently zinc therapy.

PRECAUTIONS

- Remain aware of altered drug metabolism related to reduced first-pass extraction if APSS develop or altered hepatic metabolism/biotransformation in dogs with severe centrilobular necrosis and remodeling.
- Avoid NSAID administration—metabolized by p450 cytochromes in centrilobular region where toxin adducts with oxidative injury augmented by Cu accumulation.

FOLLOW-UP

PATIENT MONITORING

- Liver enzymes q3–6 months; evaluate body weight and condition.
- Examine hepatic biopsy and measure hepatic Cu concentration within 1 year of initiated treatment as optimal follow-up assessment.
- If using zinc therapy—assess serum zinc concentrations initially, then during first 2–3 weeks and until stable to assure values increase but remain within the non-toxic range (200–500 µg/dL), then q6 months.

POSSIBLE COMPLICATIONS

- d-Penicillamine can cause anorexia and vomiting. Start at the low end of the dose range for the first week; give 1 h before meals; small amount of food may reduce nausea but may reduce treatment efficacy when given with meals.
- d-Penicillamine side effects: glomerulonephritis, polyarthritis, drug-associated hepatopathy, or an autoimmune-like vesicular disease of the mucocutaneous junctions that resolves on

(CONTINUED)

COPPER ASSOCIATED HEPATOPATHY

C

drug withdrawal. • Excess zinc (oral dose of > 200 mg/day or blood concentration of > 800 µg/dL) can cause hemolytic anemia.

PREVENTION/AVOIDANCE

Breed only Bedlington terriers that do not carry the *COMMD1* mutation. A liver registry is available for Bedlington terriers proven unaffected on the basis of hepatic Cu concentration < 400 µg/g DW at 1 year of age or gene testing. Other breeds have unknown kindred predispositions.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is poor in acutely affected young dogs with fulminant hepatic failure or older dogs with cirrhosis; however, some of these respond to acute supportive care and chelation, as described.
- Dogs with mild to moderate acute hepatic injury usually respond to chelation therapy (prognosis is good).
- Even dogs with nodular hepatopathy and microhepatia and ascites can respond remarkably well to the described treatment protocol with resolution of many histologic lesions (including fibrosis).
- A good prognosis is warranted if Cu-AH is detected before liver remodeling or development of hepatitis (liver biopsy pursued based on high ALT activity and high index of suspicion for Cu hepatotoxicity) in dogs treated as described above.

**MISCELLANEOUS****ASSOCIATED CONDITIONS*****Age-Related Factors***

- Health evaluations that include ALT measurement helps identify at-risk dogs.

- Important to evaluate ALT in any dog placed on chronic NSAIDs where Cu retention appears to augment centrilobular hepatotoxicity; measure ALT before and 2–4 weeks after NSAID initiation or sooner if patient demonstrates inappetence, vomiting, lethargy.

PREGNANCY/FERTILITY/BREEDING

Do not breed affected Bedlington terriers or carriers; genetics of other suspected breeds has not been determined.

SYNONYMS

- Bedlington hepatitis • Chronic active hepatitis • Chronic Cu toxicity • Cu toxicosis

COPROPHAGIA AND PICA

BASICS

DEFINITION

Pica is an abnormal ingestive behavior in which non-food items are consumed. Coprophagia is a form of pica in which feces is consumed.

PATHOPHYSIOLOGY

- The pathophysiology of pica is unclear.
- Coprophagia is not usually a pathologic condition.
- Pica is a sign that may be associated with a variety of different conditions. Any medical condition leading to nutritional deficiencies, electrolyte imbalances, gastrointestinal disturbances, polyphagia, or CNS disturbances may lead to pica and/or coprophagia.
- Severely calorie-restricted diets or imbalanced diets leading to insufficiencies may also lead to pica and/or coprophagia.

SYSTEMS AFFECTED

Gastrointestinal—foreign body obstruction, GI upset leading to vomiting and diarrhea. Increased chance of GI parasitism with coprophagia.

GENETICS

None known

INCIDENCE/PREVALENCE

Unknown

SIGNALMENT

Species

Coprophagia is common in dogs but rare in cats. Pica is seen in both dogs and cats.

Breed Predilections

Oriental cat breeds such as Siamese may be at greater risk of pica.

Mean Age and Range

Pica occurs more often in puppies than in adult dogs. Pica in cats is most likely to begin during the first year of life.

SIGNS

Historical Findings

- In dogs, ingestion of inappropriate items such as rocks, clothing, and/or feces.
- In cats, ingestion of fabrics, plastic, or other inappropriate items.

Physical Examination Findings

- Halitosis if coprophagia is the presenting problem.
- Dental trauma if the dog targets hard objects.
- Pallor or weakness if anemia is a contributing condition.
- Poor body condition if malabsorption or maldigestion is a contributing condition.
- Neurologic signs if caused by neurologic disease.

CAUSES

Behavioral Causes

- Coprophagia is considered normal maternal behavior. The dam or queen licks the

anogenital region of the neonate to stimulate elimination and then consumes the excreta.

- Coprophagia may be considered a normal exploratory behavior in puppies. It has been postulated that the high levels of deoxycholic acid in feces may contribute to neurologic development.
- It is normal for dogs to seek out cat feces because it is high in protein—its odor and taste may also be appealing.
- Ungulate feces is also appealing to dogs, apparently due to the partially digested vegetable matter.
- Dogs on highly restricted diets may have a voracious appetite, leading to coprophagia and pica.
- Feces may be appetizing to some dogs, so that the behavior might be self-rewarding.
- Dogs that have been punished for eliminating in the house could learn to eat their own feces in an apparent attempt to avoid punishment.
- Dogs may also eat their own feces as a form of “nest cleaning.”
- Coprophagia may occur as a form of attention-seeking behavior if a dog learns that the behavior reliably leads to immediate owner attention.
- Coprophagia may also develop as a response to anxiety.
- Pica may occur secondarily to stealing behavior when the dog is highly motivated to prevent the owner from retrieving the stolen object or when the object has ingestive appeal.
- Pica may develop as a result of anxiety that leads to destruction and then consumption of an item.

Medical Causes

- Anemia
- Malnutrition leading to polyphagia
- Endocrinopathies—hyperthyroidism, diabetes mellitus, hyperadrenocorticism
- Maldigestion/malabsorption (e.g., exocrine pancreatic insufficiency)
- Inflammatory bowel disease
- Small intestinal bacterial overgrowth
- Central nervous system disease
- Portosystemic shunt
- Intestinal parasitism

Drug-Induced Causes

Administration of drugs such as corticosteroids, progestins, phenobarbital, or benzodiazepines can lead to polyphagia.

RISK FACTORS

- Early weaning of kittens has been postulated to lead to sucking and ingestion of fabrics.
- Cats fed low-roughage diets and/or not allowed access to roughage sources such as grass.
- Dogs lacking an appropriately stimulating environment, adequate activity, or social interactions may be at risk for pica and/or coprophagia.
- Long periods of confinement, especially in a barren environment, may predispose to coprophagia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The diagnosis is based on the history and description of the behavior.
- The history

should include

- Description of the problem—when and where does it happen

- Age of onset
- Owner's usual response, any corrections attempted so far, and their results
- Changes in household, schedule, diet, or health associated with onset of the problem
- Feeding routine of pets—when, where fed, and by whom
- Any other unusual oral behaviors
- Other behavioral problems
- House training status—when and where does the pet eliminate
- How the pet was house trained
- Relationships with other pets
- Environment, including daily schedule for play, exercise, attention, or training.
- Medical health should be evaluated, including appetite and weight, any signs of nausea or GI upset such as excessive lip licking or surface licking, and color and consistency of feces.
- Pica must be differentiated from destructive chewing, where items may be torn apart but not consumed.
- Pica must also be differentiated from those instances where an animal consumes a non-food item because the item smells and/or tastes like food.

CBC/BIOCHEMISTRY/URINALYSIS

- Results suggesting diabetes mellitus, hyperadrenocorticism, hyperthyroidism, or drug-induced causes of polyphagia.
- Anemia or hypoproteinemia.
- Results suggesting the presence of a portosystemic shunt—microcytosis, target cells, hypoalbuminemia, low BUN, ammonium biurate crystalluria.
- Peripheral eosinophilia may occur due to gastrointestinal parasitism or eosinophilic inflammatory bowel disease.

OTHER LABORATORY TESTS

- TLI—may be low if exocrine pancreatic insufficiency exists.
- Serum folate and cobalamin to evaluate for small intestinal bacterial overgrowth and small intestinal mucosal disease.
- Fecal fat and fecal trypsin may help to evaluate for exocrine pancreatic insufficiency and other malabsorption-/maldigestion-related conditions.
- Thyroid panel to determine if hyperthyroid.
- Fecal examinations to screen for intestinal parasites.
- Bile acids to evaluate for the presence of a portosystemic shunt.
- ACTH stimulation test to evaluate for hyperadrenocorticism.

IMAGING

Survey abdominal radiographs and/or abdominal ultrasonography may be necessary to rule out foreign body obstruction. May also demonstrate microhepatitis if a portosystemic shunt is present.

DIAGNOSTIC PROCEDURES

Small intestinal biopsy samples may be needed to evaluate for infiltrative small bowel disease. Cultures of the small intestine to evaluate for small intestinal bacterial overgrowth.

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

Treatment of Pica

- Prevent access to non-food items that are likely targets. ◦ Confine the animal away from targeted non-food items. ◦ Muzzle dogs; watch for overheating in warm climates and when worn for prolonged periods of time.
- Booby traps may be used to keep the pet away from certain areas and items.
- Change to a diet higher in fiber. • Provide feeding toys and acceptable foraging opportunities (e.g., green plants such as grass or catnip for cats). • Teach dogs a “Drop it” or “Leave it” command so the owner can prevent consumption of inappropriate items. • If diagnosis consistent with compulsive disorder see appropriate section in text for treatment.

Treatment of Coprophagia

- Prevent access to feces. • Walk dog on leash and pick up feces immediately.
- Muzzle; observe precautions to avoid overheating in warmer climates. ◦ Head collar for increased ability to guide pet away from feces and reward “turning away” after defecation. Use a remote-activated citronella collar to distract the animal every time it tries to sniff or ingest feces. ◦ This must be used every time the animal has access to feces in order for it to be effective. ◦ Dogs should then be rewarded with a tasty treat for returning to the owner on command.
- There is no evidence that changing the taste or texture of the stool helps to decrease coprophagia. • Taste aversion can be taught by treating the feces with a powerfully aversive substance (e.g., hot sauce, cayenne pepper, etc.). • All feces that the dog can come in contact with must be treated in order for this to be effective. However, even if effective, dogs can learn to recognize the smell of the treated feces, avoid it, and ingest untreated feces.

ACTIVITY

- Increased mental and physical stimulation may help in the treatment and prevention of pica and coprophagia. • More regular, predictable schedules of interaction and exercise can decrease anxiety and may aid in the treatment of pica and coprophagia.

DIET

Dietary changes may be helpful in some cases of coprophagia. A more highly digestible diet or the addition of plant-based enzyme supplements or meat tenderizers may rarely be successful in decreasing coprophagia.

CLIENT EDUCATION

- Owners should be counseled that coprophagia is, in most cases, normal canine behavior and not harmful unless the dog consumes feces containing pathogens or

parasites. • Owners should avoid the use of any form of direct or confrontational punishment for pica or coprophagia due to the risk of increasing anxiety, possibly worsening the behavior, and/or leading to other problem behaviors. Close supervision and preventing access are the best approach.

MEDICATIONS

DRUG(S) OF CHOICE

If the behavior is determined to be secondary to anxiety, psychoactive drugs including an SSRI such as fluoxetine or a TCA such as clomipramine may be indicated. (See Compulsive Disorders—Cats and Compulsive Disorders—Dogs).

CONTRAINdications

The use of any drugs that might contribute to polyphagia should be avoided when possible.

PRECAUTIONS

- Avoid the use of TCA in animals with aggression, a history of seizures, cardiac problems, glaucoma, or urine or stool retention. • Anticholinergic side effects are not uncommon. • Clomipramine and fluoxetine may potentiate the side effects of some CNS depressants, such as benzodiazepines, barbiturates, and general anesthetics.

POSSIBLE INTERACTIONS

Fluoxetine and clomipramine should not be given in conjunction with inhibitors or within 2 weeks of discontinuation of MAOIs. Clomipramine should not be combined with an SSRI.

FOLLOW-UP

PATIENT MONITORING

- Client should be contacted in 1–2 weeks to verify compliance and determine if there is improvement. • If no or minimal improvement, further diagnostics should be recommended.

PREVENTION/AVOIDANCE

- Prevent access to the items likely to be consumed. • Careful supervision during house training may help to prevent puppy exploration of feces and reinforcement of coprophagia. • Administration of monthly parasiticide to control GI parasites.

POSSIBLE COMPLICATIONS

Foreign body obstruction is the most common sequelae to pica in both dogs and cats.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is guarded if: ◦ The condition has been present for a long period of time.

COPROPHAGIA AND PICA

C

- The owner is not willing to closely supervise the dog when it eliminates.
- If owner is willing to supervise the dog and comply with treatment recommendations, the prognosis improves.

MISCELLANEOUS

AGE-RELATED FACTORS

In adult or geriatric onset of pica or coprophagia, primary underlying medical conditions should be strongly suspected.

PREGNANCY/FERTILITY/BREEDING

- The use of TCA's should be avoided in pregnant and nursing females. • Owners of wool-sucking cats should be cautioned that the behavior appears to have a breed disposition, so avoiding breeding of this individual may be the prudent and responsible action. • If this behavior is believed to be associated with a compulsive disorder, the animal should not be bred, as compulsive disorders appear to have a hereditary basis.

SYNOMYS

- Depraved appetite • Wool sucking or wool chewing in cats

SEE ALSO

- Compulsive Disorders—Cats • Compulsive Disorders—Dogs

ABBREVIATIONS

- ACTH = adrenocorticotrophic hormone
- CNS = central nervous system • GI = gastrointestinal • MAOI = monoamine oxidase inhibitor • SSRI = selective serotonin reuptake inhibitor • TCA = tricyclic antidepressant • TLI = trypsin-like immunoreactivity

CORNEAL AND SCLERAL LACERATIONS

BASICS

DEFINITION

- Penetrating—a wound or foreign body enters but does not completely pass through the cornea or sclera.
- Perforating—a wound or foreign body completely passes through the cornea or sclera; greater risk of vision loss than penetrating.
- Simple—involves only the cornea or sclera; may be penetrating or perforating; other ocular structures intact.
- Complicated—perforating; involves other structures besides the cornea or sclera; uveal, vitreal, or retinal incarceration or prolapse through the wound; traumatic cataract; hyphema; lid lacerations.

PATOPHYSIOLOGY

- Sharp trauma—wounds by an outside-in mechanism.
- Blunt trauma—wounds by an inside-out mechanism; eye undergoes sudden changes in its equatorial and axial dimensions and IOP; actual wound may be at a site other than the point of impact; often more damaging than sharp trauma.
- All or a portion of the foreign object initiating the injury may be retained in the wound or eye.

SYSTEMS AFFECTED

- Musculoskeletal—surrounding skull or orbital tissue
- Nervous—unconsciousness or brain injury
- Ophthalmic

INCIDENCE/PREVALENCE

Common

SIGNALMENT

Species

Dog and cat

SIGNS

Historical Findings

- Usually acute onset.
- Often a history of running through heavy vegetation, being hit by gunshot pellets or other projectiles, or being scratched by a cat.
- Trauma may not be observed.

Physical Examination Findings

- Varies with tissues affected.
- Common—corneal, scleral, or eyelid deformity; edema; hemorrhage.
- May see a retained foreign body.
- Often rapidly seals; may appear only as a subconjunctival hematoma.
- May also see iris defects, pupil distortion, hyphema, cataract, vitreal hemorrhage, retinal detachment, and exophthalmia.

CAUSES

Blunt or sharp trauma

RISK FACTORS

- Preexisting visual impairment
- Young, naive, or highly excitable animals
- Hunting or running through heavy vegetation
- Fighting

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- History or a retained foreign body usually diagnostic.
- Traumatic event not observed and no foreign body found—consider non-traumatic causes of corneal ulceration, hyphema, etc.
- Traumatic hyphema—almost invariably accompanied by corneal or scleral lesions and subconjunctival or periocular hemorrhage.
- Traumatic cataracts—disrupted lens capsule common.
- Traumatic retinal detachment—almost invariably accompanied by intraocular hemorrhage.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually noncontributory.
- Consider as a preanesthesia screen or when non-traumatic cause is possible.

OTHER LABORATORY TESTS

- Cytologic examination and aerobic culture and sensitivity testing of the wound and foreign body—recommended even if infection is not apparent; may need to collect specimen under general anesthesia at the time of surgery.
- Consider other tests (platelet count, coagulation profile, etc.) if non-traumatic causes are possible.

IMAGING

- Ocular ultrasonography—if the ocular media are opaque; may clarify the extent and nature of intraocular disease; may detect foreign body.
- Orbital radiographs, CT or MRI (if non-metallic)—may help determine projectile's course; may detect foreign body.

DIAGNOSTIC PROCEDURES

- Determine the nature, force, and direction of impact of the object—help identify which tissues may be involved.
- Do not put pressure on the eye until rupture or laceration of the globe has been ruled out.
- Assess vision—menace response; aversion to bright light.
- Periocular skin and orbit—examine for lacerations or deformities; suspect globe involvement if a lid laceration crosses the eyelid margin or penetrates the orbital septum; entry sites are often small and quickly seal.
- Abnormal ocular motility—suggests extraocular muscle trauma, orbital hemorrhage or edema, retained foreign bodies or peripheral nerve or CNS damage.
- Scleral rupture—consider this possibility with subconjunctival hemorrhage, especially if the anterior chamber is abnormally deep or shallow, there is vitreal hemorrhage, or the eye is abnormally soft.
- Pupils—size; shape; symmetry; direct and consensual light reflexes.
- Detailed ophthalmoscopy—assess clarity of ocular media and fundus integrity; rule out intraocular foreign body.
- Seidel test—if any question of corneal or scleral leaking; use a dry to slightly moist fluorescein strip to paint a thin coat of fluorescein over the surface of

the defect; leaking aqueous combines with the orange fluorescein, forming a bright green rivulet (seen best with cobalt illumination).

PATHOLOGIC FINDINGS

- Depends on wound and affected tissues.
- Usually correlates closely with clinical examination findings.
- Vitreal hemorrhage—may organize into a fibrous band that applies traction to the retina, causing it to detach.
- Post-traumatic sarcoma (cats)—may occur months to years after severe ocular trauma.

TREATMENT

APPROPRIATE HEALTH CARE

- Depends on severity.
- Outpatient—if integrity of the globe is ensured.

NURSING CARE

- Sedation—consider for excited or fractious patients.
- When walking—apply an Elizabethan collar and use a harness or put ipsilateral foreleg through the leash to avoid increasing intraocular pressure in affected eye.
- Avoid third eyelid flaps in patients with perforations or deep/long penetrating wounds until the wound is stable.

Injuries Considered for Medical Treatment

- Non-perforating wounds with no wound edge override or gape—apply an Elizabethan collar; give topical antibiotic or atropine ophthalmic solutions.
- Non-perforating wounds with mild wound gape or shelfed edges—apply a therapeutic soft contact lens and an Elizabethan collar; give topical antibiotic or atropine ophthalmic solutions.
- Simple full-thickness, pinpoint corneal perforation with a negative Seidel test that has a formed anterior chamber and no uveal prolapse—sedentary patients; use a therapeutic soft contact lens and an Elizabethan collar; give topical antibiotic or atropine ophthalmic solutions; reexamine a few hours after applying the lens and at 24 and 48 hours.

ACTIVITY

Usually confined indoors (cats) or limited to leash walks until healing is complete. A harness is preferred to a collar to reduce pressure on the neck and the risk of increased intraocular pressure and wound leaks.

CLIENT EDUCATION

Warn client that the full extent of the injury (cataracts, retinal detachment, infection) may not be apparent until several days or weeks after the injury and that long-term follow-up is necessary.

SURGICAL CONSIDERATIONS

Injuries Requiring Surgical Exploration or Repair

- Full-thickness corneal lacerations with a

(CONTINUED)

CORNEAL AND SCLERAL LACERATIONS

C

positive Seidel test. • Full-thickness wounds with iris incarceration or prolapse. • Full-thickness scleral or corneoscleral lacerations. • Suspected retained foreign body or a posterior scleral rupture. • Simple non-perforating wound with edges that are moderately or overtly gaping and that are long or more than two-thirds the corneal thickness.

Injuries Considered for Surgical Exploration or Repair

- Small full-thickness corneal lacerations with a negative Seidel test and no uveal incarceration or prolapse. • Large conjunctival lacerations. • Partial-thickness corneal or scleral lacerations in an active patient.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics

• Complicated wounds, those with retained plant material, and those caused by blunt trauma with tissue devitalization—*infection common*. • Bacterial endophthalmitis—5–7% of perforations; very rare in wounds that only penetrate but do not perforate the cornea. • Penetrating—topical antibiotics alone (e.g., neomycin, polymyxin B, and bacitracin) or gentamicin solution q6–8h; usually sufficient. • Perforating wounds with negative Seidel test—systemic ciprofloxacin (dogs, 10–20 mg/kg PO q24h); topical cefazolin (33 mg/mL by adding injectable cefazolin to artificial tears) and fortified gentamicin or tobramycin (add injectable aminoglycoside to the commercial ophthalmic solution to achieve a final concentration of 14 mg/mL), both drugs q4–6h. • Perforating wounds with positive Seidel test—systemic ciprofloxacin (dogs, 10–20 mg/kg PO q24h); topical cefazolin and fortified gentamicin or tobramycin as noted above, only after defect has been made watertight.

Anti-Inflammatories

• Topical 1% prednisolone acetate or 0.1% dexamethasone solution q6–12h; as soon as the wound is sutured or has epithelialized (becomes fluorescein stain negative), as long as infection is not present. • Systemic prednisone 0.5–1 mg/kg q12h–q24h; for sutured or epithelialized wounds when inflammation is severe; when the lens or more posterior structures are involved; when the wound is infected or not epithelialized and control of inflammation is mandatory to preserve the eye. • Topical NSAIDs—flurbiprofen or one of several others; may be used if topical corticosteroids are contraindicated and control of inflammation is mandatory to preserve the eye.

Mydriatics

- 1% atropine ophthalmic solution q6–12h; when there is significant miosis or anterior chamber reaction.

Analgesics

- Topical atropine or oral aspirin (dogs, 10–15 mg/kg PO q12h to q8h)—may provide sufficient pain relief. • Carprofen 2.2 mg/kg PO q12h or 4.4 mg/kg PO once daily. • Tramadol—start at 1–2 mg/kg q12h and can increase up to 5 mg/kg q6h or as needed. • Butorphanol: dogs, 0.2–0.4 mg/kg; cats, 0.1–0.2 mg/kg IV, SC, or IM q2–4h or as needed; acute mild pain; sedation not required. • Oxymorphone: dogs, 0.05–0.1 mg/kg; cats, 0.05 mg/kg IV, SC, or IM q4–6h or as needed; acute severe pain; sedation required. • Naloxone 0.04 mg/kg IV, SC, or IM; to reverse narcotics.

CONTRAINDICATIONS

- Topical ophthalmic ointments—avoid in perforations with positive Seidel test until wound closed. • Systemic ciprofloxacin—avoid in small and medium dog breeds aged 2–8 months; avoid in large dog breeds aged 2–12 months; avoid in giant dog breeds aged 2–18 months; potential for damaging rapidly growing articular cartilage.

PRECAUTIONS

- Aminoglycosides—topical application may be irritating and may impede reepithelialization if used frequently or at high concentrations; possibility of toxicity when given to very small patients or when giving by more than one route. • Topical solutions may be preferable to ointments if corneal integrity is questionable. • Atropine—may exacerbate KCS and glaucoma. • Topical or systemic NSAIDs—use cautiously with hyphema; safety of topical NSAIDs in cats unknown.

POSSIBLE INTERACTIONS

Systemic NSAIDs—may potentiate the nephrotoxicity of aminoglycosides; ensure good hydration and adequate renal function, especially in small dogs.

ALTERNATIVE DRUG(S)

Topical ciprofloxacin ophthalmic solution—may be used instead of the combination of topical cefazolin and a fortified aminoglycoside; some streptococcus are resistant.

FOLLOW-UP

PATIENT MONITORING

- Deep or long penetrating wounds that have not been sutured and perforating wounds—recheck q24–48h for the first several days to ensure integrity of the globe, to monitor for infection, and to check control of ocular inflammation. • Superficial penetrating wounds—usually recheck at 3- to 5-day

intervals until healed. • Antibiotic therapy—alter according to culture and sensitivity results.

PREVENTION/AVOIDANCE

- Take care when introducing new puppies to households with cats that have front claws. • Minimize running through dense vegetation or the owner should consider having a bottle of saline eyewash to irrigate foreign debris from the eye. • Minimize visually impaired or blind dog's exposure to dense vegetation.

POSSIBLE COMPLICATIONS

- Loss of the eye or vision. • Chronic ocular inflammation or pain. • Post-traumatic sarcoma—may develop in blind cat eyes that have been severely traumatized.

EXPECTED COURSE AND PROGNOSIS

- Most eyes with corneal lacerations or a retained corneal foreign body are salvageable. • The more posterior the injury, the poorer the prognosis for retention of vision. • Poor prognosis—scleral or uveal involvement; no light perception; perforating injuries involving the lens or with significant vitreal hemorrhage or retinal detachment.
- Penetrating injuries usually better prognosis than perforating injuries. • Blunt trauma carries a poorer prognosis than sharp trauma.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Depends on nature and extent of injury.

PREGNANCY / FERTILITY/ BREEDING

- Systemic corticosteroids—may complicate pregnancy. • Systemic ciprofloxacin—probably should be avoided during pregnancy.

SEE ALSO

- Cataracts • Hyphema • Keratitis, Ulcerative • Proptosis • Retinal Detachment

ABBREVIATIONS

- CNS = central nervous system • CT = computed tomography • IOP = intraocular pressure • KCS = keratoconjunctivitis sicca • NSAID = nonsteroidal anti-inflammatory drug

CORNEAL OPACITIES—DEGENERATIONS AND INFILTRATES

BASICS

OVERVIEW

Corneal degeneration—an acquired corneal disorder characterized by lipid or calcium deposition. May be unilateral or bilateral, have distinct margins, and occur secondary to other ocular or systemic disorders.

SIGNALMENT

Corneal degeneration occurs primarily in dogs, uncommon in cats. Lipid deposition most commonly in geriatric dogs. May be associated with systemic hyperlipoproteinemia.

SIGNS

- Clinical signs vary based on type of deposit and associated ocular or systemic disorders.
- Lipid—gray-white or crystalline; can be band-shaped, irregular, or circular.
- Calcium—dense white to crystalline; irregular, punctate to band-shaped lesions in the superficial stroma. • Frequently associated with inflammatory disorders such as keratitis or uveitis. • Corneal vascularization, edema, and pigmentation often present. • With progression the cornea may develop a roughened appearance; the epithelium may become disrupted, leading to ulceration.
- Associated ocular conditions that may lead to corneal degeneration—corneal scars, KCS, exposure keratitis, chronic uveitis, episcleritis, phthisis bulbi, chronic topical steroid therapy, limbal neoplasia. • When lipid deposition occurs secondary to systemic hyperlipoproteinemia, a perlimbal annular ring (arcus lipoides cornea) may form with a clear zone between affected cornea and limbus; often bilateral but may be asymmetrical; vascularization is variable.

CAUSES & RISK FACTORS

- Lipid—hyperlipoproteinemia: may increase risk, may worsen preexisting deposits; can be secondary to hypothyroidism, diabetes mellitus, hyperadrenocorticism, dietary indiscretion, pancreatitis, nephrotic syndrome, liver disease, primary hyperlipidemia of miniature schnauzers.
- Calcium—hypercalcemia, hyperphosphatemia, hypervitaminosis D, hyperadrenocorticism, uremia, geriatric patients. • Both—lipid and calcium are frequently seen together.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of corneal opacities. • Corneal scar—non-painful lesion, gray to white depending on severity; fluorescein negative; relatively smooth corneal surface; distinct margins. • Corneal stromal

dystrophies—bilateral, often symmetrical foci of deposition, gray to white in appearance, distinct margins; heritable, not associated with ocular inflammation; do not retain fluorescein stain; often occur away from the limbus. • Edema—bluish to gray; usually more homogeneous; can vary in size depending on severity; indistinct margins; can retain fluorescein stain if corneal erosion/ulceration also present. • Corneal ulcer—results in ocular pain, retains fluorescein stain, varying degrees of edema may surround the lesion. • Inflammatory cell infiltrates—results in ocular pain, gray to tan to yellow with indistinct margins; cytologic examination of cornea reveals white blood cells, microorganisms.

CBC/BIOCHEMISTRY/URINALYSIS

- *Systemic tests only necessary if hyperlipidemia is suspected; no systemic tests necessary for most cases.*
- Lipid—evaluate fasting cholesterol, triglyceride, blood glucose levels.
- Calcium—evaluate serum calcium levels.
- Other laboratory tests
- Lipid—hypothyroidism: low thyroid hormone concentrations and depressed response to TSH. • Cushing's—ACTH stimulation test. • If suspect pancreatitis—PLI test.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

May retain fluorescein around margins of deposit if raised.

TREATMENT

- Treat primary ocular disease if present.
- Usually benefit from low-fat diet if hyperlipoproteinemia; treat primary systemic disease if present; both may help slow or stop progression of the disease. • Corneal deposits that are causing patient discomfort or are impairing vision may benefit from corneal debridement or superficial keratectomy, followed by medical treatment; deposits are likely to recur following treatment if underlying cause not corrected beforehand.

MEDICATIONS

DRUG(S)

- Topical broad-spectrum antibiotics (i.e., triple antibiotic) for ulcerated cornea; frequency depends on severity; usually uncomplicated ulcers treated q8–12h.
- Topical nonsteroidal anti-inflammatory q8–12h—indicated if uveitis noted.
- Topical 0.2% cyclosporine—to improve tear film quality, reduce inflammation.
- Topical 1% atropine q8–24h—indicated to

reduce pain if uveitis or ulceration is present.

- Topical EDTA solution 0.4%–1.38% q6h; may help minimize calcium deposits; usually used following debulking procedure to improve efficacy.
- Artificial tear ointment q6–12h; may prevent or reduce frequency of secondary corneal ulceration; provides lubrication and improves comfort when corneal surface is irregular.

CONTRAINdications/POSSIBLE COMPLICATIONS

- Topical corticosteroids—not recommended, may worsen severity; contraindicated with corneal ulceration.
- Topical atropine—contraindicated with KCS, glaucoma, lens luxations.

FOLLOW-UP

PATIENT MONITORING

Monitor serum cholesterol and triglycerides to assess efficacy of dietary management in hyperlipidemic patients; monitor treatment of primary disease if present.

EXPECTED COURSE AND PROGNOSIS

- Corneal ulceration—may be associated with worsening of disease. • Vision—may be affected in advanced disease; may be severe if primary ocular disease present (e.g., uveitis).
- Deposits may recur in patients following superficial keratectomy.

CORNEAL OPACITIES—DYSTROPHIES

BASICS

OVERVIEW

- Primary, inherited (or familial), bilateral, and often symmetrical condition of the cornea that is not associated with other ocular or systemic diseases.
- Three types based on anatomic location—epithelial: associated with dyskeratotic and necrotic epithelial cells, focal absence of epithelial basement membrane, and increased cells in anterior corneal stroma; stromal: lipid deposition within the corneal stroma; and endothelial: characterized by abnormal, dystrophic endothelial cells.

SIGNALMENT

Usually dogs; rare in cats.

Epithelial

Shetland sheepdogs—age of onset 6 months–6 years; slow progression.

Stromal

- Usually young adult dogs at age of onset.
- Affected breeds—Afghan hound, Airedale terrier, Alaskan malamute, American cocker spaniel, beagle, bearded collie, bichon frise, Cavalier King Charles spaniel, German shepherd, Lhasa apso, mastiff, miniature pinscher, rough collie, Samoyed, Siberian husky, Weimaraner, whippet, and others; inheritance pattern identified in only a few breeds.

Endothelial

- Dogs—primarily affects Boston terriers, Chihuahuas, and dachshunds; may affect other breeds; typically middle-aged or older at onset of clinical signs; female predilection suggested.
- Cats—affects young animals; described most often in domestic shorthairs; a similar condition that occurs without endothelial disease is inherited in Manx as an autosomal recessive disorder.

SIGNS

All cause some degree of opacity in the cornea.

Epithelial

- Can be asymptomatic or have blepharospasm; multifocal white or gray circular to irregular opacities or rings; sometimes associated with multifocal corneal erosions.
- Vision—usually not affected.

Stromal

- Usually asymptomatic with no associated inflammation.
- Central—most common; gray, white, or silver oval to circular opacity of the central or paracentral cornea; with magnification may note multiple fibrillar to coalescing opacities that have a crystalline or ground-glass appearance (crystalline corneal dystrophy).
- Diffuse—affects Airedales; more

diffuse, dense opacity than with central dystrophy.

- Annular—affects Siberian huskies most commonly; doughnut-shaped opacity of the paracentral or peripheral cornea.
- Vision—usually not affected; visual deficit possible with advanced or diffuse disease.

Endothelial

- Asymptomatic in early stages.
- Edema of temporal or inferio-temporal cornea that usually progresses to involve the entire cornea after months to years.
- Corneal epithelial bullae (bullos keratopathy) and subsequent corneal erosion ulceration may develop; erosions or ulceration may cause blepharospasm due to pain.
- Vision—may be impaired with advanced disease.

CAUSES & RISK FACTORS

- Epithelial—result of degenerative or innate abnormalities of the corneal epithelium and/or basement membrane.
- Stromal—innate abnormality or localized error in corneal lipid metabolism; may be affected by hyperlipoproteinemia (may increase opacity).
- Endothelium—degeneration of the endothelial cell layer; subsequent loss of endothelial cell pump function results in corneal edema.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Epithelial, stromal—other causes of corneal opacity: corneal degenerations, ulcers, scars, inflammatory cell infiltrates.
- Endothelial—other causes of diffuse corneal edema: uveitis and glaucoma.

CBC/BIOCHEMISTRY/URINALYSIS

Epithelial, stromal—high concentrations of cholesterol and triglyceride levels may modify the course of the disease but are not the cause.

DIAGNOSTIC PROCEDURES

- Stromal—usually does not retain fluorescein stain.
- Epithelial or endothelial—may retain fluorescein stain, often in multifocal punctate areas, particularly with advanced disease.
- Tonometry—to eliminate glaucoma as cause of corneal edema.

TREATMENT

- Advanced epithelial or endothelial disease with ulceration—may require treatment for ulcerative keratitis.
- Stromal—usually none required; may perform superficial keratectomy to remove lipid deposits if severe

but usually unnecessary and deposits may recur.

- Inform client that some corneal dystrophies are inherited.
- Advanced endothelial dystrophy—may use therapeutic soft contact lens with or without debridement of redundant corneal epithelial tags; conjunctival flap surgery; thermal cautery of the cornea; penetrating keratoplasty (corneal transplant) may be of benefit but success rates vary (fair to good for cats, poor for dogs).

MEDICATIONS

DRUG(S)

- Corneal ulceration—topical antibiotics and possibly atropine (see Keratitis, Ulcerative).
- Epithelial—1–2% cyclosporine in oil or 0.2% ointment q8–24h as needed to relieve clinical signs.
- Endothelial—topical 5% sodium chloride ointment; palliative treatment; does not markedly clear cornea but may prevent progression and rupture of corneal epithelial bullae.

CONTRAINdications/POSSIBLE INTERACTIONS

Topical corticosteroids—no benefit to lipid (stromal) dystrophy; of questionable benefit to other forms of dystrophy.

FOLLOW-UP

- Reexamination—necessary only if ocular pain or corneal ulceration develops.
- Corneal opacity—may wax and wane with lipid dystrophy; unlikely to resolve.
- Corneal ulceration—may accompany progression of epithelial or endothelial dystrophy.
- Vision—not substantially affected except in advanced cases.

CORNEAL SEQUESTRUM—CATS

BASICS

OVERVIEW

- Corneal sequestrum is a focal, light brown to black, plaque-like area of stromal coagulation necrosis usually located axially or paraxially.
- Usually caused by chronic corneal ulceration, trauma or exposure.
- Synonyms—keratitis nigrum.

SIGNALMENT

- Cats—any breed, age.
- Brachycephalic (Persian, Himalayan) breeds, Siamese predisposed.
- Colorpoints may be genetically predisposed.

SIGNS

- Unilateral or bilateral, focal round to oval, variably sized areas of corneal discoloration ranging from a translucent golden-brown (early) to opaque black (chronic).
- Often has a chronic non-healing corneal ulcer.
- Corneal vascularization and edema.
- Often had previous episodes of feline herpesvirus-1 (FHV-1) keratoconjunctivitis.
- Blepharospasm and/or ocular discharge.
- Conjunctival hyperemia and chemosis.
- Miotic pupil.
- May be static for long periods or may rapidly progress.
- With chronicity, corneal vascularization may result in extrusion of the plaque.

CAUSES & RISK FACTORS

- Exact cause unknown but thought to involve chronic mechanical corneal irritation or ulceration with subsequent corneal necrosis and desiccation.
- Proposed risk factors include chronic corneal ulceration, chronic trichiasis or entropion, brachycephalic conformation, lagophthalmia (incomplete blink), keratoconjunctivitis sicca (KCS), qualitative tear film disorders (lipid or mucin deficiency), FHV-1 infection, topical drug use (corticosteroids), and iatrogenic trauma (multiple grid keratotomy).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Corneal perforation/iris prolapse—protruding iris is fleshy and is yellow to light brown.
- Corneal foreign body—usually obvious.
- Corneal pigmentation—rare in cats.
- Corneal neoplasia—melanocytoma occurs at the limbus and is typically non-painful.

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities

OTHER LABORATORY TESTS

- Schirmer tear test—very low values suggest KCS but some normal cats can have low

values.

- Corneal culture and cytology to rule out secondary corneal infection if corneal ulceration or inflammatory cellular infiltrate is present.
- Fluorescein stain to determine if ulcerated.
- Tear film breakup time (TBUT)—normal time to breakup of the fluorescein-stained tear film is 21 seconds. TBUT may be decreased in cats with sequestra or FHV-1 due to mucin tear film deficiency or secondary to the corneal disease.
- Corneal histopathology to confirm diagnosis and evaluate completeness of excision.
- The acellular necrotic cornea is undermined by inflammatory cells.
- Nested PCR for FHV-1 DNA—of limited value since normal healthy cats may carry FHV-1 and have positive PCR results.
- Conjunctival biopsy for goblet cell density—goblet cell numbers may be decreased secondary to conjunctival inflammation and/or FHV-1.

TREATMENT

- Lesion depth, degree of ocular pain, and financial status of the client are important factors in development of a treatment plan.
- Medical—supportive care while waiting for sequestrum to spontaneously slough; ocular pain may persist for months and sloughing of sequestrum may lead to deep corneal ulceration or perforation.

SURGICAL CONSIDERATIONS

- Lamellar keratectomy is surgical procedure of choice. If performed early, it can rapidly relieve ocular pain, promote faster corneal healing, and may prevent the lesion from involving the deeper corneal stroma.
- Adjunctive corneal grafting procedures should be performed if $\geq 50\%$ of the corneal stroma has been excised. Options include conjunctival pedicle grafting; grafting with synthetic, autogenous, or heterologous biomaterials; and corneoscleral transposition.
- Postoperative corneal ulcer management with a broad-spectrum topical antibiotic, atropine ointment, and a tear supplement.

MEDICATIONS

DRUG(S)

- Topical oxytetracycline HCl with polymyxin B (Terramycin) or bacitracin-neomycin-polymyxin B q6–8h as prophylaxis.
- Topical 1% atropine sulfate ointment q12–24h to improve ocular comfort..
- Topical lubricants (e.g., carboxymethylcellulose gel) q6–8h to reduce mechanical irritation and prevent corneal desiccation; may also prevent progression of early non-ulcerated sequestra.

- Adjunctive topical and/or systemic antiviral therapy in cases with history or clinical signs compatible with FHV-1 infection.

- Topical interferon-a-2b (1,000–3,000 units/mL) q6–8h. Anecdotal reports of clinical improvement in sequestra, particularly those related to FHV-1 infection.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Topical antibiotics (neomycin) may be irritating and cause chemical conjunctivitis.

FOLLOW-UP

PATIENT MONITORING

- If managing medically, examine weekly to monitor progression and for complications associated with sloughing of the sequestrum.
- If managed by keratectomy, examine every 5–7 days until the corneal defect has reepithelialized (usually occurs within 7–14 days).
- Sequestra may recur or occur in the contralateral eye. Recurrence is more likely in cats with low Schirmer tear tests, with full-thickness lesions, or in cases in which keratectomy did not result in complete excision of the pigmented corneal tissue or the predisposing cause was not addressed.

POSSIBLE COMPLICATIONS

Corneal perforation may occur if a sequestrum sloughs, leaving a full-thickness defect, and/or if sloughing results in a deep stromal corneal ulcer that becomes malacic or infected.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Corneal ulceration—cats
- Eyelid conformational abnormalities (trichiasis, entropion, etc.)

ABBREVIATIONS

- FHV-1 = feline herpesvirus-1
- KCS = keratoconjunctivitis sicca
- PCR = polymerase chain reaction
- TBUT = tear film breakup time

BASICS

DEFINITION

• A sudden and often repetitively occurring defense reflex that helps clear large airways of excess secretions, irritants, foreign particles, and microbes, or clear foreign material from upper airways. • The cough reflex consists of three phases: inhalation, forced exhalation against a closed glottis, and violent expulsion of air from the lungs following opening of the glottis, usually accompanied by a sudden noise. Coughing can happen voluntarily as well as involuntarily, although in dogs and cats it is presumed to be essentially involuntary.

PATOPHYSIOLOGY

• A physiologic reflex in healthy animals that protects the lower airways from inhalation of foreign particles and helps clear particles that have been entrapped in the mucus; acts in conjunction with the mucociliary clearance mechanism. • The cough pathway includes cough receptors, (sensory nerves in the airways), the vagus nerve, the central cough center, and effector muscles. • The cough pathway can be stimulated by mechanical or chemical factors. Endogenous triggers include airway secretions and inflammation. Exogenous triggers include smoke and aspirated foreign material. • Cough receptors include rapidly adapting stretch receptors (sensitive to mechanical stimuli) that are located within the mucosa of the tracheobronchial tree (especially larynx and trachea), and pulmonary/bronchial C-fibers, which are more sensitive to chemical stimulation. Coughing mechanisms and pathways are very complex and are not fully understood, even in humans.

SYSTEMS AFFECTED

• Respiratory—cough of any origin can be an inciting factor for inflammation that aggravates and perpetuates further cough. • Cardiovascular—enlargement or impaired function of the right ventricle can result from a respiratory disorder (cor pulmonale); cough syncope can occur from a vasovagal response.

SIGNALMENT

• Dogs and cats of all ages and breeds. • Much more common clinical sign in dogs than in cats. • Cough of tracheal origin is less common in cats than in dogs. • Age, breed, and sex predispositions vary with inciting cause.

SIGNS

• Cough must be differentiated from similar signs such as reverse sneezing, gagging, retching, and vomiting. • Description of the cough can be helpful in identification of the anatomic structures involved in dogs (i.e., honking cough is typical of tracheal or airway

collapse, harsh sonorous cough followed by terminal retch characterizes cough of tracheal or bronchial origin, faint moist cough is heard in moderate to severe pneumonia). • Cough can be described as dry or moist, productive, honking, short or harsh, faint or sonorous, followed by gagging or retching. • Cough can be elicited by traction on the collar (laryngeal or tracheal origin), aggravated by exercise or excitement (tracheal collapse), or can occur after a period of rest (cough due to heart failure). • Can be accompanied by stertor or stridor (laryngeal, tracheal origin) or labored breathing (many areas).

CAUSES

Upper Respiratory Tract Diseases

• A variety of sinonasal conditions cause extension of inflammation and/or secretions into the pharynx and/or larynx and can lead to the “upper airway cough syndrome” (UACS), previously referred to as “post-nasal drip syndrome.” • Laryngeal disease (inflammation, paralysis, tumor, granuloma, collapse). • Tracheal disease (inflammation, infection, foreign body, collapse, stenosis, tumor).

Lower Respiratory Tract Diseases (Tracheobronchial or Bronchopulmonary Disease)

• Inflammatory (feline bronchitis syndrome; dogs: chronic bronchitis, eosinophilic bronchopneumopathy). • Infectious—bacterial, viral (distemper, kennel cough [dog]; calicivirus, herpesvirus [cat]), parasitic (*Filaroides* spp. [dog], *Aelurostrongylus abstrusus* [cat], *Paragonimus kellicotti* [dog, cat], *Dirofilaria immitis* [dog, cat], *Capillaria aerophilia* [dog], *Crenosoma vulpis* [dog]), protozoal (toxoplasmosis [cat]; pneumocystosis [dog]), fungal (blastomycosis, histoplasmosis, coccidiomycosis, cryptococcosis, aspergillosis). • Neoplastic (primary, metastatic, compression due to enlarged lymph nodes). • Chemical or traumatic (aspiration, near drowning, noxious fumes, foreign body, trauma, hemorrhage).

Other Diseases

• Cardiovascular diseases (pulmonary edema, heart-base tumor, embolism). • Gastroesophageal reflux. • Compression of the respiratory structures by adjacent organs (cardiomegaly, megaeosophagus, hilar lymph node enlargement) or by pleural effusion. • Non-cardiogenic pulmonary edema (multiple causes). • Passive smoking inhalation. • Adverse drug reaction—potassium bromide in cats.

RISK FACTORS

Breed

• Toy and miniature breeds at risk for tracheal collapse. • Terrier breeds at risk for pulmonary fibrosis. • Husky, rottweiler, Labrador, and Jack Russell terrier, at risk for eosinophilic bronchopneumopathy. • Giant

breeds at risk for dilated cardiomyopathy.

- Labrador retriever, large breeds at risk for laryngeal paralysis. • Siamese cats at risk for feline bronchitis syndrome.

Environmental Factors

- Longhaired cats that are infrequently groomed will periodically retch, cough, and then vomit up mats of hair.

Drugs

- Potassium bromide in cats

Geographic Area (or Travel History)

- Certain diseases are common in specific areas (e.g., dirofilariasis, angiostrongylosis).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Many conditions result in similar signs.
- Coughing can be confused with other signs such as sneezing, reverse sneezing, gagging, panting, retching, and vomiting. The presence of terminal retch is often misinterpreted as vomiting.

CBC/BIOCHEMISTRY/URINALYSIS

Minimum database may suggest acute bacterial infection (leukocytosis with left shift) or eosinophilic airway disease (peripheral eosinophilia).

OTHER LABORATORY TESTS

- Filter test for microfilaria and/or heartworm antigen serology—for heartworm disease.
- Serum antibody titer—toxoplasmosis, *Angiostrongylus vasorum*. • Coagulation profile—for any patient that presents with cough associated with either epistaxis or hemoptysis. • Fecal examination (Baermann test: identification of *Angiostrongylus* (dogs), *Aelurostrongylus* (cat) or other parasites (*Filaroides*, *Crenosoma*). • PCR diagnosis available for several micro-organisms. • Tests for evaluation of systemic diseases (e.g., hyperadrenocorticism, potentially predisposing to pneumonia or causing pulmonary thromboembolism).

IMAGING

- Thoracic radiographs are the first step prior to any additional testing; provide essential information about intrathoracic airways, lung parenchyma, pleural space, mediastinum and cardiovascular system. • Fluoroscopy—helpful to investigate diseases in which dynamic obstruction is suspected (tracheal collapse, bronchial collapse, bronchomalacia).
- Echocardiography—helpful when heart failure or dysfunction is suspected. • Thoracic ultrasonography—in case of pleural effusion or when a pulmonary or mediastinal mass is suspected.

DIAGNOSTIC PROCEDURES

- Endoscopy allows visualization of both static (tumor, granuloma, abnormal mucosa,

COUGH

(CONTINUED)

C

excessive secretions) and dynamic (laryngeal paralysis, dynamic airway collapse) airway abnormalities. • When bronchial and/or alveolar infiltrates are present—samples from lower airways can be obtained for diagnostic purpose (cytology, bacterial/mycologic cultures) by broncho-alveolar lavage or tracheal wash. • Transthoracic (fine-needle aspiration) biopsy or thoracoscopy—allow biopsy sample when interstitial infiltration is prominent. • Thoracocentesis—allows sampling of pleural fluid, can be performed under ultrasonographic guidance. • Pulse oximetry and blood gas determination. • Pulmonary function tests—require sophisticated material and/or experienced technicians, not readily available in private practice.

TREATMENT

• Usually treated as outpatient. • The most successful management of cough involves treatment and resolution of the underlying cause rather than use of medications that suppress signs. • If chronic cough is related to acute or chronic inflammation, anti-inflammatory therapy is preferred to cough suppressant therapy. • The use of cough suppressant therapy must be limited to cases in which the cause of the cough can neither be treated medically nor resolved, and in which excessive coughing leads to exhaustion of the patient or insomnia of the owners, as well as aggravation of the disease.

MEDICATIONS

DRUG(S) OF CHOICE

Antimicrobial Therapy

- Indicated for infectious tracheobronchitis or bronchopneumonia.

Anti-inflammatory Therapy

- Indicated in feline bronchitis syndrome, canine chronic bronchitis, or canine eosinophilic bronchopneumopathy.
- Oral prednisolone 0.5 mg/kg q12h in dogs and cats, then taper the dose progressively to q48h.
- Nebulized fluticasone with a metered dose inhaler including a spacer with face mask and inspiratory valve (variable concentrations exist, the most appropriate dose is not well established).

Antihistamines

- H1-receptor antagonists.
- May be helpful in suspected allergic tracheitis or bronchitis, or when light sedation is a positive side effect.

Antitussives

- Hydrocodone (dog only): 0.22 mg/kg PO q12h.

- Butorphanol (dog only): 0.5 mg/kg PO q12h.
- No antitussive available for cats. In humans, gabapentin (a neuromodulator) was recently described to treat refractory chronic cough. Not evaluated in dogs.

Bronchodilators

Theophylline (for Dogs and Cats)

- Pharmacokinetics are form- and species-dependent. Slow-release formulations exist. Dosage: dog, 5–10 mg/kg PO q12h; cats, 15–20 mg/kg/day PO in the evening.
- Beneficial effects of theophylline include relaxation of bronchial smooth muscle, improved diaphragmatic contraction, and probably some anti-inflammatory effects.
- Side effects are related to inotropic and chronotropic effects, as well as to an increase in blood pressure; can also cause nausea, diarrhea, arrhythmias, and CNS excitation.

β -2 Agonists (Essentially for Cats)

- Can be delivered via an injection, as a tablet, in syrup form, by nebulization, or via an inhaler; administered IV or SQ in emergency situations. Short-acting (salbutamol, terbutaline, fenoterol) or long-acting (salmeterol, formoterol) drugs.
- Can be administered temporarily to cause immediate and temporary relief but not as a long-term management; have a limited effect.
- Side effects include dry mouth, tachycardia, nausea. Regular inhalation of racemic and S-albuterol (but not R-albuterol) induces airway inflammation in both healthy and asthmatic cats.

Expectorants

- Guafenesin—included in some preparations but benefit not extensively studied or proven.

CONTRAINDICATIONS

Antitussive agents are strictly contraindicated when cough is needed to clean the airways, i.e., in infectious or inflammatory airway disease, bronchiectasis.

POSSIBLE INTERACTIONS

Theophylline—clearance is inhibited by other drugs such as fluoroquinolones, increasing the risk of theophylline toxicity.

FOLLOW-UP

PATIENT MONITORING

- Acute cough must be adequately treated in order to avoid chronic cough, which can lead to possibly irreversible lesions.
- Conditions leading to chronic cough sometimes can only be alleviated but not cured; communicate with client to ensure successful management of cough.

POSSIBLE COMPLICATIONS

- Aggravation of tracheal collapse.
- Progression toward chronic bronchitis,

chronic obstructive pulmonary disease, lung emphysema, irreversible bronchial and parenchymal remodeling, bronchiectasis.

- Acute severe cough might lead to syncope, rib fracture, or pneumothorax.
- Right heart dysfunction.

MISCELLANEOUS

AGE-RELATED FACTORS

• In dogs with anatomic disorders of inherited (e.g., primary ciliary dyskinesia) or congenital origin, signs might start early in life. • Puppies and kittens are more likely to suffer from infectious disease. • Inflammatory disorders affect middle-aged adults. • Heart failure and tumors are more common in older animals.

PREGNANCY/FERTILITY/BREEDING

- Dogs affected with primary ciliary dyskinesia more than cats. • Possible decreased fertility (in male and female dogs) as cilia from the urogenital tract and flagellated cells can be affected.
- Proven hereditary in some breeds (Old English sheepdog, carrier test detection exists).

CRANIOMANDIBULAR OSTEOPATHY

BASICS

OVERVIEW

- A non-neoplastic, non-inflammatory proliferative disease of the bones of the head.
- Primary bones affected—mandibular rami; occipital and parietal; tympanic bullae; zygomatic portion of the temporal. • Bilateral symmetric involvement most common.
- Affects musculoskeletal system.

SIGNALMENT

- Scottish, cairn, and West Highland white terrier breeds—most common. • Labrador retrievers, Great Danes, Boston terriers, Doberman pinschers, Irish setters, English bulldogs, bullmastiffs, Shetland sheepdogs, and boxers—may be affected. • Usually growing puppies 4–8 months of age. • No gender predilection. • Neutering may increase incidence.

SIGNS

Historical Findings

- Usually relate to pain around the mouth and difficulty opening the mouth progressively worsening. • Difficulty in prehension and mastication—may lead to starvation.

Physical Examination Findings

- Temporal and masseter muscle atrophy—common. • Palpable irregular thickening of the mandibular rami and/or TMJ region. • Inability to fully open jaw, even under general anesthesia. • Intermittent pyrexia. • Bilateral exophthalmos.

CAUSES & RISK FACTORS

- Believed to be hereditary—occurs in certain breeds and families. • West Highland white terriers—autosomal recessive trait. • Scottish terriers—possible predisposition. • Young terrier with periosteal long bone disease—monitor for disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Osteomyelitis—bones not symmetrically affected; generally not as extensive; lysis; lack of breed predilection; history of penetrating wound. • Traumatic periostitis—bones not symmetrically affected; generally not as extensive; history of trauma. • Neoplasia—mature patient; not symmetrically affected; more lytic bone reaction; metastatic disease.
- Calvarial hyperostosis—young patient—frontal, parietal, and occipital bones; does not involve mandible; may have long bone involvement.

CBC/BIOCHEMISTRY/URINALYSIS

- Serum ALP and inorganic phosphate—may be high • May note hypogammaglobulinemia or α_2 -hyperglobulinemia.

OTHER LABORATORY TESTS

Serology—rule out fungal agents; indicated in atypical cases.

IMAGING

- Skull radiography—reveals uneven, bead-like osseous proliferation of the mandible or tympanic bullae (bilateral); extensive, periosteal new bone formation (exostoses) affecting one or more bones around the TMJ; may show fusion of the tympanic bullae and angular process of the mandible. • CT—may help evaluate osseous involvement of the TMJ.

DIAGNOSTIC PROCEDURES

Bone biopsy and culture (bacterial and fungal)—necessary only in atypical cases; rule out neoplasia and osteomyelitis.

PATHOLOGIC FINDINGS

- Bone biopsy—reveals normal lamellar bone being replaced by an enlarged coarse-fiber bone and osteoclastic osteolysis of the periosteal or subperiosteal region. • Bone marrow—replaced by a vascular fibrous-type stroma. • Inflammatory cells—occasionally seen at the periphery of the bony lesion.

TREATMENT

- Palliative only. • Surgical excision of exostoses—results in regrowth within weeks.
- High-calorie, protein-rich gruel diet—helps maintain nutritional balance. • Surgical placement of a pharyngostomy, esophagostomy, or gastrostomy tube—considered to help maintain nutritional balance.

MEDICATIONS

DRUG(S)

- Analgesics and anti-inflammatory drugs—palliative use warranted.
- NSAIDs—inhibit cyclooxygenase enzymes.
- Deracoxib (1–2 mg/kg PO q24h, chewable).
- Carprofen (2.2 mg/kg PO q12h or 4.4 mg/kg q24h).
- Etodolac (10–15 mg/kg PO q24h).
- Meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h—liquid).
- Tepoxalin (load 20 mg/kg, then 10 mg/kg PO q24h).
- Firocoxib (5 mg/kg PO q24h).

FOLLOW-UP

PATIENT MONITORING

Frequent reexaminations—mandatory to ensure adequate nutritional balance and pain control.

PREVENTION/AVOIDANCE

- Do not repeat dam-sire breedings that resulted in affected offspring. • Discourage breeding of affected animals.

EXPECTED COURSE AND PROGNOSIS

- Pain and discomfort may diminish at skeletal maturity (10–12 months of age); the exostoses may regress. • Prognosis—depends on involvement of bones surrounding the TMJ. • Elective euthanasia may be necessary.

MISCELLANEOUS

SYNONYMS

- Lion jaw • Craniomandibular osteoarthropathy • Craniomandibular osteodystrophy • Mandibular periostitis • Westie jaw • Scotty jaw

CRUCIATE LIGAMENT DISEASE, CRANIAL

BASICS

DEFINITION

The acute or progressive failure of the cranial cruciate ligament, which results in partial to complete instability of the stifle joint.

PATHOPHYSIOLOGY

- Function of the CrCL includes passive constraint of the stifle joint by limiting internal rotation and cranial displacement of the tibia relative to the femur; it also limits stifle hyperextension.
- Two distinct bands—craniomedial band is taut on both flexion and extension of the joint (primary check) and caudolateral band is taut in extension and lax in flexion (secondary check).
- Without the CrCL, the active constraints (muscles) around the stifle are the main limits to slippage of the tibia cranially.
- Protective mechanism of hamstring activation during stifle loading decreases strain on CrCL.
- Avulsion—occurs in skeletally immature animals in which an acute load results in avulsion of the ligament for the femoral or more commonly tibial attachment site.
- Acute rupture—caused by traumatic actions exceeding the strength of the ligament; usually hyperextension, excessive limb loading, or internal rotation; generally, results in a midsubstance tear of the CrCL and osteophytosis are absent; most common cause in cats.
- Progressive (chronic) degeneration pathogenesis remains elusive; biomechanical and histologic changes occur in the CrCL with age and body weight > 15 kg. Changes include decreases in elasticity, stress/strain energy, failure to maintain collagen fiber organization, and chondroid metaplasia.
- Repetitive subclinical injury may be due to neuromuscular incoordination, aging, conformational abnormalities (excessive TPA, medial luxating patella, narrow intercondylar notch), breed variations, poor muscle tone related to sedentary habits or limb immobilization, and possibly immune-mediated damage.
- Microruptures of individual ligament fiber bundles leave the main structure intact but functionally compromised; cumulative weakening leads to ultimate disruption of CrCL even if from a minor insult; complete and partial tears exist in varying degrees.
- Untreated instability leads to degenerative osteoarthritic changes within a few weeks; severe within a few months.
- Medial meniscal (caudal horn) damage occurs in 33.2–77% of cases. Likely due to shearing force on caudal horn of medial meniscus.

SYSTEMS AFFECTED

Musculoskeletal, ± neurologic

GENETICS

Suspected

INCIDENCE/PREVALENCE

The most common cause of hind limb lameness in dogs; major cause of DJD in the stifle joint.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog; uncommon in cat

Breed Predilections

- All susceptible—especially large to giant breeds
- Rottweiler and Labrador retriever—increased incidence when < 4 years of age
- West Highland white terrier—overrepresented affected small breed

Mean Age and Range

- Incidence increases with age > 5 years.
- Large- to giant-breed dogs may present earlier in life; approx. 2 years of age.

Predominant Sex

Female—neutered

SIGNS

General Comments

Severity of lameness—related to the degree of rupture (partial vs. complete), the mode of rupture (acute vs. chronic), the occurrence of meniscal injury, and the severity of inflammation and DJD. The condition and therefore the lameness may be bilateral.

Historical Findings

- Athletic or traumatic events—generally precede acute injuries.
- Normal activity resulting in acute lameness—suggests degenerative rupture.
- Subtle to marked intermittent lameness (for weeks to months)—consistent with partial tears that are progressing to complete rupture.

Physical Examination Findings

- Varying degrees of lameness and joint effusion, pain, and/or crepitus; the affected limb generally held in partial flexion while standing.
- Cranial drawer test—diagnostic for rupture; test in flexion, normal standing angle, and extension.
- Tibial compression test—cranial movement of tibia relative to the femur when tightening the gastrocnemius by flexing the hock.
- Palpable thickening on the medial aspect of the stifle (medial buttress).
- Presence of click or pop within the joint is 63% accurate in detecting meniscal injury.
- Hind limb muscle atrophy—especially the quadriceps muscle group.
- False-negative drawer or compression tests with chronic or partial tears and in painful or anxious patients that are not sedated or anesthetized.

CAUSES

- Trauma
- Repetitive microinjury; excessive stifle loading
- Progressive degeneration

RISK FACTORS

- Obesity
- Patella luxation
- Conformational abnormalities
- Excessive caudal slope of tibial plateau
- Narrowed intercondylar notch

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Puppy laxity—positive drawer motion that stops abruptly as the CrCL is stretched taut.
- Patella luxation (medial or lateral)—alone or with CrCL rupture.
- Collateral ligament injury, long digital extensor tendon injury.
- Osteochondritis dissecans of the femoral condyle.
- Neoplasia (e.g., synovial sarcoma, osteosarcoma, chondrosarcoma).
- Traumatic fractures or avulsions.
- Caudal cruciate ligament rupture—uncommon.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

Radiography

- Warranted to verify secondary intra-articular changes such as DJD and rule out other differentials.
- Common findings—joint effusion with capsular distention and effacement of the infrapatellar fat pad; periarticular osteophytes; CrCL avulsion fractures; calcification of the CrCL and/or menisci.
- Cats commonly have mineralized menisci present (incidental finding).
- Necessary for pre-operative planning with some surgeries.

Alternative Diagnostic Imaging

- Ultrasound and MRI—facility and operator dependent.

DIAGNOSTIC PROCEDURES

- Arthrocentesis—joint cytology to classify synovial changes and rule out sepsis or immune-mediated disease.
- Arthroscopy—gold standard; allows direct visualization and magnification of the cruciate ligaments, menisci, and other intra-articular structures; allows for description and repair of meniscal pathology.

PATHOLOGIC FINDINGS

- Varying degrees of synovitis, cartilage fibrillation and erosion.
- Periarticular osteophyte formation.
- Meniscal damage.
- Ruptured fibers of the CrCL—hyalinization; fibrous tissue invasion; necrosis; loss of the parallel orientation of ligament bundles.

TREATMENT

APPROPRIATE HEALTH CARE

- Stabilization surgery—recommended; speeds rate of recovery; reduces degenerative changes; enhances function.
- Conservative management—NSAIDs, physical rehabilitation, and 10% weight loss; approx. 66% of patients have normal function over

(CONTINUED)

CRUCIATE LIGAMENT DISEASE, CRANIAL

C

the course of > 1 year; DJD is progressive; not generally recommended.

NURSING CARE

Post-surgery—restricted activity with physical rehabilitation (e.g., ice packing, range-of-motion exercises, massage, and muscle electrical stimulation); important for improving mobility and strength.

ACTIVITY

Restricted—duration depends on method of treatment and progress of patient.

DIET

- Weight control—important for decreasing the load and thus stress on the stifle joint.
- Joint health diets rich in omega-3 fatty acids and chondroprotectants may support overall joint health.

CLIENT EDUCATION

- Regardless of the method of treatment, DJD is common and progressive.
- Return to full athletic function is possible but requires early surgical intervention and rehabilitation.
- Rupture of contralateral CrCL can occur in 37–48% of patients.

SURGICAL CONSIDERATIONS

- No one technique has proven consistently superior to the others clinically or radiographically.
- Recent force plate studies show slight differences between common techniques; dogs with TPLO procedure achieve normal limb loading faster than extracapsular repair patients.
- In patients with concurrent meniscal injury, partial meniscectomy aims to alleviate pain associated with injury; however, has been shown to reduce and alter meniscal function and cause osteoarthritis.

Extra-articular Methods

- Wide variety of techniques that use a heavy-gauge implant to laterally tether the tibia to the femur to mimic the CrCL and restore stability; these techniques rely on periarticular fibrosis for long-term stability.
- Implant material—should be placed in the most isometric points of the CrCL origin and insertion.
- Alternative method includes fibular head transposition to realign and tension the lateral collateral ligament in order to restrict internal rotation and cranial drawer.

Intra-articular Methods

- Designed to replace the CrCL anatomically with autografts (patellar ligament, fascia), allografts, xenografts, and synthetic materials.
- Femoral intercondylar notchplasty—recommended to minimize graft injury.

Osteotomy Procedures**Cranial Tibial Closing Wedge Osteotomy**

- Involves leveling the TPA by removing a cranially based wedge of bone from the proximal tibia and eliminates cranial thrust.
- Held in place with a bone plate and screws.
- Can potentially shorten the tibia and alter stifle biomechanics.

Tibial Plateau Leveling Osteotomy

- Rotational osteotomy of the proximal tibia to level TPA and neutralize cranial tibial thrust.
- Held in place with a bone plate and screws.
- Can accomplish correction for angular and torsional deformities.

Tibial Tuberosity Advancement

- Tibial crest osteotomy; crest is held in an advanced position with a cage and plate; bone graft fills the defect.
- Active control of cranial tibial displacement is improved, which helps stabilize the stifle.
- Can combine technique with lateral transposition of tibial tuberosity to correct concurrent medial luxating patella.

**MEDICATIONS****DRUG(S) OF CHOICE**

- NSAIDs—minimize pain; decrease inflammation.
- Meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg daily PO).
- Carprofen (2.2 mg/kg PO q12h).

CONTRAINdications

Avoid concurrent use of corticosteroids with NSAIDs.

PRECAUTIONS

NSAIDs may cause gastrointestinal irritation/ulceration, liver toxicity, and renal damage; may preclude use in some patients.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Chondroprotective drugs (polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate) may help reduce cartilage damage and improve regeneration.

**FOLLOW-UP****PATIENT MONITORING**

- Most techniques require 2–4 months of rehabilitation.

PREVENTION/AVOIDANCE

Avoid breeding animals with conformational abnormalities.

POSSIBLE COMPLICATIONS

- Subsequent meniscal injury can occur in 6–22% of patients.
- Incisional and/or implant related infection.
- Tibial tuberosity avulsion and/or fractures.
- Patellar luxation.
- Delayed bone healing (osteotomy procedures).
- Pivot shift—unknown clinical significance < 2%.

EXPECTED COURSE AND PROGNOSIS

Regardless of surgical technique, the success rate is better than 85%.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Meniscal damage

Cryptococcosis

BASICS

DEFINITION

A localized or systemic fungal infection caused by the environmental yeast *Cryptococcus* spp, most commonly *C. neoformans* and *C. gattii*.

PATHOPHYSIOLOGY

- *C. neoformans*—grows in bird droppings and decaying vegetation; soil disturbance increases risk of infection.
- Dogs and cats inhale the yeast and a focus of infection is established, usually in the nasal passages; smaller dried, shrunken organisms may reach the terminal airways (uncommon). There may be colonization or subclinical infection of the nasal passages that spontaneously resolves.
- Stomach and intestinal infections suggest that primary GI entry can occur.
- Dissemination—hematogenously spread via macrophages from the nasal passages to the brain, eyes, lungs, and other tissues; by extension to the skin of the nose, eyes, retro-orbital tissues, and draining lymph nodes.

SYSTEMS AFFECTED

- Cats—mainly upper respiratory signs affecting the nose and sinuses; skin; nasal planum; nasopharynx; CNS; eyes.
- Dogs—mainly the head and brain, nasal passages, and sinuses; skin over the nose and sinuses; mucous membranes; draining lymph nodes; eyes; periorbital areas; occasionally lungs and abdominal organs.

INCIDENCE/PREVALENCE

- Dogs—rare in United States; prevalence 0.00013%.
- Cats—7–10 times more common than in dogs; most common systemic mycoses of cats.

GEOGRAPHIC DISTRIBUTION

- Worldwide.
- Some areas of southern California and Australia have an increased incidence and an outbreak has occurred on Vancouver Island in British Columbia, Canada.
- *C. gattii* grows well on eucalyptus trees.

SIGNALMENT

Species

Cat and dog

Breed Predilections

- Dogs—American cocker spaniels, Great Danes, Doberman pinschers, and boxers appear overrepresented.
- Cats—Siamese breed may be at increased risk.

Mean Age and Range

- Most commonly young cats and dogs <4 years of age.
- May occur at any age but has been seen often in dogs <6 months of age.

Predominant Sex

- Dogs—none.
- Cats—males may be overrepresented.

SIGNS

Historical Findings

- Lethargy.
- Varies depending on organ systems involved.
- May have a history of problems for weeks to months.

Dogs

- Neurologic—seizures, ataxia, paresis
- Ocular signs—periorbital swelling, blindness
- Skin ulceration
- Lymphadenopathy
- Vomiting and diarrhea

Cats

- Nasal discharge and ocular signs
- Neurologic signs—seizures, disorientation, vestibular signs
- Granulomatous tissue seen at the nares
- Firm swellings over the bridge of the nose
- Lymphadenopathy
- Respiratory abnormalities less commonly noted

Physical Examination Findings

- Mild fever—<50% of patients.
- Dogs—anorexia; nasal discharge; multifocal CNS signs; ataxia; anterior uveitis.
- Cats—increased respiratory noise; ulcerated crusty skin lesions on the head; lymphadenopathy; neurologic (behavior change, circling, vestibular signs, ataxia); ocular (blindness, optic neuritis, retinal detachment).

CAUSES

Exposure to cryptococcal organisms and inability of the immune system to prevent colonization and invasion into tissues.

RISK FACTORS

- Exposure to disrupted soil
- Prior infection with FeLV or FIV

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dogs

- Other causes of focal or diffuse neurologic disease—distemper; inflammatory meningoencephalomyelitis; bacterial meningoencephalitis; CNS neoplasia; rickettsial diseases; other fungal diseases.
- Nasal lesions, especially at the mucocutaneous junction—considered immune-mediated.
- Lymphoma—possible cause of the lymphadenopathy.
- With chorioretinitis and optic neuritis—consider other fungal infections, distemper, and neoplasia.

Cats

- Nasal lesions—similar to nasal tumors, chronic rhinitis, and chronic sinusitis.
- Ulcerative skin changes—may be the result of bacterial infection, fights, or neoplasia (especially squamous cell carcinoma of the nasal planum).
- Ocular and brain signs—consider lymphoma, FIP, and toxoplasmosis.

CBC/BIOCHEMISTRY/URINALYSIS

- Mild anemia in some cats
- Eosinophilia occasionally seen
- Chemistries usually normal

OTHER LABORATORY TESTS

- Latex agglutination or ELISA—detect cryptococcal capsular antigen in serum or CSF; highly sensitive assay; most infected animals have measurable capsular antigen titers; magnitude of titer correlates with extent of infection.
- Antigen assay may be less sensitive in dogs.
- May be positive when only colonization but antigen titers of 1:32 or greater are seen with fungal invasion.

IMAGING

- Nasal radiographs (cats)—soft tissue density material filling the nasal passage; occasional bone destruction of the nasal dorsum.
- Contrast-enhanced CT or MRI best for identifying brain and nasal lesions.
- Thoracic radiographs—not indicated, unless signs of lower respiratory tract disease.

DIAGNOSTIC PROCEDURES

Dogs

Neurologic disease—additional procedures: CNS imaging, cytologic examination and culture of CSF, measurement of CSF capsular antigen.

Cats

- Aspirates of the mucoid material in the nasal passages or biopsy of the granulomatous tissue protruding from the nares.
- Aspirates of lymph nodes or subcutaneous swellings often yield organisms.
- Patients with upper respiratory obstruction or severe respiratory noise—may identify a granuloma in the nasopharynx (pulling the soft palate forward with a spay hook to expose the mass or retroflexion of endoscope in nasopharynx to allow biopsy).
- Biopsy—skin lesions.
- Cultures—confirm the diagnosis; determine drug susceptibility if poorly responsive infection.

PATHOLOGIC FINDINGS

- Gross lesions—gray, gelatinous mass produced by the polysaccharide capsule; usually found in the nose, sinuses, and nasopharynx of cats; skin lesions are usually ulcerative.
- Neurologic lesions—usually seen in dogs; diffuse or fungal CNS granulomas.

(CONTINUED)

- Chorioretinitis with or without retinal detachment or optic neuritis—dogs and cats.
- Histologic response—usually pyogranulomatous; inflammatory cell infiltrate may be mild because the polysaccharide capsule interferes with neutrophil migration; organism characterized by capsulate yeast with narrow-neck budding.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient if stable.
- Neurologic signs—may initially require inpatient supportive care.

NURSING CARE

Cats—nasal obstruction influences appetite; encourage patients to eat by offering palatable food.

ACTIVITY

No restrictions in most cases.

DIET

- No special diet.
- Patients treated with itraconazole—give medication in fatty food (e.g., canned food) to improve absorption.

CLIENT EDUCATION

- Inform client that this is a chronic disease that requires months of treatment.
- Reassure client that the infection is not zoonotic.

SURGICAL CONSIDERATIONS

Remove granulomatous masses in the nasopharynx to reduce respiratory difficulties.

MEDICATIONS

DRUG(S) OF CHOICE

- Fluconazole—preferred for ocular or CNS involvement because it is water-soluble and better penetrates the CNS; cats, 50 mg PO q12–24h; dogs, 5 mg/kg PO q12h, most economical drug choice.
- Itraconazole capsules—give with a high-fat meal to maximize absorption; cats, 10 mg/kg PO daily; dogs, 5 mg/kg PO q12h; pellets in the capsule can be mixed with food; no apparent adverse taste. Itraconazole liquid: better absorption on empty stomach; compounded itraconazole: variable absorption and not recommended.
- Amphotericin B may have some advantage in severe disease at an intravenous dose of 0.5 mg/kg every 48 hours given over 3–4 hours. Monitor renal function closely.
- Terbinafine at a dose of 5 mg/kg q12h has been effective in treatment of cats with resistant infections.

CONTRAINDICATIONS

Caution with steroid use.

PRECAUTIONS

- Triazoles—hepatotoxicity; anorexia signals problems; monitor liver enzymes after first 3–4 weeks of treatment.
- Terbinafine—monitor for hepatic toxicity and anorexia.
- Amphotericin B—nephrotoxicity; caution if patient is azotemic but not an absolute contraindication if the infection is life-threatening.
- Itraconazole—ulcerative dermatitis (differentiate from the skin lesions of cryptococcosis); new skin lesions after the disease is much improved should be considered a drug reaction.

ALTERNATIVE DRUG(S)

- Cryptococcal organisms are prone to becoming resistant to antifungal treatment.
- Amphotericin B (intravenous)—dogs and cats that do not respond to a triazole; monitor creatinine closely for evidence of renal damage.

FOLLOW-UP

PATIENT MONITORING

- Monitor liver enzymes monthly (especially early in treatment) in patients receiving a triazole antifungal agent.
- Improvement in clinical signs, resolution of lesions, improvement in well-being, and return of appetite measure the response to treatment.
- Capsular antigen titers—after 2 months of treatment, the titers should decrease substantially if treatment is effective; if ineffective, try the terbinafine, because the organism can become resistant.
- Continue monitoring antigen titers every 1–2 months during treatment and after discontinuing treatment to identify recurrence of disease.
- Ideally treat until the cryptococcal antigen titers reach zero (can be > 2 years of treatment).

PREVENTION/AVOIDANCE

The organism is ubiquitous and cannot be avoided.

POSSIBLE COMPLICATIONS

Patients with neurologic disease may have seizures and permanent neurologic changes.

EXPECTED COURSE AND PROGNOSIS

Treatment—anticipated duration 4 months–1 year plus; patients with CNS disease may require life-long maintenance; median time of successful treatment with fluconazole was 4 months; median time for itraconazole treatment was 8 months.

C

Cryptorchidism

BASICS

OVERVIEW

- The incomplete descent of one or both testes into the scrotum is the most common congenital anomaly of the testes.
- Inguinal—retained testis often palpable.
- Abdominal—testis difficult to palpate or identify by radiology; ultrasonography is the best available option to determine size and location of testis.
- Descent to final scrotal position—expected to be complete by 2 months postpartum; may occur later in some breeds, but rarely after 6 months in any individual; presume the diagnosis if no palpable testes at 2 months.
- Beagles—testes at the exterior inguinal ring by day 5 postpartum, between the inguinal ring and scrotum by day 15, and in the scrotum by day 40.

SIGNALMENT

- Dog—reported in almost all breeds; Chihuahua, toy poodle, Pomeranian, Yorkshire terrier; toy and miniature breeds are 2.7 times at greater risk to be cryptorchid than larger breeds; in certain populations German shepherd dog, boxer, and Staffordshire bull terrier also have greatly increased risk; unilateral more common than bilateral (75:25); right testis retained twice as often as left in dogs; right and left testis retained at equal frequency in cats.
- Incidence—dogs, ranges of 0.8–10% have been reported, incidence increases with the proportion of purebred dogs in the population; cats, 1–1.7%; 50% incidence in miniature schnauzer affected with persistent Müllerian duct syndrome.
- Genetics (dogs)—exact mode of inheritance unknown; complex genetic basis; likely polygenic recessive trait; likely heritable.
- Genetics (cats)—may be inherited, but no data documents hereditary defect; Persians overrepresented in surveys.

SIGNS

- Bilaterally cryptorchid animals are infertile; unilaterally cryptorchid animals are typically fertile.
- Rarely associated with pain or other signs of disease.
- Acute onset of abdominal pain—spermatic cord of retained testes at increased risk for torsion; 36% of retained testes with torsion of the spermatic cord were neoplastic.
- Feminizing paraneoplastic syndrome—estrogen-secreting Sertoli cell tumors in retained testes produce feminizing signs: gynecomastia, symmetrical alopecia of trunk and flanks, hyperpigmentation of inguinal skin, pendulous preputial sheath, prostatic squamous metaplasia.

CAUSES & RISK FACTORS

- Removal of affected males from breeding lines—believed to cause a reduction in

frequency; heritability thought to involve more than one gene.

- Non-hereditary predisposing factors (e.g., birth weight)—identified in humans; not reported in dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Castration—differentiate bilateral condition from previous castration, previous castration of single scrotal testis with retained abdominal testis, or anorchidism (rare).
- Bilaterally cryptorchid cats may have urine odor and behavior of intact cats.

OTHER LABORATORY TESTS

hCG stimulation test—doubles blood testosterone with bilateral condition; doubles blood testosterone with unilateral condition in which only the scrotal testis has been removed; differentiates between cryptorchidism and castration; administration of 750 IU hCG IV or 50 µg GnRH IM with blood sample collection pre- and 2–3 hours post-injection; castrated dogs have testosterone concentrations < 0.1 ng/mL and do not stimulate with hCG or GnRH administration. Determination of blood canine anti-Müllerian hormone (produced by Sertoli cells; Spaycheck®) has also become commercially available for the diagnosis of cryptorchidism (uni- or bilateral conditions).

IMAGING

Transabdominal ultrasonography—useful to locate testes in the inguinal or abdominal regions. Recommended before laparotomy or laparoscopy to remove cryptorchid testes.

TREATMENT

- None except castration of both retained and scrotal testes generally recommended.
- Orchiopexy—surgical placement of a retained testis into the scrotum; considered unethical.
- hCG or GnRH—anecdotal evidence of causing descent when given to dogs < 4 months of age.
- Warn client of the increased risk of testicular neoplasia in dogs with retained testes; 53% of Sertoli cell tumors and 36% of seminomas occur in retained testes.

MEDICATIONS

DRUG(S)

- hCG (dogs)—100–1,000 IU IM four times in a 2-week period before 16 weeks of age (dogs); after 16 weeks, generally unsuccessful.
- GnRH (dogs)—50–750 µg one to six times between 2 and 4 months of age.

FOLLOW-UP

- Migration of testes into the scrotum after 4 months is unlikely; after 6 months, rare.
- Risk of testicular neoplasia thought to be approximately 13.6 times greater in affected dogs than in normal dogs; undescended testes at increased risk of torsion of the spermatic cord.

MISCELLANEOUS

CRYPTOSPORIDIOSIS

BASICS

OVERVIEW

- *Cryptosporidium* spp.—apicomplexan protozoan; causes gastrointestinal disease in dogs, cats, humans, calves, and rodents; ubiquitous in nature; worldwide distribution; enteric life cycle.
- Infection—when sporulated oocysts are ingested, sporozoites are released and penetrate intestinal epithelial cells; after asexual reproduction, merozoites are released to infect other cells.
- Prepatent period—cats, 5–10 days.
- Immunocompetent animals—intestinal disease.
- Immunocompromised animals—intestinal, liver, gallbladder, pancreatic, and respiratory infection.
- Cats—serology suggests approximately 15% exposure rate in US cats.

SIGNALMENT

- Dogs and cats. • No sex or breed predilection.
- Dogs—virtually all clinical cases have occurred in animals ≤ 6 months of age; old dogs can excrete oocysts without clinical signs.
- More common in young and newborn kittens < 6 months of age.

SIGNS

- Most infections subclinical
- Principally small bowel diarrhea
- Large bowel diarrhea reported

CAUSES & RISK FACTORS

- *C. canis* (dogs) and *C. felis* (cats)—acquired by ingestion of contaminated water or feces.
- Morphologically, species very similar.
- Some species are host-specific (*C. canis* and *C. felis*); others (*C. parvum*) infect multiple species.
- Virtually all clinical cases reported in immunocompromized cats.
- Immunosuppression—major risk factor; common causes are FeLV (cats), canine distemper virus (dogs), canine parvovirus, and intestinal lymphoma (cats and dogs).
- Immunocompetent—usually asymptomatic intestinal infection with fecal oocyst shedding for 2 weeks.
- Immunocompromised—enteritis and possibly respiratory, liver, biliary, and pancreatic infections.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dietary indiscretion or intolerance.
- Drugs—antibiotics.
- Toxins—lead.
- Parasites—giardiasis, trichuriasis.
- Infectious agents—parvovirus, coronavirus, FIP, *Salmonella*, *Campylobacter*, *Rickettsia*, *Histoplasma*.
- Organ disease—cardiac, renal, hepatic, and pancreatic exocrine insufficiency.

- Metabolic—hypoadrenocorticism, hyperthyroidism (cats).
- Neoplasia—intestinal lymphoma.
- Infiltrative diseases—e.g., inflammatory bowel disease.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal, unless an underlying immunosuppressive disease.

DIAGNOSTIC PROCEDURES

Sugar and zinc sulfate flotation—specific gravity = 1.18; concentrates fecal oocysts (oocysts are 5 µm, so routine salt flotation often fails); oocysts best visualized after staining with modified acid-fast stain.

- Oocysts often appear to have a slight pink color
- Fecal antigen detection test (ProSpecT *Cryptosporidium* Microtiter Assay; Color-Vue *Cryptosporidium*) available.
- Fluorescent antibody techniques—available in some laboratories (Meridian Diagnostics).
- Submitting feces to a laboratory—mix 1 part 100% formalin with 9 parts feces to inactivate oocysts and decrease health risk to laboratory personnel.
- PCR techniques—available from Michigan State Animal Disease Diagnostic laboratory; approximately 10–100 times more sensitive for the diagnosis of cryptosporidiosis in cats than other techniques.

PATHOLOGIC FINDINGS

- Gross lesions—enlarged mesenteric lymph nodes; hyperemic intestinal (particular ileum) mucosa; fix specimens in Bouin's or formalin solution within hours of death because autolysis causes rapid loss of the intestinal surface containing the organisms.
- Microscopic lesions—villous atrophy; reactive lymphoid tissue; inflammatory infiltrates in the lamina propria; parasites may be found throughout the intestines but most numerous in the distal small intestine.

TREATMENT

- Outpatient.
- In immunocompetent animals—diarrhea is usually mild and self-limiting; withhold food for 24–48 hours to control diarrhea; oral glucose-electrolyte solution in mild diarrhea; parenteral fluids (isotonic with potassium added) in severe diarrhea.

MEDICATIONS

DRUG(S)

- Paromomycin (Humatin), 125–165 mg/kg PO q12h for 5 days, is an aminoglycoside antibiotic effective in treating acute intestinal patients. It may cause nephropathy in young animals with a damaged gastrointestinal

barrier. Toxicity responds to diuresis; monitor renal toxicity by monitoring urine for casts.

- Tylosin 11 mg/kg PO q12h for 28 days; effective in treating an affected cat that also had lymphocytic duodenitis.

- Nitazoxanide (Alinia, 25 mg/kg PO q24h for 7–28 days); stops oocyst shedding in cats; dosing usually associated with vomiting, which can be ameliorated by antiemetics (e.g., chlorpromazine). Has only been used in a limited number of cats with cryptosporidiosis and needs further evaluation. Few side effects other than vomiting.

FOLLOW-UP

- Monitor clinical improvement for treatment efficacy.
- Monitor oocyst shedding in the feces 2 weeks after completion of treatment or if signs persist.
- Prognosis excellent if cause of immunosuppression can be overcome.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Warn clients of potential zoonotic transmission from organisms in feces and that immune-compromised people are at great risk. However, genetic sequencing has revealed that dog and cat isolates of the parasite are host-specific and transmission of *Cryptosporidium* from dogs and cats to people is extremely rare.

Disinfection

- Resistant to commercial bleach (5.25% sodium hypochlorite) and chlorination of drinking water.
- A 10% formaldehyde solution and 5% ammonia solution will kill oocysts but requires 18 hours of exposure.
- Higher concentrations of ammonia (50%) will kill oocysts in 30 minutes; moist heat (steam or pasteurization, > 55°C), freezing and thawing, or thorough drying effective.

ABBREVIATIONS

- FeLV = feline leukemia virus
- FIP = feline infectious peritonitis
- HIV = human immunodeficiency virus
- PCR = polymerase chain reaction

CRYSTALLURIA

BASICS

DEFINITION

Appearance of crystals in urine

PATHOPHYSIOLOGY

- Crystals form only in urine that is, or recently has been, supersaturated with crystalloidal substances; thus crystalluria represents a risk factor for urolithiasis.
