Except for patients with primary hypoadrenocorticism caused by granulomatous or metastatic disease and secondary hypoadrenocorticism caused by a pituitary mass, the vast majority of patients carry a good to excellent prognosis following with proper stabilization, treatment, and monitoring.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Concurrent endocrine gland failure occurs in up to 5% of dogs—hypothyroidism, diabetes mellitus, and/or hypoparathyroidism.

BASICS

DEFINITION

Hypoalbuminemia defined as measured value less than the reference range.

PATHOPHYSIOLOGY

- Albumin—constitutive protein exclusively synthesized in the liver. • Provides 75–80% of plasma colloid oncotic pressure. • Low oncotic pressure due to serum albumin < 1.5 g/dL may permit fluid extravasation into interstitial and potential third-space compartments, causing edema and body cavity effusion. • Albumin of 1.5–2.5 g/dL does not cause edema or effusion unless other factors (e.g., increased hydrostatic pressure [venous occlusion, vascular bed hypertension, renal water or sodium retention, fluid overload], increased vascular permeability [vasculitis]) are present.

SYSTEMS AFFECTED

- Cardiovascular and respiratory—transudative effusions (e.g., pleural effusion, ascites); peripheral edema; pulmonary edema.

INCIDENCE/PREVALENCE

Accompanies many primary diseases processes: primary necroinflammatory liver disorders, protein losing enteropathy (PLE), protein losing nephropathy (PLN), enteric hemorrhage, negative acute phase response in chronic disease.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Numerous disease or syndromes may have propensity for breed specificity.

Mean Age and Range

Varies with syndrome association.

Predominant Sex

N/A

SIGNS

General Comments

- Reflects primary disease or syndrome leading to hypoalbuminemia. • Development of hypoalbuminemia influences: metabolite and xenobiotic protein binding, plasma oncotic pressure, third space fluid distribution, acid base balance, and ability to maintain intravascular perfusion pressure.

HISTORICAL FINDINGS

- Varies with the underlying primary disease or syndrome causing hypoalbuminemia.
- May demonstrate increased drug related effects due to reduced protein binding.

PHYSICAL EXAMINATION FINDINGS

- Varies with the underlying primary disease or syndrome causing hypoalbuminemia.
- Severe hypoalbuminemia (< 1.5 g/dL) associated with anasarca and increased

propensity for third-space fluid distribution with altered Starling forces.

CAUSES

Decreased Albumin Production

- Chronic hepatic insufficiency—chronic hepatitis; cirrhosis; idiopathic hepatic fibrosis; granulomatous hepatitis; congenital portosystemic shunt (dogs). • Inadequate nutritional intake/absorption

EXTRACORPOREAL ALBUMIN LOSS

- PLN—amyloidosis; glomerulonephritis
- PLE—lymphangiectasia; lymphoma; severe inflammatory bowel disease; histoplasmosis; pythiosis; chronic intussusception
- Severely exudative cutaneous lesions
- Chronic severe blood loss—usually enteric
- Repeated large volume paracentesis—abdominal or pleural effusion

Sequestration: Body Cavities/Tissues

- Inflammatory effusions—pancreatitis; septic or aseptic peritoneal or pleural effusions; chylous effusions.
- Vasculopathies—immune-mediated (SLE); infectious (Ehrlichia, Rocky Mountain spotted fever); sepsis syndrome; other.

Miscellaneous

- Downregulated albumin synthesis—hyperglobulinemia, negative acute-phase response, negative nitrogen intake, catabolism.
- Loss—hypoalbuminocorticism.

RISK FACTORS

- Diseases of the liver, kidney, intestines, and blood vessels
- Negative nitrogen balance; poor nutrition

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

- Severe hepatic disease—may see jaundice; HE; polyuria—polydipsia; or ascites
- PLE—diarrhea common but inconsistent
- Cutaneous lesions—must be severe and exudative (e.g., burns, TEN, vasculitis, tumors, trauma)
- External blood loss—pallor due to anemia; evidence of extracorporeal blood loss (enteric, urinary, other)
- Malnutrition—causes mild hypoalbuminemia
- Aggressive fluid therapy (especially colloids)—exacerbates low albumin, may cause transient abnormality.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Depends on underlying disease
- Severe hepatic disease—RBC microcytosis (occasional) suggests portosystemic shunting
- Severe blood loss—regenerative anemia or microcytic/hypochromic anemia

Biochemistry

- Fractionation of total protein not helpful.
- Chronic hepatic disease—low albumin; normal to high globulin.
- PLE—low albumin; low to high globulin.
- PLN—low

HYPOALBUMINEMIA

albumin; globulin usually normal but may be low with non-selective proteinuria (severe PLN).

- Exudative losses—low albumin; variable globulin.
- Malnutrition—low albumin; normal globulin.
- Severe blood loss—low albumin; low to normal globulin.
- Cholesterol—low with chronic hepatic disease, severe PLE, Addison's disease, and severe malnutrition; high with PLN and pancreatitis.
- Hepatic enzymes—ALT may be high with chronic hepatitis, inflammatory bowel disease causing PLE; high ALP often seen with systemic inflammation.

- Bilirubin—sometimes high with chronic hepatic disease.
- BUN—often low with hepatic insufficiency or patients undergoing diuresis; high with reduced renal function or dehydration.
- Hyperkalemia and hyponatremia—suggest hypoalbuminocorticism, third-space effusions, or gut-associated pseudohypoalbuminocorticism.
- Spurious hypocalcemia—due to low protein.

Urinalysis

- Rules out PLN and urologic blood loss.
- Obtain urine by cystocentesis to avoid lower-tract contamination; **caution:** beware cystocentesis-induced microhematuria.
- Proteinuria—confirm dipstick detection with chemical determination.
- Urine protein:creatinine (UP:UCr) ratio—important; > 3.0 compatible with nephrotic range proteinuria; must evaluate urine sediment—spurious positive values with active sediment (i.e., substantial pyuria or macroscopic hematuria); many dogs with glomerulonephritis have hyaline, waxy, or granular casts.
- Microalbuminuria: not helpful; need UP:UCr.
- Ammonium biurate crystalluria—hepatic insufficiency, congenital or APSS.

OTHER LABORATORY TESTS

- TSBA—usually high with severe hepatic disease; sometimes spurious low values with PLE (fat malabsorption).
- Physicochemical evaluation of effusion—transudate (usually pure) if hypoalbuminemia is a major causal factor.
- Antithrombin (AT)—anticoagulant with molecular weight similar to albumin and synthesized largely in liver; may be low with PLE, PLN, and hepatic synthetic failure.
- Protein C (PC)—anticoagulant; may be low with severe hepatic disease/failure, portosystemic shunting, sepsis.

IMAGING

- Thoracic radiography—pleural effusion; pulmonary edema.
- May reveal lymphadenopathy, metastatic disease, cardiac or pulmonary disorders.
- Abdominal radiographs—effusion; altered hepatic size; mass lesions; quadrant signs of pancreatic disease.
- Abdominal ultrasonography—helps identify visceral abnormalities (e.g., small liver, lymphangiectasia in intestinal wall/mucosa), mass lesions, fluid pockets, altered portal blood flow, mesenteric

Hypoalbuminemia

(CONTINUED)

lymphadenopathy, and biliary tree abnormalities.

DIAGNOSTIC PROCEDURES

- Hepatic biopsy—after evaluating coagulation (mucosal bleeding time, PIVKA, PT, APTT, platelet count) status; request hepatic staining panel (H&E, rhodanine, Prussian blue, reticulin, Mason's trichrome staining).
- Renal biopsy—differentiates amyloidosis from glomerulonephritis; submit samples for special renal panel staining and ultrastructure studies otherwise biopsy features unlikely to influence treatment.
- Intestinal biopsy—endoscopic or surgical; severe hypoalbuminemia may cause post-laparotomy delay wound healing and seroma formation.

PATHOLOGIC FINDINGS

Diverse depending on underlying causal disease.

TREATMENT

APPROPRIATE HEALTH CARE

- Diverse, depends on cause.
- Pleural effusion restricting ventilation—perform thoracentesis, may require chest tube.

NURSING CARE

Provide physical therapy and walk patient to improve mobilization of peripheral edema.

DIET

- Achieve positive energy and nitrogen balance.
- Hepatic encephalopathy—restrict protein intake (see Hepatic Encephalopathy).
- Effusions or edema due to hypoalbuminemia—restrict sodium.
- PLE associated with lymphangiectasia—feed ultra-low-fat diet.

SURGICAL CONSIDERATIONS

Severe hypoalbuminemia may complicate healing rate, anesthetic drug metabolism, body cavity effusions may complicate drug dosing and dispersal, surgical approach, patient ventilation.

MEDICATIONS

DRUG(S) OF CHOICE

- Depends on underlying disease.
- Glucocorticoids—for some types of chronic hepatitis and some PLE's; prednisolone is preferred if it is effective; dexamethasone lacks mineralocorticoid effects which lessens sodium and water retention, but has greater potential for ulceration/erosion.
- Diuretics—assist in mobilization and excretion of excess body water and sodium; furosemide (1–4 mg/kg IV, IM, or PO q4–12h) in combination with spironolactone (1–4 mg/kg

q12h) in patients with hepatic or cardiac disease, use judiciously to avoid intravascular volume contraction. For body cavity effusion mobilization, taper diuretic dose after initial positive response; individualize chronic treatment to response; diuretics may be used intermittently to mobilize recurring ascites.

- Antithrombotic treatment (low AT, PC, evidence of thrombi)—clopidogrel (0.5–1.0 mg/kg PO q24h) especially in PLN.
- Enalapril (0.5 mg/kg PO q12–24h)—for dogs with PLN; alternative is benazepril or telmisartan: angiotensin receptor blocker (ARB), is an alternative diuretic worthy of consideration.

CONTRAINdications

Synthetic colloids—avoid with anuria, renal failure, congestive heart failure, severe coagulopathy, or von Willebrand disease.

PRECAUTIONS

- Fluid therapy—large doses of synthetic colloids given to patients with severe hypoalbuminemia may cause volume overload with acute worsening of effusions and coagulopathy; avoid over-dosing crystalloid fluids when administered with synthetic colloids as these are rapidly distributed into interstitial spaces (70% volume within 1 hour) aggravating antecedent pulmonary or limb edema, and body cavity effusions; restrict maintenance fluid volume of crystalloids to one-third normal (depending on contemporary losses) when used with colloids.
- Transfusion of canine plasma or human albumin—may be complicated by transfusion or allergic reactions; plasma and albumin transfusions of dubious value if severe contemporary extra-corporeal albumin loss (e.g. PLN, PLE, vasculitis).
- Diuretic therapy—may cause serious volume contraction leading to azotemia, hypotension, and electrolyte and acid-base derangements.
- Unanticipated drug side effects—owing to reduced albumin drug binding.
- Use of DDAVP for bleeding—may aggravate fluid retention and associated complications.
- Glucocorticoids—mineralocorticoid effects of some drugs may worsen fluid accumulation, necessitating use of synthetic glucocorticoids without mineralocorticoid effects.

POSSIBLE INTERACTIONS

Inadvertent overdosing of drugs with high-protein binding

FOLLOW-UP

PATIENT MONITORING

- Body weight—especially during fluid therapy; monitors fluid retention.
- Vital signs, thoracic auscultation for crackles—monitor for pulmonary edema.
- Sequential

serum albumin concentrations.

- Blood pressure—monitors vascular expansion.

- Abdominal girth—monitors ascites.
- Central venous pressure—unreliable; monitors fluid balance; avoid central venous catheters in patients with bleeding or thrombotic tendencies.

PREVENTION/AVOIDANCE

- Limit glucocorticoid exposure.
- Use alternate-day therapy with prednisolone; titrate to lowest effective dose; use alternative medications to control primary illness.

POSSIBLE COMPLICATIONS

- PLN—may be complicated by thromboembolism; minimize IV catheterization and trauma.
- Hypovolemia—in dehydration, Addisonian crisis, blood loss, or diuretic over-dose can predispose to acute renal failure, DIC or HE.

EXPECTED COURSE AND PROGNOSIS

Depends on underlying cause.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Numerous diverse diseases or syndromes

BASICS

DEFINITION

Low total and ionized serum calcium concentration

PATHOPHYSIOLOGY

- Of the total circulating serum calcium, 40–50% is protein-bound, 40–50% is ionized, and 10% is complexed with other substances. Protein-bound and complexed calcium are unavailable for use by tissues. Only ionized calcium is available to tissues and is responsible for clinical problems (hypocalcemia and hypercalcemia). Routine measurement of ionized calcium is difficult; many biochemical profiles record only total serum calcium, but some blood analyzers can measure ionized calcium. Mechanisms of hypocalcemia include: Low concentrations of binding proteins—hypoalbuminemia • Reduced intestinal absorption—deficient vitamin D (renal disease, severe intestinal disease, rickets, chronic glucocorticoid treatment) • Reduced renal and bone resorption—hypoparathyroidism • Inadequate dietary intake • Excessive loss—lactation (eclampsia)
- Sequestration—saponification (acute pancreatitis) • Binding/complexing with administered, ingested, or endogenous chemicals—phosphate-containing enemas, citrate toxicosis (multiple citrate-containing anticoagulant transfusions), ethylene glycol toxicosis, oxalate toxicosis, low calcium/high phosphorus diet (nutritional secondary hyperparathyroidism), acute tumor lysis syndrome (hyperphosphatemia from cancer therapy-induced rapid destruction of tumor cells) • Impaired synthesis or refractoriness to PTH—hypomagnesemia • Target organ calcitriol (vitamin D) resistance (vitamin D-dependent rickets type 2) • Multifactorial—ionized hypocalcemia in the critically patient

SYSTEMS AFFECTED

- Cardiovascular—ECG changes and bradycardia • Gastrointestinal—anorexia and vomiting (especially cats) • Nervous/Neuromuscular—seizures, tetany, ataxia, and weakness • Ophthalmic—posterior lenticonal cataracts • Respiratory—panting

SIGNALMENT

Species

Dog and cat

Breed Predilections

Varies depending on the underlying cause

Mean Age and Range

Varies depending on the underlying cause

Predominant Sex

Varies depending on the underlying cause

SIGNS

General Comments

Signs of the underlying disease may be seen without clinical signs of hypocalcemia,

because the latter do not occur until total serum calcium falls below 6.7 mg/dL.

Historical Findings

- Seizures • Muscle trembling, twitching, or fasciculations • Ataxia or stiff gait • Weakness • Panting • Facial rubbing • Vomiting • Anorexia

Physical Examination Findings

- Ataxia, stiff gait, weakness, muscle fasciculation, trembling, twitching. • Fever.
- Posterior lenticonal cataracts in patients with primary hypoparathyroidism.

CAUSES

Non-pathologic Hypocalcemia

- Laboratory error—repeat serum calcium determinations to confirm true hypocalcemia, especially if significant hypocalcemia despite absence of clinical signs.
- Hypoalbuminemia—most common cause; accounts for more than 50% of patients; reduction of protein-bound calcium without affecting ionized calcium; not associated with clinical signs. • Alkalosis—causes a reduction in both ionized and total measured calcium; not associated with clinical signs unless in cases of borderline low serum ionized calcium concentrations.

Pathologic Hypocalcemia

- Primary hypoparathyroidism.
- Hypoparathyroidism secondary to bilateral thyroidectomy (or other corrective hyperthyroid therapies, such as ultrasound-guided thyroid gland ethanol injection or thyroid gland radiofrequency heat ablation) and parathyroid damage.
- Hypoparathyroidism secondary to ultrasound-guided parathyroid gland radiofrequency heat ablation (for hyperparathyroidism/parathyroid masses) and parathyroid damage. • Renal failure—acute or chronic. • Ethylene glycol toxicosis.
- Oxalate toxicosis (lily, philodendron, etc.).
- Acute pancreatitis. • Puerperal tetany—eclampsia. • Phosphate-containing enemas.
- Nutritional secondary hyperparathyroidism.
- Puerperal tetany (eclampsia).
- Hypomagnesemia. • Intestinal malabsorption. • Citrate toxicosis—multiple blood transfusions or improper citrate-blood ratio. • Post-hyperparathyroid correction due to prolonged negative feedback-induced hypofunction of normal parathyroid glands.
- Rickets – rare in dogs and cats (hypovitaminosis D, decreased plasma calcitriol) or vitamin D-dependent rickets type 2 (target organ calcitriol receptor resistance). • Acute tumor lysis syndrome.
- Ionized hypocalcemia in the critically ill patient. Multifactorial: parathyroid dysfunction; cytokine suppression of parathyroid function; vitamin D deficiency; hypomagnesemia; calcium chelation; accumulation of calcium in soft tissues, body fluids, and cells.

RISK FACTORS

- Puerperal tetany (eclampsia)—small-breed bitches during first 21 days of nursing, but can rarely affect large breeds and can rarely occur preparturient. Preparturient eclampsia has also been reported in cats. • Post-corrective procedures for hyperthyroidism and hyperparathyroidism (parathyroid damage or prolonged negative feedback-induced hypofunction of normal parathyroid glands).

DIAGNOSIS

H

DIFFERENTIAL DIAGNOSIS

- Clinical signs of hypocalcemia—rule-out primary hypoparathyroidism, hypoparathyroidism secondary to corrective hyperthyroid and hyperparathyroid therapy and parathyroid damage, puerperal tetany (eclampsia), and intoxication leading to rapid calcium binding/complexing (e.g., phosphate-containing enemas, ethylene glycol); other causes rarely lower the serum calcium enough to cause clinical signs. • Polyuria and polydipsia—rule-out renal failure.
- Neurologic signs—rule-out ethylene glycol toxicosis. • Vomiting and diarrhea—rule-out acute pancreatitis, intestinal malabsorption, renal failure, and ethylene glycol toxicosis. • Bone pain or fractures—rule-out nutritional secondary hyperparathyroidism.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

- Sodium bicarbonate may cause alkalosis and lower the serum calcium concentration.
- Samples collected in EDTA tubes may have a falsely low serum calcium concentration because of calcium chelation.

Disorders That May Alter Laboratory Results

- Lipemia can raise the serum calcium significantly. • Hypoalbuminemia can falsely lower the serum calcium (see causes of non-pathogenic hypocalcemia).

CBC/BIOCHEMISTRY/URINALYSIS

- Low calcium. • Mild-to-moderate anemia possible with chronic renal failure, nutritional secondary hyperparathyroidism, or intestinal malabsorption. • Leukocytosis possible with acute pancreatitis. • Hypoalbuminemia with hypoproteinemia-induced hypocalcemia—intestinal malabsorption, protein-losing nephropathy, other causes. • High total CO₂ with alkalosis-induced hypocalcemia. • High BUN and creatinine with acute and chronic kidney injury, ethylene glycol toxicosis, or oxalate toxicosis. • High phosphorus with acute and chronic kidney injury, ethylene glycol toxicosis, oxalate toxicosis, primary hypoparathyroidism, hypoparathyroidism secondary to hyperthyroid or hyperparathyroid corrective procedures and parathyroid

HYPOCALCEMIA

(CONTINUED)

damage, acute tumor lysis syndrome, or in patients receiving phosphate-containing enemas. • High amylase and lipase in many, but not all, patients with acute pancreatitis.

- Isosthenuria with chronic kidney injury, moderate-to-advanced acute kidney injury, ethylene glycol toxicosis, or oxalate toxicosis.
- Glucosuria in some patients with acute kidney injury, ethylene glycol toxicosis, or oxalate toxicosis.

OTHER LABORATORY TESTS

- Ionized calcium—helps determine if clinical signs are due to hypocalcemia as this is the active form of calcium.
- Ethylene glycol test—indicated in patients suspected of ingesting ethylene glycol within the previous 12–16 hours (questionable reliability).
- Pancreatic lipase immunoreactivity—indicated in patients suspected of having acute pancreatitis.
- PTH assay—indicated when primary hypoparathyroidism is suspected.
- Serum magnesium concentration—hypomagnesemia is a rare cause of hypocalcemia.
- Plasma calcitriol (vitamin D, 1,25 dihydroxycholecalciferol) concentration—indicated to screen for rickets or vitamin D—dependent rickets type 2 (rare).

IMAGING

- Radiography usually normal.
- Possibly, small kidneys with chronic renal disease and large kidneys with acute kidney injury, hyperechoic renal parenchyma on ultrasound with ethylene glycol toxicosis, or oxalate toxicosis.
- Possibly, osteopenia and pathologic fractures with nutritional secondary hyperparathyroidism.
- Possibly, mild pleural effusion and decreased anterior abdominal detail from effusion with pancreatitis.

DIAGNOSTIC PROCEDURES

ECG changes include prolongation of the ST and QT segments; sinus bradycardia and wide T waves or T wave alternans in some patients.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient treatment for clinical hypocalcemia.
- Emergency treatment is usually only needed with primary hypoparathyroidism, hypoparathyroidism secondary to hyperthyroid or hyperparathyroid corrective procedures and parathyroid damage, puerperal tetany (eclampsia), recent phosphate-containing enema administration, citrate toxicosis (rare), and ethylene glycol toxicosis.
- Long-term and short-term treatments are usually needed only to treat primary hypoparathyroidism and puerperal tetany (eclampsia), respectively.
- Puerperal tetany (eclampsia)—remove puppies from bitch and hand-nurse until weaned.

DIET

Diet change recommended for nutritional secondary hyperparathyroidism (to a balanced diet) and renal failure (see Renal Failure, Chronic).

MEDICATIONS

DRUG(S) OF CHOICE

Emergency Treatment

- Calcium gluconate 10% solution—5–15 mg/kg (0.5–1.5 mL/kg) give IV slowly to effect over a 10-minute period; monitor heart rate and stop temporarily if bradycardia occurs; if ECG monitoring is possible, QT interval shortening is an indication to temporarily stop administration.
- Calcium chloride 10% solution—also effective; extremely caustic if administered extravascularly, and three times more potent than calcium gluconate; the mg/kg dosage is the same as for calcium gluconate (5–15 mg/kg), but only one-third the volume is needed (0.15–0.5 mL/kg).

Short-Term Treatment Immediately After Correction of Tetany for Hypoparathyroidism

- With calcium gluconate 10% solution, relapse of clinical signs after emergency treatment can be prevented by use of constant-rate IV infusion of 60–90 mg/kg/day (6.5–9.75 mL/kg/day) added to fluids that do not contain bicarbonate. This follow-up treatment is rarely necessary for postparturient eclampsia.
- Subcutaneous calcium gluconate 10% diluted 2–4 times with saline can be administered 3 or 4 times daily for initial control of tetany (reported to be safe in most patients but there have been reports of marked inflammatory calcinosis cutis associated with the subcutaneous treatment option).

Long-Term Treatment

See Hypoparathyroidism.

CONTRAINDICATIONS

Avoid bicarbonate as alkalinization may further decrease serum calcium levels.

POSSIBLE INTERACTIONS

- Calcium salts may precipitate if added to solutions containing bicarbonate, lactate, acetate, or phosphates. • See Hypoparathyroidism.

FOLLOW-UP

PATIENT MONITORING

- For patients requiring long-term hypocalcemia therapy, serum calcium should be assessed 4–7 days following initial treatment, then (if normocalcemic) monthly

for the first 6 months, then every 2–4 months.

- Goal is to maintain serum calcium concentration between 8 and 10 mg/dL.

EXPECTED COURSE AND PROGNOSIS

- Varies depending on the underlying cause.
- Recurrence of hypocalcemia following calcium administration is common; monitoring is advised.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- Hypocalcemia can lead to weakness and dystocia.
- Puerperal tetany (eclampsia) usually is seen in small-breed bitches during the first 21 days of nursing a litter.

SEE ALSO

- Eclampsia • Ethylene Glycol Toxicosis
- Hypoalbuminemia • Hypomagnesemia
- Hypoparathyroidism • Lily Toxicosis
- Pancreatitis • Renal Failure, Acute • Renal Failure, Chronic

ABBREVIATIONS

- Ca = calcium • ECG = electrocardiogram
- EDTA = ethylene diamine tetraacetic acid
- PTH = parathyroid hormone

HYPOTHOLOREMIA

BASICS

DEFINITION

Serum chloride concentration below the lower limit of normal—dogs, < 105 mEq/L; cats, < 117 mEq/L (values may vary from laboratory to laboratory).

PATHOPHYSIOLOGY

- Chloride is the most abundant anion in the extracellular fluid.
- Chloride concentration is controlled by electrochemical gradients resulting from the active transport of sodium.
- In general, chloride concentration varies directly with sodium concentration and inversely with bicarbonate concentration.

SYSTEMS AFFECTED

Depends on underlying disorder

CAUSES

- Gastric vomiting
- Hypoadrenocorticism
- Metabolic alkalosis
- Chronic respiratory acidosis
- Salt-losing nephropathy
- Diuretic therapy

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

If the degree of hypochloremia exceeds that of hyponatremia, it suggests selective chloride loss as seen in patients with gastric vomiting.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

Furosemide, thiazides, bicarbonate, and laxatives lower the serum concentration.

Disorders That May Alter Laboratory Results

Lipemia and hyperproteinemia can falsely lower chloride concentration if ion-specific electrodes are not used.

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- Low chloride.
- Other abnormalities depend on underlying disorder, possibly hyponatremia, hyperkalemia, and high bicarbonate concentration

OTHER LABORATORY TESTS

- Measurement of urine fractional excretion of chloride may demonstrate high excretion.
- Blood gas measurement may reveal metabolic alkalosis.

HYPOGLYCEMIA

BASICS

DEFINITION

Abnormally low blood glucose concentration

PATHOPHYSIOLOGY

- Mechanisms responsible for hypoglycemia:
- Excess insulin or insulin-like factors (e.g., insulinoma, extrapancreatic paraneoplasia (IGF2), xylitol toxicosis, and iatrogenic insulin overdose)
- Reduced hepatic gluconeogenesis and glycogenolysis (e.g., hepatic disease, glycogen storage diseases, hypoadrenocorticism, and sepsis)
- Excessive metabolic use of glucose (e.g., in hunting dogs, pregnancy, neoplasia, polycythemia, and sepsis)
- Reduced intake or underproduction of glucose (e.g., in puppies and kittens, toy breeds, glycogen storage disease, and severe malnutrition or starvation).

SYSTEMS AFFECTED

- Musculoskeletal
- Nervous

SIGNALMENT

- Dog and cat
- Variable, depending on the underlying cause

SIGNS

- Seizures
- Posterior paresis
- Weakness
- Collapse
- Muscle fasciculations
- Abnormal behavior
- Lethargy and depression
- Ataxia
- Polyphagia
- Weight gain
- PU/PD
- Exercise intolerance
- Some animals appear normal aside from findings associated with underlying disease
- Many animals have episodic signs
- Polyneuropathy

CAUSES

Endocrine

- Insulinoma
- Extrapancreatic paraneoplasia associated with insulin-like growth factor overproduction (e.g., hepatocellular carcinoma, hepatocellular adenoma, intestinal leiomyoma, intestinal leiomyosarcoma)
- Iatrogenic insulin overdose
- Hypoadrenocorticism

Hepatic Disease

- Portosystemic shunt
- Cirrhosis
- Severe hepatitis (e.g., toxic and inflammatory)
- Glycogen storage diseases

Overuse

- Hunting dog hypoglycemia
- Pregnancy
- Polycythemia
- Neoplasia
- Sepsis—increased glucose utilization induced by increased cytokine production in macrophage-rich tissues

Reduced Intake/Underproduction

- Young puppies and kittens
- Toy-breed dogs
- Severe malnutrition or starvation
- In sepsis there is also cytokine-induced inhibition of gluconeogenesis in the setting of nutritional glycogen depletion

Toxicosis

- Iatrogenic insulin overdose
- Xylitol toxicosis
- Antihyperglycemic agent toxicosis (e.g., sulfonylureas)

RISK FACTORS

- Low energy intake predisposes to hypoglycemia in patients with conditions causing overuse and underproduction.
- Fasting, excitement, exercise, and eating may or may not increase the risk of hypoglycemic episodes in patients with insulinoma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Patients with hyperinsulinism—signs of hypoglycemia or a normal physical examination
- Patients with hypoadrenocorticism—waxing, waning, nonspecific signs (e.g., vomiting, diarrhea, melena, and weakness); Addisonian patients that present in a crisis usually display hypovolemia and hyperkalemia rather than hypoglycemia (e.g., shock, bradycardia, and dehydration)
- Patients with portosystemic shunts—usually young to middle-aged; often thin or appear to have stunted growth; rarely, they have ascites or edema
- Patients with cirrhosis and severe hepatitis usually have other signs of their disease (e.g., gastrointestinal signs, icterus, and ascites or edema)
- Patients with sepsis—critical; usually in shock; pyrexia or hypothermia revealed by examination; may have gastrointestinal signs
- Glycogen storage diseases—rare; usually seen in animals < 1 year old
- Extrapancreatic paraneoplasia and large neoplastic processes that cause hypoglycemia can often be detected by physical examination

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

None

Disorders That May Alter Laboratory Results

Delayed separation of serum causes falsely low serum glucose values; if blood cannot be centrifuged and the serum separated within 30 minutes of collection, it should be collected in a sodium fluoride tube

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- Patients with hyperinsulinism may have normal results
- Patients with hypoadrenocorticism may have hypocholesterolemia, hypoalbuminemia, lymphocytosis, eosinophilia, hyperkalemia, hyponatremia, azotemia, or hypercalcemia
- Patients with congenital portosystemic shunts may have microcytosis

hypoalbuminemia, low BUN, mildly high liver enzyme activities, ammonium biurate crystals, and low urinary specific gravity. Serum bilirubin concentration sometimes increased. • Patients with cirrhosis, severe hepatitis, and hepatic neoplasia may have anemia associated with chronic disease, high liver enzyme activities, hyperbilirubinemia, hypoalbuminemia, bilirubinuria, and low urinary specific gravity. • Patients with polycythemia have a PCV > 65. • Patients with xylitol toxicosis may have hypokalemia, high liver enzyme activities, and hyperbilirubinemia.

OTHER LABORATORY TESTS

- Simultaneous fasting glucose/insulin determination—indicated when insulinoma is suspected; high plasma insulin in the face of hypoglycemia suggests insulinoma
- AIGR—indicated when insulinoma is suspected:

$$\text{AIGR} = \frac{\text{plasma insulin } [\mu\text{U/mL}] \times 100}{\text{plasma glucose } [\text{mg/dL}] - 30}$$

- Use 1 as denominator if glucose is < 30; AIGR > 30 suggests an insulinoma; AIGR = 19–30 is a gray zone—repeat test; AIGR < 19 indicates insulinoma is unlikely. (Note: false-positive results are possible, especially when the blood glucose concentration is < 40 mg/dL.)
- ACTH stimulation test—indicated when hypoadrenocorticism is suspected
- Fasting and postprandial serum bile acids—indicated when portosystemic shunt or functional hepatic disease is suspected (results uninterpretable if serum bilirubin is elevated)
- Bacterial culture of blood—indicated when sepsis is suspected
- Fructosamine—chronic hypoglycemia will result in low fructosamine concentrations

IMAGING

- Abdominal radiography and ultrasonography—useful in patients with extrapancreatic paraneoplasia and large neoplastic processes (may see organomegaly or masses), as well as portosystemic shunt (microhepatitis), cirrhosis (microhepatitis, hyperechogenicity), and severe hepatitis (hepatomegaly). Not very sensitive nor specific for detecting insulinoma. Abdominal computed tomography (CT) more accurately detects pancreatic endocrine tumors
- Ultrasound-guided, laparoscopic, or surgical hepatic biopsy—useful to evaluate for cirrhosis, hepatitis, and glycogen storage diseases
- Technetium-99m per rectal quantitative hepatic scintigraphy—useful to detect portosystemic shunt
- Mesenteric portography—useful to detect portosystemic shunt (requires surgery)

DIAGNOSTIC PROCEDURES

- ECG—useful to evaluate bradycardia in patients with hypoadrenocorticism

(CONTINUED)

- Ultrasound-guided or surgical tissue biopsy—useful to evaluate for cirrhosis, hepatitis, glycogen storage diseases, and extrapancreatic neoplasia.

TREATMENT

- Treat animals with clinical hypoglycemia whose underlying disease needs support as inpatients. • If able to eat (i.e., responsive, no vomiting), feeding should be part or all of initial treatment. • If unable to eat, start continuous fluid therapy with 2.5% dextrose; if clinical signs persist, use a 5% dextrose solution. • Surgery is indicated if a portosystemic shunt or insulin secreting neoplasia is the cause of hypoglycemia.

MEDICATIONS

DRUG(S) OF CHOICE

Emergency/Acute Treatment

- In hospital—administer 50% dextrose, 1 mL/kg (0.5 g/kg) IV slow bolus (1–3 minutes). Glucagon IM or IV at 0.03 mg/kg usually effective in cases of insulin-secreting tumors. • At home—do not attempt to have the client administer medication orally during a seizure; hypoglycemic seizures usually abate within 1–2 minutes; if a seizure is prolonged, recommend transportation to hospital; if a short seizure has ended or other signs of a hypoglycemic crisis exist, recommend rubbing corn syrup or 50% dextrose on the buccal mucosa, followed by 2 mL/kg of the same solution orally once the patient can swallow; then seek immediate attention.
- Owners of diabetic animals can be taught to inject prescribed glucagon IM. • Initiate frequent feeding of a diet low in simple sugars or, if patient is unable to eat, continuous fluid therapy with 2.5% dextrose.

Long-Term Treatment

- See Insulinoma for treatment of insulinoma and extrapancreatic paraneoplasia. • Hunting dog hypoglycemia—feed moderate meal of fat, protein, and complex carbohydrates a few hours before hunting; can feed snacks (e.g., dog biscuits) every 3–5 hours during the hunt. • Toy-breed hypoglycemia—increase the frequency of feeding. • Puppy and kitten hypoglycemia—increase the frequency of feeding (nursing or hand-feeding). • Other causes of hypoglycemia require treating the underlying disease and do not usually need long-term treatment.

CONTRAINDICATIONS

- Insulin. • Barbiturates and diazepam in patients with hypoglycemic seizures—they do

not treat the cause of the seizure and they may potentially worsen hepatoencephalopathy in patients with portosystemic shunt, cirrhosis, or xylitol toxicosis—induced hepatic failure.

PRECAUTIONS

- 50% dextrose causes tissue necrosis and sloughing if given extravascularly; never give dextrose in concentrations over 5% without confirmed vascular access. • Administering a dextrose bolus without following with frequent feedings or continuous IV fluids with dextrose can predispose to subsequent hypoglycemic episodes.

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- At home—for return or progression of clinical signs of hypoglycemia; assess serum glucose if signs recur. • Single, intermittent serum glucose determinations may not truly reflect the glycemic status of the patient because of normal production of counterregulatory hormones. • Other monitoring is based on the underlying disease. • If due to insulin overdose in the diabetic, reassess response to insulin with a blood glucose curve and adjust the insulin dose accordingly.

POSSIBLE COMPLICATIONS

Recurrent, progressive episodes of hypoglycemia

MISCELLANEOUS

ASSOCIATED CONDITIONS

Prolonged hypoglycemia can cause transient (hours to days) to permanent dementia and blindness from laminar and pseudolaminar necrosis involving many areas of the cerebral cortex. The cerebellum and brainstem nuclei can also be adversely affected.

AGE-RELATED FACTORS

Neonatal animals have poor glycogen storage capacity and a reduced ability to perform gluconeogenesis; thus, short periods of fasting (6–12 hours) can cause hypoglycemia.

Important to remember when fasting young patients prior to anesthesia.

PREGNANCY/FERTILITY/BREEDING

- Hypoglycemia can lead to weakness and dystocia. • Pregnancy coupled with fasting causes hypoglycemia in rare instances.

HYPOKALEMIA

BASICS

DEFINITION

Serum potassium concentration < 3.5 mEq/L (normal range: 3.5–5.5 mEq/L).

PATHOPHYSIOLOGY

- Potassium is primarily an intracellular electrolyte (98% of total body potassium is intracellular); serum levels, however, may not accurately reflect total body concentrations.
- It is predominantly responsible for the maintenance of intracellular fluid volume and required for normal function of many enzymes.
- The resting cellular membrane potential is determined by the ratio of intracellular to extracellular potassium concentration and maintained by the Na^+ , K^+ -ATPase pump. Conduction disturbances in susceptible tissues (cardiac, nerve, and muscle) are caused by rapid shifts in this ratio causing myoneural membrane hyperpolarization.
- Hypokalemia can be caused by decreased intake, loss (via the gastrointestinal tract or kidneys), or translocation of potassium from the extracellular to the intracellular fluid space.

SYSTEMS AFFECTED

- Neuromuscular—muscle weakness, including skeletal and muscles of respiration.
- Cardiac—electrocardiac changes and arrhythmias.
- Renal—hyposthenuria, nephropathy, and renal failure.
- Metabolic—acid-base balance (metabolic alkalosis); glucose homeostasis.

SIGNALMENT

- Dogs and cats with predispositions to increased potassium loss, translocation of potassium, or decreased intake of potassium.
- Young Burmese cats with recurrent hypokalemic periodic paralysis episodes.

SIGNS

- Generalized muscle weakness or paralysis
- Muscle cramps
- Lethargy and confusion
- Vomiting
- Anorexia
- Carbohydrate intolerance and weight loss
- Polyuria
- Polydipsia
- Decreased bowel motility (humans; maybe dogs and cats)
- Hyposthenuria
- Ventroflexion of the neck (cats and dogs)
- Respiratory muscle failure

CAUSES

Decreased Intake

- Anorexia or starvation
- Administration of potassium-deficient or potassium-free intravenous fluids

- Bentonite clay ingestion (e.g., clumping cat litter)

Gastrointestinal Loss

- Vomiting
- Diarrhea
- Both upper and lower gastrointestinal obstruction; especially pyloric outflow obstruction

Urinary Loss

- Chronic renal disease
- Renal tubular acidosis
- Hypokalemic nephropathy
- Post-obstructive diuresis
- Dialysis (hemodialysis or peritoneal)
- Intravenous fluid diuresis
- Hyperaldosteronism
- Hypocholeremia
- Drugs (loop diuretics, amphotericin B, penicillins, rattlesnake envenomation)

Translocation (Extracellular to Intracellular Fluid)

- Glucose administration
- Insulin administration
- Sodium bicarbonate administration
- Catecholamines
- Alkalemia
- β_2 -adrenergic agonist overdose (e.g., albuterol)
- Hypokalemic periodic paralysis (Burmese cats)
- Rattlesnake envenomation (mechanism unknown)

RISK FACTORS

- Acidifying diets with negligible potassium
- Diuresis or dialysis with potassium-deficient fluids
- Chronic illness (sustained anorexia and muscle wasting)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- PU/PD, hyperglycemia, and glucosuria—rule out diabetes mellitus.
- PU/PD, azotemia, and isosthenuria—rule out chronic renal failure and nephropathy.
- Vomiting, metabolic alkalosis, and hypocholeremia—rule out upper gastrointestinal obstruction.
- Metabolic acidosis with urine pH > 6.5—rule out renal tubular acidosis.
- Urethral obstruction—rule out post-obstructive diuresis.
- Young Burmese cat with episodic muscle weakness—rule out hypokalemic periodic paralysis.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

Falsely elevated potassium measurement can be caused by excessive K_3EDTA relative to the blood sample, as found in “purple-stoppered”

blood tube for hematology; not a problem with “red-stoppered” tubes for serum).

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- Hyperglycemia, glucosuria, \pm ketonuria, \pm ketoacidosis in patients with diabetes mellitus.
- Normocytic, normochromic, nonregenerative anemia in patients with chronic renal failure.
- Elevated BUN and creatinine, with isosthenuria in patients with chronic renal failure or hypokalemic nephropathy.
- Low total CO_2 or HCO_3^- in patients with renal tubular acidosis (RTA) or renal failure.
- Normal anion gap metabolic acidosis in RTA.
- Urine pH > 6.5 in patients with distal tubular acidosis.
- High total CO_2 or HCO_3^- in patients with metabolic alkalosis.

OTHER LABORATORY TESTS

- Increased aldosterone and decreased renin in patients with primary hyperaldosteronism.
- Elevated urinary fractional excretion of potassium in patients with chronic renal failure or hypokalemic nephropathy.
- ACTH stimulation tests are used to diagnose adrenal gland disorders.

IMAGING

- Radiography, ultrasonography are helpful to diagnose gastrointestinal tract obstructions (mass or foreign bodies), pancreatitis, chronic renal failure workup, adrenal gland diseases (hyperadrenocorticism, hyperaldosteronism, and adrenal tumors).
- Upper gastrointestinal barium study to additionally diagnose gastrointestinal obstructions (anatomic or functional).
- Computed tomography or magnetic resonance imaging to further diagnose adrenal gland diseases.

OTHER DIAGNOSTIC PROCEDURES

Upper gastrointestinal endoscopy to diagnose upper gastrointestinal disorders.

TREATMENT

- Mild hypokalemia (3.0–3.5 mEq/L) can be treated by oral supplementation.
- Moderate hypokalemia (2.5–3.0 mEq/L) is best treated by inpatient administration of oral \pm intravenous supplementation and carefully monitored.
- Severe hypokalemia (< 2.5 mEq/L) should be hospitalized for intensive intravenous potassium supplementation. Patients, especially cats, should be carefully monitored for cardiac arrhythmias and impaired ventilation.

(CONTINUED)

HYPOKALEMIA**Table 1**

Patient's K ⁺ Concentration	KCl/L (mEq)
3.5–4.5	20
3.0–3.5	30
2.5–3.0	40
2.0–2.5	60
<2.0	80

Note: do not exceed an intravenous supplementation rate or 0.5 mEq/kg/h unless continually monitoring and on the verge of ventilator muscle failure. With severe life threatening hypokalemia (serum potassium < 2.0), potassium chloride can be administered at a rate of 1.0–1.5 mEq/kg/h with ECG monitoring.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Oral supplementation with potassium gluconate (e.g., Tumil-K) is effective in mildly affected patients. The initial dosage is 1/4 teaspoon (2 mEq) per 4.5 kg body weight in food twice daily.
- Parenteral supplementation is required in anorectic or vomiting patients or in patients with moderate-to-severe hypokalemia (<3.0). Potassium chloride is added to intravenous fluids according to Table 1, best delivered via infusion pump or with a pediatric fluid administration set (60 drops/mL/minute). Monitor and taper accordingly.

CONTRAINDICATIONS

- Glucose supplementation
- Insulin administration
- Sodium bicarbonate administration
- Untreated hypoadrenocorticism

- Hyperkalemia
- Renal failure or severe renal impairment
- Acute dehydration
- Severe hemolytic reactions
- Impaired gastrointestinal motility

PRECAUTIONS

Administer with caution, avoid oversupplementation, monitor frequently.

POSSIBLE INTERACTIONS

Concurrent potassium supplementation with ACE inhibitors (e.g., enalapril), potassium-sparing diuretics (e.g., spironolactone), prostaglandin inhibitors (e.g., nonsteroidal anti-inflammatory drugs), beta-blockers (e.g., atenolol), or cardiac glycosides (e.g., digoxin) can cause adverse effects.

ALTERNATIVE DRUG(S)

Potassium phosphate can be used in patients with concurrent hypophosphatemia where one-half of the potassium dose is administered in the form of potassium phosphate solution.

**FOLLOW-UP****PATIENT MONITORING**

Check serum potassium every 6–24 hours based on severity of hypokalemia.

POSSIBLE COMPLICATIONS

Electrolyte disturbances and arrhythmias. It is essential to close the IV fluid outflow valve and thoroughly mix the fluid contents while adding potassium chloride solution to the parenteral fluid bag.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Hypokalemic nephropathy
- Hypophosphatemia
- Hypomagnesemia
- Metabolic alkalosis

HYPOMAGNESEMIA

BASICS

DEFINITION

- Dogs—serum magnesium < 1.89 mg/dL
- Cats—serum magnesium < 1.8 mg/dL

PATHOPHYSIOLOGY

• Magnesium is second only to potassium as the most abundant intracellular cation; is found primarily in bone (60%) and soft tissue (38%), with most soft tissue magnesium residing in skeletal muscle and liver; is required for many metabolic functions; is an activator or catalyst for more than 300 enzyme systems including phosphatases and enzymes that involve ATP. • Serum magnesium is present in three forms: protein-bound form (approximately 25–30%) and chelated and ionized forms (together account for 70–75%). • Because only 1–2% of total magnesium resides in the extracellular compartment, serum magnesium concentration does not always reflect the whole-body magnesium status. • Magnesium absorption occurs primarily in the ileum. Absorption also occurs in the jejunum and colon. • The kidneys maintain magnesium balance with 10–15% reabsorbed in the proximal tubule, 60–70% in the thick ascending limb of the loop of Henle, and 10–15% reabsorbed in the distal convoluted tubule. Reabsorption within the distal convoluted tubule is under hormonal and neurohormonal control and determines the final urine concentration of magnesium. • Hypomagnesemia has many causes; incidence rates > 50% have been reported in critically ill humans. • Magnesium is an important cofactor in the sodium-potassium ATPase pump that maintains an electrical gradient across membranes. Magnesium is also important in the production and elimination of acetylcholine; a low concentration of magnesium in the extracellular fluid can increase concentrations of acetylcholine at motor endplates and cause tetany. • Interference with the electrical gradient can change resting membrane potentials and repolarization disturbances, resulting in neuromuscular and cardiac abnormalities. • Magnesium regulates calcium movement into smooth muscle cells and is important to contractile strength and peripheral vascular tone. • Hypomagnesemia can alter the functions of the skeletal muscles, resulting in tetany and a variety of myopathies observed in patients receiving cisplatin and other nephrotoxic drugs. • Magnesium regulates calcium movement into cardiac muscle cells and is important in cardiac conduction, excitability, and contraction. • Magnesium depletion can affect the membrane pump on cardiac cell membranes, resulting in the depolarization of cardiac cells and tachyarrhythmias; cardiac arrhythmias

associated with hypomagnesemia include ventricular arrhythmias, torsades de pointes, QT prolongation, ST segment shortening, and widening of T waves; hypomagnesemia increases the risk of digoxin toxicity because both inhibit the membrane pump.

- Hypomagnesemia causes resistance to the effects of PTH and can increase the uptake of calcium into bone.

SYSTEMS AFFECTED

- Multiple organ systems
- Cardiovascular
- Endocrine
- Gastrointestinal
- Neuromuscular
- Renal

SIGNALMENT

Dog and cat

INCIDENCE/PREVALENCE

Hypomagnesemia has been reported in 28–54% of critically ill dogs and cats.

SIGNS

- Hypomagnesemia occurs with a variety of diseases with diverse signs:
 - Weakness
 - Muscle fibrillation
 - Ataxia and depression
 - Hyperreflexia
 - Tetany
 - Behavior changes
 - Arrhythmias

CAUSES

- There are four general causes—gastrointestinal, renal, endocrine, and miscellaneous. • Severe malnutrition or significant malabsorptive intestinal diseases can lead to hypomagnesemia; hypomagnesemia can occur after excessive loss of body fluids (e.g., severe, prolonged diarrhea); magnesium is found in high concentrations in the lower gastrointestinal tract, so secretory diarrhea in humans has been associated with profound hypomagnesemia; this has been reported in a dog with protein-losing enteropathy.
- Magnesium homeostasis is regulated by the kidney; renal control of tubular reabsorption takes place primarily in the ascending limb of the loop of Henle; renal magnesium loss can be due to nephrotoxic drugs, including cisplatin, aminoglycosides, and amphotericin B; magnesium reabsorption can also be impaired with osmotic diuresis (diabetes mellitus), loop diuretics, hypercalcuria, and tubular acidosis. Hypomagnesemia associated with diuretic administration is a significant problem in human heart failure patients and has been noted experimentally in mice.
- Hypomagnesemia develops during chronic thiazide diuretic therapy by downregulation of the epithelial Mg²⁺ channel transient receptor and accompanying Na⁺-Cl⁻ cotransporter inhibition or inactivation. Endocrine problems associated with hypomagnesemia include hypercalcemia, hyperthyroidism, and hyperparathyroidism.
- Lactation can cause excessive magnesium loss. • Magnesium can be redistributed by refeeding after starvation, insulin therapy in diabetic patients, following parathyroidectomy, with the use of a total parenteral nutrition formulation with inadequate magnesium

content, and in patients with acute pancreatitis or conditions of catecholamine excess.

- Causes of hypomagnesemia in the critically ill include decreased intake, lack of magnesium in parenteral fluids in patients receiving long-term fluid therapy or dialysis, excessive gastrointestinal loss, redistribution, and sequestration. • Hypomagnesemia is associated with diabetes mellitus in humans, with nearly 25% of human diabetic outpatients having low serum magnesium.
- While one study showed no difference in presentation of ionized magnesium levels in dogs with diabetes when compared to controls, hypomagnesemia should still be considered in diabetic patients following aggressive insulin therapy for diabetic ketoacidosis.

RISK FACTORS

- Total parenteral nutrition
- Polyuric renal disease
- Diuretic administration
- Peritoneal dialysis
- Diabetes mellitus and diabetic ketoacidosis
- Lactation
- Gastrointestinal malabsorption syndromes

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Signs of hypomagnesemia are vague and multisystemic; therefore, other causes of neuromuscular abnormalities, especially other electrolyte abnormalities, must be investigated. • Consider cardiac abnormalities, intoxications, and renal diseases.

LABORATORY FINDINGS

Note: 12 mg of magnesium = 1 mEq of magnesium; to convert from mg/dL to mEq/L, divide by 1.2.

Drugs That May Alter Laboratory Results

- Serum is favored over plasma because the anticoagulant used for plasma samples can contain citrate or other ions that bind magnesium. • EDTA, sodium fluoride-oxalate, sodium citrate, and intravenous calcium gluconate can falsely decrease serum magnesium values.

Disorders That May Alter Laboratory Results

- Hemolysis can falsely elevate serum magnesium. • Hypercalcemia (> 16 mg/dL) and hyperproteinemia (> 10 g/dL) can also falsely elevate serum magnesium.
- Hyperbilirubinemia and lipemia can cause falsely decreased serum magnesium.

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- Low serum magnesium. • If patient is azotemic, consider renal causes. • Tubular casts in urinary sediment might indicate nephrotoxicity. • Hypokalemia,

(CONTINUED)

hyponatremia, and hypocalcemia are common findings with hypomagnesemia and should alert the clinician to the possibility of hypomagnesemia.

OTHER LABORATORY TESTS

- Diagnosis of magnesium depletion can be difficult since <1% of total body magnesium is located in serum; only 55% of the magnesium in plasma is in the active (ionized) form; 33% is bound to plasma proteins and 12% is chelated with divalent anions such as phosphate and sulfate; magnesium assays (spectrophotometry) measure all three fractions.
- Ionized magnesium can be measured with an ion-selective electrode or by ultrafiltration of plasma; alternative methods of evaluating magnesium status include measurement of mononuclear blood cell magnesium levels or quantifying retention from a loading dose.
- Urinary magnesium determination might help differentiate conditions associated with high urinary magnesium loss from conditions of low intake or absorption.
- Human studies suggest that retention of >40–50% of an administered magnesium load indicates magnesium depletion, while retention of <20% indicates adequate magnesium stores.

DIAGNOSTIC PROCEDURES

Electrodiagnostics (e.g., electromyography and electrocardiography) might reveal effects of hypomagnesemia but will not differentiate the cause.

TREATMENT

APPROPRIATE HEALTH CARE

- Treatment depends on the underlying cause and severity of hypomagnesemia.
- Management includes treatment of the underlying condition(s) and magnesium replacement.
- Mild hypomagnesemia might resolve with treatment of the underlying disorder; however, if hypomagnesemia is severe, intensive care and magnesium replacement are needed.

NURSING CARE

Hypomagnesemia is a common finding in critically ill, hospitalized veterinary patients. Nursing should focus on the underlying disorder(s).

ACTIVITY

Activity restrictions should be based on concurrent conditions.

DIET

There are no dietary recommendations for hypomagnesemia other than meeting the patient's caloric requirements with a balanced, appropriate diet that takes into account all concurrent problems.

MEDICATIONS

DRUG(S) OF CHOICE

- Magnesium sulfate can be diluted in 5% dextrose in water.
- Emergency loading is accomplished with 0.15–0.3 mEq/kg of magnesium sulfate or magnesium chloride over 5–60 minutes.
- Rapid replacement can be accomplished by administering 0.75–1 mEq/kg/day (0.03 mEq/kg/h) of magnesium sulfate or magnesium chloride as a constant-rate intravenous infusion; the solution of magnesium salts should be <20%; the magnesium infusion should use a separate intravenous line to minimize interactions with other minerals.
- Administer 0.3–0.5 mEq/kg/day (0.013–0.02 mEq/kg/h) of magnesium sulfate or magnesium chloride for slow replacement.

CONTRAINdications

- Do not use aminoglycosides; hypomagnesemia potentiates their nephrotoxicity.
- Do not use cisplatin chemotherapy.

PRECAUTIONS

- Discontinue digoxin if possible.
- Use diuretics with caution.
- Hypermagnesemia is possible with overzealous treatment of hypomagnesemia.
- Azotemic patients requiring magnesium therapy should receive a lower dose and more frequent monitoring than patients with normal kidney function to prevent iatrogenic hypermagnesemia.

POSSIBLE INTERACTIONS

- Magnesium sulfate is incompatible with sodium bicarbonate, hydrocortisone, and dobutamine HCl; avoid mixing other drugs with magnesium sulfate solution.
- Avoid calcium-containing compounds; they lower the serum magnesium concentration.
- Additive CNS depression can occur when parenteral magnesium sulfate is used with CNS depressant sedatives, neuromuscular blocking agents, and anesthetics.
- Combined use of parenteral magnesium sulfate and non-depolarizing neuromuscular blocking agents has resulted in excessive neuromuscular blockade.
- Use magnesium supplementation cautiously with digitalis compounds to avoid serious conduction disturbances.
- Calcium supplements might negate the effects of parenteral magnesium.

FOLLOW-UP

PATIENT MONITORING

- Measurement of serum magnesium and calcium concentrations daily
- Continuous

HYPOMAGNESEMIA

ECG monitoring, especially during magnesium infusion

POSSIBLE COMPLICATIONS

Severe hypomagnesemia can be fatal.

EXPECTED COURSE AND PROGNOSIS

Outcome is dependent on resolution of the underlying disease(s).

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Hyperthyroidism • Hypocalcemia
- Hypokalemia • Hyponatremia
- Hypoparathyroidism • Hypophosphatemia

PREGNANCY/FERTILITY/BREEDING

Effects on the fetus are identical to effects on the dam.

H

HYPOMYELINATION

BASICS

OVERVIEW

- Also known as “shaking puppies.”
- Congenital deficit in myelin deposition caused by either delayed myelination or a permanent lack of myelin at birth.
- Axons > 1–2 mm in diameter have a myelin cover produced by oligodendrocytes in the central nervous system (CNS), and Schwann cells in the peripheral nervous system (PNS). Myelin insulates axons and facilitates propagation of action potentials.
- Affected axons with deficit in myelin deposition can alter impulse conduction or trigger spontaneous discharges and then generate tremors. The degree of tremor is usually correlated with the severity of the abnormal myelin deposition.

H

SIGNALMENT

CNS

- Clinical signs appear at birth or when the puppy starts to ambulate.
- Dog—Springer spaniel, Samoyed, Chow Chow, Weimaraner, Bernese mountain dog, Dalmatian, Catahoula, rat terrier, border terriers, and Lurchers.
- Cat—Siamese and presumed in domestic shorthair and Birman cats.
- Predominant sex (X-linked)—Springer spaniel and Samoyed male puppies clinically affected, whereas females remain largely asymptomatic carriers; no sex differences reported in other breeds.

PNS

- Dog • Golden retriever—reported in both sexes

SIGNS

CNS

- Action-related repetitive myoclonus—rapid contractions and relaxation of diffuse skeletal muscles manifested as generalized body tremors that worsen with exercise and subside during rest or sleep. Some affected dogs and cats appear “bouncing.”
- The tremors diminish with time in the majority of affected dogs and usually resolved by 12 months of age or earlier; however, some dogs can retain a persistent fine tremor of the pelvic limbs.
- Some dogs also present with head bobbing and nystagmus.
- In Rat terriers, associated with goiter and clinical signs of congenital hypothyroidism.
- Springer spaniels and Samoyeds are usually affected for life.

PNS

- Clinical signs appear at 5–7 weeks of age.
- Generalized weakness, pelvic limb ataxia and paresis, muscle wasting and hyporeflexia that improve with age.
- Tremors are not present.

CAUSES & RISK FACTORS

- Genetic—X-linked recessive condition for CNS disease in Springer spaniels and autosomal recessive gene in Rat terriers,

Weimaraners, and border terriers.

- Genetic basis speculative for other breeds.
- Mutation identified in Weimaraners and Rat terriers.
- The carrier frequency in Weimaraners has been estimated to be 4.3%.
- Viral or toxic—possible in some breeds.
- PNS—undetermined; possibly genetic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

CNS

- Cerebellar hypoplasia or abiotrophy—tremors in neonates; but cerebellar ataxia (hypermetric gait) and intention tremors more prominent.
- Storage diseases—associated with tremors; neonates are normal.
- Generalized tremor syndrome in dogs (historically identified as “white shakers” but other hair coat colors can be affected)—affected dogs are usually > 8 months old.
- Metabolic diseases (hypocalcemia, hypernatremia, hyponatremia, hypoglycemia).
- Feline polioencephalomyelitis—young to middle-aged cats and other neurologic signs are present (pareisis, seizures, hyperesthesia).
- Toxic—organophosphates, permethrins, mycotoxins: history of exposure to a toxic product.

PNS

- Muscular dystrophy—serum creatine kinase highly elevated.
- Congenital myasthenia gravis.
- Other polyneuropathies or myopathies.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

IMAGING

MRI—may detect white matter changes on CNS form.

DIAGNOSTIC PROCEDURES

CNS

- Presumed diagnosis based on signalment, clinical signs, and evolution.
- Histopathology (necropsy).
- DNA test for causative genetic mutation (currently available for Weimaraners and Rat terriers).

PNS

- Electromyography—usually normal to mild diffuse spontaneous activity.
- Motor nerve conduction velocity—small or no evoked potentials and slowed conduction.
- Nerve biopsy—insufficient myelin surrounding peripheral axons.

TREATMENT

None effective for either form.

MEDICATIONS

DRUG(S)

N/A

FOLLOW-UP

PREVENTION/AVOIDANCE

Avoid breeding from affected animals in which a genetic cause is suspected.

EXPECTED COURSE AND PROGNOSIS

- CNS—Springer spaniels and Samoyeds affected for life; other breeds usually improve by 1 year of age.
- PNS—dogs have normal lifespan.

MISCELLANEOUS

ABBREVIATIONS

- CNS = central nervous system
- MRI = magnetic resonance imaging
- PNS = peripheral nervous system

BASICS

DEFINITION

Serum sodium concentration below the lower limit of the reference range.

PATHOPHYSIOLOGY

Sodium is the most abundant cation in the extracellular fluid. Hyponatremia usually, but not always, reflects hypo-osmolality and is typically associated with a decreased total body sodium content. Either solute loss or water retention can theoretically cause hyponatremia. Most solute loss occurs in iso-osmotic solutions (e.g., vomit and diarrhea) and, as a result, water retention in relation to solute is the underlying cause in almost all patients with hyponatremia. In general, hyponatremia occurs only when a defect in renal water excretion is present.

SYSTEMS AFFECTED

- Nervous—severe neurologic dysfunction is not usually seen until serum sodium concentration falls below 110–115 mEq/L. Clinical signs may be more related to the rate of decline in serum sodium concentration than the actual nadir. Dogs with chronic hyponatremia often have mild, if any, clinical signs.
- Overly rapid correction of hyponatremia can also cause neurologic damage.

SIGNALMENT

Species

Dog and cat

SIGNS

- Lethargy
- Weakness
- Confusion
- Nausea/vomiting
- Seizures
- Obtundation
- Coma
- Other findings depend on the underlying cause.

CAUSES

Normal Osmolar Hyponatremia

- Hyperlipidemia
- Hyperproteinemia

Hyperosmolar Hyponatremia

- Hyperglycemia
- Mannitol infusion

Hypoosmolar Hyponatremia

Normovolemic

- Primary polydipsia
- Hypothyroid myxedema coma
- Hypotonic fluid infusion
- SIADH

Hypervolemic

- Congestive heart failure
- Hepatic cirrhosis

- Nephrotic syndrome
- Severe renal failure

Hypovolemic

- Gastrointestinal losses
- Renal failure
- Third space losses
- Cutaneous losses
- Diuresis
- Hypoadrenocorticism

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypoadrenocorticism
- Severe GI disease
- Metabolic or respiratory acidosis (DKA)
- Congestive heart failure
- Primary polydipsia

LABORATORY FINDINGS

Drugs That May Alter Lab Results

- Mannitol can cause pseudohyponatremia.
- Diuretic administration can cause hyponatremia.

Disorders That May Alter Lab Results

Hyperlipidemia, hyperglycemia, and hyperproteinemia can cause pseudohyponatremia.

Valid if Run in a Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- Low serum sodium concentration.
- Other abnormalities may point to the underlying cause.

OTHER LABORATORY TESTS

- Plasma osmolality is usually low; if plasma osmolality is normal or high, exclude hyperlipidemia, hyperglycemia, hyperproteinemia, and mannitol administration.
- Urine osmolality < 100–150 mOsmol/kg indicates primary polydipsia or reset osmostat. Urine osmolality > 150–200 mOsmol/kg indicates impaired renal water excretion.
- Urine sodium concentration < 15–20 mEq/L indicates low effective circulating volume, pure cortisol deficiency, primary polydipsia with high urine output. Urine sodium concentration > 20–25 mEq/L indicates syndrome of inappropriate ADH secretion, adrenal insufficiency, renal failure, reset osmostat, diuretic administration, or vomiting with marked bicarbonate loss.

TREATMENT

Inpatient versus outpatient treatment depends on severity of hyponatremia, associated neurologic dysfunction, and the underlying disorder.

MEDICATIONS

DRUG(S) OF CHOICE

- Treatment consists of addressing the underlying cause and increasing the serum sodium concentration if necessary. Overly rapid normalization of the hyponatremia can have potentially severe neurologic sequela and may be more detrimental than the hyponatremia itself. Therefore, isotonic saline is the fluid of choice in the large majority of cases. More aggressive correction of the serum sodium concentration with hypertonic saline is rarely necessary.

- Hypervolemic (edematous) patients are typically managed with diuretics and salt restriction. Isotonic saline and furosemide may be useful in more affected patients.

- Hypovolemic patients are managed by replacing the volume deficit with isotonic saline.

- The use of hypertonic saline may be considered in selected patients with severe symptomatic hyponatremia. The sodium deficit is estimated by $0.5 \times \text{lean BW (kg)} \times (120 - \text{serum sodium concentration})$. The serum sodium concentration is corrected by 10–12 mEq/L/day (0.5 mEq/L/h) or less. Once the serum sodium concentration reaches 120–125 mEq/L discontinue hypertonic saline and continue to slowly normalize the serum sodium concentration using isotonic saline or water restriction as dictated by the underlying cause of the hyponatremia.

- Other therapeutic interventions are dictated by the underlying cause of the hyponatremia.

H

PRECAUTIONS

Overly rapid correction of hyponatremia can result in neurologic damage (demyelination); avoid increasing serum sodium concentration by more than 10–12 mEq/L/day (0.5 mEq/L/h).

FOLLOW-UP

PATIENT MONITORING

- Serial serum sodium determinations to avoid overly rapid correction of the serum sodium concentration and to assure appropriate response to NaCl and other indicated therapies.
- Monitor hydration status.
- Monitor other serum electrolyte concentrations as indicated by the patient's clinical condition and underlying disorder.

PREVENTION/AVOIDANCE

Depends on the underlying disorder

POSSIBLE COMPLICATIONS

Depends on the underlying disorder

HYPONATREMIA

(CONTINUED)

EXPECTED COURSE AND PROGNOSIS

Depends on the underlying disorder

MISCELLANEOUS

ASSOCIATED CONDITIONS

Other electrolyte and acid-base abnormalities are often associated with the clinical disorders that cause hyponatremia.

HYPOPARTHYROIDISM

BASICS

DEFINITION

Absolute or relative deficiency of parathyroid hormone secretion leading to hypocalcemia.

PATHOPHYSIOLOGY

- Dogs—most commonly idiopathic immune-mediated parathyroiditis.
- Cats—most commonly iatrogenic secondary to damaged or removed parathyroid glands during thyroidectomy for hyperthyroidism; idiopathic atrophy and immune-mediated parathyroiditis also seen (uncommon).

SYSTEMS AFFECTED

- Cardiovascular—ECG changes and bradycardia caused by altered neuromuscular activity.
- Gastrointestinal—anorexia and vomiting of unknown cause, possibly changes in gastrointestinal muscular activity.
- Nervous/Neuromuscular—seizures, tetany, ataxia, and weakness caused by increased neuromuscular activity resulting from diminished neuronal membrane stability.
- Ophthalmic—posterior lenticular cataracts of unknown cause.
- Renal/Urologic—PU/PD of unknown cause.
- Respiratory—panting caused by neuromuscular weakness and anxiety associated with neurologic and neuromuscular changes.

GENETICS

Unknown

INCIDENCE/PREVALENCE

- Dog—uncommon; exact prevalence not reported.
- Cat—common in bilaterally thyroidectomized cats (10–82% of patients, depending on surgical technique and surgical skill); spontaneous occurrence rare (nine cases reported in literature, five additional cats discussed in *Canine and Feline Endocrinology and Reproduction* textbook—see “Suggested Reading”).

SIGNALMENT

Species

Dog and cat

Breed Predilections

Toy poodles, miniature schnauzers, German shepherds, Labrador retrievers, and terrier breeds; mixed-breed cats.

Mean Age and Range

Dogs—mean age, 4.8 years; range, 6 weeks–13 years.

Cats—secondary to thyroidectomy, mean age 12–13 years, range 4–22 years; cats—spontaneous, mean age 2.25 years, range 6 months–7 years.

Predominant Sex

Dogs—female (60%); cats—male (64%)

SIGNS

Historical Findings

Dogs

- Seizures (49–86%)
- Ataxia/stiff gait (43–62%)
- Facial rubbing (62%)
- Muscle trembling, twitching, and fasciculations (57%)
- Growling (57%)
- Panting (35%)
- Weakness
- PU/PD
- Vomiting
- Anorexia

Cats

- Lethargy, anorexia, and depression (100%)
- Seizures (50%)
- Muscle trembling, twitching, and fasciculations (83%)
- Panting (33%)
- Bradycardia (17%)

Physical Examination Findings

Dogs

- Tense, splinted abdomen (50–65%)
- Ataxia/stiff gait (43–62%)
- Fever (30–70%)
- Muscle trembling, twitching, and fasciculations (57%)
- Panting (35%)
- Posterior lenticular cataracts (15–32%)
- Weakness
- Up to 20% may have normal physical examination results

Cats

- Muscle trembling, twitching, and fasciculations (83%)
- Panting (33%)
- Posterior lenticular cataracts (33%)
- Bradycardia (17%)
- Fever (17%)
- Hypothermia (17%)

CAUSES

See “Pathophysiology”

RISK FACTORS

- Dogs—N/A
- Cats—bilateral thyroidectomy for hyperthyroidism

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The main problems associated with hypoparathyroidism, which must be differentiated from other disease processes, are seizures, weakness, and muscle trembling, twitching, and fasciculations.

Seizures

- Cardiovascular—syncope
- Metabolic—hepatoencephalopathy and hypoglycemia

- Neurologic—epilepsy, neoplasia, toxin, and inflammatory disease

Weakness

- Cardiovascular—congenital anatomic defects, arrhythmias, heart failure, and pericardial effusion
- Metabolic—hypoadrenocorticism, hypoglycemia, anemia, hypokalemia (especially cats), and hypothyroidism
- Neurologic/neuromuscular—myasthenia gravis, polymyositis, polyradiculoneuropathy, and spinal cord disease
- Toxic—tick paralysis, botulism, chronic organophosphate exposure, and lead poisoning

Muscle Trembling, Twitching, and Fasciculations

- Metabolic—puerperal tetany (i.e., eclampsia) and other causes of hypocalcemia
- Toxic—tetanus, strychnine poisoning, Eastern coral snake envenomation

CBC/BIOCHEMISTRY/URINALYSIS

- Results of hemogram and urinalysis usually normal; these tests are performed to rule-out other differential diagnoses.
- Hypocalcemia (usually < 6.5 mg/dL) and normal or mild to moderate hyperphosphatemia.
- Evaluate serum albumin carefully in all patients with hypocalcemia; hypoalbuminemia is the most common cause of hypocalcemia.
- The only other intrinsic disease process that reduces serum calcium and raises serum phosphorus is renal failure, which is easily distinguished from hypoparathyroidism by the presence of azotemia. Highly concentrated phosphate enema solutions can also cause hyperphosphatemia and hypocalcemia.

OTHER LABORATORY TESTS

Serum PTH determination—demonstrates undetectable or very low concentration of PTH; patients with other processes causing hypocalcemia (e.g., renal failure) have a normal-to-high concentration of PTH.

IMAGING

Radiography and ultrasonography are normal.

DIAGNOSTIC PROCEDURES

- ECG changes seen in patients with hypocalcemia include prolongation of the ST and QT segments; sinus bradycardia and wide T waves; T wave alternans is occasionally seen.
- Cervical exploration reveals absence or atrophy of the parathyroid glands.

PATHOLOGIC FINDINGS

- Dogs—normal tissue with mature lymphocytes, plasma cells, and fibrous connective tissue along with chief cell degeneration.
- Cats—parathyroid gland atrophy is more common, although histopathologic findings similar to those in dogs are found in cats.

H

HYPOPARATHYROIDISM

(CONTINUED)

Table 1

Vitamin D preparations.			
Preparation	Dose	Maximal Effect	Size
1,25 Dihydroxycholecalciferol (active vitamin D ₃ , calcitriol)	0.03–0.06 µg/kg/day Initial: 0.02–0.03 mg/kg/day Maint: 0.01–0.02 mg/kg/24–48h	1–4 days 1–7 days	0.25 and 0.5 µg capsules, 1.0 µg/mL oral solution, and 1 and 2 µg/mL injectable Currently unavailable; formerly available as 0.125 mg, 0.2 mg, 0.4 mg tablets and 0.2 mg/mL syrup
Ergocalciferol (vitamin D ₂)	Initial: 4,000–6,000 U/kg/day Maint: 1,000–2,000 U/kg/day-week	5–21 days	25,000 and 50,000 U capsules and 8,000 U/mL syrup

H**TREATMENT****APPROPRIATE HEALTH CARE**

- Hospitalize for medical management of hypocalcemia until clinical signs of hypocalcemia are controlled and serum calcium concentration is > 7 mg/dL.
- See Hypocalcemia for emergency inpatient management and appropriate fluid therapy.

NURSING CARE

Usually not required; hydration and nutritional support if anorexic.

ACTIVITY

Normal

DIET

Avoid calcium-poor diets; for dogs, puppy diets generally higher in calcium than adult dog food.

CLIENT EDUCATION

- Naturally occurring primary hypoparathyroid will require lifelong therapy and monitoring.
- Most cases of iatrogenic hypoparathyroidism (e.g., bilateral thyroidectomy) will recover over days to months and only require transient management and monitoring.

SURGICAL CONSIDERATIONS

None

**MEDICATIONS****DRUG(S) OF CHOICE*****Emergency/Acute Therapy***

See Hypocalcemia

Short-Term Post-tetany Therapy

See Hypocalcemia

Long-Term Therapy

- Vitamin D administration is needed indefinitely for primary hypoparathyroidism and total parathyroidectomy. The dosage should be increased or tapered on the basis of serum calcium concentration.
- Shorter-acting preparations of vitamin D are preferred so that overdosage (hypercalcemia) can be quickly corrected (see Table 1).
- A more economical approach to treatment is to maximize oral administration of calcium and reduce oral administration of vitamin D; calcium is usually less expensive than vitamin D (see Table 2). Dosage is influenced by each product's available elemental calcium content.

CONTRAINDICATIONS

See Hypocalcemia

Table 2

Calcium preparations.			
Preparation	Dose of Elemental Calcium	Available Calcium	Size Available (Needs to Be Converted to Elemental Calcium)
Calcium carbonate	Canine: 1–4 g/day Feline: 0.5–1 g/day	40%	Tablets—500, 600, 650, 1,250, 1,500 mg Chewable tablets—400, 420, 500, 750, 850, 1,000, 1,250 mg Capsules—1,250 mg Oral suspension—250 mg/mL
Calcium gluconate	Canine: 1–4 g/day Feline: 0.5–1 g/day	10%	Tablets—500, 650, 975 mg Chewable tablets—500 mg Capsules—500, 700 mg Powder for suspension—70 mg/ml
Calcium lactate	Canine: 1–4 g/day Feline: 0.5–1 g/day	13%	Tablets—650, 770 mg Capsules—500 mg
Calcium acetate	Canine: 1–4 g/day Feline: 0.5–1 g/day	25%	Tablets, gelcaps, and capsules—667 mg
Calcium citrate	Canine: 1–4 g/day Feline: 0.5–1 g/day	21%	Tablets—950, 1,150 mg Effervescent tablets—2,380 mg Capsules—850, 1,070 mg Powder for oral suspension—725 mg/ml
Calcium glubionate	Canine: 1–4 g/day Feline: 0.5–1 g/day	30%	Syrup—360 mg/ml

(CONTINUED)

PRECAUTIONS

All calcium preparations given orally can cause gastrointestinal disturbances; calcium carbonate may be less irritating because of its high calcium availability and lower dosage requirement.

POSSIBLE INTERACTIONS

- Injectable calcium solutions are reportedly incompatible with tetracycline drugs, cephalothin, methylprednisolone sodium succinate, dobutamine, metoclopramide, and amphotericin B.
- Thiazide diuretics used in conjunction with large doses of calcium may cause hypercalcemia.
- Patients on digitalis are more likely to develop arrhythmias if calcium is administered intravenously.
- Calcium administration may antagonize effects of calcium channel blocking agents (e.g., diltiazem, verapamil, nifedipine, and amlodipine).

ALTERNATIVE DRUG(S)

None

**FOLLOW-UP****PATIENT MONITORING**

- Hypocalcemia and hypercalcemia are both concerns with long-term management.
- Once serum calcium is stable and normal, assess serum calcium concentration monthly for the first 6 months, then every 2–4 months; goal is to maintain serum calcium between 8 and 10 mg/dL.
- Inform clients about clinical signs of hypocalcemia and hypercalcemia.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Hypocalcemia
- Hypercalcemia, which can lead to nephrocalcinosis and kidney injury (see Hypercalcemia)

EXPECTED COURSE AND PROGNOSIS

- With close monitoring of serum calcium and client dedication, the prognosis for long-term survival is excellent.
- Adjustments in vitamin D and oral calcium administration can be expected during the course of management, especially during the initial 2–6 months.
- Cats with hypoparathyroidism secondary to thyroidectomy usually require only transient treatment because they typically regain normal parathyroid function within 4–6 months, often within 2–3 weeks.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Excess muscular activity can lead to hyperthermia, which may necessitate treatment.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

Hypocalcemia can lead to weakness and dystocia.

SEE ALSO

- Hypercalcemia
- Hyperthyroidism
- Hypocalcemia

HYPOPARATHYROIDISM**ABBREVIATIONS**

- Ca = calcium
- ECG = electrocardiography
- PTH = parathyroid hormone
- PU/PD = polyuria and polydipsia

H

HYPOPHOSPHATEMIA

BASICS

DEFINITION

Serum phosphorus concentration
 $< 2.5 \text{ mg/dL}$

PATOPHYSIOLOGY

- Control of phosphorus is influenced by the actions and interactions of PTH and vitamin D with the gastrointestinal tract, bone, kidneys, and parathyroid glands.
- Decreased serum phosphorus concentration can be caused by translocation of phosphorus from the extracellular fluid in cells, decreased renal reabsorption, or decreased intestinal absorption of phosphorus.
- Low serum phosphorus can lead to ATP depletion, which affects cells with high ATP-energy demands (skeletal muscle, cardiac muscle, nerve tissue, and RBCs).
- Many important enzyme systems dependent on adequate phosphorus levels including: glycolysis, ammonogenesis, 1-hydroxylation of 25(OH)-cholecalciferol, and 2,3-diphosphoglycerate, which are essential for energy production, acid excretion, calcium balance, and tissue oxygenation, respectively.
- Required for maintenance of cell membrane integrity by playing an essential role in the production of ATP, guanosine triphosphate, cyclic AMP, and phosphocreatinine.
- Diabetic (ketotic and non-ketotic) patients at increased risk due to depleted phosphorus stores, lost muscle mass, and urinary losses. Insulin administration yields ATP from glycolysis, causing translocation of phosphorus.

SYSTEMS AFFECTED

- Hemic/Lymphatic/Immune—hemolysis, impaired oxygen delivery to tissues, impaired leukocyte and platelet function.
- Neurologic—impaired glucose uptake leads to encephalopathy, seizures, and coma.
- Musculoskeletal—rhabdomyolysis, weakness, pain, ventilator failure, and gastrointestinal ileus.
- Cardiac—impaired contractility.

SIGNALMENT

- Older dog and cat
- Diabetic patient

SIGNS

Historical Findings

Usually consistent with the primary condition responsible for the hypophosphatemia; however, evidence of severe hypophosphatemia (e.g., hemolysis) is usually not observed unless serum concentrations decrease to 1.0 mg/dL or less.

Physical Examination Findings

- Hemolytic anemia causes pallor, tachypnea, dyspnea, and/or red discolored urine.
- Skeletal and respiratory muscle weakness.
- Mental dullness.

CAUSES

- Maldistribution (translocation)—treatment of diabetes ketoacidosis, insulin administration or carbohydrate load, total parenteral nutrition or nutritional recovery, hyperventilation or respiratory alkalosis.
- Reduced renal reabsorption (increased renal loss)—primary hyperparathyroidism, renal tubular disorders (e.g., Fanconi syndrome), proximal tubule diuretics (e.g., carbonic anhydrase inhibitors), eclampsia (hypocalcemic tetany), hyperadrenocorticism, sodium bicarbonate administration.
- Reduced intestinal absorption (decreased intake)—phosphorus-deficient diets, vitamin D deficiency, malabsorption disorders, phosphate binders.
- Laboratory error—hemolysis, icterus, osmotic diuretic (e.g., mannitol) administration.

RISK FACTORS

- Phosphorus-deficient diets or parenteral nutrition (refeeding syndrome)
- Diabetes mellitus
- Prolonged anorexia, malnutrition, or starvation
- Primary hyperparathyroidism

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Concurrent hyperglycemia, glucosuria, ketonuria, and high anion gap metabolic acidosis—rule out diabetic ketoacidosis.
- Concurrent glucosuria, normoglycemia, isosthenuria \pm azotemia—rule out renal tubular defects.
- Concurrent hypercalcemia and proteinuria—rule out primary hyperparathyroidism.
- Concurrent hypocalcemia—rule out hypocalcemic tetany.
- Concurrent high serum alkaline phosphatase—rule out hyperadrenocorticism.
- Concurrent panhypoproteinemia—rule out intestinal malabsorption.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

Osmotic diuretics (e.g., mannitol) may falsely lower serum phosphorus concentrations.

Disorders That May Alter Laboratory Results

Hemolysis and icterus may falsely lower serum phosphorus concentrations.

Valid If Run In Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- Serum phosphorus $< 2.5 \text{ mg/dL}$.
- Hyperglycemia, glucosuria, ketonuria, and high anion gap metabolic acidosis with diabetic ketoacidosis.
- Glucosuria, normoglycemia, isosthenuria, or azotemia with renal tubular defect.

- Hypercalcemia with primary hyperparathyroidism.
- Hypocalcemia with hypocalcemic tetany.
- High serum alkaline phosphatase, proteinuria with hyperadrenocorticism.
- Panhypoproteinemia with intestinal malabsorption.

OTHER LABORATORY TESTS

- Serum fructosamine—to diagnose or rule out diabetes mellitus.
- Parathyroid hormone assay—to diagnose or rule out hyperparathyroidism.
- PTH-rp for hypercalcemia of malignancy.
- Vitamin D metabolite measurement—to diagnose or rule out vitamin D deficiency.

IMAGING

- Radiography may reveal urolithiasis in cases of primary hyperparathyroidism or poor bone quality/pathologic fractures with disorders of vitamin D metabolism.
- Ultrasonography (cervical) may reveal parathyroid mass.

OTHER DIAGNOSTIC PROCEDURES

Surgical exploration of the cervical area may reveal a parathyroid mass.
 Urine anion gap can reveal renal tubular secretory defect.

TREATMENT

- Prevention is preferred.
- Asymptomatic patients with low (1.5–2.5 mg/dL), but not depleted, phosphorus concentrations may not need phosphate treatment.
- If caused by insulin administration or hyperalimentation, administer supplemental phosphorus.
- Severe hypophosphatemia ($< 1.5 \text{ mg/dL}$): patients need hospitalization and monitoring for hemolysis or hemolytic crisis. Intravenously administer isotonic electrolyte solution without calcium, supplemented with potassium phosphate.
- Fresh whole blood transfusion for severe hemolytic crisis.

MEDICATIONS

DRUG(S) OF CHOICE

- Potassium phosphate (3 mMol phosphate/mL and 4.4 mEq potassium/mL) given intravenously.
- Sodium phosphate (3 mMol phosphate/mL and 4 mEq sodium/mL) intravenously.
- Dosage—0.01–0.12 mMol/kg/h CRI. Monitor serum phosphorus every 6–8 hours.
- Discontinue therapy when serum phosphorus concentration reaches 2 mg/dL in order to avoid iatrogenic hypocalcemia and hyperphosphatemia.

(CONTINUED)

CONTRAINDICATIONS

- Hyperphosphatemia
- Hypocalcemia
- Hypercalcemia
- Renal failure
- Hyperkalemia
- Concurrent D_{2,5} and D₅ in LRS and dobutamine administration

PRECAUTIONS

- Concurrent diuretic administration, especially carbonic anhydrase inhibitors
- Renal disease

POSSIBLE INTERACTIONS

- ACE inhibitor (e.g., enalapril) administration
- Cardiac glycoside (e.g., digoxin) administration
- Potassium-sparing diuretics (e.g., spironolactone)

ALTERNATIVE DRUG(S)

- Oral phosphate supplement (e.g., phospho-soda) if not vomiting
- Milk (skim or low-fat) may be supplemented

**FOLLOW-UP**

- Measure serum phosphorus levels every 6–8 hours until within normal range.
- Monitor patients for hyperphosphatemia and discontinue treatment immediately.
- Check serum potassium level daily until both stable.

POSSIBLE COMPLICATIONS

- Hemolysis
- Respiratory depression and failure
- Cardiac arrest

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Concurrent hypokalemia is common in patients with diabetic ketoacidosis.
- Concurrent hypercalcemia in Keeshond dogs.

AGE-RELATED FACTORS

Usually presents in older dogs.

PREGNANCY/FERTILITY/BREEDING

- Concurrent hypocalcemia in the periparturient animal is caused by PTH-promoted renal excretion of phosphorus causing hypophosphatemia.

SEE ALSO

- Diabetes Mellitus with Ketoacidosis
- Hyperparathyroidism

HYPOPHOSPHATEMIA**ABBREVIATIONS**

- ACE = angiotensin converting enzyme
- ATP = adenosine triphosphate
- LRS = lactated Ringer's solution
- PTH = parathyroid hormone

H

HYPOPITUITARISM

BASICS

OVERVIEW

- A condition resulting from destruction of the pituitary gland by a neoplastic, degenerative, or anomalous process.
- Associated with low production of pituitary hormones including TSH, ACTH, luteinizing hormone, follicle-stimulating hormone, and GH.

SIGNALMENT

- Dog
- Age: 2–6 months
- Breeds—German shepherd, Karelian bear dog, spitz, toy pinscher, and Weimaraner
- Simple autosomal recessive in German shepherd and Karelian bear dog; mutation of the *Lhx3* gene

SIGNS

Historical Findings

- Mental retardation manifested as difficulty in housebreaking
- Slow growth noticed in first 2–3 months of life
- Proportionate dwarfism

Physical Examination Findings

- Retained puppy hair coat
- Thin, hypotonic skin
- Shriek bark
- Truncal alopecia
- Cutaneous hyperpigmentation
- Infantile genitalia
- Delayed dental eruption

CAUSES & RISK FACTORS

Congenital

- Cystic Rathke's pouch
- Isolated GH deficiency

Acquired

- Pituitary tumor
- Trauma
- Radiotherapy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypothyroid dwarfism; breed predilection and disproportionate dwarfism observed in patients with hypothyroidism.

- Other causes of stunted growth—portosystemic shunt, diabetes mellitus, hyperadrenocorticism, malnutrition, parasitism.

CBC/BIOCHEMISTRY/URINALYSIS

- Eosinophilia
- Lymphocytosis
- Hypophosphatemia
- Hypoglycemia

OTHER LABORATORY TESTS

- Corticotropin and TSH response tests; subnormal response to TSH and ACTH.
- Growth hormone and insulin-like growth factor assays; growth hormone assay not currently available in the United States; recommend measurement of IGF-1, which is low.
- Ghrelin-stimulation test—monitors changes in GH levels in response to ghrelin; requires GH assay.
- DNA testing.

IMAGING

Radiography may reveal epiphyseal dysgenesis and abnormal retention of phyeal growth plates.

TREATMENT

Manage medically on an outpatient basis.

MEDICATIONS

DRUG(S)

- Growth hormone—human, porcine, or bovine, if available; 0.1 IU/kg SC three times weekly for 4–6 weeks; repeat if necessary.
- Medroxyprogesterone acetate (2.5–5 mg/kg IM q 3 weeks, then q6 weeks after normal stature is achieved).
- Treat hypothyroidism with levothyroxine (22 µg/kg PO q24h).
- Glucocorticoids (e.g., prednisone, 0.2 mg/kg PO q24h) if ACTH response test results are subnormal; higher dosage of steroids is needed during periods of stress.

CONTRAINDICATIONS/POSSIBLE

INTERACTIONS

Hypersensitivity reactions and carbohydrate intolerance may develop with growth hormone supplementation.

FOLLOW-UP

PATIENT MONITORING

- Blood and urinary glucose concentration.
- Stop growth hormone supplementation if glucosuria develops or blood glucose is > 150 mg/dL.

POSSIBLE COMPLICATIONS

Neurologic complications caused by expansion of Rathke's pouch.

EXPECTED COURSE AND PROGNOSIS

- Skin and hair coat improve within 6–8 weeks of initiating growth hormone and thyroid supplementation.
- Generally no increase in stature because growth plates have usually closed by the time of diagnosis.
- Dogs often die at a young age (3–4 years) because of neurologic complications.
- Poor long-term prognosis.

HYPOPYON

BASICS

OVERVIEW

- Hypopyon—accumulation of white blood cells in the anterior chamber of the eye. Inflammatory breakdown of blood-aqueous barrier allows entry of blood cells into the anterior chamber; chemoattractants mediate influx. Cells often settle in the ventral anterior chamber because of gravity. • Lipid flare—resembles hypopyon but turbidity of the anterior chamber is caused by a high concentration of lipids in aqueous humor. Requires breakdown of the blood-aqueous barrier and concurrent hyperlipidemia to occur.

SIGNALMENT

Affects both dogs and cats; no age or sex predilection.

SIGNS

- Hypopyon—white to yellow opacity within anterior chamber; may be a ventral accumulation of cells or may completely fill the anterior chamber. Fibrin accumulation in anterior chamber may prevent discrete settling of white blood cells, resulting in cells suspended within fibrin matrix. Concurrent ophthalmic signs include blepharospasm, epiphora, diffuse corneal edema, aqueous flare, miosis, iridal swelling, and vision loss.
- Lipid flare—diffuse milky appearance to anterior chamber. Concurrent ophthalmic signs may include vision loss, mild blepharospasm, and mild to moderate diffuse corneal edema.

CAUSES & RISK FACTORS

Hypopyon

Any cause of uveitis can result in hypopyon. Most commonly, hypopyon is associated with severe uveitis. Hypopyon can also result from neoplastic cell accumulation in ocular lymphoma.

Lipid Flare

Lipid flare results from hyperlipidemia and concurrent uveitis. Hyperlipidemia may also destabilize the blood-aqueous barrier directly. Post-prandial lipemia may occasionally result in lipemic aqueous if uveitis is present.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Hypopyon

Fibrin in anterior chamber—generally forms an irregular clot, not a ventrally located horizontal line.

Lipid Flare

- Severe aqueous flare—does not appear as milky/white as lipid flare. Animals with severe aqueous flare generally exhibit much more

ocular pain than animals with lipid flare. • Diffuse corneal edema—severe corneal edema may be confused with anterior chamber opacity, but corneal stromal thickening, keratoconus, and corneal bullae are noted with the former.

CBC/BIOCHEMISTRY/URINALYSIS

Hypopyon

Often normal; abnormalities related to underlying cause of uveitis may be present.

Lipid Flare

Elevated serum triglycerides and cholesterol; other abnormalities may be present related to underlying metabolic disorder(s).

OTHER LABORATORY TESTS

Hypopyon

None if hypopyon is related to obvious corneal disease; if related to uveitis, look for underlying cause of uveitis (see Anterior Uveitis—Dogs; Anterior Uveitis—Cats).

Lipid Flare

See Hyperlipidemia.

DIAGNOSTIC PROCEDURES

Anterior chamber centesis indicated with suspicion of neoplastic hypopyon (e.g., lymphoma); unrewarding under other circumstances.

TREATMENT

- Hypopyon requires aggressive treatment for uveitis and underlying cause. Outpatient treatment is adequate. • Lipid flare requires treatment for uveitis and underlying metabolic disorder. Outpatient treatment is adequate.

MEDICATIONS

DRUG(S)

Hypopyon

Corticosteroids

Topical

- Prednisolone acetate 1%—apply 2–6 times daily, depending on severity of disease.
- Dexamethasone 0.1%—apply 2–6 times daily, depending on severity of disease.
- Taper medication frequency as condition resolves.

Subconjunctival

- Triamcinolone acetonide 4–6 mg (dog); 4 mg (cat) by subconjunctival injection.
- Methylprednisolone 3–10 mg (dog); 4 mg (cat) by subconjunctival injection. • Indicated as one-time injection followed by topical and/or systemic anti-inflammatories.

Systemic

- Prednisone 0.5–2.2 mg/kg/day (dog); 1–3 mg/kg/day (cat); taper dose after 7–10 days. • Only use if systemic infectious causes of uveitis have been ruled out.

Nonsteroidal Anti-inflammatory Drugs

Topical

- Flurbiprofen—apply 2–4 times daily, depending on severity of disease.
- Diclofenac—apply 2–4 times daily, depending on severity of disease. • Much less effective than corticosteroids.

Systemic

- Carprofen 2.2 mg/kg PO q12h or 4.4 mg/kg PO QD (dog). • Meloxicam 0.2 mg/kg PO QD (dog). • Robenacoxib 1 mg/kg PO q24h; limit duration of use to 3 days (cat). • Meloxicam 0.2 mg/kg IV, SC, PO once, then 0.05 mg/kg IV, SC, PO q24h for 2 days, then 0.025 mg/kg q24–48h; limit duration of use to 4 days (cat). • Do not use concurrently with systemic corticosteroids.

Topical Mydriatic/Cycloplegic

- Atropine sulfate 1%—apply 1–4 times daily, depending on severity of disease. Use ointment instead of solution in cats to minimize salivation.

Lipid Flare

Topical Corticosteroids

- Prednisolone acetate 1%—apply 2–4 times daily, depending on severity of disease.
- Dexamethasone 0.1%—apply 2–4 times daily, depending on severity of disease.
- Taper medication as condition resolves.

Topical Mydriatic/Cycloplegic

Atropine sulfate 1%—apply 1–2 times daily, if necessary for perceived ocular discomfort.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Avoid the use of topical miotic medications.
- Topical and subconjunctival corticosteroids contraindicated if ulcerative keratitis is present. • Out of concern for secondary glaucoma, topical atropine should be used judiciously and IOP should be monitored.

FOLLOW-UP

PATIENT MONITORING

Recheck in 2–3 days. Intraocular pressure should be monitored to detect secondary glaucoma. Frequency of subsequent rechecks dictated by response to treatment.

EXPECTED COURSE AND PROGNOSIS

- Hypopyon—prognosis guarded to good; depends on underlying disease and response to treatment. • Lipid flare—prognosis good; generally responds quickly (within 24–72 hours) to moderate anti-inflammatory therapy; recurrence possible.

HYPOTHENURIA

BASICS

DEFINITION

Urinary specific gravity between 1.000 and 1.006

PATHOPHYSIOLOGY

The ability to concentrate urine normally (dogs, > 1.030; cats, > 1.035) depends on a complex interaction between ADH, the protein receptor for ADH on the renal tubule, and a hypertonic renal medullary interstitium; interference with the synthesis, release, or actions of ADH, damage to the renal tubule, and altered tonicity of the medullary interstitium (medullary wash-out) can cause hyposthenuria.

H

SYSTEMS AFFECTED

Depends on the underlying disorder

SIGNALMENT

Species

Dog and cat

Breed Predilections

None

Mean Age and Range

None

Predominant Sex

None

SIGNS

- Polyuria and polydipsia
- Urinary incontinence—occasional
- Other signs depend on the underlying disorder

CAUSES

Any disorder or drug that interferes with the release or action of ADH, damages the renal tubule, causes medullary wash-out, or causes a primary thirst disorder (see "Differential Diagnosis").

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pyometra
- Cushing's disease
- Central diabetes insipidus (little or no ADH produced)
- Nephrogenic diabetes insipidus (resistance to ADH)
- Pyelonephritis
- Hyperthyroidism
- Hypercalcemia
- Early renal failure
- Primary liver disease
- Hypokalemia
- Hypoadrenocorticism

- Primary polydipsia—compulsive water drinking

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

Cortisone, lithium, demeclocycline, methoxyflurane, thiazide diuretics, and intravenous administration of fluids can all lower urine specific gravity into the hyposthenuric range.

Valid if Run in a Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- Low urinary specific gravity (1.000–1.006), other abnormalities may point to the underlying cause.
- High serum ALP activity suggests hyperadrenocorticism or primary liver disease.
- High cholesterol common in patients with hyperadrenocorticism.
- Leukocytosis with a left shift in some patients with pyometra or pyelonephritis.
- Hyperkalemia and hyponatremia suggest hypoadrenocorticism.
- Low serum potassium confirms hypokalemia.
- Inflammatory sediment or bacteriuria consistent with pyelonephritis.
- Proteinuria common in patients with pyelonephritis, pyometra, and hyperadrenocorticism.

OTHER LABORATORY TESTS

ACTH levels to determine the cause of hyperadrenocorticism (i.e., pituitary-dependent vs. adrenal tumor).

IMAGING

- Radiography to assess renal size and shape and to detect calcified adrenal tumor or large uterus.
- Intravenous pyelogram to help diagnose pyelonephritis.
- Ultrasonography to assess adrenal size, renal and hepatic size and architecture, and uterine size.
- MRI or CT scan to assess a pituitary or hypothalamic mass that may be the cause of central diabetes insipidus or hyperadrenocorticism.

DIAGNOSTIC PROCEDURES

- ACTH stimulation test to screen for hyperadrenocorticism and hypoadrenocorticism.
- Low-dose dexamethasone-suppression test and urine/cortisol creatinine test to screen for hyperadrenocorticism.
- Serum bile acids to evaluate liver function.
- Note: dogs with hyperadrenocorticism often have mildly high bile acids.
- Modified water deprivation test to differentiate diabetes insipidus from

psychogenic polydipsia; see Appendix II for test protocol.

TREATMENT

- Depends on the underlying disorder.
- Do not restrict patient's water intake unless appropriate to the definitive diagnosis.
- Depends on the underlying disorder.

MEDICATIONS

DRUG(S) OF CHOICE

Depends on the underlying disorder

FOLLOW-UP

BASICS

Due to limited clinical literature in veterinary science much of the information below has been extrapolated from the human medical literature and experimental studies in animals.

DEFINITION

- Core body temperature drops below that required for normal metabolism. In primary hypothermia, the healthy individual's compensatory responses to heat loss are overwhelmed by exposure, whereas secondary hypothermia complicates many systemic diseases.
- Stage I—90–95°F (32–35°C)
- Stage II—82–90°F (28–32°C)
- Stage III—75–82°F (24–28°C)
- Stage IV—any temperature <75°F (24°C).

PATHOPHYSIOLOGY

• Normal thermoregulation balances heat gained or lost to the environment with heat produced via central thermogenesis. It is controlled by the hypothalamus with input from thermoreceptors. Heat can be gained or lost to the environment via four mechanisms including evaporation, radiation, convection, and conduction. Central thermogenesis generates heat via basal metabolism, muscle activity, and uncoupling of brown fat (neonates). • Heat production can be augmented via shivering and increased basal metabolic rate. Activation of both the sympathetic nervous and endocrine systems results in increased circulating levels of thyroid-releasing hormone, catecholamines, growth hormone, and glucocorticoids, which all contribute to increased glucose utilization and basal metabolic rate. • Adaptations to minimize heat loss include cutaneous vasoconstriction, piloerection, and behavioral responses such as curling up, sharing body heat, and seeking shelter.

SYSTEMS AFFECTED

- Cardiovascular—in mild hypothermia, sympathetic stimulation induces tachycardia and peripheral vasoconstriction with normal or elevated cardiac output and blood pressure (BP). As the patient becomes colder, depolarization of cardiac pacemaker cells is slowed resulting in bradycardia resistant to treatment with atropine; the resultant fall in cardiac output is balanced by an increase in systemic vascular resistance. At lower temperatures, bradycardia becomes progressively extreme and systemic vascular resistance falls as catecholamine release and adrenergic receptor responsiveness is blunted. Classic ECG findings include the presence of Osborn or J-waves, atrial and ventricular dysrhythmias, and prolongation of the PR, QRS, and QT intervals. Progression from sinus bradycardia through atrial fibrillation to ventricular fibrillation and ultimately asystole.
- Endocrine—sympathetic activation and

release of counter-regulatory hormones trigger increased glycogenolysis, gluconeogenesis, and lipolysis as well as inhibit the release and uptake of insulin resulting in hyperglycemia. When hypothermia develops slowly or is long-lasting, glycogen stores become depleted and hypoglycemia develops.

- Gastrointestinal—increased gastric acid production and reduced duodenal bicarbonate secretion may predispose patients to gastrointestinal ulceration. Ileus is common.
- Hemic—plasma shifts to the extravascular space, and the consequent hemoconcentration may lead to hyper- and hypocoagulopathy. Depressed enzymatic activity of clotting factors and platelet hyporeactivity may exacerbate hypocoagulability.
- Hepatobiliary/Pancreatic—hypoxia leads to hepatocellular damage and pancreatitis.
- Musculoskeletal—increased viscosity of joint fluid and muscle stiffness.
- Nervous—as core temperature falls, CNS metabolism and level of consciousness decrease in a linear fashion, and nerve conduction velocity progressively slows. Mild incoordination is followed by lethargy, obtundation and coma.
- Renal—peripheral vasoconstriction increases renal blood flow and glomerular filtration rate resulting in increased urine production. As core body temperature falls, progressive tubular dysfunction and antidiuretic hormone resistance contribute further to cold-diuresis. Later, urine production decreases as a result of falling cardiac output. Acute kidney injury may ensue.
- Respiratory—initial tachypnea is replaced by decreased respiratory rate and tidal volume and increased production of airway secretions. As the temperature falls protective airway reflexes are reduced. At temperatures below 93.2°F (34°C) ventilatory drive is attenuated and increased pulmonary vascular resistance leads to ventilation-perfusion mismatch. Progressive hypoventilation, apnea, and (more rarely) pulmonary edema may develop. Hypothermia also causes the oxyhemoglobin dissociation curve to shift to the left. This effect may be masked by concurrent lactic and respiratory acidosis that may become so profound it results in an overall right-shift.
- Skin—edema develops secondary to increased vascular permeability.

GENETICS

Unknown

INCIDENCE/PREVALENCE

Varies with geographic location

GEOGRAPHIC DISTRIBUTION

Most common in cold climates

SIGNALMENT

Species

Dogs and cats

Breed Predilections

Smaller breeds with increased surface area

Mean Age and Range

More common in neonates and geriatrics

SIGNS

General Comments

A thorough search should be made to find precipitating, comorbid conditions.

Historical Findings

- Known prolonged exposure to cold ambient temperatures.
- Possibly, disappearance from home or a history of trauma.

Physical Examination Findings

- Stage I—90–95°F (32–35°C)
- Stage II—82–90°F (28–32°C)
- Stage III—75–82°F (24–28°C)
- Stage IV—any temperature <75°F (<24°C)

Stage I 90–95°F (32–35°C)

- General
 - Lethargy
 - Weakness
 - Vigorous shivering (variable)
 - Cardiovascular
- Variable heart rate, rhythm, and BP
- Light pink to pale mucous membranes
- Neurologic
 - Confusion, agitation, or obtundation
 - Respiratory
 - Variable respiratory rate

Stage II 82–90°F (28–32°C)

- General
 - Collapse
 - Reduced shivering (variable)
 - Cardiovascular
- Bradyarrhythmia with hypotension
- Pale mucous membranes
- Musculoskeletal
- Muscle and joint stiffness
- Neurologic
- Obtundation, stupor, or coma
- Ataxia and hyporeflexia
- Respiratory
 - Reduced depth and rate of respiration

Stage III 75–82°F (24–28°C)

- General
 - Moribund with cold, edematous skin
 - Loss of shivering (variable)
- Cardiovascular
 - Bradyarrhythmia with hypotension
 - Pale mucous membranes
- Musculoskeletal
 - Muscle and joint stiffness
- Neurologic
 - Coma with fixed, dilated pupils
 - Areflexia
 - Respiratory
 - Reduced depth and rate of respiration or respiratory arrest
 - Pulmonary edema

Stage IV <75°F (<24°C)

- General
 - No vital signs
 - Cardiac arrest

CAUSES

- Inadequate thermogenesis
 - Normal thermogenesis is overwhelmed
 - Serious illness
 - Extreme heat loss
 - Excessive evaporation, conduction, convection, and radiation
 - Inability to vasoconstrict blood vessels or piloerect hair
 - Loss of behavioral adaptations
 - Thermoregulatory center failure
 - Hypothalamic injury or disease

RISK FACTORS

- Extremes of age
- Low body fat and glycogen stores
- Burn injury
- Intracranial injury or disease
- Hypothyroidism
- Diabetic ketoacidosis
- Sepsis
- Trauma
- General anesthesia
- Use of medications including but not limited to beta-blockers, barbiturates, narcotics, phenothiazines

H

HYPOTHERMIA

(CONTINUED)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary CNS disease, hypoglycemia, anemia, hepatic encephalopathy, myxedema, electrolyte disturbances, sepsis, intoxication, neoplasia, and death
- Bradyarrhythmia—cardiac disease, medication side effects, and intoxication

CBC/BIOCHEMISTRY/URINALYSIS

- Results are variable depending on the degree of hypothermia and presence of comorbid conditions
- CBC—hemoconcentration and thrombocytopenia
- Biochemistry—azotemia, hyper- and hypoglycemia, elevated liver enzyme activity, hyperbilirubinemia
- Urinalysis—isosthenuria, glucosuria

OTHER LABORATORY TESTS

- Blood gas—variable but metabolic and respiratory acidosis is common.
- Coagulation—hyperfibrinogenemia, DIC. In vivo prolongation of blood clotting times may not be reflected by in vitro assays and should correct with rewarming.
- Thyroid hormone evaluation may confirm underlying hypothyroidism.

IMAGING

To investigate recovery complications or comorbid conditions

DIAGNOSTIC PROCEDURES

None

PATHOLOGIC FINDINGS

- Findings in patients who succumb to primary accidental hypothermia are variable and nonspecific. If body cooling and death occur rapidly, necropsy findings are minimal but may include reddish discoloration of skin, hemorrhagic gastric erosions, and lipid deposits in epithelial cells of renal proximal tubules and other organs.
- Patients who die from secondary hypothermia may have similar findings; however, they will also have evidence of a separate and significant disease process.

TREATMENT

APPROPRIATE HEALTH CARE

Emergency inpatient intensive care until normothermic and stable

NURSING CARE

- Active external rewarming using warm blankets, heating pads, radiant heat, warm baths, or forced warm air, and administration of warm parenteral fluids (stage II) is used in patients with stage I-II hypothermia. Complications include core temperature after-drop whereby the return of cold blood from the periphery to the central circulation causes further core cooling. Rewarming of the trunk should be performed before the

extremities to minimize this risk.

- Techniques to warm patients with stage III-IV hypothermia include administration of warm humidified oxygen, warmed intravenous fluids, and bladder or gastric lavage with warm saline. More invasive and technically demanding methods include closed thoracic and peritoneal lavage, hemodialysis, continuous arteriovenous or veno-venous rewarming, and cardiopulmonary bypass.
- Whole-body immersion in hot water is contraindicated, as it will cause massive vasodilatation and hypotension and is likely to provoke dysrhythmias and cardiovascular collapse.
- Fluid therapy—most patients are initially volume depleted but must be closely monitored during resuscitation for volume overload. Crystalloid fluids administered intravenously should be warmed to 104°F (40°C).
- Hypotension is treated with volume resuscitation. The use of inotropic drugs is considered only in cases unresponsive to volume resuscitation.
- Patients with respiratory failure must be mechanically ventilated.

ACTIVITY

Minimally affected patients should be encouraged to be active, as muscle activity will generate more endogenous body heat.

DIET

- Withhold oral intake until patient is alert.

CLIENT EDUCATION

Prevention of exposure to cold temperatures is imperative in preventing primary hypothermia. Clients with very young and very old patients as well as those with serious medical conditions or taking medications that inhibit thermoregulatory ability should be counseled to keep their pets indoors and to take protective measures if they are to be exposed to cold temperatures.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

Hypoglycemic patients warrant dextrose supplementation.

CONTRAINDICATIONS

There is no evidence to support the routine use of steroids or antibiotics.

FOLLOW-UP

PATIENT MONITORING

- Continuous core body temperature.
- Continuous ECG and frequent BP (q1h) during rewarming.
- Frequent assessment (q6–12h) of electrolytes (sodium, potassium,

chloride, ionized calcium, magnesium, and phosphorus), acid-base status, packed cell volume, total protein, and blood glucose.

- Daily monitoring of blood urea nitrogen, urine specific gravity, coagulation indices, and liver enzymes in severely affected patients.

PREVENTION/AVOIDANCE

- Avoid prolonged exposure to cold.
- Monitor and maintain body temperature in anesthetized animals.

POSSIBLE COMPLICATIONS

- Peripheral vasodilation during rewarming may further drop body temperature.
- Iatrogenic burns.
- Return of cool peripheral blood to the heart may precipitate cardiac arrhythmias.
- Cardiac arrest.

EXPECTED COURSE AND PROGNOSIS

Variable—affected by severity of hypothermia, underlying cause, and general patient health status.

MISCELLANEOUS

ASSOCIATED CONDITIONS

None

AGE-RELATED FACTORS

Sick or hypoglycemic neonates can become markedly hypothermic in normal environments.

BASICS

DEFINITION

Clinical manifestations that result from inadequate production of thyroxine (T_4) and 3,5,3'-triiodothyronine (T_3) by the thyroid gland. Characterized by a generalized decrease in cellular metabolic activity.

PATHOPHYSIOLOGY

Acquired Hypothyroidism

- In dogs acquired hypothyroidism can be primary, secondary, or tertiary.
- Primary hypothyroidism is associated with a defect localized to the thyroid gland. The thyroid tissue has been destroyed or replaced and thus becomes less responsive to TSH and T_3 and T_4 levels gradually decline, with a compensatory increase in TSH.
- There are two common forms of primary hypothyroidism. Lymphocytic thyroiditis is an immune-mediated process characterized by chronic and progressive lymphocytic infiltration and destruction of the thyroid gland. This process is gradual and accounts for the slow onset of clinical signs associated with hypothyroidism. The immune-mediated process is associated with production of auto-antibodies, predominantly against thyroglobulin; however, auto-antibodies against T_3 and T_4 have been reported.
- Idiopathic thyroid atrophy is a separate form of thyroid destruction that does not demonstrate an inflammatory component and is caused by the replacement of normal thyroid tissue with adipose tissue.
- Together, these processes account for 95% of the clinical cases of hypothyroidism in dogs, each account for 50% of reported cases. Rare causes of primary hypothyroidism include neoplastic destruction of thyroid tissue, iodine deficiency, infection, and iatrogenic destruction secondary to drugs, surgery, or radioiodine treatment.
- Secondary acquired hypothyroidism is rare. The defect is localized to the pituitary, where the ability to synthesize and secrete TSH is impaired. Secondary hypothyroidism may be caused by pituitary tumors, congenital malformation of the pituitary, infection, or TSH suppression. Drugs, hormones, or concurrent illness can cause TSH suppression.
- Tertiary hypothyroidism (not reported in the veterinary literature) is hypothalamic in origin, and production of TRH is either decreased or non-existent.

Congenital Hypothyroidism

- Congenital hypothyroidism is a rare disease that is categorized as goitrous or non-goitrous. Goiter (enlargement of the thyroid gland) develops when there is increased release of TSH, along with an intact thyroid TSH receptor.

- An autosomal recessive form of congenital hypothyroidism has been reported in toy fox terriers, giant schnauzers, and Abyssinian cats. Affected animals have a thyroid peroxidase deficiency.
- Congenital hypothyroidism is also noted as an element of panhypopituitarism.

SYSTEMS AFFECTED

- Behavioral
- Cardiovascular
- Endocrine/Metabolic
- Gastrointestinal
- Nervous
- Neuromuscular
- Ophthalmic
- Reproductive
- Skin/Exocrine

GENETICS

- No known genetic basis for heritability associated with primary hypothyroidism in dogs.
- An autosomal recessive form of congenital hypothyroidism has been reported in toy fox terriers, giant schnauzers, and Abyssinian cats.

INCIDENCE/PREVALENCE

- Primary hypothyroidism is the most common endocrinopathy in dogs. Prevalence appears to average about 1:250.
- Hypothyroidism is rare in cats.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog, rarely cat

Breed Predilections

Larger-breed dogs are more likely to develop hypothyroidism (golden retriever, Doberman pinscher, Great Dane, Irish setter), though several smaller-breed dogs do appear to also be predisposed (miniature schnauzer, cocker spaniel, poodle, dachshund).

Mean Age and Range

Most commonly seen in middle age dogs, with the average age of onset being 7 years.

Predominant Sex

None

SIGNS

General Comments

Clinical signs associated with hypothyroidism are vague and involve many different systems.

Historical Findings

- Lethargy, weight gain, and hair loss are the most common signs reported by owners (40–50% of all cases).
- Pyoderma (often recurrent), hyperpigmentation of the skin and a dry, brittle hair coat (10% of cases).
- Rarely (< 5% of cases) facial paralysis, weakness, or conjunctivitis.

Physical Examination Findings

- The most commonly findings include dermatologic abnormalities, weight gain,

lethargy, and weakness. Most changes appear to be secondary to decreased metabolism due to a lack of circulating thyroid hormones.

- Dermatologic changes are common but are not noted in every patient.

- A dry, lackluster hair coat may be seen. Bilateral symmetrical non-pruritic truncal alopecia is reported in 88% of hypothyroid dogs. Hair loss is noted in areas of increased wear and usually includes the ventral thorax and neck, ventral abdomen, elbows and tail. Loss of primary hair is most common, with retention of guard hairs, resulting in a short, fine hair coat.
- Seborrhea is common and may be localized or have a more generalized distribution pattern.

- Pyoderma is noted in 14% of hypothyroid dogs and may be recurrent in nature. A lack of thyroid hormone will decrease T-cell function and humoral immunity, causing the skin to become more susceptible to infection. Generalized demodicosis and *Malassezia* spp. infections are common. Though primary dermatologic conditions are non-pruritic, pruritis may accompany secondary parasitic, yeast, or bacterial infections. Chronic changes to the skin can result in thickening and hyperpigmentation.

- Otitis externa.
- Weight gain.
- Decreased activity level.
- Most neurologic signs are associated with polyneuropathy and include weakness, facial nerve paralysis, vestibular signs (usually peripheral), and hyporeflexia. No data support an association between megaesophagus or laryngeal paralysis and hypothyroidism.
- Central nervous system signs, including seizures, ataxia and coma (myxedema coma) are rare.
- In males, decreased fertility, testicular atrophy, poor semen motility, and decreased libido have been reported in hypothyroid dogs. In females, hypothyroidism has been suggested to be associated with prolonged interestrous periods, failure to cycle, decreased libido, and inappropriate mammary gland development. However, data are lacking to support an association between decreased thyroid hormone levels and reproductive failure in males or females.

- Cardiovascular abnormalities, are rare. Bradycardia, arrhythmias, decreased conduction, decreased contractility, and diastolic dysfunction have been reported.
- Ocular changes including corneal cholesterol deposits, KCS, and conjunctivitis are seen in less than 1% of hypothyroid dogs.

Congenital Hypothyroidism

- Lethargy and general inactivity
- Dwarfism
- Alopecia
- Constipation (more common in cats)

CAUSES

- Lymphocytic thyroiditis

HYPOTHYROIDISM

(CONTINUED)

- Idiopathic thyroid atrophy
- Neoplasia
- Pituitary disease
- Congenital abnormalities
- Iodine deficiency (dietary)
- Iatrogenic (secondary to surgery or radiation)

RISK FACTORS

Surgical removal (bilateral) of the thyroid gland

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary dermatologic disease
- Other endocrinopathies (hyperadrenocorticism, diabetes mellitus, growth hormone deficiency)
- Pancreatitis
- Nephrotic syndrome
- Hepatobiliary disease

CBC/BIOCHEMISTRY/URINALYSIS

- Useful to rule out non-thyroidal illness.
- Normochromic, normocytic, and nonregenerative anemia is a common finding. 28–32% of hypothyroid dogs demonstrate anemia. The hypothyroid state does not affect erythrocyte lifespan.
- Hyponatremia.
- Hypercholesterolemia is present in over 75% of hypothyroid dogs.
- Hypertriglyceridemia.
- Elevated levels of cholesterol and triglycerides have been associated with atherosclerosis in dogs, although this is rare.
- No specific changes are noted on urinalysis.

OTHER LABORATORY TESTS

- Diagnosing hypothyroidism is complex. The TSH stimulation test is a reliable single test used to diagnose hypothyroidism and is considered the gold standard. However, there is limited access to test reagents and the cost is often prohibitive.
- Several tests are available to assess thyroid function, thyroid hormone levels, and antithyroglobulin antibody levels. These tests include the total T₄, free T₄, endogenous TSH, antithyroglobulin antibodies, anti-T₃ antibodies, anti-T₄ antibodies, total T₃, reverse T₃, and free T₃.
- Combination testing will yield a highly reliable result.

Total T₄

- Initial screening (high sensitivity) test of thyroid function.
- This test measures both protein-bound and free T₄ levels.
- Test is a direct assessment of the ability of the thyroid gland to produce hormone.
- A decreased total T₄ level is a common finding in hypothyroid animals but is not diagnostic of hypothyroidism as concurrent

illness can cause an artificial decrease in total T₄ level.

- Total T₄ level can be measured by ELISA, chemiluminescence, or radioimmunoassay. There is indication that in-house ELISA is less reliable than radioimmunoassay.

Free T₄

- Most valuable as a screening test (high sensitivity).
- Measures metabolically active portion of the total T₄ level.
- Hypothyroid animals would be expected to have a low free T₄ level.
- Concurrent illness has less effect on the free T₄ level compared with the total T₄ level.
- Measurement by equilibrium dialysis (fT₄ED) has been demonstrated to be more reliable than radioimmunoassay because it mitigates the influence of antithyroglobulin antibodies.
- Newer methods of fT₄ analysis utilize chemiluminescent technology with comparable sensitivity and specificity to fT₄ED.

Endogenous TSH Level

- Measurement of endogenous TSH is available using a canine assay.
- Cross-reactivity allows this assay to be used in cats; however, it may be accurate only 50% of the time in cats.
- This test has high specificity and low sensitivity, best used as a confirmatory test and not as a screening test.
- TSH level is expected to be elevated in primary hypothyroid animals due to loss of negative feedback.
- Interpretation of the TSH level requires knowledge of the total or free T₄ level.
- Methods of assessing TSH levels are less sensitive at low levels and evaluation of endogenous TSH cannot be used to diagnose secondary hypothyroidism.

Antithyroglobulin Antibodies

- Antithyroglobulin antibodies include antithyroglobulin, anti-T₃, and anti-T₄ antibodies.
- A positive titer is predictive of immune-mediated thyroiditis, and suggestive of hypothyroidism.
- Anti-T₃ and -T₄ antibodies are similar to T₃ and T₄ and can cross-react to falsely elevate these assay levels. In animals who are slightly hypothyroid (as measured by total T₄), the presence of anti-T₄ antibodies will make it appear as if these animals are euthyroid, leading to a delay in the diagnosis and treatment of hypothyroidism.

TSH Stimulation Test

- Historically considered the gold standard for diagnosing hypothyroidism.
- Pharmaceutical-grade bovine TSH was used to conduct this test; however, production has been halted.
- Recombinant human TSH can be used safely in both dogs and cats to effectively

conduct the test, but is expensive. Therefore, this test is unlikely to become routine and replace the total and free T₄ tests and the TSH assay as the preferred diagnostics.

Total T₃, Reverse T₃, and Free T₃

- Total T₃ measurement is an unreliable indicator of thyroid function.
- The total T₃ level has been demonstrated to be normal in up to 90% of hypothyroid dogs.
- The reverse T₃ level has not been validated in companion animals.
- Evaluation of total T₃, reverse T₃, and free T₃ levels is not recommended to assess thyroid function.

Non-thyroid Factors That Alter Thyroid Function Tests

- In addition to sick euthyroid syndrome, other factors alter the results of thyroid function tests, which may result in a misdiagnosis.
- Most non-thyroid factors cause an artificial decrease in thyroid hormone levels.
- Some drugs can decrease thyroid hormone levels and may result in an animal developing clinical signs of hypothyroidism. Sulfonamides, glucocorticoids, phenobarbital, NSAIDs, and clomipramine can decrease circulating thyroid hormone levels.
- With sulfonamides this effect is noted to occur within weeks of initiation of therapy and disappears 2 weeks after therapy has been discontinued.
- Glucocorticoids inhibit the entire hypothalamic-pituitary-thyroid axis and have a direct effect against thyroid hormone.
- Phenobarbital causes a decrease in thyroid levels only in animals receiving long-term treatment. Phenobarbital should not be administered for 4 weeks prior to thyroid function testing.
- The influence of NSAIDs is variable and evaluation of thyroid function should be made with caution and preferably after stopping NSAIDs well in advance of testing.
- Well-conditioned and athletic dogs consistently have lower total and free T₄ levels. Certain breeds have normal ranges of thyroid hormones that are different from other breeds. Greyhound, Scottish deerhound, Saluki, and whippet have total T concentrations that are well below the mean concentrations. Alaskan sled dogs have serum T₄, T₃, and fT₄ concentrations below the normal reference range.
- Recent vaccination causes a transient increase in circulating auto-antibody levels, which may cause a truly hypothyroid animal to appear euthyroid. Thyroid function testing should not be conducted if a patient has been vaccinated within the previous 2 weeks.

IMAGING

Radiographic Findings

Developmental bone problems (delayed epiphyseal ossification or dysgenesis) are

(CONTINUED)

usually noted with congenital hypothyroidism.

Ultrasonographic Findings

- Significant differences in thyroid gland volume and echogenicity exist between hypothyroid and euthyroid patients.
- No significant difference is noted between euthyroid and sick euthyroid subjects.
- Ultrasonography can be an adjunctive diagnostic tool to assist in the diagnosis of canine hypothyroidism.

PATHOLOGIC FINDINGS

- Lymphocytic thyroiditis is characterized by chronic and progressive lymphocytic infiltration and destruction of the thyroid gland. Cytotoxic T cells initiate inflammation, leading to thyrocyte destruction and parenchymal fibrosis.
- Idiopathic thyroid atrophy is characterized by the replacement of normal thyroid parenchyma with adipose and connective tissue.
- Many cutaneous changes are nonspecific. However, certain findings, including dermal thickening, myxedema, and vacuolation of arrector pili muscles, are most characteristic.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient medical management

CLIENT EDUCATION

- Life-long therapy required.
- Easily managed with oral thyroid hormone supplementation.
- Dose adjustments are common in the early stages of treatment.
- Most clinical signs will resolve over time with appropriate thyroid hormone supplementation.

MEDICATIONS

DRUG(S) OF CHOICE

- Synthetic thyroid hormone supplementation easily treats hypothyroidism.
- Levothyroxine sodium is available as both human and veterinary products.
- Generic forms of the drug should be avoided as human studies have demonstrated wide variability in the bioavailability of generic forms. If a generic form is used, always prescribe the same formulation.
- Hormone supplementation is initiated at 0.02 mg/kg PO q12h. Supplementation levels can be increased to a maximum of 0.8 mg per dog per treatment.
- Supplementation can often eventually be decreased to once daily once proper control is achieved.

- Levothyroxine doses for dogs exceed those for humans and may confuse pharmacists or human endocrinologists.

PRECAUTIONS

Patients with concurrent metabolic conditions (hepatic disease, endocrinopathies, renal disease, cardiac disease) should have supplementation started slowly (about 25% of recommended dose) and slowly increased over time (3 months) to the recommended maintenance level.

POSSIBLE INTERACTIONS

- Glucocorticoids, NSAIDs, furosemide may increase metabolism of levothyroxine.
- GI protectants can decrease absorption and administration should be separated from thyroid hormone supplementation by 2 hours.

ALTERNATIVE DRUG(S)

- If T_4 levels do not normalize after attempting monitoring and treatment with several different brands of levothyroxine, treatment can be attempted with liothyronine (4–6 mg/kg PO q8–12h).
- Monitoring is based on T_3 levels. However, there is no reliable method by which to measure T_3 .

FOLLOW-UP

PATIENT MONITORING

- Thyroid function testing is recommended 6 weeks after therapy has begun and then every 6–8 weeks for the first 6–8 months and then once to twice yearly.
- The total T_4 level should be monitored and timed so that blood is taken 6 hours after pill administration.
- Once stable and well controlled, the total treatment dose may be given once daily with excellent clinical results.
- For animals receiving supplementation once daily, blood should be taken immediately before the medication is given and then again 6 hours later.
- When supplementation therapy is appropriate, the total post-dose T_4 level should be high normal to slightly above normal.
- If the total T_4 level is significantly increased above normal, the medication dose should be decreased or the frequency of administration reduced.
- If the total T_4 level is low, an increase in the dose may be necessary.
- Before increasing dose, assess client compliance, evaluate gastrointestinal status to ensure there is no impact on absorption, and confirm there has been no change in the levothyroxine formulation.

PREVENTION/AVOIDANCE

Adequate hormone supplementation with routine monitoring should avoid recurrence of this condition.

POSSIBLE COMPLICATIONS

- If untreated hypothyroid animals are at increased risk of developing myxedema, myxedema coma and atherosclerosis.
- Oversupplementation of thyroid hormone can result in iatrogenic hyperthyroidism.

EXPECTED COURSE AND PROGNOSIS

- Primary hypothyroidism can be easily and successfully controlled, the prognosis for affected animals, when appropriately treated, is excellent. Resolution of clinical signs is an important predictor of adequate supplementation therapy.
- Significant improvement in attitude, activity level, and alertness should occur within 1 week of starting therapy.
- Dermatologic abnormalities improve slowly, with complete resolution taking up to 3 months.
- Polyneuropathies usually begin improving quickly; complete resolution may take several months.
- Anemia and serum cholesterol levels gradually resolve in the first weeks of therapy.
- Life expectancy expected to be normal.
- Congenital hypothyroidism has a guarded-to-poor prognosis.

H

MISCELLANEOUS

ASSOCIATED CONDITIONS

May rarely be associated with other endocrinopathies.

PREGNANCY/FERTILITY/BREEDING

- No issues relating to pregnancy.
- No definitive evidence suggesting an association with altered fertility.

SEE ALSO

Myxedema and Myxedema Coma

ABBREVIATIONS

- ELISA = enzyme-linked immunosorbent assay
- GI = gastrointestinal
- KCS = keratoconjunctivitis sicca
- NSAID = nonsteroidal anti-inflammatory drug
- T_4 = thyroxine, tetraiodothyronine
- T_3 = liothyronine, 3,5,3'-triiodothyronine
- TRH = thyrotropin-releasing hormone
- TSH = thyroid stimulating hormone

BASICS

DEFINITION

- A decrease in PaO_2 , resulting in marked desaturation of hemoglobin.
- PaO_2 at sea level ranges from 80 to 100 mmHg in normal animals.

PATHOPHYSIOLOGY

Six physiologic causes

- (1) low PIO_2
- (2) hypoventilation (increase in PaCO_2)
- (3) mismatching of alveolar ventilation and perfusion so that areas of the lung that are not ventilated properly are still perfused adequately
- (4) alveolar–capillary membrane diffusion defect
- (5) right-to-left cardiac or pulmonary shunting

SYSTEMS AFFECTED

- All organs—oxygen essential for normal cellular function; individual tissue oxygen requirements vary by organ.
- Cardiovascular—can result in focal or global ischemia; if prolonged, can develop arrhythmias and cardiac failure.
- Nervous—brain and CNS most important; hypoxemia can result in irreversible brain damage because there are no large oxygen stores in brain tissue.

SIGNALMENT

Any breed, age, and sex of dogs and cats

SIGNS

Historical Findings

- Episodes of coughing
- Breathing problems—especially open-mouth breathing
- Trauma
- Gagging
- Exercise intolerance
- Cyanosis
- Collapse

Physical Examination Findings

- Tachypnea
- Dyspnea
- Orthopnea
- Pale mucous membranes
- Cyanosis
- Coughing
- Open-mouth breathing
- Tachycardia
- Poor peripheral pulse
- Abnormal thoracic auscultation

CAUSES

- Low PIO_2 —high altitude (the higher the elevation, the lower the barometric pressure, which results in a decrease in PIO_2 ; FIO_2 is fixed at 0.21); suffocation; enclosure in small areas with improper ventilation.
- Hypoventilation—result of inadequate alveolar ventilation; muscular paralysis; upper

airway obstruction; air or fluid in the pleural space; restriction of the thoracic cage, diaphragmatic hernia; CNS disease.

- Mismatching of alveolar ventilation and perfusion—most common cause of hypoxemia and occurs with virtually any lung disease: pulmonary thromboembolism; pulmonary parenchymal disease (infectious or neoplastic); lower airway disease; pneumonia; pulmonary contusions; pulmonary edema; also during anesthesia or prolonged recumbency when a large region of lung becomes atelectatic.
- Alveolar–capillary membrane diffusion impairment—rarely clinically important.
- Right-to-left cardiac or pulmonary shunting—tetralogy of Fallot; ventricular septal defect; reversed patent ductus arteriosus; intrapulmonary arteriovenous shunt.

RISK FACTORS

- Sudden move to higher elevation
- Trauma
- Bronchopneumonia
- Pleural disease
- Anesthesia
- Cardiac disease
- Bronchial disease—chronic bronchitis, feline asthma
- Geriatric pulmonary or cardiac changes
- Diseases associated with risk of embolization, e.g., immune mediated hemolytic anemia, hyperadrenocorticism, neoplasia, pancreatitis, sepsis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Signs of tachypnea and/or dyspnea
- Excitement or anxiety
- Hyperthermia
- Pyrexia
- Head trauma
- Pain

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

N/A

Disorders That May Alter Laboratory Results

- Air bubbles in the arterial blood sample—falsely high PaO_2 values.
- Improper packaging of the arterial blood sample—falsely high PaO_2 values after approximately 30 minutes at room temperature.

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- PCV—can be high with chronic condition; can be low if inflammatory or neoplastic.
- Liver enzyme elevation common with organ hypoxia.

OTHER LABORATORY TESTS

Arterial Blood Gases

- Collect arterial blood sample in an anaerobic manner, as follows: Use enough heparin to coat the needle and the inside of the syringe. Collect sample from femoral or dorsal pedal artery. Place a rubber stopper on the needle or covering the hub of the syringe, to prevent room air from entering the sample. Analyze sample within 15 minutes if left at room temperature; place sample on ice to extend safe time for analysis to 2–4 hours.
- Bedside or portable blood gas analyzers—several models available; make analysis more convenient.

IMAGING

Thoracic radiographs and echocardiography—evaluate intrathoracic disease; differentiate pulmonary and cardiac disease.

DIAGNOSTIC PROCEDURES

Pulse Oximetry

- Indirectly determines SaO_2 ; relation between PaO_2 and SaO_2 based on the oxyhemoglobin dissociation curve: $\text{SaO}_2 > 90\%$ when $\text{PaO}_2 > 60 \text{ mmHg}$.
- $\text{SaO}_2 < 95\%$ —considered abnormal, indicates $\text{PaO}_2 < 80 \text{ mmHg}$.
- Best results when probe used on the tongue of animals; thus may be limited to anesthetized, heavily sedated, or seriously ill patients with a low level of consciousness; keep tongue moistened for most accurate readings.
- Other successful probe sites—lip, ear; vulva (female), and prepuce (male); skin between toes; thin skin in the flank area.
- Poor results—least accurate in low-flow states such as hypotension (global low flow) or hypothermia (low flow to skin); falsely low values (usually < 85%) during carboxyhemoglobinemia (smoke inhalation).
- Rectal probes—should become available; will allow readings in awake patients.

Endoscopy or Lung Biopsy

Airway sampling often required to determine primary abnormality resulting in hypoxemia.

TREATMENT

Must identify and correct the primary cause.

OXYGEN THERAPY

- Most common supportive treatment.
- Corrects low-inspired oxygen, hypoventilation, and alveolar–capillary membrane diffusion defects; may not fully correct mismatching of ventilation and perfusion; does not correct right-to-left cardiac or pulmonary shunts and low cardiac output.
- May not be completely beneficial until adequate blood volume is established.

HYPOXEMIA

(CONTINUED)

- Delivery—directly from an oxygen source from the anesthetic machine via a face mask placed securely around the muzzle or from an E-tank fitted with an oxygen regulator through a face mask, intranasal catheter, or oxygen cage.
- Increase in FIO_2 —determined by the oxygen flow rate and the amount of oxygen mixed with room air.
- PPV—may be needed for ARDS or severe hypoventilation.

FLUID THERAPY

- Low cardiac output—fluid administration and inotropic support (e.g., dobutamine or dopamine) important.
- Cardiac failure—requires aggressive medical treatment; diuretics; afterload and preload reduction; inotropic support; oxygen administration; fluids indicated after institution of primary treatment; use caution with type and rate of fluids after initial stabilization.
- Hypovolemic, hemorrhagic, traumatic, or septic shock—requires aggressive fluid administration; crystalloids (90 mL/kg as fast as possible), hypertonic solutions (7% NaCl, 4 mL/kg), colloids (hetastarch, 20 mL/kg), hemoglobin-based oxygen-carrying solutions, or combination.
- Severe pulmonary contusion—hypertonic fluids or colloids, or combination preferred.

MEDICATIONS

DRUG(S) OF CHOICE

For bronchospasm—bronchodilators; terbutaline (0.01 mg/kg SC, IM, or IV q8h).

CONTRAINDICATIONS

- Aggressive fluid administration—not indicated for cardiac failure and pulmonary edema.

- Diuretics—not indicated for shock, low PIO_2 , alveolar–capillary membrane diffusion defects, mismatching of alveolar ventilation and perfusion, and right-to-left shunts.

PRECAUTIONS

- Inotropic drugs—arrhythmias may develop.
- Oxygen toxicity—from prolonged (> 12 hour) exposure to high-concentration (> 70%) oxygen; pulmonary edema, seizures, and death.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Decrease in respiratory effort and a decrease in cyanosis (if initially noted)—check efficacy of treatment and support.
- Arterial blood gas—determine resolution.
- Pulse oximetry—alternative; interpret results cautiously with hypotension, hypothermia, smoke inhalation, and non-tongue probe site.

POSSIBLE COMPLICATIONS

- Brain damage—depends on severity and duration of hypoxemia; partial or complete loss of neuronal function; dementia; seizures; loss of consciousness.
- Arrhythmias—may develop secondary to myocardial hypoxia; may be very difficult to treat effectively.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

PREGNANCY/FERTILITY/BREEDING

May adversely affect fetuses, especially during the first trimester of pregnancy.

BASICS

DEFINITION

Increased total bilirubin concentration causing yellow tissue discoloration

PATOPHYSIOLOGY

- Bilirubin—derived from degradation of heme-containing proteins; most (80%) from senescent erythrocytes; remainder from other heme-containing proteins (e.g., P450 cytochromes, myoglobin).
- Unconjugated bilirubin—transported in plasma bound to albumin; diglucuronide conjugated after hepatocellular uptake.
- Conjugated bilirubin—transported in bile and expelled into the intestines where most is converted to other products: e.g., urobilinogen can undergo enterohepatic circulation, stercobilin colors feces brown.
- Hyperbilirubinemia—caused by increased bilirubin production (increased RBC destruction; *hemolytic jaundice*); heme exceeding the hepatic capacity for uptake, conjugation, or biliary excretion (*hepatocellular jaundice*), or interrupted biliary elimination (*post-hepatocellular jaundice*).
- Non-hemolytic jaundice is caused by hepatobiliary disease or bile peritonitis.

SYSTEMS AFFECTED

- Skin/Exocrine—skin discoloration (jaundice) reflects serum bilirubin > 2.5 mg/dL.
- Hepatobiliary—retained bile acids and markedly increased bilirubin may contribute to hepatocellular injury.
- Renal/Urologic—extreme hyperbilirubinemia may cause renal tubular injury.
- Nervous—extreme unconjugated hyperbilirubinemia may cause degenerative brain lesions (rare, kernicterus).

SIGNALMENT

Species

Dog and cat

Mean Age and Range

- Most causes—diseases of adult animals
- Young, unvaccinated dogs—at risk for infectious canine hepatitis

Predominant Sex

Adult female pure-bred dogs—at risk for immune-mediated hemolytic anemia

SIGNS

Historical Findings

Increased Formation—Hemolysis

- Vague signs: lethargy, weakness
- Gastrointestinal signs: anorexia, constipation, vomiting, weight loss • Jaundice
- Recent blood transfusion • Severe trauma: bleeding into muscle, abdomen, or hematoma formation • Rhabdomyolysis (rare cause)

Decreased Elimination—Cholestasis

- Vague GI signs: anorexia, vomiting, diarrhea, change in fecal color: non-obstructive jaundice is green, orange; obstructed jaundice is acholic. • Jaundice.

- Change in urine color: orange.
- Abdominal enlargement: if ascites.
- Polyuria and polydipsia.
- Altered mentation: if HE.

Physical Examination Findings

Increased Formation—Hemolysis

- Pallor, tachycardia, tachypnea, weakness, bounding femoral pulses, anemic heart murmur • Jaundice • Hepatomegaly/ Splenomegaly: EMH, RE hyperplasia
- Lymphadenopathy • Bleeding tendencies if thrombocytopenic • Orange feces • Fever • “Gelatinous” feel to skin (vasculopathy)
- Rhabdomyolysis: weakness, pain

Decreased Elimination—Cholestasis

- Weight loss • Jaundice • Hepatomegaly/ Splenomegaly • Abdominal effusion/Mass/Pain • Melenic, Orange, Green, or Acholic feces • Fever

CAUSES

Prehepatic Jaundice

- Hemolytic disorders: immune-mediated hemolysis; certain drugs (propylene glycol carriers in cats, trimethoprim sulfate); SLE; infectious disorders; toxins (e.g. oxidative injury: zinc, onions; phenols); severe hypophosphatemia • Incompatible blood transfusion • Infections—FeLV; *Mycoplasma haemofelis*; heartworm; *Babesia*; *Ehrlichia*; *Cytauxzoon* • Large volume blood resorption—hematomas, body cavities (e.g. hemangiosarcoma, warfarin)

Hepatic Jaundice

- Chronic idiopathic or familial hepatitis
- Adverse drug reactions—e.g., anticonvulsants; acetaminophen; trimethoprim sulfate; carprofen; stanozolol (cats); benzodiazepines (cats) (see Hepatotoxins)
- Cholangitis/cholangiohepatitis • Infiltrative neoplasia—lymphoma
- Cirrhosis (dogs) • Hepatic lipidosis (cats) • Massive liver necrosis: e.g., aflatoxin, cycad, NSAIDs (carprofen), copper associated injury • Systemic illnesses with hepatic involvement—leptospirosis (dogs); histoplasmosis; FIP; hyperthyroidism (cats); toxoplasmosis (cats) • Bacterial sepsis—originating anywhere in the body; may elaborate bacterial products that impair hepatic bilirubin processing/elimination.

Posthepatic Jaundice

Transient or persistent mechanical bile duct obstruction: (1) pancreatitis (transient obstruction); (2) neoplasia—bile duct, pancreas, duodenum; (3) intraluminal duct occlusion—cholelithiasis, sludged bile, liver flukes (cats), immune-mediated duct destruction (sclerosing cholangitis in cats), GB mucocele (dogs); (4) ruptured biliary tree causing bile peritonitis.

RISK FACTORS

- Young unvaccinated dogs—infectious disease, canine infectious hepatitis.
- Breed predisposition for familial hepatic disease—Labrador retriever, Doberman pinscher, Bedlington terrier, Cocker spaniel, Dalmatian

- Middle-aged, obese dogs—pancreatitis
- Anorectic, obese cats—hepatitis
- Lipidosis • Hepatotoxic drugs • Blunt abdominal trauma, chronic biliary tract disease, gallbladder mucocele—bile peritonitis
- Hemolytic anemia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Prehepatic jaundice—usually abrupt onset; mucous membrane pallor; mild to moderate jaundice; weakness; tachypnea; cardiac murmur with severe anemia.
- Hepatic jaundice—breed risk for familial hepatitis; variable jaundice; otherwise normal mucous membranes; alteration in liver size (large or small); abdominal effusion (pure or modified transudate); polyuria and polydipsia; behavioral abnormalities of HE; coagulopathy.
- Posthepatic jaundice—chronic and/or recurrent bouts of apparent GI signs or pancreatitis with cholelithiasis; moderate or marked jaundice; otherwise normal mucous membranes; diffuse or cranial abdominal pain; cranial abdominal mass; abdominal effusion (septic, nonseptic, or bile peritonitis); bleeding tendencies; acholic feces unless melena.

LABORATORY FINDINGS

Disorders That May Alter Laboratory Results

- Bilirubin assay—based on the diazo reaction; assesses direct-reacting and total serum bilirubin; most yield reasonable total bilirubin results; values for direct bilirubin vary.
- Higher readings in heparinized plasma.
- Sample management—important; total bilirubin may decrease by 50% per hour with direct exposure to sunlight or artificial lighting.
- Hemolysis—variable effects on total bilirubin measured by spectrophotometry.
- Lipemia—falsely increases total bilirubin values measured by endpoint assays.
- Fractionation into conjugated and unconjugated—*unable to define causes of jaundice*, contrary to dogma.

CBC/BIOCHEMISTRY/URINALYSIS

Prehepatic Jaundice

- CBC—severe anemia (usually regenerative); blood smear may reveal autoagglutination, spherocytes, Heinz bodies, or parasites; hemoglobinemia with intravascular hemolysis, normal to low platelets, and normal to high WBCs, with a left shift.
- Biochemistry—normal to high ALT and ALP activity and BUN concentration; normal to low albumin; normal to high globulin; normal glucose and cholesterol; high bilirubin.

Hepatic Jaundice

- CBC—mild nonregenerative anemia; low MCV with chronic liver disease and

ICTERUS

(CONTINUED)

portosystemic shunting; variable WBC count. • Biochemistry—mildly to markedly high ALT ± ALP; normal to low albumin, BUN, glucose, and cholesterol. • Urinalysis—normal to dilute urine; bilirubinuria precedes hyperbilirubinemia; bilirubinuria is important in cats.

Posthepatic Jaundice

- CBC—± mild nonregenerative anemia; variable WBC count. • Biochemistry—increased ALT and moderate to markedly increased ALP; usually normal albumin, BUN, and glucose concentrations; normal to high cholesterol.

OTHER LABORATORY TESTS

- In-Saline autoagglutination slide test—with suspected RBC agglutination; may have reported high MCV. • Direct Coombs' test—submit if no evidence of autoagglutination.
- Osmotic fragility test—detects likelihood of RBC hemolysis tonicity challenge. • Blood smears—hemoparasites, spherocytes, schistocytes, anisocytosis (regenerative).
- Plasma zinc—if hemolytic anemia.
- ANA—with hemolytic anemia. • Serum bile acids—redundant if nonhemolytic jaundice already suspected. • Serology—for infectious diseases (e.g., FeLV, leptospirosis, mycoses) with signs of multisystemic illness and hepatic jaundice. • Abdominal effusion—characterize cell and protein content.
- Coagulation tests—prolonged values, especially PIVKA and PT, with bile duct occlusion; vitamin K₁ responsive. • Microbial culture and sensitivity—blood ± other specimens if inflammatory leukon and suspected bacterial infection (e.g., urinary tract, biliary tract, liver).

IMAGING

- Abdominal radiography—obscured by effusion; may reveal hepatomegaly, mass effect, mineral or gas interface in liver (emphysematous cholecystitis, choleliths); splenomegaly (hemolytic anemia, portal hypertension, abdominal neoplasia); metallic foreign body with zinc-induced hemolysis.
- Thoracic radiography—may reveal metastatic disease; sternal lymphadenopathy (reflecting abdominal disease); general lymphadenopathy (lymphosarcoma, systemic infection [fungal]). • Abdominal ultrasonography—may distinguish parenchymal liver disease from extrahepatic biliary obstruction; characterizes hepatic parenchymal lesions; may disclose abdominal neoplasia; may determine cause of abdominal effusion; used to target lesions, fluid, or cystocentesis sampling (aspirates or needle biopsy).

OTHER DIAGNOSTIC PROCEDURES

- Fine-needle aspiration—cytology of mass, lymph node, hepatic parenchyma, bile.
- Liver biopsy—bacterial culture of liver, bile, and other specimens obtained via celiotomy, blind percutaneous, keyhole, laparoscopic, or

ultrasound-guided techniques. • Surgical intervention—required for diagnosis and treatment of posthepatic disorders.

**TREATMENT**

- Depends on underlying cause
- Inpatient—for initial medical care. • Cage rest—to facilitate liver regeneration or reduce oxygen requirements if severe anemia.
- Diet—important for hepatic and posthepatic jaundice; nutritionally balanced with maximum protein tolerated by patient; carbohydrate based (dogs) with restricted protein for hepatic encephalopathy; restrict sodium if ascites. • Vitamin supplementation—water-soluble vitamins in all patients; parenteral vitamin K₁ for bile duct obstruction or severe cholestasis.

**MEDICATIONS****DRUG(S)**

- Prehepatic jaundice—eliminate inciting cause; see Anemia, Immune-Mediated; whole blood transfusion for life-threatening anemia.
- Hepatic/Posthepatic jaundice—treat specific disorders based on imaging, biopsy, and culture.

CONTRAINDICATIONS

- Avoid known hepatotoxic drugs. • Avoid tetracyclines unless clearly indicated—suppress hepatic protein synthesis, promote hepatic lipidosis. • Avoid analgesics, anesthetics, barbiturates—with hepatic failure.

PRECAUTIONS

- Sedatives—may precipitate HE.
- Corticosteroids—for nonseptic inflammation; increases risk for infection; may aggravate ascites (water and sodium retention), promotes VH (dogs) and hepatic lipidosis (cats).

POSSIBLE INTERACTIONS

Consider influence of altered hepatic metabolism on drug therapy; hypoalbuminemia influences potency of protein-bound drugs, enhancing effects (may lead to toxicity).

**FOLLOW-UP****PATIENT MONITORING**

- Prehepatic jaundice—recheck PCV and blood smears as needed; may require repeat transfusions; taper immunosuppressive drugs.
- Hepatic and posthepatic jaundice—recheck serum biochemical profile as dictated by underlying disease; continue symptomatic

and specific treatments until remission, varies with disease process.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Patients with immune-mediated hemolysis treated with immunosuppressive doses of corticosteroids are predisposed to thromboembolism, gastrointestinal ulcers, and infection. • Patients in hepatic failure: are susceptible to infections, enteric bleeding, and ascites. • Patients with reconstructive biliary surgery have risk for recurrent bacterial cholangitis.

IDIOVENTRICULAR RHYTHM

BASICS

DEFINITION

If conduction of sinus node pacemaker impulses to the ventricles is blocked or the impulses decrease in frequency, the lower regions of the heart automatically take over the role of pacemaker for the ventricles, which results in ventricular escape complexes (Figure 1) or an idioventricular rhythm (Figure 2).

ECG Features

- A series of ventricular escape beats with a heart rate < 65 bpm in dogs and < 100 bpm in cats; heart rates of 65–100 bpm in dogs and 100–160 bpm in cats are often termed accelerated idioventricular rhythms.
- P waves may be absent or may precede, be hidden within, or follow the ectopic QRS complex.
- P waves are unrelated to the QRS complexes.
- QRS configuration—wide and bizarre; similar to that of a ventricular premature complex.

PATOPHYSIOLOGY

- May be hemodynamically important with slow ventricular rates.
- Does not occur in healthy animals.
- Subsidiary pacemakers seem to discharge more rapidly in cats than in dogs.

SYSTEMS AFFECTED

Cardiovascular

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

SIGNALMENT*Species*

Dog and cat

Breed Predilections

- Atrial standstill in English springer spaniels and Siamese cats
- Pugs, miniature schnauzers, and Dalmatians prone to conduction abnormalities

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS*Historical Findings*

- Some animals asymptomatic
- Weakness
- Lethargy
- Exercise intolerance
- Syncope
- Heart failure

Physical Examination Findings

- Irregular rhythm associated with pulse deficits
- Variation in heart sounds

- Possible intermittent “cannon” waves in the jugular venous pulses (with AV block)

CAUSES

- Not a primary disease—a secondary result of a primary disease
- The escape rhythm is a safety mechanism to maintain cardiac output

Causes of Sinus Bradycardia and Sinus Arrest

- Increased vagal tone (high intracranial pressure, high ocular pressure)
- Drugs—digoxin, tranquilizers, propranolol, quinidine, and anesthetics
- Addison’s disease
- Hypoglycemia
- Renal failure
- Hypothermia
- Hyperkalemia
- Hypothyroidism

Causes of AV Block

- Congenital
- Neoplasia
- Fibrosis
- Lyme disease

RISK FACTORS

N/A

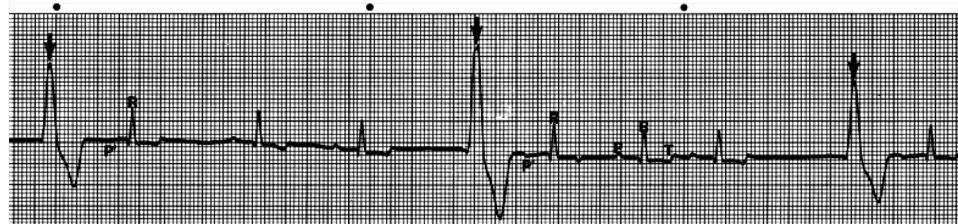

Figure 1.

Ventricular escape complexes (arrows) during various phases in the dominant sinus rhythm in a dog during anesthesia. The sinus rate increased (not shown) after anesthesia was stopped; 1/2 cm-1 mv. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

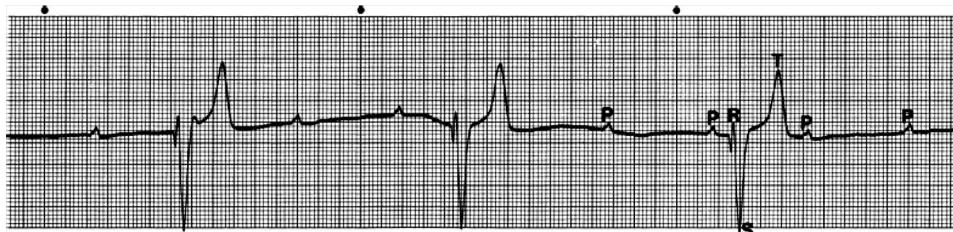

Figure 2.

Complete heart block. The P waves occur at a rate of 120, independent of the ventricular rate of 50. The QRS configuration is a right bundle branch block pattern. The regular rate and stable QRS indicate that the rescuing focus is probably near the AV junction. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

IDIOVENTRICULAR RHYTHM

(CONTINUED)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ventricular tachycardia—dogs have a cardiac rate > 100 bpm; cats > 150 bpm.
- Slow heart rate in animals with right bundle branch block, left bundle branch block, or left anterior fascicular block; animals with these disturbances have the P waves associated with the QRS complexes.

CBC/BIOCHEMISTRY/URINALYSIS

- No specific findings
- Complete blood testing may suggest a metabolic abnormality

OTHER LABORATORY TESTS

- Drug toxicity
- Lyme's titer in animals with complete AV block

IMAGING

Echocardiogram may show structural heart disease.

DIAGNOSTIC PROCEDURES

Electrocardiography

PATHOLOGIC FINDINGS

Depend on underlying cause

TREATMENT

APPROPRIATE HEALTH CARE

- Rhythm is an escape or safety mechanism for maintaining cardiac output; do *not* direct treatment toward suppressing this escape rhythm, but toward the primary disease process that allows the escape rhythm to assume pacemaker control of the heart.
- Symptomatic treatment is directed toward increasing the heart rate.

NURSING CARE

May be required for underlying disease.

ACTIVITY

Symptomatic animals may require cage rest.

DIET

No modifications or restrictions unless required for management of the underlying condition.

CLIENT EDUCATION

Inform of the need to seek and specifically treat an underlying cause.

SURGICAL CONSIDERATIONS

Pacemaker implantation may be necessary.

MEDICATIONS

DRUG(S) OF CHOICE

- Atropine or glycopyrrolate usually indicated to block vagal tone or increase the heart rate.
- If those drugs are ineffective, isoproterenol, dopamine, dobutamine, or artificial pacing may be needed.

CONTRAINDICATIONS

Lidocaine, procainamide, quinidine, propranolol, diltiazem, or any other drug that slows the cardiac rate or reduces contractility.

PRECAUTIONS

Atropine is briefly vagotonic immediately post-injection and can temporarily exacerbate the condition.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Serial ECG may show clearing of the lesion or progression to complete heart block.
- Serial blood profiles may be needed to monitor progress of the primary disease process.
- Serial echocardiograms may show improvement or progressive changes in cardiac structure.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Prolonged bradycardia may cause secondary congestive heart failure or inadequate renal perfusion.

EXPECTED COURSE AND PROGNOSIS

- Arrhythmia may abate when the primary disorder is corrected.
- Guarded if condition is associated with cardiac or metabolic disorder; poor if the rate is not increased pharmacologically or if underlying cause cannot be identified and treated.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

BASICS

OVERVIEW

- Adynamic (paralytic, functional) ileus is defined as a transient and reversible intestinal obstruction resulting from inhibition of bowel motility.
- Lack of peristalsis of stomach, small bowel, or large bowel causes functional obstruction, as intestinal contents accumulate in the dependent areas of the gastrointestinal tract instead of being propelled in an aboral direction.
- Ileus is not a primary disease but a secondary complication of a number of disorders.
- Adynamic ileus is thought to occur secondary to electromechanical dissociation of the intestinal musculature due to increased sympathetic tone, release of humoral inhibitory factors (catecholamines, vasopressin, endogenous opiates), impaired release of prokinetic hormones (neurotensin, motilin), or hypokalemia.
- Secondary causes of intestinal pseudo-obstruction have been subclassified into developmental, infectious, inflammatory, auto-immune, metabolic, paraneoplastic, endocrine, and toxic etiologies.
- Lymphocytic leiomyositis represents a visceral myopathic form of chronic intestinal pseudo-obstruction that has been described in humans, dogs, horses, and cats. It is defined as lymphocytic infiltration of the muscularis propria and is thought to represent an auto-immune response to the myofibers of the muscularis propria layer of the bowel by T-lymphocytes.

SYSTEMS AFFECTED

- Gastrointestinal
- Autonomic nervous system

SIGNALMENT

Cat and dog

SIGNS

- Anorexia
- Vomiting
- Regurgitation
- Lethargy
- Diarrhea
- Weight loss
- Mild abdominal distention or discomfort secondary to accumulation of gas in the hypomotile bowel
- Failure to auscultate gut sounds after 2–3 minutes suggests ileus
- Gut sounds can be increased during the initial state (partial loss of motility).

CAUSES & RISK FACTORS

- Surgery (especially gastrointestinal surgery)
- Electrolyte imbalance (hypokalemia, hypomagnesemia, hypocalcemia)

- Acute inflammatory lesions of the bowel, peritoneal cavity, pancreas, or other abdominal organs
- Unrelieved mechanical obstruction
- Intestinal ischemia
- Gram-negative sepsis
- Endotoxemia
- Shock
- Retroperitoneal injury
- Uremia
- Autonomic neuropathies (dysautonomia, spinal cord injury)
- Visceral myopathies associated with auto-immune disease
- Use of anticholinergic drugs
- Intestinal overdistension (aerophagia)
- Lead poisoning
- Stress (cold and noise)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Adynamic ileus must be differentiated from mechanical obstruction caused by:
 - Intestinal foreign bodies
 - Inflammatory bowel disease
 - Intussusception
 - Intramural abscess
 - Incarcerated or strangulated hernia
 - Volvulus
 - Mesenteric infarction
 - Parasites
 - Adhesions
 - Postoperative stricture
 - Impaction
 - Congenital malformation
 - Inflammatory or traumatic lesions
 - Neoplasia

CBC/BIOCHEMISTRY/URINALYSIS

- Hemogram changes depend on primary cause of ileus.
- Serum chemistry profiles and urinalysis help assess electrolyte disturbances (especially hypokalemia) and presence of azotemia.

OTHER LABORATORY TESTS

- Measurement of pancreatic lipase concentration (Spec or SNAP cPL or fPL) to assess for pancreatitis.
- Fecal parvovirus ELISA test in puppies with ileus and diarrhea.

IMAGING

Abdominal Radiographic Findings

- Stomach and/or intestinal loops are distended with gas and fluid. Common radiographic patterns include:
 - Generalized gas ileus—consider aerophagia, smooth muscle paralyzing drugs, generalized peritonitis, or enteritis
 - Generalized fluid ileus—consider enteritis, diffuse intestinal neoplasia
 - Localized gas ileus—consider localized peritonitis (pancreatitis), early bowel

obstruction, disruption of the arterial supply

- Localized fluid ileus—consider foreign body, neoplastic obstruction, intussusception.

Ultrasonography

- Differentiate adynamic ileus from mechanical intestinal obstructions.
- Identify pancreatitis or peritonitis.
- Careful evaluation of the intestinal layers for loss of normal layering associated with infiltrative neoplasia, thickening of the muscularis propria layer and/or submucosal layer associated with inflammatory bowel disease or small cell lymphoma, and attenuation of the muscularis layer associated with fibrosis secondary to leiomyositis.

DIAGNOSTIC PROCEDURES

BIPS (Barium-Impregnated Polyethylene Spheres)

- Confirm adynamic ileus.
- Delayed gastrointestinal transit along with retention of BIPS in the stomach.
- Scattering of BIPS throughout the entire upper gastrointestinal tract.

Upper Gastrointestinal (GI) Series

Upper GI series can be performed to help assess for presence of partial intestinal obstructions or delayed gastric and intestinal motility. Gastric and intestinal transit times must be interpreted cautiously following administration of liquid barium in light of marked variation in emptying times from animal to animal, and the stress of hospitalization can delay gastric and intestinal transit times.

Other Procedures to Consider

- Non-invasive electrogastrography is used experimentally to assess gastric myoelectrical activity in dogs.
- Abdominocentesis with peritoneal effusion to confirm peritonitis.
- Gastrointestinal endoscopy or exploratory laparotomy to rule out mechanical obstruction.
- Full-thickness intestinal biopsies are necessary to diagnose intestinal leiomyositis because the disorder affects the muscularis propria layer of the bowel which is typically not accessible via endoscopic biopsy.
- Spinal radiographs, myelogram, spinal MRI, CT, CSF analysis to identify spinal cord injury.
- Ocular response test with 0.1% pilocarpine and 0.25% physostigmine for dysautonomia.

TREATMENT

- Identify and treat the primary underlying cause.
- Correct electrolyte abnormalities (especially hypokalemia) if present.

ILEUS

(CONTINUED)

- Use of prokinetic drugs such as cisapride, metoclopramide or erythromycin should be considered, depending on the underlying cause.
- Gastrointestinal decompression of the stomach via nasogastric tube is beneficial in select cases.

MEDICATIONS

DRUG(S)

- Metoclopramide is most effective when administered as a CRI (1–2 mg/kg/24h). Intravenous bolus injections (0.4 mg/kg IV q6h) are less effective in light of the relatively short half-life (90 min) in dogs.

Metoclopramide does not affect colonic motility and should be avoided in animals with colonic ileus or megacolon.

- Cisapride (0.3–0.5 mg/kg q12h) is a far more potent and effective prokinetic compared to metoclopramide and affects gastric, small intestinal, and colonic motility.
- Erythromycin (1–2 mg/kg PO q12h) has prokinetic activity on the stomach and small intestine.
- Cyclosporine (5 mg/kg q12–24h) can be administered for management of intestinal leiomyositis or other immune-mediated disorders affecting the intestinal tract.
- Prednisone (1 mg/kg q12h with progressive tapering over 10–12 weeks) can be administered for management of leiomyositis or inflammatory bowel disease.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Anticholinergic drugs (e.g., atropine, glycopyrrrolate)

- Opiates (e.g., morphine, hydromorphone, oxymorphone, butorphanol)
- Opiate antidiarrheals (e.g., paregoric, diphenoxylate hydrochloride/atropine sulfate, loperamide hydrochloride)

FOLLOW-UP

PATIENT MONITORING

- Monitor and correct electrolyte imbalance if present.
- Abdominal auscultation to evaluate gastrointestinal motility.
- Survey abdominal radiographs to evaluate gastric and intestinal distension.

PREVENTION/AVOIDANCE

Avoid anticholinergic drugs and opiates if not indicated.

POSSIBLE COMPLICATIONS

Animals with adynamic ileus are predisposed to the development of intestinal dysbiosis, bacterial translocation, and sepsis.

EXPECTED COURSE AND PROGNOSIS

Prognosis depends on successful resolution of primary disease process.

MISCELLANEOUS

ASSOCIATED CONDITIONS

See "Causes & Risk Factors"

PREGNANCY/FERTILITY/BREEDING

Ileus has been reported in a lactating bitch with hypomagnesemia and hypocalcemia.

SYNONYMS

- Adynamic ileus—functional ileus, paralytic ileus.
- Pseudo-obstruction—chronic, more segmental adynamic ileus.
- Mechanical ileus—generally addressed in current literature as mechanical obstruction.

ABBREVIATIONS

- CSF = cerebrospinal fluid
- CT = computed tomography
- ELISA = enzyme-linked immunosorbent assay
- MRI = magnetic resonance imaging

ILICIT/CLUB DRUG TOXICOSIS

BASICS

OVERVIEW

Intoxication with illicit and club drugs covers a wide range of pharmaceuticals. Included in this list are barbiturates, benzodiazepines (see Benzodiazepines and Other Sleep Aids Toxicosis), cocaine, GHB, LSD, marijuana, MDMA, methamphetamine and other designer amphetamines (see Amphetamines and ADD/ADHD Medication Toxicosis), opioids, and PCP.

PATHOPHYSIOLOGY

- Barbiturates: sedative hypnotics with anticonvulsant effects causing CNS depression.
- Cocaine: increases CNS norepinephrine, serotonin and dopamine levels, increases catecholamine release and is a myocardial stimulant causing CNS and cardiac stimulatory signs.
- GHB: synthetic GABA derivative causing CNS depression.
- LSD: CNS stimulation and hallucinations by increasing serotonin and glutamate in the CNS, binds dopamine and α -adrenergic receptors.
- Marijuana: binds to cannabinoid receptors in the CNS, and affects dopamine, GABA, histamine, 5-HTP, norepinephrine, and prostaglandin levels leading to sedation or agitation.
- MDMA: increases serotonin, catecholamine and dopamine in the CNS, leading to CNS stimulation and hallucinations.
- Opioids: bind to opioid receptors causing CNS depression.
- PCP: Inhibits glutamate and stimulates α -adrenergic receptors, which potentiates the effects of norepinephrine, epinephrine, and serotonin. It is a sympathomimetic and hallucinogen.

Systems Affected

- Cardiovascular: Cocaine, GHB, LSD, MDMA, methamphetamine, PCP—arrhythmias, hypertension; Barbiturates, marijuana, opioids—arrhythmias, hypotension.
- Musculoskeletal: Cocaine, PCP—tremors.
- Nervous: Cocaine, LSD, MDMA—stimulatory effect; Barbiturates, GHB—depressive effect; Marijuana, opioids, PCP—sedative to stimulatory effects, ataxia.
- Ophthalmic: Cocaine, LSD, MDMA—mydriasis; Opioids – miosis.
- Respiratory: Barbiturates, opioids—respiratory depression (rare).

SIGNS

- Barbiturates—sedation (rarely agitation), ataxia, bradycardia, hypotension, respiratory depression (rare), coma.
- Cocaine—agitation, mydriasis, tachycardia, hypertension, tremors, seizures.
- GHB, opioids—lethargy, weakness, coma, respiratory depression.
- LSD—mydriasis, disorientation, hallucinations, agitation (rarely sedation), tachycardia.
- Marijuana—sedation (sometimes agitation), ataxia,

hypotension, coma.

- MDMA—agitation, mydriasis, hyperthermia, tachycardia, tremors, hallucinations, seizures, death.
- PCP—depression to agitation, hypertension, tachycardia, tremors, seizures.

CAUSES & RISK FACTORS

Ingestion of club drugs may occur in animals that live with people who take these pharmaceuticals or police dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Barbiturates, GHB, opioids—meningitis, meningoencephalitis, hepatic encephalopathy, ethanol, ethylene glycol, phenothiazines.
- Cocaine—caffeine, metaldehyde, MDMA.
- LSD, PCP—ketamine, MDMA, psilocybin.
- Marijuana—psilocybin, MDMA, amphetamines, benzodiazepines, barbiturates, serotonergic medications (SSRIs, TCAs, MAOIs).
- MDMA—meningitis, meningoencephalitis, hepatic encephalopathy, amphetamines, cocaine, metaldehyde, psilocybin, serotonergic medications (SSRIs, TCAs, MAOIs).

CBC/BIOCHEMISTRY/URINALYSIS

No direct abnormalities. May detect CK and K elevation (rhabdomyolysis) and myoglobinuria secondary to tremors.

OTHER LABORATORY TESTS

OTC illicit drug screens (urine) are available for barbiturates, benzodiazepines, cocaine, marijuana, MDMA, methamphetamine, opioids, and PCP. The OTC tests are not approved for use in animals but appear to be reliable except for the marijuana test (false negatives). All can be detected using GC/MS in a human hospital or diagnostic laboratory but turn-around time decreases the usefulness of these tests.

TREATMENT

- Inpatient care should be provided in a dark quiet place. Thermoregulation is important, along with fluid therapy to maintain body temperature and BP. Fluids will also help to protect the kidneys from myoglobinuria.
- Monitor for respiratory depression (barbiturates, opioids). Intubate and ventilate if needed.
- Emesis (if asymptomatic and recent ingestion) or gastric lavage (if large amount ingested).

MEDICATIONS

DRUG(S)

- Activated charcoal (1–2 g/kg PO) with cathartic (if severe signs are expected).

- Agitation: phenothiazines (acepromazine 0.025–0.05 mg/kg IV, titrate up as needed); cyproheptadine (dog, 1.1 mg/kg; cat, 2–4 mg PO q4–6h or can be given rectally if vomiting).
- Agitation, seizures: benzodiazepines (diazepam 0.5–2 mg/kg IV) (see "Contraindications").
- Tremors: methocarbamol (dog, cat 50–150 mg/kg IV).
- Tachycardia: propranolol (dog, cat 0.02 mg/kg IV).
- Naloxone: reversal agent for opioids (dog, cat 0.01–0.1 mg/kg IV).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Do not use diazepam when treating agitation secondary to MDMA (increases dysphoria and morbidity).

FOLLOW-UP

PATIENT MONITORING

Blood pressure, heart rate, urine color: q1h, then less frequently as the patient remains stable.

EXPECTED COURSE AND PROGNOSIS

Signs occur quickly (within minutes to hours). Most will have a good prognosis if treated and will recover in 24–36 hours. Marijuana ingestion signs could last up to 72 hours.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Barbiturates, LSD, cocaine, and MDMA have been associated with severe birth defects in humans and animals. Opioids and PCP cross the placenta and have been associated with fetal intoxications and low birth weight.

SEE ALSO

- Amphetamines and ADD/ADHD Medication Toxicosis
- Antidepressant Toxicosis—SSRIs and SNRIs
- Benzodiazepines and Other Sleep Aids Toxicosis

ABBREVIATIONS

- CK = creatine kinase
- GHB = gamma hydroxybutyric acid
- LSD = lysergic acid diethylamide
- MAOI = monoamine oxidase inhibitor
- MDMA = methylenedioxymethamphetamine, ecstasy
- PCP = phencyclidine
- SSRI = selective serotonin reuptake inhibitor

IMMUNODEFICIENCY DISORDERS, PRIMARY

BASICS

DEFINITION

Diminished ability to mount an effective immune response due to heritable defects in the immune system.

PATHOPHYSIOLOGY

- Defects in the cell-mediated, humoral, complement, and phagocytic systems have all been described in the veterinary literature.
- Defects involving the humoral immune response—associated with a high susceptibility to bacterial infection.
- Defects involving the cell-mediated immune response—associated with a high susceptibility to viral, fungal, and protozoal infections.
- Defects in the phagocytic or complement system—associated with disseminated infection.

SYSTEMS AFFECTED

- Hemic/Lymphatic/Immune—defect in a specific cell population in lymphoid tissue.
- Skin/Exocrine/Respiratory/Gastrointestinal—chronic or recurrent infections.
- Other organ systems—dissemination of infection, failure to thrive.

GENETICS

Typically breed-specific with variable modes of inheritance.

INCIDENCE/PREVALENCE

Rare

SIGNALMENT

Species

Dog and cat

Breed Predilections

- X-linked severe combined immunodeficiency—basset hounds, Cardigan Welsh corgis.
- Severe combined immunodeficiency disease—Jack Russell terriers.
- IgA deficiency—beagles, German shepherds, and Chinese Shar-Peis.
- IgM deficiency—Doberman pinschers.
- Thymic hypoplasia—dwarfed Weimaraners.
- Cyclic hematopoiesis—gray collies.
- Chediak-Higashi syndrome—Persian cats.
- Leukocyte adhesion deficiency—Irish setters.
- Complement deficiency—Brittany spaniels.
- Bactericidal defect—Doberman pinschers.
- Transient hypogammaglobulinemia—Samoyeds.

Mean Age and Range

Primary immunodeficiency diseases typically expressed in the first year of life.

Predominant Sex

X-linked recessive severe combined immunodeficiency disease of basset hounds—males affected and females are carriers.

SIGNS

General Comments

Depends on the level at which the immune response is defective; ranges from chronic respiratory and gastrointestinal signs and skin infections to life-threatening conditions.

Historical Findings

- High susceptibility to infection and failure to respond to appropriate, conventional antibiotic therapy.
- Lethargy.
- Anorexia.
- Skin infection.
- Failure to thrive.
- Signs often appear when maternal antibody concentrations decline.
- Vaccine-induced disease by modified live virus preparation.

Physical Examination Findings

- Hallmark—failure to thrive.
- Clinical signs attributable to infections.

CAUSES

Congenital

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Patients must be rigorously evaluated for underlying disease process that may cause secondary (acquired) immunodeficient state (e.g., hyperadrenocorticism, FeLV, and FIV).
- Patients are typically young with recurrent infection that fails to respond to conventional treatment.

CBC/BIOCHEMISTRY/URINALYSIS

CBC may indicate deficiencies in specifically affected cell lines or chronic inflammation.

OTHER LABORATORY TESTS

- Serum protein electrophoresis—demonstrate gross deficiency in immunoglobulin concentration.
- Serum immunoglobulin quantitation—evaluate humoral immune system, identify selective immunoglobulin deficiency, support diagnosis of agammaglobulinemia.
- The lymphocyte transformation test—evaluate the cell-mediated immune system and identify animals with T-lymphocyte deficiency.
- Bactericidal assays—evaluate neutrophil function.
- Serum concentration of complement components—diagnose complement deficiency.

- Enumeration of lymphocyte subsets by immunofluorescence with monoclonal antibodies—identify deficiency of specific cell lines.

- Other more specific tests to evaluate immune function in veterinary species are available, but obtaining reliable results generally requires access to research laboratories that perform these tests.

DIAGNOSTIC PROCEDURES

In some patients, bone marrow and lymph node biopsy aids in classifying the type of immune deficiency.

PATHOLOGIC FINDINGS

- Lesions vary; depend on the specific defect; most are the result of recurrent or opportunistic infection involving the skin, ear canal, and respiratory and gastrointestinal systems.
- Lesions of septicemia common in animals with severe defects.
- T-lymphocyte defects—hypoplastic or dysplastic lesions of the thymus and T-lymphocyte-dependent areas of secondary lymphoid tissues.
- B-lymphocyte defects—hypoplastic or dysplastic lesions of the bone marrow or B-lymphocyte-dependent areas of secondary lymphoid tissues.
- Lymphoid hypoplasia or hyperplasia may be seen, depending on the overall defect and the occurrence of infection.

TREATMENT

APPROPRIATE HEALTH CARE

- Hospitalization may be necessary to control life-threatening infection.
- Outpatient management possible for some patients.

NURSING CARE

Supportive care appropriate to the nature of the infection.

ACTIVITY

Determined largely by the severity of the defect and the occurrence of infection.

DIET

- Dietary management may be required to ensure that the patient is maintained at an adequate level of nutrition.
- Potential sources of infectious agents such as raw meat must be avoided.

CLIENT EDUCATION

- Inform client that the animal cannot be cured.
- Discuss why the patient has high susceptibility to infection.

(CONTINUED)

IMMUNODEFICIENCY DISORDERS, PRIMARY

- Discuss and advise as to the heritability of the disease.
- Discuss the possibility of littermates being affected.
- Avoid exposure to ill animals.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Antibiotics to control infections
- γ -Globulin or plasma preparations can be used in conjunction with antibiotics to control infection in patients with humoral defect.
- Symptomatic treatment for secondary disease states.

CONTRAINDICATIONS

γ -Globulin or plasma preparations should not be administered to patients with selective IgA deficiency because many affected patients have high concentrations of anti-IgA antibodies and may develop anaphylaxis.

PRECAUTIONS

Modified live virus vaccines should not be administered to patients with suspected T-lymphocyte deficiencies because they may induce disease in these patients.

**FOLLOW-UP****PATIENT MONITORING**

- For clinical signs of secondary infection.
- Routine physical examination to assess efficacy of antibiotic therapy.

PREVENTION/AVOIDANCE

- Do not breed affected animals.
- Pedigree analysis to determine the mode of inheritance and prevent propagating the defect.

POSSIBLE COMPLICATIONS

Infection

EXPECTED COURSE AND PROGNOSIS

- The severity of the defect determines the course and prognosis.
- Patients with minor defects can be successfully managed.

Consulting Editor Alan H. Rebar

I

IMMUNOPROLIFERATIVE ENTEROPATHY OF BASENJIS

BASICS

OVERVIEW

- An immunologically mediated disease characterized by progressive, chronic intermittent diarrhea, anorexia, and weight loss. These are associated with an intense lymphoplasmacytic, infiltrative gastroenteritis or enteritis and concurrent evidence of protein-losing enteropathy, malabsorption, and maldigestion.
- Hypergammaglobulinemia is present due to increased concentrations of serum IgA.
- Systems affected include gastrointestinal, immune, skin, renal, endocrine, and hepatobiliary.

I

SIGNALMENT

- Young to middle-aged Basenji—usually < 3 years of age
- Related dogs often affected

SIGNS

- Chronic intermittent diarrhea
- Severe progressive weight loss
- Anorexia often preceding diarrhea
- Bilaterally symmetric alopecia
- Decreased body condition score
- Attitude—usually bright and alert
- Vomiting is variable in severity but common

CAUSES & RISK FACTORS

- Pathogenesis is unclear but an interaction between abnormal immune responses, genotype and possibly a contribution by environmental factors is hypothesized.
- Mode of inheritance is not known.
- Episodic worsening of symptoms has been associated with stressful events—boarding, estrus, transport, vaccination, etc.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Lymphangiectasia, lymphoplasmacytic enteritis, eosinophilic enteritis, histoplasmosis, exocrine pancreatic insufficiency, intestinal lymphoma, intestinal microbial dysbiosis, giardiasis, metabolic disorders, intestinal parasitism.

CBC/BIOCHEMISTRY/URINALYSIS

- Hypoproteinemia
- Severe hypoalbuminemia
- Hyperglobulinemia
- Mature neutrophilia often present
- Poorly regenerative anemia associated with chronic inflammatory disease
- Moderately increased hepatic enzymes—seen with advanced disease

OTHER LABORATORY TESTS

- Hypergammaglobulinemia due to increased serum IgA.
- Depression of xylose absorption curve correlates with severity of clinical disease.
- May have hypergastrinemia and hyperchlorhydria.
- No one test or histologic finding is definitive or pathognomonic.

IMAGING

Abdominal ultrasound may demonstrate diffuse small bowel thickening (4–6 mm) or normal gastrointestinal wall layering, and lack of other visceral abnormalities.

OTHER DIAGNOSTIC PROCEDURES

- Endoscopic appearance of the small bowel usually appears abnormal but may be normal. Biopsies are always required for an accurate diagnosis.
- Genetic testing (DNA) is not available at this time.

PATHOLOGIC FINDINGS

- Consistent pathologic lesions include uniform thickening of the small bowel, generalized infiltration of the intestinal lamina propria with lymphocytes and plasma cells, and blunting and fusion of villous tips.
- May be gastric rugal fold hypertrophy, lymphocytic gastritis and/or gastric mucosal atrophy, blunting and widening of intestinal villi, and mild dilation of lacteals.
- Presence and severity of gastric lesions do not correlate with severity of intestinal lesions.
- Other associated lesions include thyroid parafollicular cell atrophy, ulceration of the pinna, gastric acinar atrophy, and glomerulonephritis.

TREATMENT

- Outpatient medical management unless dehydration or other severe complications exist.
- Advise clients not to breed affected dogs or their littermates.
- Minimize stressful episodes.
- Use dietary trials, often with reduced long chain triglycerides, to determine what diet is best tolerated.

MEDICATIONS

DRUG(S)

Immunosuppressive/Anti-inflammatory Drugs

- Variable success reported but considered the mainstay of treatment.

- Prednisone (1 mg/kg PO q12h for 2–4 weeks, then slowly taper over 3–4 months to achieve 0.5–1 mg/kg PO q48h).
- Chlorambucil (0.25 mg/kg PO q72h with monitoring for adverse effects) or other immunosuppressive medications can be tried.

Antibiotics

- Trials of antibiotics are variably helpful for affected individuals that may have intestinal microbial dysbiosis.
- Metronidazole (10–20 mg/kg PO q12–24h).
- Tylosin (5–10 mg/kg PO q24h).

Nutritional Supplements/Adjunctive Treatment

- Use of omega-3 fatty acid-rich diets or supplements is thought to potentially favor improved membrane stability and decreased inflammatory responses in the affected gut but there is little specific data available to support this hypothesis.
- Use of probiotics is commonly advised and may favor reduced risk of dysbiosis and a lowered state of inflammatory responses by the gut associated lymphoid tissues but no specific data are available to support this hypothesis.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Anticholinergics contraindicated

FOLLOW-UP

- Diarrhea and weight loss usually show initial improvement with treatment.
- Recurrence of signs is common.
- Long-term prognosis poor over the course of months to a few years.

Consulting Editor Stanley L. Marks

Client Education Handout
available online

BASICS

DEFINITION

Inability to retain feces, resulting in involuntary passage of fecal material.

PATHOPHYSIOLOGY

- Reservoir fecal incontinence develops when disease processes reduce the capacity or compliance of the rectum.
- Sphincter incontinence develops when the external anal sphincter is anatomically disrupted (i.e., non-neurogenic sphincter incontinence) or denervated (i.e., neurogenic sphincter incontinence).
- Neurogenic sphincter incontinence can be caused by pudendal nerve damage, sacral spinal cord disease, autonomic dysfunction, and generalized peripheral neuropathy or myopathy.
- Damage to, or degeneration of, the levator ani and coccygeus muscles may also contribute.

SYSTEMS AFFECTED

- Gastrointestinal • Nervous

GENETICS

No known genetic basis for development of any types of incontinence—reservoir, sphincter or neurogenic.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

- Dog and cat.
- Although any age animal may be affected, incidence increases in older patients.

SIGNS

Historical Findings

- Reservoir incontinence—promotes an urge to defecate; signs include frequent, conscious defecation without dribbling of feces; defecation may be associated with tenesmus, dyschezia, or hematochezia.
- Sphincter incontinence—associated with involuntary expulsion or dribbling of fecal material, especially during excitement or barking and coughing.
- Question clients about previous neurologic disease, anorectal surgery and/or trauma, house training, deworming, and whether the pet seems to defecate voluntarily or involuntarily; also obtain information regarding the pet's diet, current medications, and concurrent systemic clinical signs, especially neurologic signs.
- Concurrent urinary incontinence suggests neurogenic sphincter incontinence.

Physical Examination Findings

- Reservoir incontinence—may include anorectal sensitivity or pain on digital palpation, a rectal mass or thickening of the rectal mucosa; external anal sphincter

tone and non-neurogenic sphincter incontinence anal reflex are normal.

- Non-neurogenic sphincter incontinence—may include evidence of perineal trauma or perianal fistulas; the anal reflex is present, but the external anal sphincter may not completely close if the sphincter has been anatomically disrupted.
- Neurogenic sphincter incontinence—may include loss of tone to the external anal sphincter, but anal tone is a poor indicator of anal sphincter function; the anal reflex is absent or diminished.
- Do a complete neurologic examination on all animals with sphincter incontinence; additional findings suggesting lumbosacral spinal cord disease include loss of voluntary movement and tone to the tail, lumbosacral pain, flaccid posterior paresis or paralysis, and hyporeflexic myotatic reflexes to the pelvic limbs.
- Diffuse lower motor neuron signs suggest generalized peripheral neuropathy or myopathy; upper motor neuron signs to the pelvic limbs suggest CNS disease cranial to the lumbosacral plexus.

CAUSES

Reservoir Incontinence

- Colorectal disease—colitis, irritable bowel syndrome, and neoplasia.
- Diarrhea—large volumes of feces from any cause can overwhelm the absorptive and storage capacity of the colon.

Non-neurogenic Sphincter Incontinence

- Traumatic anal injuries—bite wounds, severely abscessed anal sacs, laceration, or gunshot.
- Iatrogenic—the external anal sphincter and levator ani muscles can be anatomically disrupted during anorectal surgery.
- Perianal fistulas.

Neurogenic Sphincter Incontinence

- CNS—degenerative myelopathy, spinal dysraphism, spina bifida, trauma, intervertebral disc extrusion, neoplasia, meningoileitis (various causes), fibrocartilaginous embolism, other vascular compromises.
- Cauda equina syndrome—L6–L7 or L7–S1 intervertebral disc extrusion, spondylosis deformans, congenital spinal canal stenosis, lumbosacral instability, discospondylitis, and neoplasia.
- Peripheral neuropathy—fungal, immune-mediated, drug-induced (e.g., vincristine sulfate), dysautonomia, and idiopathic.
- Myopathy/neuromuscular disorder.
- Degeneration (aging)—multiple factors are likely involved, including atrophy of the muscles involved in fecal continence, weakness, degenerative neuropathy, and senility.

RISK FACTORS

- Colonic disease
- Anorectal disease and surgery
- CNS disease and peripheral neuropathy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Gastrointestinal disease from any cause can increase the urge to defecate without directly altering the reservoir capacity of the colon.
- Unlike sphincter incontinence, gastrointestinal disease is often associated with weight loss, vomiting, tenesmus, dyschezia, and hematochezia.
- Behavior disorders (e.g., separation anxiety), unlike fecal incontinence, are often associated with destructive activities or excessive vocalization.
- Inadequate house training usually occurs in young dogs or dogs recently introduced to an indoor environment or in cats with litter box aversion (not enough boxes, soiled box, poor location, new litter, etc.).

CBC/BIOCHEMISTRY/URINALYSIS

- Results usually unremarkable.
- Urinalysis may show evidence of lower urinary tract infection (e.g., pyuria, hematuria), especially with concurrent urinary incontinence.

OTHER LABORATORY TESTS

- Perform fecal flotation to help rule out parasitism as a cause of diarrhea.
- A rectal scraping is indicated in regions where histoplasmosis or pythiosis are endemic.

IMAGING

- Lateral and ventrodorsal survey radiography of the lumbosacral spine may show evidence of intervertebral disc extrusion, discospondylitis, vertebral neoplasia, spina bifida, lumbosacral trauma, or vertebral malformation.
- Myelography and epidurography are also useful in demonstrating compressive lesions within the spinal canal.
- CT and MRI may be necessary to demonstrate some compressive lesions and intraparenchymal spinal cord lesions.

OTHER DIAGNOSTIC PROCEDURES

- Electromyography to evaluate external anal sphincter, levator ani, and coccygeus muscles for evidence of denervation or myopathy.
- Evaluation of other muscles recommended to help localize the neurologic lesion—diffuse denervation vs. focal spinal cord lesion.
- Can evaluate the pudendal-anal reflex electrophysiologically.
- Muscle and nerve biopsy for myopathy and peripheral neuropathy.
- Analysis of cerebrospinal fluid collected by lumbar puncture may reveal evidence of a CNS infectious or inflammatory process, neoplasia, or trauma.
- Perform colonoscopy and colorectal mucosal biopsy if reservoir incontinence is suspected.

TREATMENT

- If possible, identify the underlying cause; fecal incontinence may resolve if the

INCONTINENCE, FECAL

(CONTINUED)

underlying cause is successfully treated (e.g., spinal cord decompression, colitis, etc.). • Dietary—fecal volume can be reduced by feeding low-residue commercial diets or foods such as cottage cheese and rice and/or tofu. Feed pet at established times to better control times needed to defecate. Increasing fecal volume with high insoluble fiber diets is contraindicated. • Frequent warm water enemas will diminish the volume of feces in the colon and thus decrease the incidence of inappropriate defecation. • Environmental changes (e.g., making the pet an outside pet) may increase client satisfaction and thus avoid euthanasia of an otherwise healthy animal. • Reflex defecation can sometimes be induced in animals with posterior paralysis (e.g., a mild pinch of the toe on a pelvic limb or tail); similarly, applying a warm washcloth to the anus or perineum may stimulate defecation. • Surgical reconstruction of anorectal lesions may markedly improve fecal continence in patients with non-neurogenic sphincter incontinence. • Fascial slings and silicone elastomer slings have met with variable success in treating neurogenic sphincter incontinence in dogs. • Prognosis is poor if the underlying cause cannot be identified and successfully corrected; discuss the prognosis with the client early in the evaluation to avoid unrealistic expectations.

MEDICATIONS

DRUG(S) OF CHOICE

- Opiate motility-modifying drugs (e.g., diphenoxylate hydrochloride and loperamide hydrochloride) increase segmental contraction of the bowel and slow passage of fecal material, thus increasing the amount of water absorbed from the feces.
- Anti-inflammatory agents, such as glucocorticoids and sulfasalazine, may benefit patients with suspected reservoir incontinence due to inflammatory bowel disease or colitis.
- Improvement in signs may be achieved if specific therapy for perianal fistula, IBD, or other reservoir or non-neurogenic causes of incontinence can be given, but there are no specific drugs effective in patients with neurogenic incontinence.

CONTRAINDICATIONS

- Do not use motility-modifying drugs in patients with diarrhea if an infectious or toxic cause is suspected.
- Do not use opiate motility modifiers in patients with respiratory disease; use cautiously in patients with liver disease.
- Use of opiates in cats is generally not recommended.
- Do not use diets containing high concentrations of insoluble fibers as this will produce a large, bulky stool that is difficult to pass or may cause obstipation (especially in cats).

PRECAUTIONS

- Motility-modifying drugs may cause constipation and bloat.
- Opiate motility-modifying drugs may cause sedation.

POSSIBLE INTERACTIONS

Increased sedation and respiratory depression are possible when opiates are used concurrently with other CNS depressants (e.g., barbiturates, general anesthetics, and tranquilizers).

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- If fecal incontinence is due to an underlying neurologic cause, use serial neurologic examinations to monitor patient progress.
- Radiographic procedures, EMG, CSF analysis, and electrodiagnostic studies can also be used to follow progress.
- Check fecal consistency and volume and make sure the pet does not become constipated.
- Adjust diet and motility-modifying drug dosages to find the appropriate therapy for each individual patient.

POSSIBLE COMPLICATIONS

- Neurogenic sphincter incontinence is often unresponsive despite appropriate dietary, medical, and surgical treatment.
- 50% of pets with fecal incontinence were euthanized in a recent study.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

- Exposure to animal feces increases the risk of exposure to zoonotic parasites.
- Advise clients about zoonotic diseases (e.g., cutaneous and visceral larval migrans and toxoplasmosis).

INCONTINENCE, URINARY

BASICS

DEFINITION

Loss of voluntary control of micturition, usually observed as involuntary urine leakage.

PATHOPHYSIOLOGY

Usually a disorder of the storage phase of micturition. Urine storage failure is caused by impaired urinary bladder accommodation, failure of urethral continence mechanisms, or anatomic bypass of urinary storage structures. Partial outlet obstruction and other causes of urinary bladder overdistension may cause paradoxical, or overflow, urinary incontinence.

SYSTEMS AFFECTED

- Renal/Urologic.
- Nervous.
- Skin/Exocrine—urine scald and perineal and ventral dermatitis, recessed vulva.

INCIDENCE/PREVALENCE

Urinary incontinence may affect ~ 20% of spayed female dogs, especially large-breed dogs.

SIGNALMENT

- Dog and (rarely) cat.
- Most common in middle-aged to old neutered female dogs; also observed in juvenile females and (rarely) neutered males.
- Medium- to large-breed dogs most often affected.

CAUSES*Neurologic*

- Disruption of local neuroreceptors, peripheral nerves, spinal pathways, or higher centers involved in the control of micturition can disrupt urine storage. Generalized peripheral lower motor neuron disorders or autonomic disorders also can cause urinary incontinence.
- Lesions of the sacral spinal cord, such as a congenital malformation, cauda equina compression, lumbosacral disc disease, or traumatic fractures or dislocation, can result in a flaccid, overdistended urinary bladder with weak outlet resistance. Urine retention and overflow incontinence develop.
- Lesions of the cerebellum or cerebral micturition center affect inhibition and voluntary control of voiding, usually resulting in frequent, involuntary urination or leakage of small volumes of urine.

Urinary Bladder Storage Dysfunction

- Poor accommodation of urine during storage or urinary bladder overactivity (detrusor instability) leads to frequent leakage of small amounts of urine.
- Urinary tract infections, chronic inflammatory disorders, infiltrative neoplastic lesions, external compression, and chronic partial outlet obstruction are potential causes.
- Congenital urinary bladder hypoplasia may accompany ectopic ureters or other developmental disorders of the urogenital tract.
- Idiopathic

detrusor instability has been associated with feline leukemia virus infection in cats and unknown causes in dogs.

Urethral Disorders

- If urethral closure provided by urethral smooth muscle, striated muscle, and connective tissue does not prevent leakage of urine during storage, intermittent urinary incontinence is observed.
- Examples—congenital urethral hypoplasia or incompetence, acquired urethral incompetence (i.e., reproductive hormone-responsive urinary incontinence), urinary tract infection or inflammation, prostatic disease or prostatic surgery.

Anatomic

- Developmental or acquired anatomic abnormalities that divert urine from normal storage mechanisms or interfere with urinary bladder or urethral function.
- Ectopic ureters can terminate in the distal urethra, uterus, or vagina.
- Patent urachal remnants divert urine outflow to the umbilicus.
- Vestibulovaginal anomalies, congenital urocystic hypoplasia, or urethral hypoplasia.
- Intrapelvic bladder neck location may contribute to urine leakage due to urethral incompetence.
- Vulvar and perivulvar conformation abnormalities may contribute to urine pooling and intermittent urine leakage.

Urine Retention

- Overflow observed when intravesicular pressure exceeds outlet resistance.

Mixed Urinary Incontinence

- Mixed or multiple causes may occur in dogs and cats, e.g., combinations of urethral and bladder storage dysfunction and combinations of anatomic and functional disorders.

RISK FACTORS

- Neutering increases the risk of development of urethral incompetence, especially in large dogs (> 20 kg).
- Early neutering (< 3 months) increases the risk of urinary incontinence in female dogs.
- Conformational characteristics such as bladder neck position, urethral length, and concurrent vaginal anomalies may increase the risk of urinary incontinence in female dogs.
- Obesity may increase the risk of urinary incontinence in neutered female dogs.
- Other possible risk factors for urethral incompetence include breed, large body size, polyuria, and early tail docking.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiating Similar Signs

- Voluntary but inappropriate urination (usually behavioral).
- Urethral discharges, often associated with prostatic disease in male dogs and vaginal disorders in female dogs.

- Urine spraying or inappropriate urination in cats can be confused with urinary incontinence.
- Polyuria—may precipitate or exacerbate urinary incontinence or lead to nocturia and inappropriate urination; a urine specific gravity may rule in or out clinically important polyuria.

Differentiating Causes

- Neurogenic causes of urinary incontinence—usually cause a large, distended urinary bladder and other neurologic deficits such as weak anal or tail tone, depressed perineal sensation, and proprioceptive deficits.
- Dogs with urethral incompetence typically exhibit intermittent occurrences of urinary incontinence, observed most often at night or while the animal is sleeping. Physical examination reveals a small urinary bladder and no other defects.
- Urine pooling—affected dogs may leak small amounts of urine after voiding.
- Historical and physical findings in patients with urinary bladder storage dysfunction resemble those observed in patients with urethral incompetence, although increased frequency of urination or apparent urgency may be additional clinical signs.
- Historical signs in male dogs with prostatic disease include tenesmus, hind limb weakness, dysuria, and pollakiuria. Physical findings include prostatomegaly, lumbosacral pain, pain on prostatic palpation, and hind limb trembling or weakness.
- Recessed or juvenile vulvar conformation may contribute to urine pooling.

CBC/BIOCHEMISTRY/URINALYSIS

- Hematologic and biochemical analyses may be indicated in patients with polyuria disorders (see Polyuria and Polydipsia).
- Urinalysis may reveal evidence of urinary tract infection (e.g., pyuria, hematuria, and bacteria) or polyuria (e.g., low urine specific gravity).

OTHER LABORATORY TESTS

- Test cats for feline leukemia virus infection
- Urine culture in dogs with urethral incompetence

IMAGING*Radiographic Findings*

- Contrast radiography is indicated in juvenile animals and animals exhibiting urinary incontinence shortly after surgical procedures or traumatic incidents.
- Excretory urography, contrast tomography, or magnetic resonance nephrography allows visualization of the kidneys, ureteral terminations, and urinary bladder.
- Retrograde vaginourethrography allows visualization of the vaginal vault, urethra, and urinary bladder. Ectopic ureters usually fill with contrast media in these retrograde studies.
- Double-contrast cystography may be required for full visualization of bladder structure and identification of urinary bladder lesions.

INCONTINENCE, URINARY

(CONTINUED)

Ultrasonographic Findings

- Can use for evaluation of the kidneys, ureters, and urinary bladder to identify uroliths, masses, hydronephrosis or hydroureter, or evidence of pyelonephritis.

DIAGNOSTIC PROCEDURES

- Neurologic examination—examination of anal tone, tail tone, perineal sensation, and bulbospongiosus reflexes.
- Urethral catheterization—may be required to assess patency of the urethra if urine retention is observed.
- Cystoscopy—may visualize bladder, urethra, and ectopic ureteral terminations.

TREATMENT

I

APPROPRIATE HEALTH CARE

- Usually as outpatient.
- Address partial obstructive disorders and primary neurologic disorders specifically if possible.
- Identify urinary tract infection and treat appropriately.
- Ectopic ureters and congenital urethral hypoplasia can often be surgically corrected; endoscopic-guided laser ablation has been utilized for intramural ectopic ureters. Functional abnormalities of urethral competence or urinary bladder storage may accompany the anatomic disorder and require ancillary medical treatment.
- Teflon or collagen bulking agents can be injected into urethral submucosa to control incontinence.
- Surgical procedures such as colposuspension, cystourethropexy, and prosthetic sphincter implantation have been described for the treatment of refractory incontinence.

MEDICATIONS

DRUG(S) OF CHOICE

Urethral Incompetence

- Manage with α -adrenergic agonists (e.g., phenylpropanolamine 1–1.5 mg/kg PO q8–12h or 1.5 mg/kg PO q24h, ephedrine 1–4 mg/kg PO q8–12h) or reproductive hormones (e.g., conjugated short-acting estrogens, estradiol 1–2 mg/dog PO q24h for 7 days, then 0.5–1 mg/dog q24–48h if required, and testosterone or diethylstilbestrol 0.1–1 mg/dog PO q24h for 5–7 days then 0.1–1 mg/dog PO q4–7 days PRN).
- α -adrenergics and reproductive hormones can be co-administered for a synergistic therapeutic effect.
- Depot deslorelin, a gonadotropin-releasing hormone analogue (5–10 mg/dog, or dogs \leq 30 kg use a 4.7 mg implant, for dogs $>$ 30 kg use a 9.4 mg implant) or depot leuprorelin (1 mg/kg or

11–25 mg/dog) have also been used in refractory cases.

- Imipramine (5–15 mg/dog PO q12h), a tricyclic antidepressant with anticholinergic and α -agonist actions, provides an alternative method of treatment especially if there may be inappropriate voiding with a suspected behavioral origin.

Detrusor Instability

- Manage with anticholinergic or antispasmodic agents (e.g., oxybutynin, approximately 0.2 mg/kg PO q8–12h, up to 5 mg total dose q8–12h).

Prostatic Disease

- See Prostatomegaly; Prostatitis and Prostatic Abscess.

CONTRAINDICATIONS

- Estrogen in immature bitches with congenital USMI (urethral sphincter mechanism incompetence), intact bitches, or male dogs.
- Adrenergic agonists in patients with cardiac disease, renal disease, and hypertensive disorders.
- Anticholinergic agents in patients with glaucoma or cardiac disease.

PRECAUTIONS

- Long-acting estrogen compounds rarely cause signs of estrus and bone marrow suppression, and exacerbate immune-mediated disease. However, bone marrow suppression due to estrogen therapy is usually fatal. Therefore, use the minimum effective dose for the minimum amount of time.
- Testosterone administration can cause signs of aggression or libido, exacerbate prostatic disease, and contribute to the development of perineal hernia or perianal adenoma.
- Adrenergic agonists can cause restlessness, tachycardia, and hypertension.
- Anticholinergic agents can cause nausea, vomiting, and constipation.

POSSIBLE INTERACTIONS

- Do not administer tricyclic antidepressants concurrently with monoamine oxidase inhibitors (e.g., selegiline). • The risk of hypertension increases if α -adrenergic agonists are administered concurrently with tricyclic antidepressants.

FOLLOW-UP

PATIENT MONITORING

- Patients receiving α -adrenergic agents—observe during the initial treatment period for adverse effects.
- Patients receiving long-term estrogen—initial, 1 month, and periodic hemograms.
- Periodic urinalysis and urine culture.
- Expect excellent response to medical treatment in 60–90% of treated patients.
- Once a therapeutic effect is achieved, slowly reduce the dose and

frequency of drugs to the minimum required.

- Consider combination treatment (α -adrenergic agonist with reproductive hormones or anticholinergic agents), deslorelin or surgical options if poor response to single-agent medication.

POSSIBLE COMPLICATIONS

- Recurrent and ascending urinary tract infection
- Urine scald and perineal and ventral dermatitis
- Refractory and unmanageable incontinence.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Urinary tract infection
- Vaginitis

PREGNANCY/FERTILITY/BREEDING

Although urinary incontinence is rare in pregnant animals, the use of estrogens or anticholinergic agents is not advised.

SYNONYMS

Enuresis

**Client Education Handout
available online**

BASICS

DEFINITION

Complaint that occurs in bitches historically showing abnormal cycling, copulation failure, conception failure, or pregnancy loss.

PATHOPHYSIOLOGY

- Normal fertility—requires normal estrous cyclicity with ovulation of normal ova into a patent, healthy reproductive tract; fertilization by normal spermatozoa; implantation of the conceptus into the endometrium; formation of the normal zonary placenta; and maintenance of pregnancy in the presence of high progesterone concentration throughout the approximately 2-month gestation.
- Breakdown in any of these processes causes infertility.

SYSTEMS AFFECTED

Reproductive

SIGNALMENT

- Animals of all ages; more common in old animals.
- Dogs > 6 years old—more likely to have underlying cystic endometrial hyperplasia; may be predisposed to uterine infection and failure of conception or implantation.
- Dog breeds predisposed to hypothyroidism—may have a higher prevalence; include golden retrievers, Doberman pinschers, dachshunds, Irish setters, miniature schnauzers, Great Danes, poodles, and boxers.

SIGNS

Historical Findings

- Failure to cycle.
- Failure to cycle normally—shortened interestrous interval (interestrous interval 4 months or less).
- Failure to copulate, poor semen quality or lack of functional spermatozoa.
- Failure to become pregnant and/or maintain pregnancy after normal copulation. Persistent estrus (> 3 weeks).

Physical Examination Findings

- Negative pregnancy exam after mating
- Positive pregnancy with no subsequent parturition

CAUSES

Animals acquired when already mature—possibility of previous ovariohysterectomy.

Dogs

- Insemination at the improper time in the estrous cycle—most common
- Subclinical uterine infection
- Cystic endometrial hyperplasia
- Male infertility factors
- Hypothyroidism
- Hypercortisolism
- Anatomic abnormality
- Chromosomal abnormality
- Abnormal ovarian function
- Brucella canis*
- Silent estrus

Cats

- Similar causes to those of dogs
- Lack of sufficient copulatory stimulus to induce

ovulation

- Systemic viral or protozoal infection

RISK FACTORS

- B. canis* (dogs)
- Hypothyroidism (dogs)
- Hypercortisolism (dogs and cats)—endogenous or exogenous
- Systemic viral infection (dogs and cats)—canine herpesvirus; FeLV; FIV
- Systemic protozoal infection (dogs and cats)—e.g., toxoplasmosis
- Any chronic, debilitating disease condition (dogs and cats)
- Congenital vaginal anomaly (dogs and cats)
- Old age

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Historical Information

- Extremely useful in distinguishing causes.
- Is the patient cycling? Primary anestrus = no overt estrous cycle by 2 years of age; secondary anestrus = no overt estrous cycle within 1 year of a normal cycle.
- Has the patient conceived or given birth in the past? If so, how recently? Litter size? Percentage of stillbirths? Percentage of litter weaned?
- Is the patient free of systemic viral or protozoal infection?
- Is the patient capable of normal copulation?
- Was the patient bred to a male of proven fertility (i.e., litter whelped within previous 6 months) at the proper time of the estrous cycle?
- Did the patient ovulate during the estrous cycle and maintain progesterone concentration consistent with pregnancy during the entire gestation?
- Is the bitch euthyroid?

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

*Serologic Test for *B. canis* (Dogs)*

- Rapid slide agglutination test—used as a screen; sensitive but not specific.
- If positive results—recommend recheck by an agar gel immunodiffusion test (Cornell University Diagnostic Laboratory, 607-253-3900) or bacterial culture or PCR of whole blood or lymph node aspirate.

Serum Progesterone Measurement

- Should remain high throughout gestation.
- May measure at the time of examination.
- If concentration < 2 ng/mL in mid-gestation and pregnancy loss occurs, insufficient luteal function indicated (hypoluteodism) [see Abortion, Spontaneous (Early Pregnancy Loss)—Dogs, and Premature Labor].
- Concentration > 2 ng/mL—may indicate diestrus; silent heat—estrus with no overt behavioral or physical changes; or pathologic production of progesterone from a luteal ovarian structure, functional ovarian neoplasm, or the adrenal gland.
- Quantitative (chemiluminescence,

fluorescence, enzyme immunoassay) progesterone assay is important to detect levels < 2.0 ng/mL. Rapid in-hospital assays are least accurate between 2 and 5 ng/mL.

Dogs

- Progesterone may be measured during proestrus and estrus to predict ovulation time and optimize breeding management.
- Concentration and ovulation—
1–1.9 ng/mL, probable ovulation in 3 days (recheck); 2–2.9 ng/mL, ovulation in 2 days; 3–3.9 ng/mL, ovulation in 1 day;
4–10 ng/mL, ovulation that day.
- Optimal breeding day for single breeding to produce maximum litter size—2 days after ovulation.
- Day of ovulation from onset of proestrus or estrus extremely variable; not well correlated with standing behavior (see Breeding, Timing).

Cats

- Progesterone may be measured after breeding to assess induction of ovulation.
- Concentration > 2 ng/mL—indicates functional luteal tissue.

Other Tests

- Bacterial culture for uterine organisms (dogs and cats)—vaginal discharge originating in the uterus during proestrus or estrus is collected directly by hysterotomy or transcervical catheterization, or indirectly from the anterior vagina using a guarded swab.
- Thyroid hormone testing (dogs)—may measure resting serum concentration of T₃ or T₄ and cTSH.
- Serologic testing—canine herpesvirus and toxoplasmosis [see Abortion, Spontaneous (Early Pregnancy Loss)—Dogs]; FeLV, FIV, and toxoplasmosis [see Abortion, Spontaneous (Early Pregnancy Loss)—Cats].
- Karyotype (dogs and cats)—performed on heparinized blood samples of patients with primary or persistent anestrus; look for chromosomal abnormalities that can cause abnormal sexual differentiation (testing done by Molecular Cytogenetics Laboratory, Texas A&M University, (979)-862-2879/458-0520; Veterinary Genetics Laboratory, Univ. Calif. Davis, (530) 752-2211) (see Sexual Development Disorders).
- Serum cortisol assay (dogs and cats)—if the resting serum concentration is high, investigate the underlying cause.
- Semen evaluation (dogs and cats)—direct evaluation to rule out oligospermia or azoospermia recommended; alternatively, may test-breed the male to another female to prove fertility; rule out azoospermia in tomcat by finding spermatozoa in a vaginal flush or swab specimens from the queen or in urine collected by cystocentesis from the tom. (See Infertility, Male—Dogs.)
- Serum AMH/progesterone, LH/estrogen for determination of ovarian presence.

INFERTILITY, FEMALE—DOGS

(CONTINUED)

IMAGING

- Radiography and ultrasonography—normal ovaries and a non-gravid uterus usually not visible with radiography; normal ovaries and non-gravid uterus visible with newer high-resolution equipment and frequency near-field imaging; large ovaries may indicate cystic ovarian disease or neoplasia; visible uterus may indicate cystic endometrial hyperplasia.
- Positive-contrast procedures—vaginography in dogs; hysteroscopy in dogs and cats; performed prepubertally or when the patient is in estrus; may reveal anatomic abnormality (e.g., abnormal structure and impatency) (see Vaginal Malformations and Acquired Lesions).
- Ultrasound—may diagnose pregnancy as early as 20–24 days after ovulation; useful for documenting pregnancy loss; useful for detecting suspected cystic ovarian or neoplastic ovarian disease, cystic endometrial hyperplasia, and intraluminal fluid.

I

DIAGNOSTIC PROCEDURES

- Laparotomy (dogs and cats)—assess anatomy of the tubular tract and gonads.
- Hysterotomy—to obtain a direct uterine culture specimen; biopsy of the uterus or ovaries.

TREATMENT

- Cats—seasonal breeders; depend on photoperiod; cycle when exposed to long day length, normally from late January to mid-October; induce year-round cycling by a daily light exposure of ≥ 12 hours; for a non-cycling cat during the physiologic breeding season, ask client about the queen's housing and exposure to light.
- Heritable cause (e.g., thyroid insufficiency)—counsel owner regarding the advisability of retaining the patient in the breeding program.
- Surgical resection of vaginal anomalies (dogs)—may ease natural service and vaginal delivery of pups.
- Surgical repair of impotent tubular tract (dogs and cats)—difficult procedure; prognosis for future fertility guarded.
- Surgical drainage of ovarian cysts (dogs and cats)—efficacy unknown.
- Unilateral ovariectomy of neoplastic ovary (dogs and cats)—future fertility depends on resumption of normal function of the remaining ovary and lack of metastasis.
- Estrus suppression for one to two estrous cycles may benefit bitches with short interestrous interval (4 months or less).
- Prognosis for future fertility—initially good, because the most common cause is improper breeding management; worsens with other causes.

MEDICATIONS

DRUG(S) OF CHOICE

- Antibiotics (dogs and cats)—for uterine infection; choice depends on bacterial culture and sensitivity test of the uterus or of vaginal discharge during proestrus or estrus.
- L-Thyroxine—for thyroid insufficiency; dogs: 0.01–0.02 mg/kg PO q12h; prognosis for future fertility with return to euthyroid state guarded.

Gonadotropin Therapy

- For induction of ovulation.
- GnRH, which causes release of endogenous LH from the pituitary, or hCG, which has LH-like activity.
- Cats not adequately stimulated to ovulate at the time of copulation—GnRH (25 µg/cat IM or hCG 250 IU/cat IM) at time of breeding.
- Ovarian cystic disease—cats: GnRH (25 µg/cat IM) or hCG (250 IU/cat IM); dogs: GnRH (50 µg/dog IM) or hCG (1,000 IU/dog half IV, half IM); causes ovulation or luteinization of cystic ovarian tissue.
- Estrus induction (dogs)—diethylstilbestrol (5 mg q24h PO for 9 days or until signs of proestrus induced); bromocriptine (20 µg/kg q12h PO for 21 days); cabergoline (5 µg/kg q24h PO for up to 30 days or until signs of proestrus induced); deslorelin (2.1 mg implant, Ovuplant; placed in vestibule; must have progesterone < 0.5 mg/mL at start; implant removed after ovulation confirmed: progesterone > 10 ng/mL).
- Estrus suppression (dogs)—megestrol acetate (2 mg/kg PO daily for 8 days if begun within first 3 days of proestrus or 0.5 mg/kg PO daily for 32 days if begun in anestrus) or mibolerone (dose dependent on body weight; 30 µg PO daily for dogs weighing 0.5–12 kg, 60 µg daily for 12–23 kg, 120 µg daily for 23–45 kg, 180 µg daily for greater than 45 kg and for German shepherd dogs and their crosses).

CONTRAINDICATIONS

- Treatment with progestins, including megestrol acetate, contraindicated in bitches with cystic endometrial hyperplasia or history of progesterone-dependent disease.
- Treatment with mibolerone contraindicated in Bedlington terriers and other breeds with familial liver disease.
- All hormonal therapies contraindicated in potentially pregnant bitches.

FOLLOW-UP

PATIENT MONITORING

- L-Thyroxine (dogs)—blood concentrations of T₃ and T₄ rechecked after 1 month of

supplementation to ensure adequate absorption of medication and resumption of a euthyroid state.

- Ultrasonography (dogs and cats)—to definitively diagnose pregnancy; monitor gestation.
- Progesterone assay (dogs and cats).

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Infertility caused by endocrinopathy—signs of dermatologic abnormality (e.g., alopecia with thyroid insufficiency or hypercortisolism); systemic signs of disease (e.g., polydipsia and polyuria with hypercortisolism).
- Bitches with a vaginal anatomic abnormality—persistent or recurrent urinary tract disease or vaginitis.

ZOONOTIC POTENTIAL

B. canis infection—organism is less readily shed if affected animals are gonadectomized; stress good hygiene.

BASICS

DEFINITION

- Diminished or absent fertility; does not imply sterility.
- Results from a wide range of problems that prevent the delivery of sufficient numbers of spermatozoa to fertilize ovulated, mature oocytes in the bitch or excessive numbers of biochemically/structurally compromised spermatozoa.

PATHOPHYSIOLOGY

- Spermatogenesis—encompasses the formation and development of spermatozoa from spermatogonia to mature spermatozoa; a coordinated, hormonally controlled, cyclic process; approximately 70 days required for a complete phase: the testicular phase is 61.9 days; the epididymal phase is 10–14 days. Testicular problems require at least 70 days for recovery; epididymal problems require up to 10–14 days.
- Azoospermia—no spermatozoa in the ejaculate.
- Oligozoospermia—low numbers of spermatozoa.
- Teratospermia—high numbers of abnormally shaped spermatozoa.
- Asthenospermia—reduced motility.
- Primary causes—impaired or arrested spermatogenesis; blockage of the excurrent ducts; genitourinary inflammation; testicular neoplasia; environmental stress; congenital abnormality; endocrine abnormality.

SYSTEMS AFFECTED

- Reproductive
- Endocrine/Metabolic
- Musculoskeletal
- Nervous

GENETICS

- The incidence of verifiable heritable causes of infertility in the stud dog is increasing.
- Cryptorchidism—likely a heritable, sex-limited polygenic autosomal recessive trait in dogs; associated with increased frequency of inguinal/umbilical hernias, patellar luxation, preputial and penile problems.
- Alpha-L-fucosidase deficiency is a storage disorder causing acrosomal dysgenesis.
- Primary ciliary dyskinesia (PCD)—congenital abnormality of ciliary ultrastructure; absent, irregular, or asynchronous motility patterns of all ciliated cells; diagnosed by electron microscopy of spermatozoa.
- Hypothyroidism—effect on male fertility is probably minimal.

INCIDENCE/PREVALENCE

True incidence unknown; is probably increasing with continued in-breeding. The percentage is probably higher than expected as the full degree of genetic effects has not yet been realized.

SIGNALMENT

Species

Dog

Breed Predilections

Relatively higher prevalence of specific problems seen in breeds with a small genetic pool or with intensive in-breeding.

Mean Age and Range

Prevalence increases with age.

SIGNS

General Comments

General complaint—no puppies produced; whelping rate < 75% when bred with correct timing to fertile bitches; owner suspects male dog infertility.

Historical Findings

- Age of testicular descent
- Age at first attempted mating
- Dog's temperament (high-strung)
- Libido and breeding behavior
- Frequency and number of matings
- Method used to time breedings
- Type of semen used for breeding (fresh, fresh-extended, chilled-extended, or frozen)
- Ability for the dog's sperm cells to survive chilling or freezing
- Handling of semen and route of insemination
- Litter size(s)
- Familial history of infertility
- Degree of in-breeding
- Fertility status of bitches bred
- *Brucella canis* status of all breeding animals
- Current and previous drug and dietary therapies, especially corticosteroids and steroid hormones
- Previous medical or surgical illnesses

Physical Examination Findings

- Sheath and penis—palpate to identify masses or adhesions.
- Non-erect penis—exteriorize to identify clinically important lesions of the superficial mucosa and any damage to the os penis.
- Testes and epididymides—palpate and examine, note the size and symmetry of the epididymides relative to the testes.
- Internal urethra and prostate—digital rectal palpation to determine location, size, and symmetry.

CAUSES

Incorrect timing of breeding—most common cause

Congenital

- Chromosomal abnormalities: XYY syndrome and XX disorder of sexual development (see Sexual Development Disorders).
- Germinal cell aplasia—biopsy reveals “Sertoli cell only” syndrome.
- Segmental aplasia of the epididymis or vas deferens—causes either oligospermia (unilateral) or azoospermia (bilateral).

Acquired

- Incomplete ejaculation—unfamiliar surroundings; slippery flooring; no estrous bitch; dominant owner or bitch present.
- Obstruction of the efferent ducts, epididymides, or ductus deferens—leads to azoospermia if bilateral; sperm granuloma, spermatocele, acute inflammation, chronic inflammatory stenosis, segmental aplasia, neoplasia, previous vasectomy, and attempts to pack testes into a scrotal location.

- Hyperthermia/heat stroke. Inflammation or infection of the testes—especially *Escherichia coli*; requires prompt and aggressive treatment to prevent infertility.
- Hypothyroidism—role unclear and extremely rare; evaluate thyroid function with poor semen quality; may be associated with decreased libido.
- Hyperprolactinemia—role unclear; evaluate prolactin levels with azoospermia.
- Hyperadrenocorticism—causes testicular atrophy and oligospermia; probably reversible.
- Drugs—parasiticides, corticosteroids, anabolic steroids, estrogens, androgens, progestagens, GnRH agonists/antagonists, ketoconazole, amphotericin B, some antifungal agents, may interfere with or interrupt spermatogenesis; assess all topical and systemic therapies.
- Environmental toxins—endocrine-disrupting contaminants can affect the hypothalamic-pituitary-gonadal axis and gonadal steroidogenesis; effects in the dog unknown but suspected.
- Trauma, environmental damage, testicular neoplasia, systemic disease, ischemia, and heat stress—may cause transient infertility or sterility.
- Prostatic disease—can markedly reduce semen quality and libido.
- In-breeding—reduces fertility; reduced-fertility lines might only be salvaged by concerted breeding program and out-crosses with highly fertile animals.
- Lymphocytic orchitis—familial in some breeds (e.g., beagles and borzois); affected animals may be fertile when young; accelerated rate of fertility loss with age.
- Retrograde ejaculation—some retrograde flow into the bladder normal.

RISK FACTORS

- Congenital disorders affecting reproductive function—not uncommon; tend to occur in selected breeds.
- Teaser bitches and stud dogs not tested for infectious diseases (e.g., *B. canis* and bacterial culture of genital tract) before clinical use.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Before extensive diagnostic work on the male, determine that the bitches are fertile (previous litters) and that the breedings were optimally timed (see Infertility, Female—Dogs, and Breeding, Timing).

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Brucellosis or prostatitis—variable changes in the leukogram (normal or leukocytosis) and urinalysis (high numbers of leukocytes); depends on the time-course of the infection; false negative Brucellosis test possible, antibiotic therapy may cause false negative.
- Systemic illness—may impair reproductive function, but infertility is usually not the primary complaint on examination.

INFERTILITY, MALE—DOGS

(CONTINUED)

OTHER LABORATORY TESTS

Endocrine Profile

- Resting testosterone—normal, intact dogs, 0.4–10 ng/mL (1–4 ng/mL common range).
- Androgenic tissue (detect bilaterally cryptorchid)—serum testosterone concentration increases 100% over the resting value 2–3 hours after injection with either 1–2 µg/kg GnRH or 40 IU/kg hCG; resting serum AMH.
- Primary testicular failure—low testosterone and high FSH and LH.
- Germinal compartment failure—normal testosterone and high FSH; FSH high due to the loss of inhibin secretion from viable Sertoli cells.
- Hypogonadism—low testosterone, FSH and LH.
- Thyroid function—evaluated by baseline T₃ and T₄, TSH values, and stimulation testing (see Hypothyroidism).
- *B. canis*—screen with 2 mercaptoethanol rapid slide agglutination test (ME-RSAT); confirm with agar gel immunodiffusion test (AGID).

I

IMAGING

Ultrasonography—identify lesions that alter the testicular and epididymal architecture (e.g., neoplasia, spermatocele, orchitis, epididymitis); evaluate the prostate gland for hyperplasia, chronic prostatitis, cyst, abscess, or neoplasia (see Prostate Disease in the Breeding Male Dog).

DIAGNOSTIC PROCEDURES

Breeding Soundness Examination

- Pivotal to ensure that all appropriate information is collected and must always consist of two semen collections.
- Sperm-rich and prostatic portions of the ejaculate—collect as separate fractions by use of a sterile artificial vagina and sterile, graduated, non-toxic plastic tubes in the presence of an estrous bitch.
- Sperm-rich fraction—volume; concentration, motility, and morphologic characteristics of sperm cells; cytologic examination; qualitative and quantitative cultures.
- Prostatic fraction and urine—cytologic examination; qualitative and quantitative cultures.
- Culture results—must be correlated with clinical and cytologic evidence of an active infection; evidence of inflammation if greater than 3–5 WBC/hpf observed (especially sperm-rich fraction).
- Prostatic fraction that indicates a clinically important infection—reevaluate by other sampling techniques that avoid contamination from the penile mucosa and prepuce; negative cytology possible with chronic prostatitis.
- Azoospermic or oligospermic ejaculate—recollect 1 hour later and again on several occasions before confirming infertility.

Epididymal Markers

ALP concentration in seminal fluid—normal 8,000–40,000 U/mL; epididymal in origin; may indicate obstruction if <5,000 U/mL

and a complete ejaculate was obtained; pathologic effects of obstruction are more easily seen from ALP concentration if ALP is performed on two ejaculates collected 1 hour apart.

PATHOLOGIC FINDINGS

- Testicular biopsy—determines the degree of spermatogenesis and the integrity of the blood-testis barrier; differentiates obstruction of efferent ducts from testicular hypoplasia and degeneration; allows an informed prognosis.
- Incisional biopsy—diagnostically superior to aspiration or needle biopsy; Bouin's fixative recommended for processing.

TREATMENT

ACTIVITY

- Restrict if activity or use is thought to be producing hyperthermia (see Heat Stroke and Hyperthermia).
- No restriction for other causes of infertility.

DIET

Ensure adequate diet and mineral supplementation; avoid supplementation of products containing excessive or undefined amounts of steroid hormones, e.g., extracts of testes, ovaries, and adrenals.

CLIENT EDUCATION

- Inform client that return to function may require at least 70 days from correction of identified cause(s).
- Stress patience and check patient regularly to ensure that the condition is not worsening.

SURGICAL CONSIDERATIONS

Reanastomosis of blocked excurrent epididymal ducts (vasectomies) has been successful for re-establishment of sperm production.

MEDICATIONS

DRUG(S) OF CHOICE

- Specific medications must be administered at a dosage and time-course that ensures tissue penetration. Antibiotics (for penetration and spectrum)—chloramphenicol, trimethoprim-sulfas, erythromycin, and enrofloxacin; recommended for a minimum of 3–4 weeks to allow adequate and sustained levels within the reproductive tract.
- Retrograde ejaculation—pseudoephedrine used with limited success in men, 4–5 mg/kg PO q8h, or 1 and 3 hours before collection; phenylpropanolamine, 4–8 mg/kg PO q24h, starting 5 days prior to collection.

CONTRAINDICATIONS

- Trimethoprim-sulfas—contraindicated if predisposed to keratitis sicca.

- Chloramphenicol and trimethoprim-sulfas—reportedly induce blood dyscrasias.
- Chloramphenicol—associated with anorexia and vomiting, but still may have the best tissue penetration.

FOLLOW-UP

PATIENT MONITORING

Recheck at intervals that take into account the length of the spermatogenic cycle (70 days) but are frequent enough to allow detection of deteriorating condition.

PREVENTION/AVOIDANCE

Avoid exposure to environmental temperature extremes (heat or cold).

POSSIBLE COMPLICATIONS

50–60% return to fertility after diagnosis and appropriate treatment.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Brucellosis infection—discospondylitis, polyarthritis, posterior paresis, fever, and uveitis.
- Prostatic disease—obstipation, locomotor difficulties, fever, hematuria, pollakiuria, and dysuria.
- Lymphocytic orchitis—lymphocytic thyroiditis.

AGE-RELATED FACTORS

- Daily sperm output and morphologically normal sperm cells decline with age.
- Difficult to assess the effect of age alone on fertility.
- Most old, infertile dogs have concurrent diseases (e.g., systemic or prostatic disease, testicular neoplasia, osteoarthritis) that have documented effects on fertility or libido.

ABBREVIATIONS

- ALP = alkaline phosphatase
- AMH = anti-müllerian hormone
- FSH = follicle-stimulating hormone
- GnRH = gonadotropin-releasing hormone
- hCG = human chorionic gonadotropin
- hpf = high power field
- LH = luteinizing hormone
- TSH = thyroid stimulating hormone
- WBC = white blood cell

INFLAMMATORY BOWEL DISEASE

BASICS

DEFINITION

A group of chronic enteropathies characterized by persistent or intermittent gastrointestinal (GI) signs with histopathologic evidence of intestinal inflammation. The form of IBD is generally categorized by the predominant mucosal cellular infiltrate, such as lymphocytic-plasmacytic enteritis, eosinophilic enteritis, or granulomatous enteritis.

PATHOPHYSIOLOGY

- Poorly understood but likely due to complex interplay between mucosal immunity and environmental factors (i.e., dietary and bacterial antigens) in genetically-susceptible dogs. Aberrant host immune responses are likely triggered by antigens derived from members of the commensal microbiota.
- Damage results from the elaboration of cytokines, release of proteolytic and lysosomal enzymes, complement activation secondary to immune complex deposition, and generation of oxygen free radicals which damage the intestinal epithelial barrier.
- Host genetic susceptibility involving defects in innate immunity is suspected in dogs, and possibly cats.

SYSTEMS AFFECTED

- Gastrointestinal
- Hepatobiliary
- Hemic/Lymphatic/Immune—rarely
- Musculoskeletal—rarely
- Ophthalmic—rarely
- Respiratory—rarely
- Skin/Exocrine—rarely

GENETICS

Defects in some host susceptibility genes have been identified in German shepherd dog, boxer, and soft-coated Wheaten terrier.

INCIDENCE/PREVALENCE

IBD is the most common histopathologic diagnosis in dogs and cats with chronic GI signs.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Some canine breeds are predisposed (e.g., immunoproliferative enteropathy of basenjis and Lundehunds, histiocytic colitis of French bulldogs and boxers, and gluten-sensitive enteropathy in Irish setters); an increased incidence is also seen in German shepherds.
- Siamese cats may be predisposed.
- Common in mongrel dogs and cats.

Mean Age and Range

Most common in middle-aged animals, although younger animals (< 2 years old) may be affected.

Predominant Sex

N/A

SIGNS

Historical Findings

- Dogs—chronic intermittent vomiting, large and/or small bowel diarrhea, and weight loss are common.
- Cats—anorexia is most common, followed by weight loss, vomiting, and diarrhea.
- Borborygmus, flatulence, hematochezia, abdominal pain, and mucoid stools are less commonly reported.

Physical Examination Findings

- Varies from an apparently healthy animal to a thin, lethargic animal.
- Poor hair coat is frequently noted.
- Abdominal palpation may reveal pain, thickened bowel loops, and mesenteric lymphadenopathy (especially in cats). Ascites may occur in dogs with protein-losing enteropathy. Abdominal palpation can also be unremarkable.

CAUSES

- Pathogenesis is unknown but most likely multifactorial.
- Etiology likely involves complex interactions between host genetics, mucosal immunity, and environmental (diet, intestinal bacteria) factors.

Infectious Agents

- Attaching and invasive *E. coli* has been associated with granulomatous mucosal lesions in dogs with granulomatous colitis.
- Giardia*, *Salmonella*, *Campylobacter*, and normal resident microbiota have been implicated.

Dietary Agents

- Meat proteins, food additives, artificial coloring, preservatives, milk proteins, and gluten (wheat) are all proposed causative agents.
- Dietary factors appear important in the pathogenesis of chronic intestinal inflammation in canine and feline IBD.

Genetic Factors

- Certain forms of IBD are more common in some breeds of dogs and cats.
- Defects in innate immunity (e.g., mutations in *TLR2*, *TLR5*, and *nod2* as seen in German shepherd dogs) that perturb mucosal homeostasis may predispose an individual susceptible to the development of IBD.
- Affected boxers have mutations in host gene *NCF2* which is required for clearance of intracellular bacteria.

RISK FACTORS

Current hypotheses suggest that IBD is a multifactorial disorder conditioned by genetic, immunologic, and environmental factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cats—hyperthyroidism, intestinal neoplasia (especially small cell lymphoma), adverse food reactions, granulomatous FIP and other viral

infections (e.g., FeLV and FIV), renal and hepatic insufficiency, exocrine pancreatic insufficiency, intestinal parasitism, and antibiotic responsive enteropathy (ARD) are primary differentials.

- Dogs—intestinal neoplasia, motility disorders, adverse food reactions, lymphangiectasia, exocrine pancreatic insufficiency, intestinal parasitism, and ARD are primary differentials.

CBC/BIOCHEMISTRY/URINALYSIS

- Results may be unremarkable; these tests more often serve to eliminate other differential diagnoses.
- Mild, nonregenerative anemia of chronic disease. Mild leukocytosis ± a left shift is sometimes seen with mucosal disruption (e.g., erosions).
- Mild peripheral eosinophilia may be seen in dogs and cats with eosinophilic enteritis, food allergy, and intestinal parasites amongst other causes.
- Cats with IBD may show alterations in serum total protein (i.e., hyperproteinemia) and albumin concentrations and with increased liver enzyme (e.g., ALT and/or ALP) activities.
- Hypoproteinemia is more common in dogs with IBD than in cats.
- Cobalamin deficiency reported in both dogs and cats with involvement of the ileum.

OTHER LABORATORY TESTS

- Useful to eliminate other differentials.
- Dogs—tests include evaluation of exocrine pancreatic function (cTLI), serology for pancreatitis (Spec cPL), and serum cobalamin and folate assays to localize small intestinal disease.
- Cats—T₄ and FeLV/FIV serology are recommended; fasting serum TLI (if exocrine pancreatic insufficiency is suspected); serology for pancreatitis (Spec fPL), and serum cobalamin and folate assays to localize small intestinal disease.

IMAGING

- Survey abdominal radiographs—usually unremarkable. Radiographic imaging is most useful in documenting abnormalities in organs outside of the alimentary tract.
- Barium contrast studies—may reveal mucosal abnormalities and thickened bowel loops. Normal findings do not eliminate the possibility of IBD.
- Ultrasonography—may indicate increased intestinal wall thickness (particularly the muscularis propria and submucosal layers) and mesenteric lymphadenopathy. However, these abnormalities, even if present, are not specific for IBD.

DIAGNOSTIC PROCEDURES

- Perform an elimination dietary trial to eliminate adverse food reactions. If GI signs resolve within 2 weeks, then a diagnosis of adverse food reaction is made and no further diagnostic work-up is required.
- Always perform fecal floatations for nematode and protozoal parasites.
- Definitive diagnosis of IBD requires intestinal biopsy and histopathology, usually obtained via endoscopy.
- Exploratory laparotomy may be

INFLAMMATORY BOWEL DISEASE

(CONTINUED)

indicated if endoscopy is unavailable or to collect full-thickness mucosal specimens.

- Use clinical scoring indices such as the canine inflammatory bowel disease activity index (CIBDAI) to define initial IBD disease burden and to assess response to therapy. Concurrent evaluation of C-reactive protein serves as a useful biomarker of active inflammation in dogs.

PATHOLOGIC FINDINGS

Morphologic evidence of mucosal inflammation including epithelial changes, architectural distortion (e.g., erosion/ulceration, crypt hyperplasia, fibrosis, loss of colonic goblet cells), and increased lamina propria cellularity. New histopathologic guidelines for defining the severity of gastrointestinal inflammation have been recently described.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient, unless the patient is debilitated from dehydration, hypoproteinemia, or cachexia.

NURSING CARE

- If the patient is dehydrated or must have food restricted because of intractable vomiting, any balanced fluid such as lactated Ringer's solution is adequate (for a patient without other concurrent disease); otherwise, select fluids on the basis of secondary diseases.
- If there is severe hypoalbuminemia from protein-losing enteropathy, consider use of colloids, such as hetastarch, to control effusions.

ACTIVITY

No restrictions

DIET

- Feed an intact protein or hydrolysate elimination diet to help reduce intestinal inflammation.
- Correct hypocobalaminemia by means of weekly parenteral cobalamin injections for the first 6 weeks and thereafter every 2–3 weeks or as needed based on repeat testing of cobalamin concentrations.
- Fiber supplementation (e.g., fermentable fiber such as pumpkin, Metamucil) is suggested in dogs and cats with colitis.
- Fish oil (n-3 fatty acids) as a free radical scavenger to reduce intestinal inflammation.
- Probiotics may be of benefit in some animals but are clinically unproven at this time. These supplements must be given continuously over several weeks for potential benefit to be realized.

CLIENT EDUCATION

- Emphasize to the client that IBD is not cured but is controllable in most instances.
- Relapses are common; clients should be patient during the various food and

medication trials that are often necessary to get the disease under control.

SURGICAL CONSIDERATIONS

No surgical procedures are available for relief of IBD in veterinary patients.

MEDICATIONS

DRUG(S) OF CHOICE

- See discussion under specific diseases.
- Affected animals with an immune cellular infiltrate should be treated with immunosuppressive drug regimens. Dogs with granulomatous colitis associated with AIEC are treated with fluoroquinolone antibiotics (see chapter, Colitis, Histiocytic Ulcerative, for details).

CONTRAINDICATIONS

If secondary problems are present, avoid therapeutic agents that might be contraindicated for those conditions.

PRECAUTIONS

See discussion under specific diseases

POSSIBLE INTERACTIONS

See discussion under specific diseases

ALTERNATIVE DRUG(S)

See discussion under specific diseases

FOLLOW-UP

PATIENT MONITORING

- Periodic (q2–4 weeks) physical and laboratory evaluations may be necessary until the patient's condition stabilizes. Serum albumin provides important prognostic information in dogs; serum cobalamin deficiency will delay complete clinical recovery in both dogs and cats.
- Monitor serum cobalamin concentrations in hypocobalaminemic dogs and cats.
- No other follow-up may be required except yearly physical examinations and assessment during relapse.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Dehydration, malnutrition, adverse drug reactions, hypoproteinemia, hypocobalaminemia, anemia, and diseases secondary to therapy or resulting from the above-mentioned problems.

EXPECTED COURSE AND PROGNOSIS

- Generally a good-to-excellent short-term prognosis.
- Poor long-term prognosis in dogs with IBD has been associated with severe clinical disease, marked endoscopic (duodenal) abnormalities, ascites, and hypoalbuminemia.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- See discussion under specific diseases.
- Cats may demonstrate concurrent inflammatory lesions in the liver and/or pancreas (so called "triaditis").

AGE-RELATED FACTORS

- See discussion under specific diseases.
- The workup and differentials are essentially the same, regardless of age.
- Some differentials are more likely in younger individuals (i.e., intestinal parasitism vs. neoplasia).
- Counsel clients about breeding and monitoring for the appearance of other diseases.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

See discussion under specific diseases

INSOLUBLE OXALATE PLANT TOXICOSIS

BASICS

OVERVIEW

- Over 200 species of plants contain insoluble oxalate crystals.
- Most houseplants are in the Araceae family; many are found in homes and offices.
- Common names vary; scientific names must be used for accurate identification.
- Insoluble oxalate crystals are not absorbed systemically and signs are often self-limiting.
- Signs are generally limited to irritation of oral mucosa; other signs occur more rarely.
- *Dieffenbachia* spp. (dumbcane) ingestion by dogs and cats is associated with more serious outcomes including death.
- Cats ingesting *Philodendron* spp. may exhibit more severe clinical signs.
- Common plants include:
 - *Aglaonema commutatum* (Chinese evergreen)
 - *Anthurium* spp. (flamingo flower)
 - *Arisaema amurense* (Jack-in-the-pulpit)
 - *Dieffenbachia* spp. (dumbcane)
 - *Epipremnum* spp. (pothos, devil's ivy, variegated philodendron)
 - *Philodendron* spp. (sweetheart vine, fiddle leaf)
 - *Schefflera actinophylla* (umbrella plant)
 - *Spathiphyllum* spp. (peace lily)
 - *Syngonium* spp. (arrowhead vine)
 - *Zantedeschia* spp. (calla lily).

SIGNALMENT

- Indoor cats and dogs primarily, although pets may be exposed by houseplants moved outside during summer months.
- Dogs tend to chew and destroy the entire plant; cats nibble on leaves.
- May occur more often in younger pets that are bored or inquisitive.

SIGNS

- Rapid onset, often within minutes of exposure.
- *Oral*: vocalization, pawing at muzzle, head shaking, hypersalivation, edema of lips, tongue or pharynx; rarely gagging, choking, and vomiting.
- *Ocular*: pawing at eyes, photophobia, conjunctival swelling.
- *Respiratory*: RARELY, dyspnea from pharyngeal swelling and inflammation.

CAUSES & RISK FACTORS

- Plants in environment.
- Insoluble oxalate crystals are arranged in bundles called raphides which are contained in idioblasts within plant stems and leaves.
- Chewing or biting on plant material releases the crystals from stems and leaves until the idioblast is emptied.
- Crystals act as miniature pins or mechanical irritants to mucous membranes but are not absorbed systemically.
- Potential for chemical irritation with release of prostaglandins, histamine, proteolytic enzymes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Caustic agents (alkalis and acids in household products; drain cleaners).
- Other agents causing oral irritation (capsaicin, detergents, topical spot-on flea and tick products).
- Quaternary ammonium compounds (> 2% in cats).
- Stinging nettle (*Urtica dioica*) ingestion.
- Systemic disease causing oral lesions.

CBC/BIOCHEMISTRY/URINALYSIS

- Rarely performed unless prolonged vomiting.
- CBC, electrolytes, serum chemistry.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Exam of oral cavity including visualization of pharynx.
- Fluorescein ophthalmic stain if ocular signs are present.

PATHOLOGIC FINDINGS

- Death rarely occurs.
- Few cases with severe erosive, ulcerative glossitis; oropharyngeal edema.

TREATMENT

- Generally limited to supportive care.
- IV fluids if dehydrated from excessive salivation or vomiting.
- *Oral*: irrigation of oral cavity with copious amounts of cool fluids; small amounts of calcium containing product (milk, yogurt, etc.) to bind oxalate crystals.
- *Ocular*: lavage for 15 minutes with tepid water.
- *Respiratory*: Endotracheal tube or temporary tracheostomy if dyspnea severe.

MEDICATIONS

No specific antidote available.

DRUGS

- Antiemetics as needed:
 - Maropitant 1 mg/kg SQ q24h.
 - Ondansetron 0.1–0.2 mg/kg IV q8–12h.
- GI protectants as needed:
 - H2 blockers (famotidine, ranitidine).
 - Omeprazole 0.5–1 mg/kg PO daily.
 - Sucralfate 0.25–1 g PO q8h.
- Pain

medication as needed:

- Butorphanol 0.1–0.5 mg/kg IV, IM, SQ.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Corticosteroids – the use is controversial, but dexamethasone phosphate 0.125–0.5 mg/kg IV, IM, SQ may be useful in severe inflammatory conditions.

FOLLOW-UP

PATIENT MONITORING

Monitor for signs of dyspnea and respiratory difficulty.

Prevention/Avoidance

Identify plants in household and keep away from pets.

POSSIBLE COMPLICATIONS

- Corneal abrasion or ulcer from pawing at eyes.
- Erosive ulcers in the mouth and gastrointestinal tract.
- Pharyngeal edema and death (rare).

EXPECTED COURSE AND PROGNOSIS

- Most signs are mild to moderate and of short duration generally lasting 2–4 hours; less often signs last 12–24 hours.
- Excellent prognosis as signs are generally self-limiting.

MISCELLANEOUS

AGE-RELATED FACTORS

Young pets are more frequently represented; likely due to boredom and inquisitive nature.

INSULINOMA

BASICS

DEFINITION

Functional pancreatic islet β -cell tumor that secretes an excess quantity of insulin independent of glucose concentration.

PATHOPHYSIOLOGY

Excessive insulin secretion leads to excessive glucose uptake and use by insulin-sensitive tissues and reduced hepatic production of glucose; this causes hypoglycemia and its associated clinical signs.

SYSTEMS AFFECTED

- Nervous—seizures, disorientation, abnormal behavior, collapse, polyneuropathy/ peripheral neuropathy, posterior paresis, and ataxia.
- Musculoskeletal—weakness and muscle fasciculations.
- Gastrointestinal—polyphagia and weight gain.

INCIDENCE/PREVALENCE

- Dogs—uncommon
- Cats—rare

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dogs—Labrador retrievers, standard poodles, boxers, fox terriers, Irish setters, German shepherds, golden retrievers, and collies.
- Cats—none; possibly Siamese.

Mean Age and Range

- Dogs—middle-aged to old; mean = 10 years; range = 3–14 years.
- Cats—mean = 15 years; range = 12–17 years.

SIGNS

General Comments

- Often episodic.
- May or may not be related to fasting, excitement, exercise, and/or eating.
- Dogs generally demonstrate more than one clinical sign with progression over time.

Historical Findings

- Dogs—generalized and/or focal seizures are most common. Additional findings may include weakness, posterior paresis, collapse, muscle fasciculations, bizarre behavior, lethargy and depression, ataxia, polyphagia, weight gain, polyuria and polydipsia and exercise intolerance.
- Cats—seizures, ataxia, muscle fasciculations, weakness, lethargy and depression, anorexia, weight loss, and polydipsia.

Physical Examination Findings

- Usually within normal limits unless in a hypoglycemic crisis with the aforementioned signs.
- Obesity is common.
- Polyneuropathy can be seen rarely in dogs (paresis to paralysis, muscle atrophy, and/or hyporeflexia).

CAUSES

Most dogs and cats have single insulin-producing B-islet cell carcinoma or

adenocarcinoma of the pancreas. Approximately 50% or greater of dogs and cats with insulinomas will develop or present with metastasis.

RISK FACTORS

For hypoglycemic episodes—fasting, excitement, exercise and eating.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Extrapancreatic tumor hypoglycemia—paraneoplastic hypoglycemia has been documented in dogs with numerous tumors including hepatocellular carcinoma, metastatic mammary carcinoma, primary pulmonary carcinoma, and others; these tumors generally secrete insulin or insulin-like factors.
- Perform a complete hypoglycemic workup and rule out causes such as iatrogenic insulin, neonatal/toy breed hypoglycemia, ingestion of oral hypoglycemic agents, hepatic failure, sepsis, hypoadrenocorticism, hunting dog hypoglycemia and glycogen storage diseases.
- Seizures and collapse—consider a variety of differentials including cardiovascular (e.g., syncope), metabolic (e.g., anemia, hepatoencephalopathy, hypocalemia, and hypoadrenocorticism) and neurologic (e.g., epilepsy, neoplasia, toxin, and inflammatory disease).

CBC/BIOCHEMISTRY/URINALYSIS

- Results often within normal limits except for hypoglycemia (<65–70 mg/dL in majority of patients).
- Normoglycemia does not rule out the presence of an insulinoma. A small percentage of patients may be intermittently normoglycemic, which is thought to be due to counter-regulatory hormone production (e.g., epinephrine, glucocorticoids, glucagon).

OTHER LABORATORY TESTS

Simultaneous Fasting Glucose and Insulin Determinations

- Upon initiating fasting (patients should always be hospitalized and monitored closely during this time due to the high risk for extreme hypoglycemia episodes), collect baseline blood samples and then hourly or bihourly for serum glucose determination and serum storage. When the serum glucose drops below 60 mg/dL, submit that serum sample for simultaneous glucose and serum insulin determination. When the insulin is elevated in the face of hypoglycemia an insulinoma is highly likely, whereas if the insulin is within normal limits in the face of hypoglycemia then insulinoma is possible. If the insulin value is below normal limits during the hypoglycemia then an insulinoma is unlikely, but multiple sampling may be necessary.

- Formulas utilizing simultaneous hypoglycemic glucose and insulin values such

as the insulin:glucose ratio and the amended insulin:glucose ratio are falling out of favor due to poor specificity.

IMAGING

- Thoracic and abdominal radiography—helpful for evaluation of metastatic disease and/or extrapancreatic tumor-induced causes of hypoglycemia as well as some other differential diagnoses.
- Ultrasonography—fewer than 50% of pancreatic masses are clearly identified through ultrasonography.
- CT—superior technique for detection of primary insulinomas in dogs; however, false-positive lymph node metastases are common and problematic; should primarily be used for preoperative delineation/ confirmation of a primary pancreatic mass.
- Scintigraphy and SPECT—intermittently successful in detecting insulinomas.
- Intraoperative ultrasound—widely used for grossly occult tumor detection in human insulinomas; rarely reported in veterinary medicine.

DIAGNOSTIC PROCEDURES

Exploratory laparotomy—indicated when insulinoma is suspected based on the aforementioned physical, biochemical and/or imaging results.

PATHOLOGIC FINDINGS

Histopathologically, primary pancreatic insulinomas in dogs are generally either B-islet cell carcinomas or adenocarcinomas and occasionally are adenomas, though dogs with adenomas may subsequently develop metastasis, suggesting limitations with delineation of malignancy potential with light microscopy of insulinomas. In cats, most have been malignant with metastasis commonly noted.

TREATMENT

APPROPRIATE HEALTH CARE

- Hospitalize for workup and surgery since life-threatening hypoglycemia is a very real possibility.
- Outpatient if the owner declines surgery and the patient is not clinically hypoglycemic.

NURSING CARE

For emergency hypoglycemic episodes, administer 50% dextrose (1 mL/kg IV slowly over 1–3 minutes) to control seizures/severe hypoglycemic signs. Once the emergency hypoglycemia clinical signs abate, follow with fluid therapy with 2.5% dextrose (increase to 5% if needed to control clinical signs). Alternatively, if the patient can eat, frequent feedings of an appropriate diet (see below) may replace dextrose-containing fluids in many patients.

ACTIVITY

Restricted

(CONTINUED)

INSULINOMA**DIET**

- Feed four to six small meals a day. • Food should be high in protein, fat, and complex carbohydrates and low in simple sugars.
- Avoid semimoist foods that dilute the aforementioned fat, protein, and carbohydrate levels.

CLIENT EDUCATION

Client should be educated about the signs of hypoglycemia and seek immediate attention if they occur.

SURGICAL CONSIDERATIONS

• Surgical management improves prognosis over medical therapy alone. • Medical management to prevent severe hypoglycemia is important before an exploratory laparotomy. Most patients respond well to frequent small feedings and corticosteroids. In rare refractory cases, the use of IV fluids containing 2.5% to 5% dextrose and/or glucagon may be necessary. • Objectives include confirmation of the diagnosis, elucidation of the presence/absence of any extra-pancreatic metastases and/or other disease and removal of as much cancerous tissue as possible. • At surgery, most insulinomas can be visualized and/or palpated. If a pancreatic mass can't be found, intraoperative ultrasound may be beneficial. In rare cases, IV 1% methylene blue (3 mg/kg added to 250 mL 0.9% NaCl, given IV slowly over 30–45 minutes) may be used to delineate an occult pancreatic insulinoma; however, hemolytic anemia, pseudocyanosis, and hemoglobinuric nephrotoxicity are possible side effects; therefore, routine use is not recommended. • Approximately 15% of dogs have multiple primary insulinomas, so always examine the entire pancreas. • Biopsy regional lymph nodes and carefully evaluate the liver (and other abdominal contents) with biopsy of any abnormalities. Approximately 40–50% of dogs will have metastasis. In one study, of 14 dogs suspected to have extra-pancreatic metastasis from a primary pancreatic insulinoma, only 8 (57%) had histologic evidence of metastasis. Therefore, the presence of what appears to be metastasis should be biopsied and not automatically lead to intraoperative euthanasia.

**MEDICATIONS****DRUG(S) OF CHOICE*****Emergency/Acute Therapy***

See "Nursing Care" above

Long-Term Therapy

- If dietary therapy is ineffective, glucocorticoids such as prednisone may be given at an initial dosage of 0.25 mg/kg PO q12h and be increased as needed to 2–3 mg/kg PO q12h. • Diazoxide (Proglycem) stimulates hepatic

gluconeogenesis/glycogenolysis and inhibits insulin secretion. Diazoxide may be given at 5–60 mg/kg PO q12h (start low and increase as needed) in addition to dietary modifications and/or glucocorticoids when they are becoming less effective. Diazoxide can be difficult to locate and be prohibitively expensive for some clients though less expensive compounded sources are becoming more readily available. • Streptozocin is a nitrosourea that semi-selectively targets pancreatic B cells. Streptozotocin may be given at 500 mg/m² slowly IV over 2 hours after a 3-hour 0.9% NaCl diuresis and followed with a 2-hour diuresis. This protocol may be repeated every 3 weeks until normoglycemia is achieved. Streptozotocin is emetogenic and can be hepatotoxic and/or nephrotoxic. • Glucagon is gluconeogenic and may be used at 5 ng/kg/minute CRI (to effect) to treat acute severe refractory hypoglycemia. • The synthetic somatostatin analogues ocreotide (10–20 µg SC q8–12h) or lanreotide (no determined dose in veterinary species) may be utilized to prevent hypoglycemia in dogs refractory to conventional treatments.

CONTRAINdications

Insulin

PRECAUTIONS

- Dextrose boluses, when given alone, may precipitate further hypoglycemic crises.
- Glucocorticoids used at high dosages for prolonged periods can cause iatrogenic hyperadrenocorticism. • Diazoxide may cause bone marrow suppression, gastrointestinal irritation, aplastic anemia, cataracts, thrombocytopenia and tachycardia in humans. • Streptozocin can cause emesis, hepatic failure, renal failure, diabetes mellitus, and pancreatitis.

POSSIBLE INTERACTIONS

Hydrochlorothiazide can potentiate diazoxide.

**FOLLOW-UP****PATIENT MONITORING**

- Teach client to monitor for return and/or progression of signs of hypoglycemia.
- In-hospital serum glucose determinations are important for monitoring for return and/or progression of insulinoma-associated hypoglycemia.

POSSIBLE COMPLICATIONS

Recurrent or progressive episodes of hypoglycemia

EXPECTED COURSE AND PROGNOSIS

- Dogs that undergo exploratory laparotomy are more likely to become and remain euglycemic longer and have longer survivals than dogs managed by medical means. Even in the presence of local metastatic disease, any

reduction of tumor burden is likely to improve glycemic control with medical therapies. The median length of euglycemia control after surgery is inversely correlated with the stage of disease and varies from 14 months for those dogs without evidence of metastasis to only 2–3 months for those dogs with nodal and/or distant metastasis. The median survival time is also inversely correlated with the stage of disease and varies from about 16–19 months (range, 2–60 months) for dogs without evidence of metastasis to 7–9 months in dogs with evidence of nodal and/or distant metastasis. More recent studies have documented even longer median survival times of 17–18 months for all dogs with insulinoma and 25–42 months for those dogs undergoing surgical and medical therapies. • Cats—mean survival time, about 6.5 months; range, 0–18 months.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Obesity due to hyperinsulinemia

AGE-RELATED FACTORS

Younger dogs have shorter survival times.

SYNONYMS

- B-cell tumor • Hyperinsulinism
- Insulin-producing pancreatic tumor
- Insulin-secreting tumor • Islet cell adenocarcinoma • Islet cell tumor

INTERSTITIAL CELL TUMOR, TESTICLE

BASICS

OVERVIEW

Benign tumor of the testicle that arises from interstitial (Leydig) cells.

SIGNALMENT

- 33–50% of all testicular tumor in dogs but rare in cats.
- Median age, 10 years.
- Boxer, German shepherd, Afghan hound, Weimaraner, Shetland sheepdog, Collie, and Maltese may be at increased risk.

SIGNS

- Usually incidental finding.
- Fertility issues in breeding dogs.
- May be associated with testosterone secretion and perianal gland hyperplasia or adenomas.
- 4–20% of dogs will have more than 1 type of testicular tumor. Up to 50% of dogs will have bilateral tumors, only 12% of contralateral tumors will be palpable.

CAUSES & RISK FACTORS

- Generally unknown
- Cryptorchidism—may predispose

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Sertoli cell tumor
- Seminoma
- Hyperadrenocorticism—with feminization
- Hypothyroidism—with feminization

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal, unless estrogen excess causes bone marrow hypoplasia (rare).
- Various cytopenias—with estrogen excess (rare).

OTHER LABORATORY TESTS

- High serum estradiol concentration.
- Low serum testosterone concentration.

IMAGING

- Testicular sonography may aid in differential diagnoses.
- Abdominal ultrasonography for retained testicles and to evaluate for concurrent malignancies.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Bilateral orchiectomy and scrotal ablation is the treatment of choice. Exploratory laparotomy for retained testicles.
- Histopathologic examination of appropriate tissue.
- Immunohistochemistry may be necessary to identify cell of origin in some cases.

MEDICATIONS

DRUG(S)

- None, unless bone marrow hypoplasia induces a dangerous cytopenia.
- Recombinant hematopoietic colony-stimulating factors—may be useful in treating bone marrow hypoplasia.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

None required, unless bone marrow hypoplasia

POSSIBLE COMPLICATIONS

Cytopenias caused by estrogen excess

EXPECTED COURSE AND PROGNOSIS

Bilateral orchiectomy and scrotal ablation are often curative.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Prostate disease—with testicular tumor
- Perianal gland hyperplasia/adenomas

INTERVERTEBRAL DISC DISEASE—CATS

BASICS

OVERVIEW

- Disc extrusion or protrusion causing myelopathy is more common in dogs; both Hansen's type I and type II disc disease, and acute, non-compressive nucleus pulposus extrusion are reported in cats.
- Type I disc disease is secondary to chondroid metaplasia and mineralization of the nucleus pulposus.
- Type II disc disease is secondary to fibroid degeneration and protrusion of the annulus fibrosus.
- With acute, non-compressive nucleus pulposus extrusion, normal nucleus pulposus is extruded through a tear in the dorsal annulus, resulting in a concussive or contusive injury, with minimal to no ongoing compression of the spinal cord.

SIGNALMENT

- For all reported cats with myelopathy secondary to disc disease—mean age 8.4 years, range 1.5–17 years.
- Cats with mineralized type I disc disease—mean age 7.3 years, range 2–13 years.
- Predominantly domestic breeds, several purebred (Oriental) breeds reported. Rare exotic large cat (tiger) reported.
- No sex predisposition.

SIGNS

- Majority of cats have thoracolumbar or lumbosacral disc disease; clinical signs are confined to pelvic limbs. Cervical disc disease is also described, in which case all four limbs may be affected.
- Signs are frequently acute but may be chronic.
- Paresis/paralysis.
- Ataxia.
- Gait abnormality, lameness, reluctance to jump.
- Spinal/back pain.
- Urinary/fecal incontinence.
- Abnormalities of tail carriage or tone.
- Loss of pain perception (if severe lesion).
- Hypoventilation (if severe cervical lesion).

CAUSES & RISK FACTORS

- Majority of cats reported had type I disc degeneration, with extrusion of mineralized nucleus pulposus into the vertebral canal resulting in spinal cord trauma and compression.
- Unlike dogs, where chondrodystrophic breeds (e.g., dachshunds) are predisposed to type I disc disease and subsequent extrusion, no obvious risk factors are apparent in cats.
- Most cats reported had clinically significant

disc protrusions or extrusions between T11 and S1. Similar to dogs, the presence of the intercapital ligament from T1–T10 may make disc protrusions in that region less likely.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Trauma • Vascular—ischemic neuromyopathy ("saddle thrombus")
- Neoplasia, especially lymphoma
- Vascular—ischemia to spinal cord
- Infectious—FIP, *Cryptococcus*, etc.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

IMAGING

- Vertebral column radiographs—narrowed disc space(s), mineralized discs in situ, mineralized disc material within the vertebral canal or overlying intervertebral foraminae.
- Myelography—extradural compressive lesion at the affected disc. • CT—extradural compression; mineralization of compressive material may be apparent. • MRI—T2 hyperintensity within injured cord; mineralized disc material appears hypointense on all imaging sequences; extradural compression may be apparent.

DIAGNOSTIC PROCEDURES

- Cerebrospinal fluid—unremarkable or contaminated with blood in most cats; neutrophilic pleocytosis noted in three cats.
- Histopathology of material removed at surgery—consistent with degenerative disc material (type I or II).

TREATMENT

- Surgical spinal cord decompression likely the most effective treatment for compressive disc disease. • Risks of spinal surgery should be discussed with the owner—hemorrhage, iatrogenic injury to the spinal cord, instability.
- Hemilaminectomy, ventral slot, lateral corpectomy, and lumbosacral dorsal laminectomy surgeries are described in the cat. • Postoperative care—good recumbent patient care, pain management, bladder management if incontinent cat (indwelling urinary catheter or manual expression), and appropriate physical therapy. • Fenestration of adjacent mineralized discs should be considered to avoid recurrence. • Medical management (cage rest, pain management) may be considered in ambulatory cats, but

more aggressive diagnostics and treatment should be considered in non-ambulatory cats and those with progressive neurologic signs.

MEDICATIONS

DRUG(S)

- Pain management, preferably opiates, if the cat tolerates them. • Efficacy of corticosteroids in feline disc disease has not been evaluated.

FOLLOW-UP

- Repeat neurologic examinations (at least 1–2 times/day) during hospitalization to monitor postoperative and medically managed patients for improvement or decline in neurologic status. • Strict cage rest for medically managed and postoperative patients for 4–6 weeks, then gradual increase in activity and physical therapy, as needed. • It is unknown whether long-term activity restriction is beneficial. • Because disc disease is uncommon in cats, possible recurrence rate is unknown, but in one cat that recovered well after hemilaminectomy, an additional mineralized disc extrusion caused paraplegia and necessitated a second surgery (unpublished data). • A few cats had persistent urinary retention in spite of good recovery of ambulation, requiring routine bladder expression by the client. • Majority of cats managed surgically (even two without pain perception) had a good-to-excellent outcome. • Very few cats were medically managed long-term, so prognosis with medical management is unknown.

MISCELLANEOUS

ABBREVIATIONS

- CT = computed tomography • FIP = feline infectious peritonitis • MRI = magnetic resonance imaging

INTERVERTEBRAL DISC DISEASE, CERVICAL

BASICS

DEFINITION

A degeneration of the cervical intervertebral discs that causes protrusion or extrusion of disc material into the spinal canal. The protruded or extruded disc material causes spinal cord compression (myelopathy) and/or nerve root compression (radiculopathy).

PATHOPHYSIOLOGY

- Classified as acute disc herniation (Hansen type I disc) or chronic disc protrusion (Hansen type II disc).
- Hansen type I disc degeneration is characterized by chondroid degeneration of the nucleus pulposus and acute rupture of the annulus fibrosus with extrusion of the nucleus pulposus into the spinal canal.
- Hansen type II disc degeneration is characterized by fibrinoid degeneration of the nucleus pulposus. This causes bulging and protrusion of the dorsal annulus fibrosus into the vertebral canal.
- Disc extrusion or protrusion into the spinal canal causes focal compression of the spinal cord (myelopathy) and/or focal compression of a nerve root (radiculopathy).
- Consequences of spinal cord compression are ischemia and demyelination.
- Dorsal disc extrusion or protrusion is more common than lateral disc extrusion or protrusion.
- Disc extrusion may be secondary to trauma but this rarely occurs.
- Surgical fusion of cervical vertebrae may alter the biomechanics of adjacent vertebral bodies and therefore predispose discs to protrusion or extrusion and this is termed the domino effect.

SYSTEM AFFECTED

Nervous system—either focal myelopathy or focal radiculopathy

GENETICS

- Not known.
- Chondrodystrophoid breeds (e.g., dachshund, beagle, Cocker spaniel) are most commonly affected with Hansen type I disc extrusion.
- Large-breed dogs (e.g., Doberman pinscher) are most commonly affected with Hansen type II disc extrusion.

INCIDENCE/PREVALENCE

- Cervical disc disease accounts for roughly 15% of all canine intervertebral disc disease.
- Eighty percent of disc extrusion occurs in dachshunds, beagles, and poodles.
- The incidence of degenerative disc disease in the overall canine population is about 2%, while the incidence in the dachshund population is about 25%.
- C3–C4 is reported to be the most common site of disc extrusion.

SIGNALMENT

Species

Dogs

Breed Predisposition

- Hansen type I—dachshund, poodle, beagle, Cocker spaniel
- Hansen type II—Doberman pinscher

Mean Age and Range

- Hansen type I—3–6 years of age
- Hansen type II—8–10 years of age

Predominant Sex

None recognized

SIGNS

Severity of clinical signs and spinal cord injury is dependent on several factors, including the rate and volume of disc protrusion or extrusion, spinal cord diameter relative to vertebral canal diameter, and the velocity of disc material that was extruded.

Historical Findings

- Neck pain—most common owner complaint.
- Stiff, stilted gait, reluctance to move the head and neck.
- Lowered head stance and muscle spasms of the head, neck, and shoulder.
- It has been reported that 10% of affected patients are tetraparetic.
- Muscle atrophy over the scapula.
- Patients may have neck pain and front leg lameness secondary to dorsolateral disc extrusion, also termed root signature or more appropriately a radiculopathy.

Physical Examination Findings

- Neck pain—elicited upon flexion and extension of the neck or by turning the neck from side to side. Pain can also be elicited by deep palpation of the cervical muscles.
- Wheelbarrow postural reflex may cause the patient to hit their nose on the ground due to neck pain.
- Herniation in the cervical region is often associated with minimal neurologic signs because the spinal canal area is greater and can accommodate more disc material before spinal cord compression.
- Occasionally patients have neck pain and apparent forelimb lameness (e.g., a thoracic limb that knuckles, appears lame, or is held in partial flexion) as a result of dorsolateral disc herniation (root signature/radiculopathy). This helps localize the lesion to C4–C7.
- Paresis with postural reaction deficits involving both thoracic and pelvic limbs may be present. The deficits can also be ipsilateral in nature.
- Pelvic limb paresis may be more severe than thoracic limb paresis.
- Pelvic limb spinal reflexes may be normal to exaggerated.
- Thoracic limb spinal reflexes may be normal to exaggerated when lesions are located in the C1–C6 spinal cord segment and may be

normal to decreased when the C6–T2 spinal cord segment is affected.

- There is no correlation between severity of clinical signs and the degree of compression.
- Bladder function may be upper motor neuron in nature or normal.

CAUSES

- Hansen type I—early chondroid degeneration of the cervical intervertebral disc and subsequent disc mineralization.
- Hansen type II—gradual fibroid degeneration of the cervical intervertebral disc.

RISK FACTORS

Obesity and repeated traumatic events in those breeds predisposed to intervertebral disc disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hansen type I disc disease
- Hansen type II disc disease
- Neoplasia
- Atlantoaxial instability
- Spinal fracture/luxation
- Discospondylitis
- Meningitis
- Fibrocartilaginous embolism
- Cervical vertebral instability
- Endocrine—hypothyroidism
- Spondylomyopathy
- Osteoarthritis
- Glycogen storage diseases

CBC/BIOCHEMISTRY/URINALYSIS

Should be performed in older animals in anticipation of general anesthesia and surgery.

OTHER LABORATORY TESTS

- CSF analysis—performed under general anesthesia prior to myelography. CSF should be collected through a cisternal tap since this site is closer to the lesion than a lumbar tap.
- CSF analysis reveals mild to moderate elevation in protein levels and mild to moderate pleocytosis.
- Hansen type I disc herniation is usually associated with more pronounced CSF changes than Hansen type II disc disease.
- EMG may be useful if the underlying cause is associated with denervation.

IMAGING

Cervical Spinal Radiography

- Well-positioned lateral and ventrodorsal survey radiographs of the cervical spine are always indicated.
- Animals should be anesthetized for this procedure.
- Classic findings include narrowed intervertebral disc space or disc space wedging, collapse of the articular facets, calcified disc material present in the intervertebral foramen or in the spinal canal.

(CONTINUED)

- Hansen type II disc disease may be associated with spondylosis deformans.
- May reveal evidence of discospondylitis, fracture/luxation, atlantoaxial instability, or lytic vertebrae suggestive of a bone tumor.

Myelography

- Survey cervical radiographs may be misleading; therefore, myelography is indicated in 90–95% of cervical disc patients.
- Either a cisternal or lumbar injection between L5 and L6 or L4 and L5 can be used but a lumbar injection is preferred.
- Lateral radiographs—reveal dorsal deviation of the ventral contrast column over the intervertebral disc space consistent with extradural compression.
- An intraforaminal or dorsolateral disc herniation is best seen on an oblique cervical radiograph, with the entire cervical spine positioned at a 45–60° angle to the table.
- Acute cases with spinal cord swelling can cause blockage of contrast material and prevent it from flowing past the obstruction, limiting the diagnostic capabilities of the image.

Enhanced Diagnostic Imaging

- MRI and CT have also been used for diagnosis of cervical intervertebral disc disease.
- MRI or CT is useful for diagnosing foraminal or lateral disc extrusions when routine radiology is normal.
- MRI is the best available method for early recognition of disc degeneration in dogs.
- MRI signs of cervical radicular compression are obliteration of epidural fat in the neural foramen, displacement of the nerve roots, facet joint degeneration, uncovertebral joint hypertrophy, and disc material within the neural foramen.
- CT may provide a diagnostic image when there is an obstruction of the contrast medium flow.

DIAGNOSTIC PROCEDURES

Cerebral spinal fluid analysis

PATHOLOGIC FINDINGS**Gross Findings**

- Hansen type I disc—white extruded disc material that has a granular consistency and is usually easily removed from the spinal canal.
- Hansen type II disc—firm protrusion of the dorsal annulus fibrosus that is adherent to the floor of the spinal canal and to the dura of the spinal cord. Type II discs are much more difficult to remove from the spinal canal.
- Spinal cord—in acute disc extrusion the spinal cord may appear bruised and swollen; in chronic disc protrusion the spinal cord may appear to be atrophied but is often normal in appearance.

Histopathologic Findings

- Hansen type I disc—shifting concentration of glycosaminoglycans, loss of water and

INTERVERTEBRAL DISC DISEASE, CERVICAL

proteoglycan content, and increased collagen content. The disc becomes more cartilaginous and undergoes dystrophic calcification.

- Hansen type II disc—a gradual fibroid metaplasia leaves the disc with increased glycosaminoglycan levels and lower collagen content. The nucleus does not undergo cartilaginous metaplasia.
- Spinal cord—dependent on the severity of the disease and type of disc disease. Hansen type II—demyelination and gliosis are seen. Hansen type I—hemorrhage and edema can be seen; with severe disease myelomalacia can be observed.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Conservative management—dependent on patient's history and presenting neurologic status. In general, conservative management is indicated with a gradual onset of clinical signs or clinical signs that are limited to hyperesthesia or mild ataxia.
- Surgical management—patients with repeated episodes of neck pain, patients presented with severe neck pain and neurologic deficits, or patients that have not responded to conservative management.

NURSING CARE

- Handling—minimal manipulation of the cervical spine and avoidance of jugular venipuncture if at all possible.
- Urination—monitor patients for complete emptying of the bladder; patients may need to have bladder manually expressed or intermittent bladder catheterization. In some cases, indwelling urinary catheter may need to be placed. Urinalysis, including culture and sensitivity, should be performed after removal of an indwelling catheter to make sure the patient did not obtain a nosocomial bacterial cystitis. Newer studies suggest performing a culture and sensitivity on the urine of all dogs undergoing spinal decompression surgery.
- Defecation—patients may need enemas and can be switched to low-residue diet to decrease the volume of feces.
- Recumbent patients—should be kept on a well-padded mat and turned every 4 hours. Patients should be checked for pressure sores over bony prominences.
- Physical therapy—hydrotherapy and passive range of motion of all joints should be performed as often as possible to prevent severe muscle atrophy.

ACTIVITY

- Minimal, no running or jumping. When patients are being walked, a harness should be used instead of a collar.
- With conservative management patients

should be strictly confined to cage rest for 3–4 weeks.

- Following surgery patients should have minimal activity and be leash-walked only for 4–6 weeks, then slowly reintroduced to full activity.

DIET

For obese patients, a reducing diet should be instituted.

CLIENT EDUCATION

- For conservative management, strict cage confinement should be emphasized.
- Weight loss if the animal is obese.
- Common clinical signs of animals with cervical disc disease.

SURGICAL CONSIDERATIONS

- When indicated the goal of surgery is to remove disc material from the spinal canal and therefore decompress the spinal cord and/or nerve root.
- Surgery usually provides immediate pain relief and eventual normal motor function.
- A ventral cervical slot is the most common surgical approach for the removal of disc material from the spinal canal.
- Disc material that has extruded dorsolaterally into the intervertebral foramen is removed via a lateral approach to the cervical spine or through a dorsal laminectomy.
- Fenestration alone for dogs with neck pain usually does not resolve clinical signs and is no longer recommended.

**MEDICATIONS****DRUG(S)**

- Low-dose glucocorticoid therapy may be beneficial in order to decrease the pain in animals that are being treated conservatively.
- Glucocorticoids given to animals without simultaneous strict cage confinement could exacerbate disc extrusion by encouraging exercise.
- NSAIDs can be used only if the animal is not currently or recently being given glucocorticoids.
- Muscle relaxants can be used, but are generally unsuccessful when used alone.

CONTRAINdications

Never use glucocorticoids with NSAIDs—this can cause severe gastrointestinal irritation and possibly intestinal perforation.

PRECAUTIONS

When using high-dose corticosteroids for cervical disc disease, patients should be placed on gastro-protectants to prevent gastrointestinal side effects associated with corticosteroids. Use of high-dose glucocorticoids is not well-supported by the literature and is generally not recommended.

INTERVERTEBRAL DISC DISEASE, CERVICAL

(CONTINUED)

POSSIBLE INTERACTIONS

NSAIDs in combination with glucocorticoids can cause gastrointestinal perforation or severe gastrointestinal bleeding, both situations leading to death.

FOLLOW-UP

PATIENT MONITORING

- Weekly evaluations should be performed until the resolution of clinical signs.
- All patients should be fitted with a harness, and neck collars should be avoided.

PREVENTION/AVOIDANCE

- Inherent in particular breeds.
- Keeping patients at an ideal weight may help.

I

POSSIBLE COMPLICATIONS

- Complications are uncommon.
- Continued neck pain,
- Deteriorating motor status,
- Subluxation/Luxation of vertebral bodies.

EXPECTED COURSE AND PROGNOSIS

- Prognosis for patients treated surgically or conservatively depends on neurologic signs at the time of presentation.
- Prognosis is generally favorable for most patients.
- Most patients treated conservatively have recurrence of disease and may require surgical intervention.
- A recovery rate of 56% has been found for patients with the loss of deep pain who underwent surgical decompression within 12 h of the onset of clinical signs. This rate falls to less than 5% if the surgical intervention is delayed for 48 h or more.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Animals predisposed to cervical disc disease are also the same breeds that are predisposed to thoracolumbar disc disease.

INTERVERTEBRAL DISC DISEASE, THORACOLUMBAR

BASICS

DEFINITION

Intervertebral discs degenerate by loss of water, cellular necrosis, and dystrophic calcification. Biomechanical properties of the disc deteriorate, and subsequently protrusion (Hansen type II) or extrusion (Hansen type I) of disc material occurs.

PATHOPHYSIOLOGY

- Intervertebral disc degeneration is initiated by one or more factors including trauma, chronic overload, decreased spinal mobility, age-related deterioration in collagen and cartilage, and hypermobility.
- Hansen type I refers to acute extrusion of nucleus pulposus through the annulus fibrosis into the vertebral canal. Hansen type I lesions typically occur in chondrodystrophic dogs, but may occur in larger non-chondrodystrophic dogs as well. Onset of neurologic signs is usually acute and often severe.
- Hansen type II lesions involve gradual protrusion (bulging) of the dorsal annular fibers into the vertebral canal associated with fibroid degeneration of the disc. Hansen type II lesions typically occur in nonchondrodystrophic dogs. The most common case presentation is of gradual onset of neurologic dysfunction and slow progression.
- Some sources describe a Hansen type III injury where the nucleus pulposus herniates with such force as to enter the spinal cord. Hansen type III injuries are rare, but carry a poor prognosis because they are commonly associated with myelomalacia and loss of deep pain response.
- Acute disc extrusion results in extruded material causing direct trauma to the spinal cord and residual disc mass leading to extradural spinal cord compression. Trauma and spinal cord compression results in ischemia and spinal cord changes that vary from mild demyelination to necrosis of both gray and white matter; events at the cellular level include release of vasoactive substances, increased intracellular calcium, and increased free radical formation and lipid peroxides.
- Pain due to dural irritation, nerve root impingement, or possibly discogenic (annular pain receptors) in origin.
- Disc herniation is rare between T3 and T10 owing to the barrier of the intercapital ligament between the dorsal annulus and spinal cord.

GENETICS

Early studies suggest a polygenic model with no dominance or sex linkage.

INCIDENCE/PREVALENCE

- Most common neurologic dysfunction in small animals; affects 2% of the canine population.

- Occurs less commonly in cats, but the exact incidence is unknown, and the disease is likely underdiagnosed or reported due to lack of suspicion as a differential diagnosis.

- In specific breeds, such as dachshunds, affected prevalence as high as 20% has been reported.
- Thoracolumbar disc disease comprises 85% of all disc herniations; 70% occur from T11 to L3.

SIGNALMENT

Species

Dog and occasionally cat

Breed Predilections

- Type I—dachshund; shih tzu, Lhaso apso; Pekingese, Cocker spaniel, Welsh corgis; toy and miniature poodles.
- Type II—large breeds but may occur in any breed.

Mean Age and Range

- Type I, 3–6 years of age
- Type II, 8–10 years of age; cats: mean age of 10 years

SIGNS

General Comments

Clinical signs depend on the type of herniation, velocity of disc contact with the spinal cord, amount and duration of cord compression, location (UMN or LMN), and regional spinal canal/spinal cord diameter ratio (cervical vs. thoracolumbar).

Historical Findings

- Onset may be peracute or acute in chondrodystrophoid dogs (type I disease) and may occur during vigorous activity.
- Larger dogs or smaller dogs with type II disease have a more insidious onset and tend to worsen with time.

Physical Examination Findings

- Thoracolumbar pain common in dogs; reluctant to ambulate and hunched posture; careful palpation of spinous processes and epaxial musculature produces distinct localized pain; often some degree of paraparesis with decreased or absent proprioception or decreased motor ability in the rear limbs.
- Spinal reflexes in the rear limbs are usually exaggerated (hyper) when lesion is between T3 and L3; reflexes are decreased (hypo) when lesion is caudal to L3.
- Superficial and deep pain perception may be decreased or absent in the rear limbs; presence of deep pain sensation is the single most reliable prognostic factor for return to acceptable function; pain perception should be conscious in nature and not confused with a withdrawal reflex (local spinal reflex). In animals with diminished deep pain, mydriasis or tachycardia may be useful in confirming the presence of deep pain.
- Forelimb function is normal with thoracolumbar disc rupture; occasionally Schiff-Sherrington phenomena may cause

increased muscle tone in the forelimbs, but this clinical sign is location related only and does not indicate a poor prognosis.

- Urinary incontinence or retention is common when the lesion affects motor function.
- Pain is less obvious in cats; the site of herniation is often lumbar.

CAUSES

- Chondroid or fibroid degeneration of the thoracolumbar intervertebral discs.
- 15% of animals with spinal fractures have been reported to have disc extrusions in addition to the fracture/luxation.

RISK FACTORS

Type I disease most often affects chondrodystrophic breeds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Type I—trauma causing fracture/luxation, neoplasia, discospondylitis, fibrocartilaginous embolism; differentiated by history, survey radiography, and myelography.
- Type II—degenerative myelopathy, spinal neoplasia, discospondylitis, orthopedic disease; differentiated by history, radiography, and careful orthopedic and neurologic examination.

CBC/BIOCHEMISTRY/URINALYSIS

- Elevation of liver enzymes common if patient has received corticosteroids for pain or neurologic disease.
- Urine retention/incontinence increases risk of urinary tract infection characterized by leukocytes, protein, and bacteruria on urinalysis.

OTHER LABORATORY TESTS

CSF analysis performed routinely in conjunction with myelography if there is high suspicion of another disease process; may be normal but more typically shows mild to moderate increase in protein with or without pleocytosis.

IMAGING

- Thoracolumbar spinal radiography with the patient anesthetized. Unanesthetized radiographs can be used to rule out neoplasia and other processes, but can be misleading for thoracolumbar disc disease.
- Survey radiographs rule out some other disease processes.
- Diagnostic radiographs taken under general anesthesia may reveal a narrowed or wedged disc space, collapsed articular facet space, and small intervertebral foramen with increased or mineralized density within the spinal canal.
- Accuracy and sensitivity of survey radiographs for determining a specific site of disc herniation is low.

INTERVERTEBRAL DISC DISEASE, THORACOLUMBAR

(CONTINUED)

DIAGNOSTIC PROCEDURES

- MRI is now considered the diagnostic mode of choice when available due to the noninvasive nature and increased information about disease process and localization obtained. Presence of a hyperintense spinal cord lesion as long as the body of L2 on a T2-weighted image in deep-pain-negative dogs is associated with a poorer prognosis.
- CT with or without contrast is often diagnostic in chondrodystrophic dogs; dystrophic calcification of extruded material is easily visualized and lateralization can be easily determined. Contrast enhancement can differentiate disc disease from neoplastic or granulomatous processes.
- Myelography performed with iohexol was previously the method of choice and is still indicated when CT or MRI is not available. The contrast agent is usually introduced at L5–L6. Positive diagnosis is an extradural mass lesion causing spinal cord compression adjacent to the affected disc; spinal cord swelling may be evidenced by thinning of contrast columns over several intervertebral spaces.
- Lateralization is more consistent when determined from both oblique and dorsoventral myelogram views..
- CSF analysis is an important addition when alternative causes of neuropathy are likely differential diagnoses or when imaging findings are equivocal or nondiagnostic.

PATHOLOGIC FINDINGS

Gross

- Extruded disc material (type I disease)—white to yellow and “toothpaste” consistency; if chronic, may be hardened and adhered to surrounding structures.
- Protruded disc material (type II disease)—usually firm, grayish-white, and may be adherent to surrounding structures.
- Spinal cord may appear normal or be swollen and discolored in acute severe disease.

Histopathologic

- Degenerated discs have decreased amounts of proteoglycans, glycosaminoglycans, and water; discs may become mineralized or cartilaginous.
- Spinal cord lesion depends upon type and severity of disc extrusion or protrusion; acute, severe disease may cause hemorrhage, edema, tissue necrosis; chronic disease demyelination of white and in some cases gray matter.

TREATMENT

APPROPRIATE HEALTH CARE

- Guidelines for therapy based on classification of clinical condition.
- Class 1—back pain only, first episode.
- Class 2—recurrent back pain, ataxia, mild paraparesis, motor ability good.

- Class 3—severe paraparesis, proprioceptive deficits, motor ability affected but still present.
- Class 4A—complete paralysis (no motor ability) with deep pain perception present.
- Class 4B—complete paralysis, no deep pain perception present.
- Class 1 patients treated medically unless pain persists.
- Class 2 patients treated medically initially with serial neurologic exam, surgery if patient remains static or condition declines.
- Classes 3 and 4A—immediate surgical therapy; prognosis good.
- Class 4B—surgical therapy and fair prognosis if within the first 12–48 hours of occurrence. Poor prognosis if deep pain perception has been absent for > 48 hours.
- Serial neurologic examination important for all affected animals.

NURSING CARE

- Absolute restricted confinement for 2–4 weeks or until ambulatory.
- Minimize spinal manipulation and support spine when handling patient.
- Ensure ability to urinate or consider bladder expression, intermittent catheterization, or indwelling urinary catheter for patients in classes 3–4B.
- Recumbent patients should be kept clean on padded bedding placed on elevated cage racks and turned frequently to prevent formation of decubital ulcers.
- Manual evacuation of the bowel or enemas may be necessary to promote defecation.
- Physical therapy with passive manipulation of rear limbs begun early followed by more intense therapy (hydrotherapy) for animals with neurologic deficits.
- Carts useful in many patients in promoting return to function; patient tolerance is limiting factor.

ACTIVITY

- Restricted movement most important part of medical management.
- Cage rest in hospital or enforced cage rest as an outpatient for 2–4 weeks for class 1 patients or postoperative animals.

DIET

Weight reduction if patient is obese.

CLIENT EDUCATION

- Some degree of restricted activity may be important for the remainder of the animal's life since it has disc disease.
- Most animals in classes 1–4A have a good to excellent prognosis for return to function, i.e., ambulation with bowel and bladder continence; patients in class 4B have a poorer but not hopeless prognosis; percentages vary but up to approximately 50% may regain deep pain and some function.

SURGICAL CONSIDERATIONS

- Strongly indicated for animals in classes 3 and 4, also within the first 12–48 hours for

class 4B dogs; also indicated for static or worsening class 1 and 2 dogs.

- Primary surgical goal is to relieve spinal cord compression by disc mass removal via hemilaminectomy, dorsal laminectomy, or pediculectomy; disc fenestration alone rarely indicated but is highly recommended as an adjunct to decompression at the primary site.
- Hemilaminectomy is the surgical procedure of choice for most thoracolumbar discs. Studies indicate improved return to function, minimized spinal destabilization, and decreased formation of compressive laminectomy scars in the long-term postoperative period.
- Foramenotomy and pediculectomy are similar to hemilaminectomy and may allow a more limited approach and decreased cord manipulation.
- Dorsal laminectomy is the procedure of choice for disc herniation in the region of the lumbosacral plexus or where extensive examination of the spinal cord is necessary.
- Recurrence of clinical signs in animals in the immediate postoperative period may be due to further extrusion of disc from the original site if unfenestrated. Later recurrence of clinical signs after recovery usually due to protrusion/extrusion at adjacent sites. Several studies indicate 8% long-term recurrence of clinical signs in dogs after initial hemilaminectomy and active site fenestration due to protrusion/extrusion at other sites.
- Surgical controversies remain over the issues of multiple site prophylactic disc fenestrations performed during the decompressive surgery and the timing and prognosis for return to function after surgery in patients showing no deep pain.

MEDICATIONS

DRUG(S) OF CHOICE

- NSAIDs or narcotics may be used as an analgesic in class 1 cases.
- Narcotic analgesics may be necessary postoperatively; hydromorphone (0.05–0.2 mg/kg IV or IM, SC q4h). Transdermal lidocaine or fentanyl may be useful modes of analgesic administration in some animals.
- Gabapentin (Neurotin), an NMDA receptor antagonist, may be useful at 5–10 mg/kg PO q12h in dogs with chronic pain sensitization.
- Methocarbamol (25–45 mg/kg q8h) may be useful in cases where muscle spasm is contributing to pain; more applicable with cervical disease.
- Bethanechol (5–15 mg/dog PO) and phenoxybenzamine (0.25 mg/kg PO q8–12h) or prazosin 1 mg/15 kg PO q8–12h variably helpful in managing bladder dysfunction associated with spinal cord lesion.

(CONTINUED)

INTERVERTEBRAL DISC DISEASE, THORACOLUMBAR

- Previous indications for methylprednisolone sodium succinate for treatment of acute pain are now controversial for efficacy. The high potential for side effects may outweigh the small gains from the drug.

PRECAUTIONS

- Glucocorticoid use is discouraged in cases of IVDD where drug side effects such as gastrointestinal hemorrhage and intestinal perforation often far outweigh benefits. Potent glucocorticoids such as dexamethasone should never be used.
- Glucocorticoids are contraindicated within 48 hours of using an NSAID in dogs.
- Use of glucocorticoids without cage confinement may decrease pain, thereby encouraging excessive activity and leading to further disc herniation and deterioration of clinical condition.

ALTERNATIVE DRUG(S) AND THERAPIES

- Acupuncture use has been described, but efficacy has yet to be determined.
- Chiropractic therapy has no proven benefits for IVDD and may potentially be harmful to the animal.
- Percutaneous therapeutic lasers do not reach the site of inflammation and are likely not efficacious.
- Discolysis by enzymatic injection or laser ablation described but not proven therapy in dogs.

**FOLLOW-UP****PATIENT MONITORING**

- Patients treated medically should be reevaluated two to three times daily for worsening neurologic signs for the first 48 hours after onset.

- If stable, reevaluate daily, then weekly, until clinical signs have resolved.
- Patients treated surgically are evaluated twice daily until improvement is noted; urinary bladder function or awaiting development of an autonomic bladder are the limiting factors for hospitalization.

POSSIBLE COMPLICATIONS

- Recurrence of signs associated with disc herniation at original or at new site.
- Deterioration of clinical signs with or without surgery; continued inflammatory processes initiated by the initial extrusion may result in myelomalacia or diminished function.
- Rarely, development of ascending or descending myelomalacia; occurs in class 4A or 4B dogs 3–5 days following injury and is characterized by variable and changing neurologic findings, possible fever, possible dyspnea; extreme pain, and progressive neurologic signs with the forward movement of the inflammation. Such animals are often euthanized when diagnosed.

EXPECTED COURSE AND PROGNOSIS

- Overall prognosis for dogs in classes 1–4A good to excellent (85–95%); those treated conservatively may experience recurrence of clinical signs.
- Recurrence rates of dogs without fenestration at the time of laminectomy range from 5–30%.
- Dogs in class 4B have a variable (10–75%) chance of recovery; overall a guarded but seemingly favorable prognosis if surgery is performed within 48 hours and the animal is allowed sufficient time to recover.

**MISCELLANEOUS****ABBREVIATIONS**

- CSF = cerebrospinal fluid
- CT = computed tomography
- IVDD = intervertebral disc disease
- LMN = lower motor neuron
- MRI = magnetic resonance imaging
- NSAID = nonsteroidal anti-inflammatory drug
- UMN = upper motor neuron

I

INTUSSUSCEPTION

BASICS

DEFINITION

- Invagination of one intestinal segment into the lumen of the adjacent segment.
- Intussusceptions are classified according to their localization within the gastrointestinal tract. • Ileocolic and jejunolejunal intussusceptions are the types most commonly encountered in small animals. Others that have been described include gastroesophageal, duodenolejunal, and cecocolic. • The segment entrapped within the lumen of the intussusception is called the intussusceptum. The engulfing segment is called the intussuscipiens. • Most commonly, the orad segment is found to be engulfed within the aborad segment.

PATOPHYSIOLOGY

- The exact mechanism of intussusception generation is not known. • Many affected animals are young (<1 year of age), and have a history of recent enteritis. • Gastrointestinal irritation may cause the orad segment to undergo a hyperperistaltic state, and invaginate into the more flaccid aborad segment. • The occurrence of an intussusception leads to a mechanical obstruction of the gastrointestinal tract. This obstruction can be either partial or complete.
- Vascular compromise commonly occurs in the intussusceptum and can occasionally occur in the intussuscipiens. Compromise of venous drainage in the face of an intact arterial blood supply leads to marked edema and intramural hemorrhage that may eventually progress to extravasation of blood into the intestinal lumen. • Persistence of the intussusception can lead to eventual decreased oxygen delivery to the mucosal layer. This can lead to the eventual failure of the mucosal barrier and loss of an effective barrier to bacteria and endotoxin entering the bloodstream from the bowel lumen. • With time, vascular compromise can lead to intestinal necrosis and eventual leakage of contents into the peritoneal cavity. This leads to the development of septic peritonitis.

SYSTEMS AFFECTED

- Gastrointestinal—mechanical obstruction, ileus. • Cardiovascular—fluid loss (vomiting and diarrhea) can lead to hypovolemia.

SIGNALMENT

Species

Intussusceptions have been reported in dogs and cats but are more common in dogs.

Breed Predilections

- German shepherd dogs appear to be predisposed to gastroesophageal intussusceptions, accounting for approximately 60% of the reported cases of

this condition. This breed also appears to be overrepresented in the other types of intussusceptions. • Siamese cats may be predisposed.

Mean Age and Range

- Due to the risk factors for development of an intussusception (i.e., parasitism, viral enteritis, dietary indiscretion, foreign body ingestion), animals affected with this disease are often younger.
- Older animals with an intussusception should be carefully screened for diseases that can cause an alteration of peristalsis such as intestinal neoplasia or other mural diseases.

Predominant Sex

- It was originally felt that males outnumber females with gastroesophageal intussusception. Recent reports have called this into question.
- There is no documented sex predilection for other types of intussusceptions in small animals.

SIGNS

General Comments

- Clinical signs associated with the intussusception depend on the anatomic region of the intussusception.
- In general, intussusceptions occurring in more orad segments have more severe clinical signs and disease progression.
- Gastroesophageal intussusceptions typically cause more severe clinical signs than intussusceptions located in a more aborad location.
- The severity of clinical signs also depends upon the completeness of the obstruction.

Historical Findings

- Vomiting.
- Diarrhea (which may or may not have fresh blood or melena present).
- Abdominal pain.
- Abdominal distention.
- Anorexia.
- Weight loss.
- These signs most commonly are acute in onset but may have been occurring for weeks or months.

Physical Examination Findings

- May display overt abdominal pain/discomfort.
- Depending on the severity of the intussusception as well as the length of time that it has been present, some patients may show signs of cardiovascular compromise.
- A sausage-shaped mass may be palpable in the abdomen. The ability to palpate the intussusception is variable.
- Ileocolic intussusceptions may present with protrusion of the intussusceptum from the rectum. This can be differentiated from a rectal prolapse via probing along the side of the protruding tissue. The presence of a blind-ending fornix indicates the existence of a rectal prolapse rather than an intussusception.

CAUSES

- Any disease that alters gastrointestinal motility may lead to an intussusception. Known causes include: enteritis, recent abdominal surgery, intestinal mural disease, and intestinal parasitism.
- Intussusceptions

occur in 8–33% of dogs that undergo renal allograft transplantation and 5% of dogs that undergo hematopoietic cell grafts. The reason for this is unclear, but may be related to immunosuppressive drugs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Any disease that can cause vomiting and diarrhea.
- Some intussusceptions can be chronic in nature; therefore, a chronic history of vomiting and/or diarrhea does not rule out an intussusception. This list includes but is not limited to intestinal parasites, viral enteritis (e.g., parvoviral infections), bacterial enteritis, foreign bodies, inflammatory bowel disease, mesenteric volvulus, and intestinal neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

- Leukogram—can range from normal to leukopenia (especially with sepsis or parvoviral infection) to leukocytosis (either stress response or in some septic patients).
- Hematocrit can be elevated (dehydration or underlying hemorrhagic gastroenteritis) or decreased (cases of intraluminal hemorrhage).
- Biochemical analysis—can show derangements of electrolytes due to loss through vomiting or diarrhea. These can include hyponatremia, hypochloridemia, hypokalemia. May be azotemic (prerenal) if significantly dehydrated. May also be hypoalbuminemic due to effusive loss into intestinal lumen. This can occur in the event of intestinal permeation changes subsequent to eventual intestinal mucosal necrosis.
- Urinalysis—may reveal elevated specific gravity in response to dehydration.

OTHER LABORATORY TESTS

- May see elevated lactate levels due to vascular compromise to intestinal segment.
- Blood gas evaluation may reveal a metabolic acidosis secondary to dehydration and hypoperfusion. Alternately, if the obstruction results in primarily gastric vomiting (pyloric obstruction), a hypochloremic, hypokalemic, metabolic alkalosis may be present.

IMAGING

- Plain radiographs may reveal an obstructive intestinal pattern. The degree of intestinal distention may be related to the degree of obstruction.
- Plain radiographs may or may not reveal evidence of a soft tissue mass consistent with the intussusception.
- With gastroesophageal intussusception, a soft tissue mass may be seen within the lumen of the esophagus near the esophageal hiatus of the diaphragm. These findings can be confused with a hiatal hernia, but the severity of the clinical signs typically associated with a hiatal hernia are much more mild compared to a

(CONTINUED)

gastroesophageal intussusception.

- Abdominal ultrasound is very helpful in the diagnosis of abdominal intussusceptions. The intussusception appears as a target patterned mass on transverse sections, and as a multitude of parallel lines on longitudinal sections.
- Upper GI contrast studies or barium enemas can be helpful in supporting the diagnosis of an intussusception.

PATHOLOGIC FINDINGS

- Examination of the intussusception reveals a telescoping of a segment of bowel into the adjacent segment.
- Histopathologic examination reveals variable degrees of venous congestion, vascular compromise, bowel wall necrosis, and peritonitis.

TREATMENT

APPROPRIATE HEALTH CARE

Initial efforts should be focused on patient stabilization as well as correction of dehydration and existing electrolyte abnormalities.

NURSING CARE

- Intravenous fluid administration to correct dehydration as well as replace anticipated ongoing losses through vomiting and diarrhea.
- Typically, isotonic crystalloids are used. Specific choice of fluid type is dictated by electrolyte derangements.

ACTIVITY

Recommend controlled activity for 10–14 days postoperatively.

DIET

- If patient is vomiting intractably—NPO. If this occurs postoperatively, ileus may be an underlying cause.
- Most patients can readily be fed within 24 hours of surgical correction.

CLIENT EDUCATION

- Immediate surgical intervention is the recommended treatment for intussusceptions.
- Stress the importance of the identification and treatment of an underlying cause.
- Complications may include: perioperative mortality, septic peritonitis, protracted hospital stay to stabilize, and recurrence. Recurrence rates have been reported to be 6–27%.

SURGICAL CONSIDERATIONS

- Surgical correction should be performed as soon as the patient is stable enough to withstand anesthesia and surgery. This is a surgical emergency.
- A full abdominal exploratory should be performed to assist in the identification of any potential underlying causes. Also, multiple intussusceptions may be present in one patient.
- Some intussusceptions can be manually reduced by gently milking the intussusceptum from

within the intussusciens. Upon reduction, the bowel may or may not be viable.

- In the event that manual reduction is not possible, or the bowel has questionable viability, an intestinal resection and anastomosis is necessary.
- Enteroplication has been proposed as a procedure for preventing recurrence. A recent article identified some dogs that necessitated a second surgical procedure to correct problems sustained from the enteroplication procedure. It is important to exercise care when performing this procedure. Briefly, the loops created in the bowel should be gentle, and sharp turns in the bowel loops are to be avoided. The submucosal layer of the adjacent loops of bowel should be included in the sutures, but the lumen should not be entered.

MEDICATIONS

DRUG(S) OF CHOICE

- The prophylactic use of antibiotics is recommended. The choice of antibiotics should be dictated by the bacteria that are encountered.
- Manual reduction of an intussusception is considered a clean surgical procedure, while an intestinal resection and anastomosis is considered a clean-contaminated procedure.
- Long-term antibiotic administration is not recommended except in cases in which septic peritonitis is present either preoperatively or postoperatively.

CONTRAINdications

Some surgeons feel that medications that stimulate peristalsis (e.g., metoclopramide) are contraindicated due to the potential for facilitating an environment for the recurrence of an intussusception.

FOLLOW-UP

PATIENT MONITORING

- Postoperatively, patients should be maintained on intravenous fluids and pain medications.
- Most recurrences occur within the first few days of surgery, but recurrences have been reported up to 3 weeks after surgery.
- Intestinal dehiscence typically occurs 3–5 days postoperatively. The signs, diagnosis, and treatment of septic peritonitis are covered elsewhere in this book.

PREVENTION/AVOIDANCE

Prevention of many of the underlying causes can be achieved through such actions as vaccination against parvovirus, intestinal parasite control, limiting situations in which patients can be exposed to dietary indiscretion or foreign body ingestion.

INTUSSUSCEPTION

POSSIBLE COMPLICATIONS

- Recurrence—6–27% of patients.
- Septic peritonitis—may result from postoperative intestinal dehiscence or intraoperative contamination.
- Short bowel syndrome is a rare complication that can occur with massive resections (generally > 70% in dogs) of the small intestine.

EXPECTED COURSE AND PROGNOSIS

- Highly dependent upon underlying cause, location of intussusception, and condition at presentation.
- Generally, as the intussusception moves more aborad, the prognosis improves as these patients are less severely affected.
- Gastroesophageal intussusceptions have a grave prognosis with mortality rates approaching 95%, while intestinal intussusceptions hold a good prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Can be associated with intestinal parasites, viral enteritis, intestinal mural diseases.
- Gastroesophageal intussusceptions are typically associated with an underlying esophageal disorder.

AGE-RELATED FACTORS

Younger patients are typically affected with underlying enteritis (viral or bacterial) or intestinal parasitism. Older patients are more commonly affected with intestinal neoplasia.

SEE ALSO

- Gastrointestinal Obstruction • Peritonitis

ABBREVIATIONS

- GI = gastrointestinal

IRIS ATROPHY

BASICS

OVERVIEW

- Degeneration of iris tissues; both the iris stroma and posterior iris epithelium can be affected, resulting in loss of iris sphincter and dilator muscle function, atrophy of iris vessels, and loss of iris pigment.
- Both the pupillary margin and more peripheral portions of the iris can be affected, resulting in an iris that is thin or has areas of full-thickness tissue loss.
- Senile or secondary change.
- Secondary iris atrophy is usually a result of chronic inflammation (uveitis).
- Iris sphincter muscle frequently affected by atrophy, resulting in incomplete pupillary constriction and possibly an abnormal pupil shape (dyscoria).
- Irregular scalloped, moth-eaten pupil margin a common manifestation.
- Pupil margin may remain unaffected; peripheral loss of iris tissue can cause large holes in the iris that resemble multiple pupillary openings.
- Vision largely unaffected.
- May cause discomfort in bright-light settings.

SIGNALMENT

- Dog—common aging change; all breeds, but affects small breeds (e.g., miniature and toy poodles, miniature schnauzers, and Chihuahuas) more commonly.
- Cat—uncommon; most common with blue irides.
- Secondary—any breed of dog or cat.

SIGNS

Historical Findings

- Large or dyscoric pupil in one or both eyes.
- Photophobia.
- Previous episodes of uveitis.

Physical Examination Findings

- Incomplete or absent pupillary light reflex accompanied by a normal menace response and dazzle reflex.
- Anisocoria may be present with unilateral or asymmetric presentation.
- Irregular, scalloped edge to the pupillary margin; dyscoria.
- Tapetal reflex visible through thin or absent areas of the iris on transillumination: translucent patches or holes within the iris stroma—may resemble additional pupils.

- Strands of iris occasionally remain, spanning across portions of the pupil.
- Secondary—may be accompanied by any sign associated with chronic uveitis.

CAUSES & RISK FACTORS

- Normal aging
- Uveitis
- Glaucoma

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Must differentiate from congenital iris anomalies.
 - Iris aplasia—rare in dog and cats.
 - Iris hypoplasia—differentiate based on age at first presentation of signs.
 - Iris coloboma—a complete, full-thickness area of lack of development of all layers of the iris; frequently associated with the merle condition; may also see associated lack of lens zonules and an indentation of the lens posterior to the colobomatous iris area; differentiate based on age and presence of associated abnormalities.
 - Polycoria—more than one pupil, each with the ability to constrict due to the presence of an iris sphincter.
 - Persistent pupillary membranes—arise from the collarette (midportion) of the iris, not from the free pupillary margin.
- Pupil dilation due to glaucoma—elevated IOP, corneal edema, conjunctival ± episcleral vascular injection, enlargement of the globe may also be present; may also be blind.
- Adhesions of the iris to the lens or cornea (posterior or anterior synechia) as a result of uveitis or trauma—differentiate based on associated abnormalities consistent with uveitis or perforating trauma (e.g., full-thickness corneal scar).

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Tonometry—low IOP possible if secondary to uveitis; high IOP if secondary to glaucoma or if the uveitis has also caused a secondary glaucoma; normal IOP if primary senile iris atrophy.

TREATMENT

- Irreversible.
- Secondary—successful treatment aimed at controlling the underlying disease may halt progression of the condition.
- Patient may exhibit photophobia because of inability to constrict the pupil; provide adequate shade.

MEDICATIONS

DRUG(S)

- Senile—none
- Secondary—depending on underlying disease

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Topical atropine—exacerbates pupillary dilation and photophobia.

FOLLOW-UP

- Senile—may continue to progress with age.
- Secondary—usually does not progress once the primary disease is controlled.

MISCELLANEOUS

SEE ALSO

- Anterior Uveitis—Cats
- Anterior Uveitis—Dogs
- Glaucoma

ABBREVIATION

- IOP = intraocular pressure

IRON TOXICOSIS

BASICS

OVERVIEW

- Iron—essential element for living organisms; may be lethal when ingested in large quantities.
- Sources of large concentrations of readily ionizable iron—multivitamins; dietary mineral supplements; human pregnancy supplements; some slug and snail baits; some types of hand warmers; some iron-fortified fertilizers; some oxygen absorber sachets (used for spoilage prevention).
- Overdose—loss of normal mucosal limitations of iron absorption; corrosive to GI mucosa.
- Circulating iron in excess of the TIBC—very reactive; causes oxidative damage to any cell type.
- Damage to mitochondria—loss of oxidative metabolism.
- Primary systems affected—gastrointestinal; hepatic; cardiovascular; nervous.

SIGNALMENT

- Dogs; possible in other species.
- All ages are susceptible.

SIGNS

General Comments

- History—generally indicates ingestion of pills or other iron-containing materials.
- Patients that remain asymptomatic for the first 6–8 hours are unlikely to develop any later signs.
- Onset occurs in four stages.

Stage I (0–6 hours)

- Vomiting • Diarrhea • Depression • GI hemorrhage • Abdominal pain

Stage II (6–24 hours)

Apparent recovery (latent period)

Stage III (12–96 hours)

- Vomiting • Diarrhea • Depression • GI hemorrhage • Shock • Tremors • Abdominal pain • Metabolic acidosis

Stage IV (2–6 weeks)

GI stricture formation

CAUSES & RISK FACTORS

- Ingestion of iron-fortified pills or other soluble iron-containing materials.
- Dogs—likely to ingest a large number of pills or other materials, owing to indiscriminate eating behavior.
- Toxic dose (dogs)— $> 20 \text{ mg/kg}$ of elemental/absorbable iron.
- Metallic iron and iron oxide (rust)—not readily ionizable/absorbable; not associated with toxicoses.
- Take care when calculating iron ingestion; iron salts vary in elemental iron content (between 12% and 63%).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of severe gastroenteritis and shock, gastric torsion, snake bite,

caustic/corrosive ingestion, viral/bacterial enteritis, garbage ingestion, heat prostration.

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis • Hyperglycemia • Normal to high AST, ALT, ALP, and serum bilirubin

OTHER LABORATORY TESTS

Metabolic acidosis

Serum Analysis for Total Serum Iron and TIBC

- Indicates poisoning and need for treatment:
- Serum iron $> 350\text{--}500 \mu\text{g/dL}$ serum or
- Serum iron concentration $>$ TIBC.
- Monitor at 2–3 hours and 5–6 hours post-ingestion in asymptomatic patients; absorption rates vary with tablet dissolution and serum iron concentrations can change rapidly.
- Use only clear, non-hemolyzed serum as hemolysis increases iron content.

IMAGING

Radiography—intact iron-containing pills may be radio-dense; pill bezoars or pills adhered to mucosa may be visible.

DIAGNOSTIC PROCEDURES

- Post-mortem analysis for iron in tissues—often ineffective due to the reactive nature of free iron and the systemic distribution of reactive binding.
- Analysis of GI or stomach contents—may aid in documenting high iron exposures.

PATHOLOGIC FINDINGS

- Primary gross lesions—hemorrhage in the GI tract and liver; hepatomegaly.
- Histopathologic lesions—GI necrosis with potential of hepatocellular and vascular endothelial necrosis

TREATMENT

- Correct hypovolemic shock—intravenous fluids.
- Correct acidosis—intravenous sodium bicarbonate if severe.

Decontamination

- Prevent further GI and systemic damage—removal of unabsorbed iron from the stomach; lessens duration and severity of signs.
- Oral milk of magnesia or aluminum hydroxide (precipitates iron in GI tract) in asymptomatic patient.
- Emesis—induced for asymptomatic patient: 3% hydrogen peroxide 1–2 mL/kg PO or apomorphine 0.04 mg/kg IV or IM.
- Gastric lavage—performed when emesis is contraindicated or when pill bezoars are identified.
- Emergency gastrotomy—indicated if lavage fails to remove adherent pills or bezoars.

Chelation

- Chelate when serum iron $> 350\text{--}500 \mu\text{g/dL}$ or serum iron $>$ TIBC.
- Deferoxamine mesylate—iron chelator of choice.
- Calcium disodium EDTA has been used but may not reduce mortality.
- Duration of therapy—until signs have resolved AND serum iron is

consistently below 300 $\mu\text{g/dL}$ or TIBC is greater than serum iron.

MEDICATIONS

DRUG(S)

- Deferoxamine mesylate (iron chelator)—15 mg/kg/h SLOW IV infusion or 40 mg/kg IM q4–6h or 40 mg/kg SLOW IV q4–6h.
- Antiemetic—maropitant 1 mg/kg SQ q24h, ondansetron 0.1–0.2 mg/kg SQ, IV q8–12h.
- GI protectant—sucralfate 0.5–1 g PO q8–12h; oral antacids.
- H2 antagonist (cimetidine, ranitidine, famotidine) or proton pump inhibitor (omeprazole 0.5–1 mg/kg PO q24h).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Activated charcoal—does not bind iron.
- Gastric lavage—contraindicated in presence of hematemesis; increased risk of perforation.
- Intravenous deferoxamine—must be given slowly or may precipitate cardiac arrhythmias.
- Deferoxamine—teratogenic; use in patients only if benefits outweigh risks.

FOLLOW-UP

- Liver enzymes—monitored up to 24 hours after excess circulating iron is controlled.
- Watch for evidence of GI obstruction for 4–6 weeks after poisoning.

MISCELLANEOUS

SEE ALSO

Poisoning (Intoxication) Therapy

ABBREVIATIONS

- ALP = alkaline phosphatase
- ALT = alanine aminotransferase
- AST = aspartate aminotransferase

IRRITABLE BOWEL SYNDROME

BASICS

DEFINITION

A condition characterized by chronic intermittent signs of gastrointestinal (often colonic) dysfunction and/or dysmotility in the absence of structural GI pathology or alternative diagnosis.

PATOPHYSIOLOGY

- A psychosomatic relationship is hypothesized to exist between the behavior of the patient and responses of the autonomic nervous system and the enteric nervous system.
- Potential interactive causes may include abnormal colonic motility, dietary fiber deficiency, dietary intolerances, stress/anxiety, and concurrent gastrointestinal pathology.

INCIDENCE/PREVALENCE

The incidence of IBS in dogs as a primary disorder is unknown but is thought by the author to be < 5%.

SIGNALMENT

Species

Dog (uncommon); cat (rare)

Breed Predilections

Any breed; suspected to be more common in active working dogs or individual dogs with anxious temperaments.

SIGNS

Historical Findings

- Chronic, intermittent signs of large bowel disease are most common: frequent passage of small amounts of feces with increased mucus and hematochezia and dyschezia. Constipation may occur with clinical signs alternating between diarrhea and constipation.
- Abdominal pain, segmental ileus (bloating), vomiting, and nausea may also occur.

RISK FACTORS

- Stress (e.g., changes in the household, change of diet, separation anxiety) may or may not be associated with episodes in some patients.

DIAGNOSIS

- Based on the exclusion of all other potential causes of large bowel signs.
- Reserve for patients that have undergone a comprehensive workup including gastrointestinal biopsies, and therapeutic deworming (particularly inclusive for whipworms), increased fiber-rich (soluble and/or insoluble) and elimination diets without resolution of signs.

DIFFERENTIAL DIAGNOSIS

Causes of Large Bowel Disease

- Whipworms • IBD • *Clostridium perfringens* or *C. difficile*—associated diarrhea

- Invasive adherent *Escherichia coli*—associated granulomatous colitis
- Fiber-responsive large bowel diarrhea
- Dietary indiscretion (foreign body–induced coloproctitis) or intolerance
- Pancreatitis can cause inflammation of the transverse colon with signs of colitis
- Histoplasmosis • Pythiosis • Colorectal neoplasia • Cecal inversion • Gluten enteropathy • Anal sacculitis • Megacolon (colorectal pseudo-obstruction)

Diseases with Similar Signs

- Dysuria/stranguria—exclude with observation, urinalysis, and imaging.
- Prostatic disease—exclude with rectal examination and imaging.
- Peritoneal adhesions.
- Disorders or injury affecting innervation of GI tract via intestinal intrinsic nervous system, vagal nerve, and pelvic nerve plexuses.

CBC/BIOCHEMISTRY/URINALYSIS

Usually unremarkable

OTHER LABORATORY TESTS

Fecal flotation and rectal scraping cytology typically unremarkable.

IMAGING

- Survey and contrast radiographic studies of the abdomen—unremarkable or may show segmental luminal gas distention.
- Abdominal ultrasonography—unremarkable.

DIAGNOSTIC PROCEDURES

Endoscopy or exploratory surgery with biopsy generally unremarkable.

PATHOLOGIC FINDINGS

- Usually unremarkable.
- Concurrent chronic intestinal disease (e.g., IBD) may be present and needs to be successfully managed prior to pursuing diagnosis and treatment for IBS.

TREATMENT

DIET

A highly digestible diet with added blend of soluble and insoluble fiber often helps (e.g., psyllium, wheat dextrin); if increased soluble fiber is not helpful, then try an increase of insoluble (methylcellulose) fiber; either may result in variable improvement in any given case.

MEDICATIONS

DRUG(S) OF CHOICE

- Drug therapy may range from several short-term (days) to life-long.
- Most cases of canine IBS can involve both gastrointestinal hypermotility (spasmodic) and potential sensory changes thought to result in forms of dysmotility via interference with GI intrinsic nervous system activity.
- Librax (an antispasmodic with anxiolytic) or gabapentin (5–10 mg/kg q12h) for possible neuropathic pain (if pelvic plexus stimulation is suspected).
- Start at lower end of dosage range.

antispasmodic with anxiolytic) or gabapentin (5–10 mg/kg q12h) for possible neuropathic pain (if pelvic plexus stimulation is suspected).

- Start at lower end of dosage range.

Motility Modifiers

- Opiate antidiarrheals improve signs by increasing rhythmic segmentation.
- Loperamide 0.1–0.2 mg/kg PO q8–12h.
- Diphenoxylate 0.05–0.2 mg/kg PO q8–12h.
- Gabapentin (1–10 mg/kg q12h) for possible neuropathic pain.
- Cisapride (prokinetic) 0.5 mg/kg to maximum of 10 mg PO q8–12h if clinical signs of constipation predominates.

Antispasmodic-Tranquilizer-Anxiolytic Combinations

- Used to relieve anxiety, abdominal cramping, bloating, and distress.
- Librax—chlor diazepoxide (anxiolytic) and clidinium bromide (anticholinergic), 0.1–0.25 mg of clidinium/kg PO q8–24h.
- Darbazine—isopropamide (anticholinergic) and prochlorperazine (tranquilizer), 0.14–0.22 mg/kg SC q12h; oral.
- Aminopentamide 0.01–0.02 mg/kg PO, IM, SC.

Parenteral Antiemetics

- If nausea and vomiting preclude the use of oral medication, administer antiemetics parenterally for 1–2 days.
- Maropitant 1 mg/kg SC dogs q24h SC in dogs.
- Prochlorperazine 0.1–0.5 mg/kg q6–24h SC or IM.

Serotonin-like Antagonists

Ramosetron is a potent and selective serotonin (5-HT3) receptor antagonist that has been helpful in humans with diarrhea-predominant IBS; no reports have been found beyond experimental testing in normal dogs.

CONTRAINDICATIONS

- Opiates—respiratory dysfunction, hepatic encephalopathy, constipation and/or severe debilitation.
- Anticholinergics—cardiac disease, renal disease, hypertension, constipation and/or hyperthyroidism.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Improved stools, decreased mucus, and relief of dyschezia and abdominal distress within 1–2 days of starting medication.
- In some dogs, signs completely resolve following therapy; others have long-term episodic signs.

IVERMECTIN AND OTHER MACROCYCLIC LACTONES TOXICOSES

BASICS

OVERVIEW

- Includes ivermectin, milbemycin, moxidectin, selamectin, and others.
- Toxicity—dogs given large extra-label dosages (> 10–15 times recommended dosage).
- Ivermectin—binds to glutamate-gated chloride ion channels in invertebrate nerve and muscle cells causing subsequent paralysis and death of the parasite. Also interacts with other ligand-gated chloride channels including those gated by gamma-aminobutyric acid.
- Sensitivity—collies and certain other breeds are more sensitive to high doses of ivermectin. This sensitivity has been associated with an inherited deletion of the ABCB1 gene that encodes a transmembrane protein pump called P-glycoprotein. P-glycoprotein is believed to transport ivermectin out of brain tissue and into circulation.

SIGNALMENT

- Dogs.
- Collies—most commonly affected.
- Dogs homozygous for the ABCB1 gene deletion also affected; heterozygous dogs can react at higher doses. The ABCB1 gene mutation has been found in Shetland sheepdogs, Australian shepherds, Old English sheepdogs, German shepherds, English shepherds, longhaired whippets, silken windhounds, and a variety of mixed-breed dogs.
- No age or sex predilections.

SIGNS

- Mydriasis
- Depression
- Drooling/salivation
- Vomiting
- Ataxia
- Tremors
- Disorientation
- Weakness, recumbency
- Non-responsiveness
- Blindness
- Bradycardia
- Hypoventilation
- Coma
- Death

CAUSES & RISK FACTORS

- Extra-label use at high dosage
- Breed sensitivity—see above

DIAGNOSIS

- Based on history and clinical signs
- No specific tests useful in confirming the diagnosis

DIFFERENTIAL DIAGNOSIS

- Overdoses of other insecticides such as pyrethrins, pyrethroids, organophosphorous and carbamate compounds
- Other toxicants or diseases affecting the CNS

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Arterial blood gases—may reveal high PaCO₂ and low PaO₂ caused by respiratory depression and hypoventilation.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Physostigmine 1 mg IV; temporary (30–40 minutes) return to consciousness or resumed alertness and muscle activity after the administration supports but does not confirm diagnosis; does not speed recovery; not indicated for treatment; glycopyrrolate administered first may prevent severe bradycardia.

TREATMENT

- Primarily supportive and symptomatic care.
- If patient is alert, activated charcoal repeated every 4–6 hours.
- Important goals—proper fluid therapy, maintenance of electrolyte balance, nutritional support, and prevention of secondary complications.
- Nutritional support— institute early, preferably within 2–3 days of exposure; severe CNS depression or coma may last for weeks.
- Frequent turning of patient, appropriate bedding, physical therapy, attentive nursing care, and other standard treatment measures for a recumbent patient important.
- Apply ocular lubricants.
- Mechanical ventilation—may be required with respiratory depression.
- Use of an intravenous lipid emulsion (ILE) has been successful in ameliorating clinical signs in some cases. May not be effective in dogs with ABCB1 homozygous mutations.

MEDICATIONS

DRUG(S)

- No known reversal agent.
- Atropine or glycopyrrolate—may be administered as needed to treat bradycardia.
- 20% intravenous lipid emulsions: bolus dose 1.5 mL/kg over 2–3 min; continuous rate infusion of 0.25 mL/kg/min for 30–60 min. Check serum q2h and if not lipemic; repeat as needed; if no clinical improvement after 3 doses, discontinue.

CONTRAINdications/POSSIBLE INTERACTIONS

- Other drugs known to cause toxicity in dogs with the ABCB1 mutation: loperamide, doxorubicin, vincristine, vinblastine, acepromazine, butorphanol, emopside, and erythromycin.
- Do not use ivermectin concurrently with ketoconazole.
- Concomitant extra-label use of ivermectin and spinosad may produce clinical signs.

FOLLOW-UP

- Prognosis and eventual outcome—depends on individual and breed sensitivity, amount of drug ingested or injected, how rapidly clinical signs develop, response to supportive treatment, and overall health of patient.
- Convalescence may be prolonged (several weeks); good supportive care in many seemingly hopeless cases has resulted in complete recovery.

MISCELLANEOUS

JOINT LUXATIONS

BASICS

DEFINITION

Luxation is the complete disruption of the contiguous articular surfaces of a joint when the supporting structures around the joint are damaged or missing. Subluxation is a partial disruption.

PATHOPHYSIOLOGY

• All synovial joints have a joint capsule that joins the articulating bones together. The fibrous layer of this capsule is a primary stabilizer of the joint. Most joints have additional ligaments that reinforce the joint capsule to improve the resistance to movement outside of the normal range of motion of that joint. All motion joints also have a system of muscles and tendons that exert forces on the joint to control movement. The co-contraction forces around a joint are very influential on the stability of that joint. Instability occurs when the stabilizing system is damaged or disrupted or does not develop normally.

• If the laxity is clinically apparent, then the situation is generally described as luxation or subluxation of that joint.

• Luxation may occur as a result of traumatic forces causing the joint to move beyond the elastic limits of the supporting tissues.

• Secondary changes are set in motion by the damage to the tissues that create early, and then later, more chronic joint damage.

SYSTEMS AFFECTED

• Musculoskeletal—primarily the intra-articular environment and the support structures around the joint including joint capsule, collateral ligaments, and support muscle/tendon units.

• Neurologic—neurologic feedback and supply to the support system may also be affected.

GENETICS

• Hyper laxity syndrome is an inherited factor in humans. Puppies may show temporary hyper laxity when confined.

• Hip dysplasia is a form of inherited laxity of the hip joint.

• Shoulder luxation is an inherited predisposition in small breeds such as miniature poodles.

• Femoropatellar instability leading to medial patellar luxation is a common inherited disease in small-breed dogs.

• Ehlers-Danlos syndrome is a congenital collagen disorder that leads to joint laxity.

INCIDENCE/PREVALENCE

Some forms of laxity/luxation (hip dysplasia and medial patella luxation) are very common.

GEOGRAPHIC DISTRIBUTION

None observed

SIGNALMENT

Breed Predilections

- Varies with the joint affected.
- Hip—large breeds show clinical signs of hip dysplasia more frequently than smaller breeds, but breeds of all sizes can have radiographic signs.
- Traumatic luxations are not breed-specific in any joint.
- Congenital shoulder luxation occurs most commonly in miniature breeds (poodle).
- Stifle luxation most commonly involves rupture of both cruciate ligaments and one of the collateral ligaments.
- Medial patella luxation is more common in small-breed dogs.
- Spinal luxations occur as a result of trauma, with associated injury to the spinal cord.

Mean Age and Range

- Traumatic—any age.
- Congenital laxity/luxation is typically seen in the juvenile dog, with secondary degenerative joint disease showing later in life.

Predominant Sex

None

SIGNS

- Abnormal anatomic position of one bone in relation to the adjoining bone.
- Hip luxation is commonly cranio-dorsal (the displacement of the femoral head in relation to the acetabulum).
- Shoulder luxation is commonly medial.
- Elbow luxation is commonly proximo-lateral.
- Carpal and tarsal luxations commonly result in varus, valgus, or hyperextension when stressed.
- Acute swelling, pain, and non-use of the limb are usually seen with acute luxation. Partial weight-bearing may occur with subluxation or chronic luxation.

CAUSES

- Traumatic displacement of normal tissues beyond their elastic limit.
- Minimal stress on abnormally unstable joints of congenital etiology.

RISK FACTORS

- Abnormal conformation, causing elevated joint stresses
- Fatigue, causing muscle weakness and incoordination
- Neurologic abnormalities
- Access to moving vehicles

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fractures
- Joint disease—immune-mediated, septic, or degenerative

CBC/BIOCHEMISTRY/URINALYSIS

- No abnormalities expected that are directly related to the luxation.
- Trauma-induced abnormalities in traumatic situations.

OTHER LABORATORY TESTS

Arthrocentesis may eliminate non-traumatic joint disease.

IMAGING

- Radiographs confirm the diagnosis by documenting the anatomic malalignment.
- Stress views may be needed in some situations.

DIAGNOSTIC PROCEDURES

- Palpation of the laxity/luxation (Ortolani, cranial drawer, medial patella luxation, stress-induced laxity/instability).
- Palpation of the position of the displaced bone.

PATHOLOGIC FINDINGS

- Trauma-induced hemorrhage, edema, and disruption of ligaments and joint capsule.
- Secondary changes related to degenerative joint disease.

TREATMENT

APPROPRIATE HEALTH CARE

Rest, reduce mobility, reduce swelling, control pain, and stabilize the joint or salvage the limb by removing the source of pain.

NURSING CARE

- Immobilize the joint with a bandage/splint if the affected joint is distal to the inguinal or axial areas.
- Cold compresses for 5–10 minutes four or five times a day initially to reduce inflammation.

ACTIVITY

Cage rest until joint stabilization, then slow return to function to encourage healing and strengthening of soft tissue support of the limb.

DIET

Normal

CLIENT EDUCATION

Activity and weight gain increase the likelihood of degenerative changes in the long term.

SURGICAL CONSIDERATIONS

- Closed reduction under anesthesia may be successful if the support structures are intact and no anatomic aberrations are present. This method is generally not recommended for the hock, carpus or stifle.
- Failing closed reduction, an open surgical approach may be used. After reduction, some form of surgical stabilization (e.g., toggle pin for hip luxation) should be applied to reduce the possibility of reluxation. After surgical closure, an external support sling is often used

(CONTINUED)

JOINT LUXATIONS

to limit movement until the tissues around the joint have healed (e.g., Ehmer sling after cranio-dorsal hip luxation reduction, spica splint after elbow luxation reduction).

- The incidence of reluxation is high, especially in the case of congenital luxations.
- Salvage procedures include prosthetic joint replacement, surgical removal of bone-to-bone contact points (femoral head and neck osteotomy), arthrodesis, and amputation.

**MEDICATIONS****DRUG(S) OF CHOICE**

- NSAIDs decrease prostaglandin synthesis by inhibiting cyclooxygenase enzymes:
 - Carprofen (2.2 mg/kg PO or SC q12h, or 4.4 mg/kg PO or SC q24h).
 - Deracoxib (1–2 mg/kg PO q24h).
 - Firocoxib (5 mg/kg PO q24h).
 - Meloxicam (0.1 mg/kg PO or SC q24h).
- Tramadol (1–4 mg/kg PO q8–12h)
- Serotonin reuptake inhibitor, in combination with NSAID.

CONTRAINDICATIONS

- Gastrointestinal sensitivity
- Liver or renal pathology

PRECAUTIONS

Stop medications if diarrhea or vomiting is seen.

POSSIBLE INTERACTIONS

- Other NSAIDs
- Steroids

ALTERNATIVE DRUG(S)

Analgesics

**FOLLOW-UP****PATIENT MONITORING**

- Always take a radiograph after reduction.
- Take follow-up radiographs when the splint/sling is removed (typically 2–4 weeks post-reduction).

PREVENTION/AVOIDANCE

- Fenced-in yards
- Keep the sling in place until healing has occurred

POSSIBLE COMPLICATIONS

- Reluxation
- Infection after surgery
- Implant failure of joint prosthetic

EXPECTED COURSE AND PROGNOSIS

- Return of function is expected unless a complication occurs.
- The high incidence of reluxation makes the prognosis guarded.
- Progressive degenerative joint disease.

**MISCELLANEOUS****SYNONYMS**

Dislocation

SEE ALSO

- Arthritis (Osteoarthritis)
- Hip Dysplasia

ABBREVIATION

- NSAID = nonsteroidal anti-inflammatory drug

KERATITIS, EOSINOPHILIC—CATS

BASICS

OVERVIEW

- Feline eosinophilic keratitis is a presumed immune-mediated inflammation of the cornea characterized by perilimbal corneal vascularization, white-pink corneal infiltrate, and corneal edema.
- Synonym—proliferative keratitis.

SIGNALMENT

Young adult to middle-aged cats most commonly affected.

SIGNS

- Unilateral or bilateral.
- Usually little to no ocular pain.
- Serous to mucoid ocular discharge.
- Limbal superficial corneal vascularization 90–360° (temporal or inferior nasal quadrants usually are first affected).
- White to pink flat or raised granular corneal infiltrate.
- Multifocal small white gritty corneal deposits.
- Corneal edema.
- With or without corneal ulceration.
- Conjunctival and third eyelid hyperemia, chemosis and thickening with or without a cobblestone texture to the surface.

CAUSES & RISK FACTORS

- Feline herpesvirus-1 may be associated with FEK but the exact role is unclear: 76% of FEK specimens were PCR positive for FHV-1 in one study but 0% were positive in another.
- The exact etiopathogenesis is unknown but proposed theories are: (1) Type I hypersensitivity with IgE mediated mast cell and eosinophil degranulation, (2) Type IV reaction where sensitized T-lymphocytes via IL-5 stimulate local eosinophil-mediated corneal damage.
- Culture, histopathology, and electron microscopy have ruled out bacterial and fungal infection as consistent etiologic causes, although secondary bacterial keratitis may occur.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Chronic corneal ulceration with secondary corneal vascularization (granulation tissue).
- FHV-1 stromal keratitis—appears similar to FEK but lacks the proliferative component, and more severe ocular pain and corneal ulceration are usually present.
- Corneal neoplasia: (1) lymphoma—concurrent conjunctival and/or uveal infiltration is common, (2) squamous cell carcinoma—rarely involves cornea in cats.
- Chlamydia psittaci* or *Mycoplasma felis*—usually conjunctival diseases without corneal involvement.

CBC/BIOCHEMISTRY/URINALYSIS

Peripheral eosinophilia may be present.

OTHER LABORATORY TESTS

- Corneal cytology provides definitive diagnosis and should be done first. See numerous eosinophils, free eosinophil granules and/or mast cells, neutrophils, lymphocytes, plasma cells and epithelial cells.
- Cytology helps rule out chlamydia and mycoplasma.
- FHV-1 nested PCR—limited diagnostic value since normal healthy cats may carry FHV-1 and have positive PCR results.
- IFA testing for *Chlamydia psittaci*.
- Fluorescein staining to evaluate for corneal ulceration.

DIAGNOSTIC PROCEDURES

- Keratectomy and histopathology may confirm a diagnosis in chronic or nonresponsive cases.
- Specimens show epithelial cell layer hypertrophy and hyperplasia, corneal vascularization, excrescences with nuclear debris and amorphous eosinophilic material, numerous eosinophils, free eosinophil granules, deeper layers of thickened basement membrane and eosinophilic material and stromal thickening with eosinophils, mixed inflammatory cells and granulation tissue.

TREATMENT

Usually medical on outpatient basis.

MEDICATIONS

DRUG(S)

- Topical cyclosporine A q8–12h, then tapered to the lowest effective frequency of application and/or discontinued. Can use in cats in which megestrol and topical corticosteroids are contraindicated (diabetes, FHV-1, etc). May be irritating or cause blepharitis.
- Topical corticosteroids—1% prednisolone acetate or 0.1% dexamethasone sodium phosphate (initially q6–12h for 5–7 days, then gradually taper to the lowest effective frequency of application, q2–7 days). May eventually be discontinued in many cats.
- Adjunctive topical and/or systemic anti-viral therapy may be warranted in cases with history or clinical signs compatible with FHV-1 infection.
- Subconjunctival corticosteroids—triamcinolone acetonide (0.1–0.2 mL q3–7 days); use only in cats that are difficult to treat with topical medications.
- Megestrol acetate—2.5 mg PO q24h × 3–5 days, then 2.5 mg PO q48h × 3–5 days, then gradually decrease frequency after every 3–5 treatments to the lowest effective

frequency (e.g., 2.5 mg PO q7 days) or eventually discontinue.

- Systemic prednisolone—start with 2.2 mg/kg PO q12h and taper. Use only if a cat will not tolerate topical corticosteroid or cyclosporine A therapy or megestrol acetate.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Topical corticosteroid administration may be associated with recrudescence of FHV-1 keratoconjunctivitis and therefore should be used judiciously and monitored carefully. The client should be advised to immediately report any adverse change in the condition of the eye (blepharospasm, corneal edema, increased ocular discharge, etc.).
- Megestrol acetate causes adrenal cortical suppression and may result in diabetes mellitus, polyphagia, temperament change, mammary gland hyperplasia, or neoplasia and pyometra. It should not be used in cats with hepatic disease or other illness.

FOLLOW-UP

- Response to therapy is usually rapid.
- Complete resolution may take several days to months. Many cats require long-term therapy to control the disease.
- Corneal vascularization and infiltrate may resolve completely with minimal corneal scarring.
- Recurrences in both the short and long term are common following discontinuation of therapy.

MISCELLANEOUS

FEK is not typically associated with the dermatologic eosinophilic granuloma complex.

ABBREVIATIONS

- FEK = feline eosinophilic keratitis/keratoconjunctivitis
- FHV-1 = feline herpesvirus-1
- IFA = immunofluorescent antibody test
- PCR = polymerase chain reaction

Consulting Editor Paul E. Miller

KERATITIS, NONULCERATIVE

BASICS

DEFINITION

An inflammatory disorder of the cornea that does not retain fluorescein stain.

PATHOPHYSIOLOGY

A pathologic response resulting in reduced corneal clarity secondary to edema, inflammatory cell infiltration, vascularization, pigmentation, lipid or calcium deposition, or scarring.

SYSTEMS AFFECTED

Ophthalmic

GENETICS

- No proven genetic basis in dogs or cats.
- Chronic superficial keratitis (pannus)—inherited predisposition considered in the German shepherd.

INCIDENCE/PREVALENCE

Common cause of eye disease in dogs and cats.

GEOGRAPHIC DISTRIBUTION

Chronic superficial keratitis is more common in regions of high UV light exposure.

SIGNALMENT

Species

- Dog—chronic superficial keratitis (pannus); pigmentary keratitis; pigmentary keratopathy of pugs; nodular granulomatous episclerokeratitis (see Episcleritis); KCS (see Keratoconjunctivitis Sicca).
- Cat—eosinophilic keratitis (see Keratitis, Eosinophilic—Cats), herpesvirus (stromal form); corneal sequestration; KCS uncommon and usually secondary to chronic herpesvirus infection.

Breed Predilections

Dogs

- Chronic superficial keratitis (pannus)—highest prevalence in German shepherds and sighthounds.
- Pigmentary keratitis—notably brachycephalic breeds with exposure keratopathy from lagophthalmia, tear film deficiencies, and trichiasis.
- Pigmentary keratopathy of pugs—suspect genetic condition that results in progressive corneal pigmentation, cause currently unknown.
- NGE—prevalent in cocker spaniels, collies, and Shetland sheepdogs.
- KCS—brachycephalic breeds, cocker spaniels, English bulldogs, West Highland white terriers, Cavalier King Charles spaniels.

Cats

- Eosinophilic keratitis—most prevalent in domestic shorthair.
- Corneal sequestration—most prevalent in brachycephalic breeds.

Mean Age and Range

- Dogs: chronic superficial keratitis—may occur at any age; higher risk between 3 and 6 years (younger in greyhounds); pigmentary keratitis—may occur at any age; pigmentary keratopathy of pugs—may occur at any age;

NGE—may occur at any age; in collies—young to middle-aged (mean 3.8 years); KCS—usually middle-aged to older.

- Cats: herpesvirus—all ages; eosinophilic keratitis and corneal sequestrum—all ages except neonates.

Predominant Sex

- Dogs: female predisposition reported for pannus and KCS.
- Cats: castrated male predisposition reported for eosinophilic keratitis.

SIGNS

Historical Findings

May cause variable corneal discoloration and ocular discomfort.

Physical Examination Findings

Dogs

- Chronic superficial keratitis—usually bilateral, cornea vascularization ranging from superficial vessels to dense granulation tissue with variable pigmentation; lateral or ventrolateral cornea with entire cornea affected in advanced cases; thickened and depigmented third eyelids; white deposits (corneal degeneration) may be present at the leading edge of corneal lesion; may lead to blindness.
- Pigmentary keratitis—appears as focal to diffuse, brown discoloration of the cornea; often associated with corneal vascularization or scarring.
- Pigmentary keratopathy of pugs—brown corneal pigmentation originating from medial cornea and progressing towards central cornea.
- NGE—bilateral or unilateral, raised, fleshy masses affecting the lateral limbus and cornea; corneal deposits, edema and vascularization may also occur in adjacent corneal stroma; slow to rapidly progressive; third eyelids may appear thickened.
- KCS—may be unilateral or bilateral; mucoid ocular discharge, conjunctival hyperemia, corneal vascularization, pigmentation, and scarring; corneal ulceration may occur.

Cats

- Herpesvirus (stromal form)—unilateral or bilateral; stromal edema, infiltrates, deep vascularization and scarring; often occurs with ulceration; may threaten vision if severe scarring.
- Eosinophilic keratitis—usually unilateral; raised vascularized lesion with pink-white infiltrates that form gritty plaques; may retain fluorescein stain at the periphery of the lesion.
- Corneal sequestrum—usually unilateral but can be bilateral; appears as amber, brown, or black plaques of the central or paracentral cornea; can vary in size and depth of the affected cornea; edges may appear raised; corneal vascularization is variable; may retain fluorescein at periphery of lesion.

CAUSES

Dogs

- Chronic superficial keratitis—presumed to be immune-mediated; high altitude and subsequent increase in UV radiation exposure increase the prevalence and severity of disease.

- Pigmentary keratitis—secondary to chronic corneal irritation; evaluate for primary underlying ocular conditions; frequently associated with exposure keratopathy and KCS.
- Pigmentary keratopathy of pugs—unknown, thought to have genetic basis.
- NGE—presumed to be immune mediated.
- KCS—bilateral—usually immune mediated or drug-induced; unilateral—congenital, iatrogenic, neurogenic.

Cats

- Herpesvirus (stromal form)—immune-mediated T-cell lymphocyte reaction to herpesvirus antigen rather than a cytopathic effect of the virus.
- Eosinophilic keratitis—possible hypersensitivity reaction; high incidence of animals PCR positive for FHV-1; fewer positive for Chlamydia-like agents.
- Corneal sequestrum—unknown; likely due to chronic corneal irritation or ulceration; suggested relationship with herpesvirus.

RISK FACTORS

Dogs—chronic superficial keratitis more likely to occur at high altitudes secondary to increased UV exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dogs

- Infectious keratitis is usually ulcerative and painful; cytology of the cornea reveals white blood cells, organisms present.
- Neoplasia—rare involvement of sclera or cornea; distinguish based on color, age of animal, breed predilection; usually unilateral; response to topical anti-inflammatory therapy.

Cats

- Infectious keratitis—usually ulcerative and painful; cytologic examination of cornea reveals white blood cells, organisms present.
- Stromal herpesvirus may be associated with ulcerative keratitis and secondary bacterial infection.
- Neoplasia—very rare.

DIAGNOSTIC PROCEDURES

Dogs

Chronic superficial keratitis: cytologic examination of corneal or conjunctival scrapings reveals lymphocytes, plasma cells, and mast cells; biopsy can be considered; clinical examination usually considered diagnostic.

NGE: biopsy of episcleral nodular mass or cornea (superficial keratectomy); Schirmer tear test for pigmentary keratitis, KCS, or any corneal disease of undetermined cause; normal values are ≥ 15 mm/min; values < 15 mm/min suggest KCS but should be interpreted with consideration of the breed and ocular findings.

Cats

Herpes: conjunctival or corneal scrapings for PCR are most successful for diagnosis; IFA or

KERATITIS, NONULCERATIVE

(CONTINUED)

viral culture are of limited value; interpretation can be difficult; eosinophilic keratitis: cytology of cornea positive for eosinophils; biopsy of the cornea (superficial keratectomy) can be considered for eosinophilic keratitis or sequestrum but is usually unnecessary.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—generally sufficient.
- Inpatient—cases that warrant surgery due to inadequate response to medical therapy.

CLIENT EDUCATION

Dogs

Typically require life-long treatment; disease is controlled rather than cured.

Cats

• Herpesvirus—ocular discomfort and keratitis often recurrent. • Eosinophilic keratitis—disease controlled rather than cured. • Corneal sequestrum—may slough spontaneously, however cornea may rupture; clinical course often protracted without surgery; removal of sequestrum by superficial keratectomy may be curative, although recurrence is possible.

SURGICAL CONSIDERATIONS

Dogs

• Chronic superficial keratitis—superficial keratectomy for severe disease in which vision is impaired due to corneal pigmentation; patients still require indefinite medical treatment to prevent recurrence; β -irradiation with a strontium-90 probe is noninvasive and may be performed in severe cases. • Pigmentary keratitis—superficial keratectomy may be performed only after initial underlying cause is corrected; only in severe cases that threaten vision. • Pigmentary keratopathy of pugs—high likelihood of recurrence after superficial keratectomy. • NGE—superficial keratectomy is diagnostic; medical treatment is still required. • KCS—parotid duct transposition or permanent partial tarsorrhaphy to reduce exposure.

Cats

• Eosinophilic keratitis—superficial keratectomy is diagnostic but not curative; medical treatment is preferred. • Corneal sequestrum—superficial keratectomy may be curative; recurrence is possible.

MEDICATIONS

DRUG(S) OF CHOICE

Dogs

- Chronic superficial keratitis—topical corticosteroids (1% prednisolone or 0.1%

dexamethasone q6–12h); topical 0.2–2% cyclosporine, 1% pimecrolimus, or 0.03% tacrolimus q8–12h; agents can be used alone or in combination for more severe cases; subconjunctival corticosteroid injection can be used as an adjunct to topical therapy in severe cases (triamcinolone acetonide 2–8 mg). • Pigmentary keratitis—treatment directed at underlying cause; topical corticosteroids if primary cause is inflammatory; lubricants and cyclosporine or tacrolimus if primary condition is KCS; cyclosporine or tacrolimus may reduce pigmentation in all cases. • Pigmentary keratopathy of pugs—topical cyclosporine 0.2–2% or tacrolimus 0.02–0.03% may arrest progression of corneal pigmentation; topical corticosteroids may help temporarily reduce density of corneal pigment. • NGE—topical corticosteroids and/or cyclosporine as described above; systemic azathioprine (2 mg/kg/day initially, then gradually reduce) may be effective when used alone or in combination with topical medications. • KCS—topical 0.2–2% cyclosporine, or 0.02–0.03% tacrolimus q8–12h (see Keratoconjunctivitis Sicca).

Cats

• Herpesvirus—topical antiviral agents recommended: cidofovir 0.5% q12h or ; trifluridine (Viroptic) q4–6h for 2 days, then taper. Systemic antiviral agents include: famciclovir 40 mg/kg PO q8h. For inflammation, topical nonsteriodals or cyclosporine q12h may be used; oral lysine (250 mg q12h to 500 mg q12–24h) may also be of benefit. • Eosinophilic keratitis—topical corticosteroids (1% prednisolone or 0.1% dexamethasone) q6–12h; patient monitored for ulceration or worsening of clinical signs; topical antivirals can be used in combination with corticosteroids if concurrent herpesvirus; use of topical cyclosporine also reported (0.2–1.5%) with variable results; megestrol acetate (Ovaban, 5 mg PO q24h for 5 days, then 5 mg q48h for 1 week, then 5 mg weekly for maintenance) is highly effective, but rarely associated with transient diabetes mellitus. • Corneal sequestrum—topical triple antibiotic q8–12h for associated corneal ulceration; artificial tear lubrication may relieve discomfort; topical antivirals can be used if herpesvirus infection is suspected; topical 1% atropine ointment q12–24h for pain associated with concurrent uveitis if present.

CONTRAINDICATIONS

Topical corticosteroids are contraindicated with corneal ulcers; topical atropine is contraindicated with KCS, glaucoma, or lens luxation.

PRECAUTIONS

• Azathioprine may cause gastrointestinal signs, pancreatitis, hepatotoxicity, and myelosuppression. • Megestrol acetate—not

FDA approved for use in cats; possible side effects include polyphagia, diabetes mellitus, mammary hyperplasia, mammary neoplasia, and pyometra. • Famciclovir—monitoring of CBC, chemistry profile recommended; anorexia, polydipsia reported.

FOLLOW-UP

PATIENT MONITORING

Periodic ocular examination recommended to evaluate efficacy of topical and systemic medications; examine at 1- to 2-week intervals, gradually lengthening the interval with remission or resolution of clinical signs; evaluate response to therapy and taper medications based on resolution of clinical signs; complete resolution of pigmentation may not occur. UV light protection (tinted goggles) is recommended for pannus.

POSSIBLE COMPLICATIONS

All of the above may lead to continued ocular discomfort, visual defects, or blindness in severe cases.

KERATITIS, ULCERATIVE

BASICS

DEFINITION

Inflammation of the cornea associated with loss of the corneal epithelium (corneal erosion) or loss of variable amounts of the underlying corneal stroma (corneal ulcer).

PATHOPHYSIOLOGY

- May be caused by any condition (traumatic or non-traumatic) that disrupts the corneal epithelium or stroma.
- Ulcers—classified as superficial or deep, uncomplicated or complicated.
- Superficial—involves the epithelium and possibly the superficial stroma.
- Deep—involves a greater thickness of stroma and may extend to Descemet's membrane (descemetocele), possibly leading to rupture of the globe.
- Complicated—persistence of underlying/inciting cause, microbial infection, or production of degradative enzymes.
- Epithelial wound healing—adjacent corneal epithelial cells loosen and begin migration over the defect within a few hours; mitosis occurs within a few days to restore normal epithelial thickness; healing process complete in 5–7 days in uncomplicated, superficial ulcers.
- Stromal wound healing—slower, more complex; can be in an avascular or vascular manner; in shallow wounds, epithelial migration may be sufficient to fill the defect; epithelium may cover some deeper ulcers even when epithelium and stromal regeneration are insufficient to restore normal corneal thickness (non-ulcerated divot defect is called a facet); stroma usually heals by fibrovascular infiltration, which may take several weeks and often results in loss of or decrease in corneal clarity.
- Stromal ulcers—often complicated by microbial infection or enzymatic destruction initiated by microbial organisms, host inflammatory cells, or corneal epithelial or stromal cells; enzymatic destruction may result in gelatinous appearance of the corneal stroma, called a melting or malacic ulcer.

SYSTEMS AFFECTED

Ophthalmic

GENETICS

- No proven basis, although breed predilections are seen.
- May be secondary to other corneal diseases that have breed predispositions and presumably a genetic basis, such as corneal epithelial dystrophy in Shetland sheepdogs and corneal endothelial dystrophy in Boston terriers.

INCIDENCE/PREVALENCE

Common

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dogs—brachycephalic breeds predisposed.
- SCCED/indolent erosion—occurs in any breed.
- Cats—Persian, Himalayans, Siamese, and Burmese predisposed to feline corneal sequestrums (see Corneal Sequestration—Cats).

Mean Age and Range

- Age of onset—variable; determined by cause.
- SCCED—middle-aged and older dogs.

SIGNS

Historical Findings

- May be acute or chronic (SCCED).
- Tearing, squinting, rubbing at eyes.
- Owners may report the appearance of a film over the eye (often corneal edema); prolapsed third eyelid.
- Herpetic ulcers (cats)—may have history of respiratory disease.

Physical Examination Findings

- Nonspecific—serous to mucopurulent ocular discharge, blepharospasm, nictitans prolapse, conjunctival hyperemia.
- Superficial—may note one or more circumscribed, linear, or geographic defects in the cornea.
- Deep stromal ulcer or descemetocele—may appear as a crater-like defect.
- Depending on cause and duration—may see neovascularization, pigmentation, scarring, inflammatory cell infiltrate (yellow to cream-colored opacity with indistinct margins, often surrounded by corneal edema), collagenolytic activity (melting) of the corneal stroma.
- SCCED—loose or redundant epithelial edges; may demonstrate fluorescein stain extending into areas with seemingly intact epithelium (ring of less intense staining).
- Reflex anterior uveitis—mild or severe, secondary to ulceration; severe may result in hypopyon; severe suggests concurrent bacterial infection.

CAUSES

- Trauma—blunt; penetrating; perforating.
- Adnexal disease—ectopic cilia, entropion, ectropion, eyelid mass, distichiasis.
- Lagophthalmos (inability to close eyelids completely)—results in exposure keratitis; may be breed related in brachycephalic dogs and cats; may be caused by exophthalmos, buphthalmos, or may be neuroparalytic from facial nerve paralysis.
- Tear-film abnormality—quantitative tear deficiency (KCS); qualitative tear film deficiency caused by mucin deficiency or some other unidentified tear abnormality.
- Infection—usually secondary in dogs; can be primary infection of herpesvirus in cats.
- Primary corneal disease—endothelial dystrophy; other endothelial disease.
- Miscellaneous—foreign body (corneal or conjunctival); chemical burns; neurotrophic keratitis (loss of trigeminal sensation); immune-mediated disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fluorescein dye retention—diagnostic.
- Other causes of a red and painful eye—conjunctivitis, uveitis, KCS, glaucoma (see Red Eye).
- May develop concurrently with other causes of a red eye (e.g., secondary to KCS).

OTHER LABORATORY TESTS

- Corneal culture and sensitivity—aerobic bacteria; particularly for complicated, deep, or rapidly progressive corneal ulcers.
- Herpesvirus (cats)—PCR or IFA for herpesvirus available; negative test does not rule out herpesvirus infection.

DIAGNOSTIC PROCEDURES

Fluorescein Staining

- Homogeneous stain uptake—superficial or stromal ulcer; may be circular to geographic, linear, or combination; location and shape may help determine cause (e.g., linear may indicate foreign body or rubbing of ectopic cilia); interpretation of depth subjective.
- SCCED—may have leakage of stain under surrounding loose epithelium.
- Crater-like defect that retains stain at the periphery but is clear at center—Descemetocele—may also see Descemet's membrane bulging forward if defect is large.
- Crater-like defect with pooling of stain transiently but can be easily rinsed—previous stromal ulcer that has epithelialized (facet); must be distinguished from a descemetocele.

Other

- Cytologic evaluation of cornea and gram, Giemsa, or Wright staining may reveal microbial or fungal organisms and may help direct initial antimicrobial therapy.
- Rose Bengal corneal stain (cats) may delineate superficial, linear, epithelial ulcers (dendritic ulcers), which are considered pathognomonic for herpesvirus infection.
- Schirmer tear test may identify ulceration associated with KCS; it is contraindicated in very deep ulcers or descemetoceles.

PATHOLOGIC FINDINGS

- Ulcers—typically suppurative inflammation, possibly neovascularization, loss of epithelium and basement membrane; possibly organisms.
- SCCEDs—superficial hyalinized zone in stroma; epithelial lipping around erosions; varying degrees and types of leukocytic infiltrate and fibrosis.

TREATMENT

APPROPRIATE HEALTH CARE

Hospitalize deep or rapidly progressive ulcers; these may require surgery and/or frequent medical treatments.

KERATITIS, ULCERATIVE

(CONTINUED)

NURSING CARE

Keep facial hair out of eyes and clean.

ACTIVITY

- Restrict with deep stromal ulcer or descemetocle to prevent rupture.
- Prevent self-trauma with Elizabethan collar.

CLIENT EDUCATION

- Instruct client to wait at least 5 minutes between medications if more than one ophthalmic drop is prescribed; wait longer between ointments.
- Advise client to contact veterinarian if patient appears more painful or the eye markedly changes in appearance.
- SCCED—discuss protracted course with client; usually achieve healing within 2–6 weeks but may require weekly rechecks and multiple procedures.

SURGICAL CONSIDERATIONS

- Superficial ulcers do not usually require surgery if the inciting cause has been eliminated.
- Ulcer that extends one-half or greater corneal thickness and particularly to Descemet's membrane may benefit from surgery.
- Descemetocle or full-thickness corneal laceration—considered a surgical emergency for possible referral.

Procedures

- SCCED—debridement of loose epithelium with a dry, sterile, cotton-tipped swab after application of topical anesthesia (50% success rate); punctate or grid keratotomy easily performed after epithelial debridement with topical anesthesia (80% success rate); superficial keratectomy is more invasive and may cause more scarring but has 100% success rate; application of a contact lens or nictitans flap after any of these procedures may improve comfort and aid healing.
- Diamond burr keratotomy for SCCED/indolent erosion only; use gently over surface of erosion; may be associated with increased risk of infection post-procedure.
- Rotational pedicle conjunctival flap, corneoscleral transposition, corneal transplant—surgical procedures for ulcers > 50% thickness of the stroma and descemetocles.
- Cyanoacrylate repair (corneal glue)—can be used for deep ulcers; promotes corneal vascularization and stabilizes cornea, but has somewhat lower success rate compared to other corneal surgeries.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics

- Topical agents—indicated for all patients.
- Frequency of application—determined by severity and the preparation used; ointments have a relatively long contact time and are

applied q6–12h; solutions are applied more frequently (4, 6, 8, or even 12 times daily) in the initial treatment of complicated ulcers; solutions probably more appropriate in deep ulcers.

- Commonly used agents—erythromycin (cats); triple antibiotic, gentamicin, and tobramycin.

- Uncomplicated ulcers or superficial erosions—combination of neomycin, polymyxin B, and bacitracin an excellent first choice; broad spectrum of antimicrobial activity; often used 2–3 times/day for prophylactic therapy.
- Complicated ulcers—often use combination therapy of cefazolin (use IV solution to make 33–50 mg solution in saline or artificial tears for topical use) with either an aminoglycoside (tobramycin, gentamicin) or fluoroquinolone (ciprofloxacin, ofloxacin); particularly in rapidly progressive, deep, or melting ulcers; frequency depends on severity but usually a minimum of q3–4h.

Atropine

- 1% ointment or solution.
- Indicated for reflex anterior uveitis; frequency—usually q8–24h to effect (mydriasis).

Antiviral Agents

- Indicated for herpetic ulcers in cats.
- Trifluridine (Viroptic) solution—q4–6h until clinical response is observed; then reduce for 1–2 weeks after clinical signs have subsided.

Nonsteroidal Anti-inflammatory Drugs

- May be indicated for anti-inflammatory and analgesic properties.
- Aspirin: dogs, 10–15 mg/kg PO q12h.

CONTRAINDICATIONS

- Topical corticosteroids—contraindicated with any corneal erosion or ulcer.
- Topical NSAIDs—contraindicated with herpetic ulcers, melting ulcers.
- Topical atropine—contraindicated with glaucoma, KCS.

PRECAUTIONS

- Topical NSAIDs (flurbiprofen, diclofenac)—may delay corneal healing, may potentiate corneal melting.
- Trifluridine, neomycin—may be irritating.
- Topical cyclosporine can be used safely in uncomplicated ulcer in KCS patients.

POSSIBLE INTERACTIONS

Combining antibiotics in solution may inactivate some antibiotics.

ALTERNATIVE DRUG(S)

- Acetylcysteine—anticollagenolytic agent used for treatment of melting ulcers; efficacy is controversial; dilute 20% stock solution to 5–10% with artificial tears; apply q2–4h.
- Autologous serum—anticollagenolytic agent; keep refrigerated; avoid contamination; discard after 48 hours.

FOLLOW-UP

PATIENT MONITORING

- Superficial ulcers—repeat fluorescein stain in 3–6 days; if it persists 7 days or longer, either inciting cause has not been eliminated or the patient has an SCCED.
- Deep stromal or rapidly progressive ulcers—assess every 24 hours initially if outpatient until improvement is seen; many of these patients are hospitalized or undergo surgery; decrease frequency of antibiotic therapy as condition improves.

PREVENTION/AVOIDANCE

- Brachycephalic dogs—lubricant ointment administration, permanent partial tarsorrhaphy surgery, or both may help prevent recurrent ulceration.
- KCS-related ulcers—lifelong treatment of KCS (cyclosporine) or parotid duct transposition surgery to prevent continued ulceration.
- Herpesvirus (cats)—may try oral lysine 250 mg PO q12h to prevent viral replication; may decrease severity and/or frequency of outbreaks.

POSSIBLE COMPLICATIONS

Progressive corneal ulceration—rupture of globe; endophthalmitis; secondary glaucoma; phthisis bulbi; blindness; blind and painful eye (may require enucleation).

EXPECTED COURSE AND PROGNOSIS

- Uncomplicated superficial ulcer—usually heals in 5–7 days.
- SCCED—may persist for weeks to months; may require multiple procedures.
- Deep corneal ulcer treated medically—may require several weeks for fibrovascular repair of defect; does not always granulate satisfactorily; continued deterioration of ulcer and globe rupture are possible.
- Deep ulcer treated with conjunctival flap—frequently results in more comfort within a few days after surgery; blood supply to flap can be cut in 4–6 weeks if healed well to decrease scarring.

MISCELLANEOUS

ABBREVIATIONS

- IFA = immunofluorescent antibody test
- KCS = keratoconjunctivitis sicca
- NSAID = nonsteroidal anti-inflammatory drug
- PCR = polymerase chain reaction
- SCCED = spontaneous chronic corneal epithelial defects

KERATOCONJUNCTIVITIS SICCA

BASICS

OVERVIEW

- Deficiency of the aqueous layer of the precorneal tear film.
- Causes corneal/conjunctival drying and resultant surface inflammation.

SIGNALMENT

- Common in dog; rare in cat.
- Predisposed dog breeds—many brachycephalic and spaniel breeds, miniature schnauzers, poodles, bloodhounds, Samoyeds, West Highland white terriers, and Yorkshire terriers.
- Inheritance—undefined.
- Age of onset—variable and depends on the inciting cause.

SIGNS

- Conjunctival hyperemia.
- Mucoid to mucopurulent ocular discharge—intermittent to persistent depending on severity.
- Blepharospasm.
- Corneal changes—dryness, superficial vascularization, pigmentation, fibrosis, ulceration.
- Blepharitis due to ocular exudates.
- Severe disease—impaired vision or blindness.
- Cats are less symptomatic than dogs.

CAUSES & RISK FACTORS

- Immune-mediated/idiopathic—most common and possibly associated with other immune-mediated diseases (e.g., atopy).
- Infectious—canine distemper virus; chronic blepharoconjunctivitis (e.g., chronic herpes in cats).
- Iatrogenic—removal of the third eyelid gland (especially in at-risk breeds); radiation therapy.
- Congenital—Yorkshire terriers overrepresented.
- Neurologic—loss of parasympathetic innervation to lacrimal gland, trigeminal nerve deficit, or dysautonomia; neurogenic parasympathetic loss may have ipsilateral dry nose.
- Traumatic—after ocular proptosis or orbit inflammation.
- Systemic disease—diabetes mellitus, Cushing's disease, hypothyroidism or any debilitating disease.
- Drug-induced—systemic sulfonamides (e.g., trimethoprim-sulfadiazine) or etodolac.
- Transient KCS—general anesthesia and atropine.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Often confused with allergic or bacterial conjunctivitis.
- Dogs with KCS may have concurrent secondary bacterial overgrowth.
- Differentiate with Schirmer tear test.

DIAGNOSTIC PROCEDURES

- Schirmer tear test—decreased results diagnostic; normal value (dogs): at least 15 mm/min of wetting; symptomatic patients: usually < 10 mm/min of wetting; difficult to interpret in cats.
- Fluorescein staining—corneal ulcers.
- Conjunctival cytology—may indicate the nature and degree of bacterial overgrowth.
- Aerobic bacterial culture and sensitivity if initial treatment is unsuccessful.

TREATMENT

- Outpatient—unless secondary severe corneal ulceration.
- Inform client that medical therapy is generally life-long.
- When solutions and ointments are prescribed, instruct client to use the solution(s) before the ointment(s) and wait at least 5 minutes between treatments.
- Advise client to call at once if ocular pain increases because patients are predisposed to corneal ulceration.
- Parotid duct transposition—surgical procedure that reroutes the parotid duct to deliver saliva to the ocular surface if KCS is refractory to lacrimogenic therapy; more common with congenital KCS; saliva can be irritating to the cornea and result in mineral deposits; some patients require ongoing topical medical therapy.

MEDICATIONS

DRUG(S)

- Lacrimostimulants: Cyclosporine 0.2% ointment or 1–2% compounded solution; tacrolimus 0.02–0.03% compounded solution or ointment—Therapy q12h recommended (q8h if severe or refractory).
- For neurogenic KCS—pilocarpine 0.2% topically q8h or very careful oral pilocarpine dosing regimen given narrow therapeutic window (see "Suggested Reading").

- For feline KCS—antiviral therapy (see Conjunctivitis—Cats).
- Lacrimomimetics: artificial tears—help moisten the ocular surface to improve comfort and reduce signs; use viscous solutions or gels q2–12h depending on severity and ointment before bedtime; can reduce frequency once patient responds to lacrimostimulant therapy.
- Broad-spectrum antibiotics—topical ointment q6–8h for 3–4 weeks; indicated for secondary bacterial overgrowth.
- Ocular cleansing: use eye wash to remove discharge and debris prior to medications; if mucoid discharge is very tenacious 5% N-acetylcysteine can be used q6–12h as a mucinolytic agent prior to eye rinsing.
- Corticosteroids—topical; minimize inflammation; helpful in reducing corneal vascularization and pigmentation once aqueous tears improve; not commonly used due to corneal ulcer risk.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Topical cyclosporine or tacrolimus—rarely irritating.
- Pilocarpine—initially irritating topically; systemic side effect risk.
- Topical corticosteroids—avoid with ulcerative keratitis or if severe KCS given ulcer predilection.

FOLLOW-UP

- Recheck at regular intervals—monitor response and progress.
- Schirmer tear test—performed 4–6 weeks after initiating cyclosporine or tacrolimus (patient should receive the drug the day of the visit).
- Usually requires life-long treatment
- Good prognosis but refractory cases may require more aggressive therapy or surgery.

MISCELLANEOUS

ABBREVIATION

KCS = keratoconjunctivitis sicca

LAUTIC ACIDOSIS (HYPERLACTATEMIA)

BASICS

DEFINITION

- Hyperlactatemia is defined as a serum lactate concentration > 1.5 mmol/L in dogs and puppies > 70 days of age and > 1.8 mmol/L in cats.
- Lactic acidosis is hyperlactatemia with an arterial pH below the normal range.

PATOPHYSIOLOGY

- Lactic acid is the end product of aerobic and anaerobic glucose metabolism; at physiologic pH, lactic acid immediately dissociates to lactate and hydrogen ions. Small amounts of lactate are formed daily in healthy individuals, but clinically significant lactate accumulation can be due to anaerobic glycolysis. Lactic acid is produced during normal physiologic processes (e.g., exercise) and during pathologic processes (e.g., shock, seizures).
- Normally, liver and kidney lactate metabolism maintains a balance between lactate production and clearance, while providing a consistent source of glucose to the brain and red blood cells, which preferentially use glucose; the hydrogen ion produced during lactic acid dissociation is used in gluconeogenesis, which is important in maintaining acid-base balance.
- In most critically ill or injured patients, hyperlactatemia and lactic acidosis are due to conditions that cause tissue hypoxia, with a shift to anaerobic glycolysis.
- Inadequate perfusion, severe hypoxemia, increased oxygen demand, decreased hemoglobin concentration, or combinations of these factors can cause tissue hypoxia.
- Depending on the duration and severity of hypoxia, hyperlactatemia and possibly lactic acidosis might develop.
- Hyperlactatemia generally develops when tissue perfusion is adequate and acid-base buffering systems are intact.
- Clinically evident tissue hypoperfusion does not usually occur in patients with hyperlactatemia alone, but "occult" hypoperfusion might be present that is not detectable by routine monitoring and might represent a precursor phase to overt hypoperfusion.
- Lactic acidosis can occur with abnormal metabolic regulation secondary to marked tissue hypoxia and hypoperfusion, certain drugs or toxins, or congenital defects in carbohydrate metabolism; buffering systems usually cannot cope with the developing acidosis.
- The severity of hyperlactatemia and acidosis in critically ill or injured patients reflects the severity of tissue hypoxia; evaluation of lactate levels helps assess the degree of tissue hypoperfusion and hypoxia.
- Studies in human trauma and shock patients demonstrate that lactate predicts

outcome and that mortality is correlated with the severity of the lactic acidosis: the higher the lactate level, the greater the mortality.

- Lactate measurement allows reliable assessment of the response of critically ill or injured people to initial and continuing resuscitative therapy.
- Lactate concentrations are increased in critically ill and injured dogs; an apparent association exists between severity of lactate increase and outcome, and differences in lactate concentrations between varying diseases/injuries (seizures, ethylene glycol and aspirin intoxication, and major trauma).
- Numerous clinical and experimental studies in critically ill humans and critically ill/injured dogs clearly show blood lactate measurement to be a useful tool for assessing the severity of tissue hypoxia, response to therapy, and prognosis.

SYSTEMS AFFECTED

- Persistent lactic acidosis can cause severe cardiovascular complications including impaired cardiac contractility, impaired pressor response to catecholamines, increased sensitivity of the myocardium to ventricular arrhythmias, and reduced cardiac output. These changes increase the likelihood of organ hypoperfusion leading to further tissue hypoxia.
- Persistent lactic acidosis can impair normal coagulation leading to hemorrhagic complications in trauma and postoperative patients.
- As acidosis and tissue hypoxia become more severe, failure of multiple organ systems and even death can occur.

SIGNALMENT

Dog and cat

SIGNS

General Comments

Usually relate more to the underlying disorder than to direct effects of acidosis. As tissue hypoperfusion, hypoxia, and acidosis worsen, signs of dysfunction can occur in any organ system.

Historical Findings

Disorders causing lactic acidosis are common; historical facts should prompt suspicion of an underlying acidosis.

Physical Examination Findings

- Tachypnea is usually present due to attempted respiratory compensation.
- Most patients with acidosis are hypovolemic and demonstrate poor tissue perfusion or dehydration—dark mucous membranes, prolonged capillary refill time, and increased skin turgor.
- Severely acidotic patients might have cardiac dysrhythmias and poor contractility.

CAUSES

- Two types, A and B, based on the clinical presence or absence of hypoperfusion or tissue hypoxia.

- Type A lactic acidosis—more common; due to decreased or inadequate oxygen delivery and oxygen consumption (i.e., poor tissue perfusion and tissue hypoxia).

- Causes of type A include shock, regional hypoperfusion, arterial obstruction, severe hypoxemia, severe anemia, carbon monoxide poisoning, severe asthma, and severe motor seizures.

- Type B lactic acidosis—includes all other causes of lactic acidosis; subdivided into 3 subsets (B₁, B₂, B₃); characterized by the absence of hypoxemia or poor tissue perfusion. Many causes of type B lactic acidosis might be "occult" hypoperfusion not detectable by routine monitoring parameters or possibly combinations of types A and B lactic acidosis.

- The most common causes of type B lactic acidosis in veterinary medicine include neoplasia, alklosis, sepsis, renal failure, liver disease, catecholamine use (norepinephrine, epinephrine), and intoxications (strychnine, cyanide, ethylene glycol, salicylates, acetaminophen, propylene glycol).

- Elevated blood lactate has been observed in patients with lymphoma and meningioma. Though the type and cause of the high lactate in these animals is not clearly understood, the presence of a high lactate should alert the clinician to evaluate other markers of perfusion (heart rate, mucous membrane color, pulse quality, capillary refill, serum creatinine) before attempting aggressive fluid resuscitation.

RISK FACTORS

- Risk factors for development of hyperlactatemia and lactic acidosis relate directly to risk factors for the specific disorders causing the underlying tissue hypoxia.
- In general, young animals are more at risk for traumatic shock and intoxications.
- Older animals are more likely to develop neoplasia, renal failure, heart failure, liver disease, severe anemia, and vascular disorders; consult the risk factors for these specific disorders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differential diagnoses for hyperlactatemia and lactic acidosis include those disorders described under "Causes."
- Any severely ill or injured animal is suspect for an underlying acidosis and evaluating the lactate concentration can aid in diagnosis.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

- Activated charcoal use, catecholamines, salicylates, acetaminophen, terbutaline, nitroprusside, halothane, bicarbonate, and propylene glycol all can cause

(CONTINUED)

mild-to-moderate increase in lactate concentration in the absence of true tissue hypoperfusion and hypoxia.

- Lower lactate concentrations are found in samples with sodium citrate anticoagulant than in those with heparin and EDTA.
- Even small amounts of lactate-containing intravenous fluids (e.g., lactated Ringer's solution) can cause false increases in circulating lactate concentration in a blood sample if not properly cleared from the catheter or tubing through which the intravenous fluid was being given.

Disorders That May Alter Laboratory Results

- Stress, trembling, resisting restraint, excitement, and venous stasis can increase lactate to 2.5–5.0 mmol/L, but in these instances lactate usually normalizes in ≤ 2 hours.
- Seizures or extreme muscular exertion can increase lactate to 4–10 mmol/L, but lactate usually normalizes in ≤ 2 hours.
- Several types of neoplasia increase lactate concentrations because tumor cells preferentially use anaerobic glucose metabolism as part of the cancer cachexia syndrome.
- Alkalosis, sepsis, liver disease, and renal failure also can increase lactate concentrations by mechanisms other than poor tissue perfusion and hypoxia.
- Failure to detect elevated lactate concentration does not ensure adequate perfusion to all organs; significant organ hypoperfusion can still exist that might ultimately lead to multiple organ failure.
- Regional hypoperfusion, especially splanchnic, occurs in the absence of, or before, increases in systemic lactate and metabolic acidosis and often despite therapy that successfully maintains blood pressure, cardiac output, heart rate, DO_2 , VO_2 , and respiratory parameters.

Valid if Run in Human Laboratory?

- Yes; semiautomated and automated techniques are available for rapid measurement of lactate concentration in microliter samples of whole blood, serum, and plasma.
- Lactate concentration is ideally measured on an arterial sample; however, clinically, there is no significant difference between sampling sites; maintain consistency with sites for serial measurement.

CBC/BIOCHEMISTRY/URINALYSIS

- Few specific CBC findings would suggest causes for hyperlactatemia and lactic acidosis.
- Biochemical and urinalysis findings help determine the underlying cause; examples include renal azotemia and markedly increased serum osmolality seen with ethylene glycol intoxication; renal azotemia, hyperkalemia, and tubular casts seen with acute renal failure; and increased lactate

concentration, increased total protein, and increased hematocrit with dehydration and poor tissue perfusion in a shock patient.

OTHER LABORATORY TESTS

- Arterial blood gas analysis might help define the extent of a concurrent respiratory disorder or a mixed acid-base disorder.
- Additional tests (e.g., ethylene glycol, serum and urine glucose, serum and urine ketones) might be helpful, depending on the suspected cause.

TREATMENT

- Hyperlactatemia alone is seldom significant enough to prompt specific therapy and is more important as a marker of possible severe or developing systemic problems. Aggressive treatment is not recommended for elevated blood lactate in the absence of other signs of circulatory shock. Fluid resuscitation is not indicated if acidosis does not accompany the high blood lactate.
- Detection of hyperlactatemia, with or without acidosis, should drive the clinician to seek causes of hypoperfusion and should dictate early therapeutic interventions to improve tissue oxygen delivery to halt organ ischemia and avert progression to circulatory shock.
- Lactic acidosis is often severe, and aggressive therapy to correct the underlying cause(s) and specifically treat the acidosis is usually indicated.

MEDICATIONS

DRUG(S) OF CHOICE

- Specific drug and fluid use depends on the underlying cause.
- Many causes of hyperlactatemia and lactic acidosis are characterized by fluid volume deficits; thus, aggressive fluid therapy is traditionally the first step in treatment.
- The use of alkalinizing and pH-neutral isotonic crystalloid fluids might be preferred in cases of hypovolemic lactic acidosis to more rapidly normalize blood pH.
- Though controversial, sodium bicarbonate therapy to correct blood $\text{pH} < 7.2$ might be indicated when the pH fails to increase in response to aggressive fluid resuscitation.

PRECAUTIONS

- Sodium bicarbonate is reserved for patients with a $\text{pH} < 7.2$ to avoid the cardiovascular effects of severe acidosis. It should only be used to correct the pH to 7.2. This can be accomplished by calculating the bicarbonate deficit or giving small empirical doses of 1–2 mEq/kg and rechecking blood pH.
- Sodium bicarbonate is likely to be more effective in patients with a normal anion gap

metabolic acidosis (normal lactate) than patients with high anion gap metabolic acidosis, as the latter develops metabolic alkalosis when organic anions (lactate or ketoacids) are converted to bicarbonate during hemodynamic recovery.

- With 10–15% of the bicarbonate immediately converted to CO_2 , it is important that the patient ventilation increases to prevent a further drop in pH.
- Possible complications of sodium bicarbonate therapy include volume overload from excess sodium, paradoxical CNS acidosis, hypocalcemic tetany and a left-shift of the oxygen-hemoglobin dissociation curve from iatrogenic alkalosis.

FOLLOW-UP

PATIENT MONITORING

- Serial lactate determinations are more valuable than single (admission, peak) lactate levels; monitor lactate over time in critical patients.
- The ability of a patient to clear lactate predicts response to therapy and survival.
- Continue checking other parameters that help gauge the response to therapy for the underlying cause.

PREVENTION/AVOIDANCE

Owners should understand the early warning signs of the condition(s) that led to lactic acidosis in their pet with instructions to seek prompt medical attention should they recur.

POSSIBLE COMPLICATIONS

- People with lactic acidosis are at greater risk of developing multiple organ failure and have a higher mortality rate than patients without lactic acidosis.
- Dogs and horses with elevated lactate concentrations and lactic acidosis have poorer outcomes as well.
- Lactate > 6 – 6.5 mmol/L suggests tissue hypoperfusion (e.g., shock) or local ischemia (e.g., gastric necrosis in GDV patients).

EXPECTED COURSE AND PROGNOSIS

- Lactic acidosis that quickly corrects with supportive therapy indicates resolution of the primary disorder. Lactic acidosis that fails to respond is a grave prognostic indicator.
- Serial blood lactate and pH concentrations will be more prognostic than single measurements as clinicians gauge response to therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Lactic acidosis can be found along with any condition causing tissue hypoxia.

LACTIC ACIDOSIS (HYPERLACTATEMIA)

(CONTINUED)

- Elevated blood lactate has been noted in patients with lymphoma and menigioma. These patients could have concurrent acidosis. In these patients, other parameters should be used to assess tissue perfusion as blood lactate can remain elevated despite adequate resuscitation.

BASICS

DEFINITION

A disturbance in gait and locomotion in response to pain, anatomic disruption, or injury.

Pathophysiology

- Severe, sharp pain—limited limb movement during all phases of locomotion, little to no load bearing in motion or at rest.
- Milder, dull, or aching pain—reduced loading and ground contact time during all phases of locomotion.
- Pain produced only during certain phases of movement—patient adjusts its motion and gait to minimize discomfort.
- Anatomic dysfunction resulting in certain normal motions being altered or impossible.

SYSTEMS AFFECTED

- Musculoskeletal • Nervous

SIGNALMENT

- Any age or breed of dog.
- Age, breed, and sex predilection—depend on specific disease.

SIGNS

General Comments

- Unilateral forelimb—head and neck moves upward when the affected limb is placed on the ground and drops when the sound limb loads.
- Unilateral hindlimb—pelvis drops when affected leg loads, rises when it unloads.
- Bilateral hindlimb—forequarters carried lower to shift weight forward.
- Always assess the patient's neurologic status, especially with a suspected proximal lesion.

Historical Findings

- Complete history—identify known trauma; alterations with weather, exercise tolerance, response to rest, effect of previous treatments.
- Determine speed of onset of lameness.
- Determine progression—static; slow; rapid.
- Determine consistency—intermittent, constant, associations.
- How does the patient show pain?

Physical Examination Findings

- Perform a complete routine examination.
- Observe posture—standing, getting up or lying down, sitting.
- Observe gait—walking; trotting; climbing stairs; doing figure eights.
- Palpate—asymmetry of muscle mass (measure and compare); bony prominences.
- Manipulate bones and joints, beginning distally and working proximally.
- Assess—instability; incongruency; pain; range of motion (measure); abnormal sounds.
- Examine suspected area of involvement last—by starting with normal limbs, patient may relax, allowing comparison of normal to abnormal reactions.

CAUSES

Forelimb

Growing Dog (< 12 Months of Age)

- Osteochondrosis of the shoulder • Shoulder luxation or subluxation—congenital

- Osteochondrosis of the elbow • Ununited anconeal process • Fragmented medial coronoid process • Elbow incongruity
- Avulsion or calcification of the flexor muscles—elbow • Asymmetric growth of the radius and ulna • Panosteitis • Hypertrophic osteodystrophy • Trauma—soft tissue; bone; joint • Infection—local; systemic
- Nutritional imbalances • Congenital anomalies

Mature Dog (> 12 Months of Age)

- Degenerative joint disease • Bicipital tenosynovitis • Calcification or mineralization of supraspinatus or infraspinatus tendon
- Contracture of supraspinatus or infraspinatus muscle • Soft tissue or bone neoplasia—primary; metastatic • Trauma—soft tissue; bone; joint • Panosteitis
- Polyarthropathies • Polymyositis
- Polyneuritis

Hindlimb

Growing Dog (< 12 Months of Age)

- Hip dysplasia • Avascular necrosis of femoral head—Legg-Calvé-Perthes disease
- Osteochondritis of stifle • Patella luxation—medial or lateral • Osteochondritis of hock
- Panosteitis • Hypertrophic osteodystrophy
- Trauma—soft tissue; bone; joint
- Infection—local; systemic • Nutritional imbalances • Congenital anomalies

Mature Dog (> 12 Months of Age)

- Degenerative joint disease (hip dysplasia)
- Cruciate ligament disease • Avulsion of long digital extensor tendon • Soft tissue or bone neoplasia—primary; metastatic • Trauma—soft tissue; bone; joint • Panosteitis
- Polyarthropathies • Polymyositis
- Polyneuritis

RISK FACTORS

Breed (size), overweight, strenuous activity

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Must differentiate musculoskeletal from neurogenic and metabolic causes.

CBC/BIOCHEMISTRY/URINALYSIS

Muscle injury elevates creatine phosphokinase levels.

OTHER LABORATORY TESTS

Depends on suspected cause

IMAGING

- Radiographs—recommend two views of region of interest.
- CT, MRI, ultrasound, and nuclear scintigraphy where appropriate.

DIAGNOSTIC PROCEDURES

- Cytologic examination of joint fluid—identify and differentiate intra-articular disease.
- EMG—differentiate chronic neuromuscular from musculoskeletal disease.
- Muscle and/or nerve biopsy—reveal and identify neuromuscular disease.

TREATMENT

Depends on underlying cause

MEDICATIONS

DRUG(S) OF CHOICE

- Analgesics and NSAIDs—minimize pain; decrease inflammation; meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg daily PO—liquid), carprofen (2.2 mg/kg PO q12h), deracoxib (3–4 mg/kg PO q24h—chewable) for 7 days for postoperative pain.

PRECAUTIONS

NSAIDs—gastrointestinal irritation or renal/hepatic toxicity may preclude use in some patients.

ALTERNATIVE DRUG(S)

Chondroprotective drugs (e.g., polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate)—may be of benefit in limiting cartilage damage and improving regeneration.

L

FOLLOW-UP

PATIENT MONITORING

Depends on underlying cause

LARYNGEAL DISEASES

BASICS

DEFINITION

- The larynx is made of cartilage structures surrounding the rima glottis. The functions of the larynx are to control airflow during respiration, protect the lower airways from aspiration during swallowing, and control phonation.
- Laryngeal diseases in dogs and cats include laryngeal paralysis, acute laryngitis, obstructive laryngitis, laryngeal collapse in brachycephalic airway syndrome (BAS), foreign body obstruction, neoplasia, and trauma.

PATOPHYSIOLOGY

- Decreased diameter of the laryngeal opening increases resistance to airflow and results in stridor on inspiration. The decrease in airflow will lead to hypoxemia, cyanosis, or respiratory distress and a decrease in heat exchange (heat intolerance, hyperthermia).
- Inflammation or lesions of the vocal cords can lead to aphonia or change in bark/meow.

SYSTEMS AFFECTED

- Respiratory—aspiration pneumonia and hypoventilation with cyanosis can occur when laryngeal function is impaired.
- Cardiovascular—hypoxemia may lead to tachycardia.
- Gastrointestinal—retching, regurgitation, vomiting, and/or dysphagia can when polyneuropathy causes laryngeal paralysis and esophageal dysfunction; esophagitis is frequently associated with BAS.
- Nervous—depression, stupor, or coma may occur if severe laryngeal obstruction leads to severe hyperthermia.

GENETICS

- Juvenile laryngeal paralysis in the Bouvier des Flandres is transmitted as a dominant trait.
- In laryngeal paralysis associated with polyneuropathy in the Leonberger dog, X-linked inheritance is suggested.
- No other laryngeal disorder has been proven to be genetic in the dog or cat, but familial conditions and breed predispositions have been reported.

INCIDENCE/PREVALENCE

- More common in dogs than in cats.
- Currently, congenital laryngeal paralysis is only sporadic in the Bouvier des Flandres.
- Idiopathic laryngeal paralysis is a common disease of older large-breed dogs; exact prevalence unknown.
- BAS is a common syndrome in French and English bulldogs.
- Laryngeal trauma and neoplasia are rare.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Familial laryngeal paralysis/polyneuropathy complex occurs in the Dalmatian, rottweiler, Leonberger, and Pyrenean mountain dog

(Great Pyrenees).

- Congenital laryngeal paralysis is found in Bouvier des Flandres, huskies, husky-crosses, white German shepherds, and probably bull terriers.

- Idiopathic acquired laryngeal paralysis is most often found in large-breed dogs (especially Labrador and golden retrievers).
- BAS is found in brachycephalic breeds of dogs.
- Golden retrievers are prone to laryngeal rhabdomyoma.
- Upper airway obstruction due to laryngeal collapse or narrowed laryngeal opening occurs in Norwich terriers.

Mean Age and Range

- Congenital and familial laryngeal paralysis—onset of signs usually in the first months of life (2 and 8 months). Later in the Leonberger, 1–9 years, and white German shepherd, 2 years.
- Acquired laryngeal paralysis—possible at any age but more frequent in older dogs.
- Neoplasia—middle-aged to old dogs.

SIGNS

Historical Findings

- Panting.
- Exercise and heat intolerance.
- Noisy respiration.
- Change of voice.
- Occasional cough.
- Severe cases—inspiratory respiratory distress, collapse, syncope, or even sudden death.
- Polyneuropathy, polymyopathy, or myasthenia gravis—regurgitation, weakness, abnormal gait (pattern of abnormalities varies).
- Absence of signs is possible in Norwich terriers with upper airway obstruction.

Physical Examination Findings

- Panting, polypnea, and inspiratory stridor in canine cases.
- Respiration is less noisy in cats with laryngeal disease.
- Cyanosis.
- Hyperthermia frequent.
- Aspiration pneumonia—fever, crackles on respiratory auscultation.
- Polyneuropathy, polymyopathy, or myasthenia gravis—paraparesis or tetraparesis with decreased spinal reflexes.
- Leonberger with familial polyneuropathy—high-stepping pelvic-limb gait with depressed spinal and cranial nerve reflexes.
- Rottweilers with laryngeal paralysis/polyneuropathy complex—cataracts frequently observed.
- Normal physical examination in some Norwich terriers with upper airway obstruction.

CAUSES

- Laryngeal paralysis:
 - Congenital—(1) neuronal degeneration of the nucleus ambiguus (Bouvier des Flandres and husky); (2) idiopathic.
 - Acquired—(1) polyneuropathy—idiopathic; familial (laryngeal paralysis-polyneuropathy complex); immune-mediated; (2) myasthenia gravis; (3) polymyopathy—idiopathic; immune-mediated; infectious (toxoplasmosis, neosporosis); (4) ventral cervical or cranial thoracic lesion—neoplasia or trauma affecting one or both recurrent nerves; examples

include lymphoma of the vagus nerve in the cat and traumatic neuropathy secondary to thyroidectomy.

- Acute laryngitis:
 - Cause often not found.
 - Virus—canine parainfluenza virus, feline herpes virus 1.

Bacteria—*Bordetella bronchiseptica*.

- Gastroesophageal reflux.
- Idiopathic chronic obstructive laryngitis (lymphoplasmacytic, granulomatous)

Laryngeal neoplasia:

- Dog—rhabdomyoma, rhabdomyosarcoma, adenocarcinoma, squamous cell carcinoma, lipoma, extramedullary plasmacytoma.

Cat—lymphoma, squamous cell carcinoma.

Trauma: injuries caused by foreign bodies.

- Neck trauma, bite wounds.
- Laryngeal collapse secondary to BAS.
- Idiopathic laryngeal malformation, collapse in Norwich terriers.

RISK FACTORS

Breed associations. Risk factors for developing severe or fatal clinical signs include obesity, hot or humid temperature (especially in a closed environment), and concurrent lower airway or pulmonary disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pharyngeal diseases—also cause gagging, stridor, and cough. Dysphagia is not seen with laryngeal disease but may be present in the case of pharyngeal lesion.
- Tracheal diseases may be confused with laryngeal disease in some cases. Cough is more frequent in tracheal disease than in laryngeal disease while inspiratory stridor is more frequent in laryngeal disease.

CBC/BIOCHEMISTRY/URINALYSIS

- No specific abnormalities.
- Leukocytosis may be present in aspiration pneumonia.
- Mild-to-moderate increase in liver enzymes if chronic hypoxemia.
- Hypercholesterolemia may be present if concurrent hypothyroidism is present.

OTHER LABORATORY TESTS

- If laryngeal paralysis secondary to polyneuropathy/polymyopathy:
 - Thyroid panel in the dog.
 - Antibody titers against *Toxoplasma gondii* (dog and cat) and *Neospora caninum* (dog).
 - Anticholinesterase receptor antibody titer.

IMAGING

- Thoracic radiographs—to rule-out aspiration pneumonia as a complication, other lower airway conditions, and a mediastinal mass as a cause of laryngeal paralysis.
- If vomiting/regurgitation present—barium swallow with fluoroscopy (to identify esophageal dysfunction, reflux esophagitis/hiatal hernia coexisting in some cases of brachycephalic airway syndrome).

(CONTINUED)

- Pharynx/larynx radiographs or ultrasonography—to identify potential mass.

DIAGNOSTIC PROCEDURES

Laryngoscopy

- Method of choice to identify laryngeal paralysis, collapse, mass, trauma, foreign body, or laryngitis. • General anesthesia or deep sedation is required. • Laryngeal paralysis:
 - Diagnosis confirmed by loss of abduction of arytenoid cartilages during deep inspiration.
 - Usually bilateral but unilateral paralysis is possible in the early course of the disease.
 - Unilateral paralysis has been described in cats. ◦ False-positive result possible because of the influence of general anesthesia on laryngeal function. Intravenous doxapram HCl (1–2 mg/kg) to increase respiratory effort is advised if the diagnosis is in doubt.

Esophagoscopy

When vomiting/regurgitation is observed to rule out reflux esophagitis or hiatal hernia.

Retrograde Rhinoscopy

When pharyngeal disease is suspected or in the case of BAS.

PATHOLOGIC FINDINGS

- Laryngeal paralysis:
 - Gross findings—redness, swelling, and thickening of the arytenoid cartilages and the vocal folds.
 - Histopathology—nonspecific edema and inflammation of laryngeal mucosa and submucosa; denervation atrophy of laryngeal muscles in the case of neuropathy of recurrent laryngeal nerve(s).
 - Idiopathic chronic obstructive laryngitis:
 - Histopathology—lymphoplasmacytic, granulomatous, or pyogranulomatous inflammation of the laryngeal submucosa.

TREATMENT

APPROPRIATE HEALTH CARE

Paralysis:

- Outpatient medical management—for stable patients awaiting surgery. • Emergency:
 - Sedation/anesthesia. ◦ Prednisolone succinate (30 mg/kg IV, then 15 mg/kg IV after 6 hours, prednisolone 0.5 mg/kg PO q12h till surgery). ◦ Cooling therapy with IV fluids, a blowing fan, and cold water on the neck or alcohol on paws.

NURSING CARE

Paralysis:

- Avoid warm, poorly ventilated environments, stress, and intense excitation as these further compromise normal cooling mechanisms and proper air exchange. • Avoid cervical collars. • Avoid weight gain.

ACTIVITY

Exercise should be severely restricted in animals suffering from laryngeal paralysis, especially in warm temperatures.

DIET

Loss of weight is advocated in overweight patients with laryngeal paralysis.

CLIENT EDUCATION

- Paralysis:
 - Discuss the importance of surgery and the risk of not performing surgery (chronic hypoxemia, heat stroke, risk of suffocation, and death).
 - Discuss potential complications of surgery.
 - Discuss the guarded prognosis with surgery in cases with polyneuropathy.
 - Discuss the potential heritability of this condition in certain breeds.
- Neoplasia:
 - Discuss surgical/chemotherapeutic options.

SURGICAL CONSIDERATIONS

- Paralysis—surgery (unilateral arytenoid lateralization) is the treatment of choice in both dogs and cats; bilateral surgical correction is not advised because it increases the risk of aspiration pneumonia; oral prednisolone therapy (anti-inflammatory doses) should be given for a few days before surgery to decrease laryngeal edema.
- Neoplasia—surgery can be curative in some cases, for rhabdomyoma, rhabdomyosarcoma, lipoma or squamous cell carcinoma; tracheostomy may improve quality of life if surgical excision is not possible.

MEDICATIONS

DRUG(S) OF CHOICE

- Paralysis—if surgery is declined, oral prednisolone therapy (0.5 mg/kg q12h for 1 week then progressive tapering of dosage to 0.5 mg/kg q48h).
- Lymphoma (mainly in cats)—chemotherapy (see Lymphoma—Cats).

PRECAUTIONS

Usual safety precautions if chemotherapy is administered.

FOLLOW-UP

PATIENT MONITORING

- Immediate post-surgical period—check rectal temperature (should remain normal).
- Monitor for aspiration pneumonia (short and long term).
- If surgery is successful, exercise, stridor, and heat intolerance should decrease.

POSSIBLE COMPLICATIONS

- Paralysis—recurrence of clinical signs are uncommon if surgery is correctly performed; aspiration pneumonia is possible as the larynx is placed in a fixed open position; risk of aspiration pneumonia increased if bilateral arytenoid lateralization is performed or if dysphagia due to pharyngeal and/or esophageal dysfunction coexists.
- Tumor—recurrence of clinical signs if complete

resection is not possible, increased risk of aspiration pneumonia in the postoperative period.

EXPECTED COURSE AND PROGNOSIS

- Idiopathic paralysis—good with surgery; guarded to poor if surgery is declined.
- Paralysis associated with esophageal dysfunction—poor.
- Tumor—guarded to good in the case of successful resection of a benign tumor; poor in the case of carcinoma, even with radiation therapy; variable in the case of feline lymphoma.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Laryngeal paralysis is sometimes associated with a mass in the anterior mediastinum or the ventral cervical region.
- Coexistence of megaesophagus, weakness, or abnormal gait with laryngeal paralysis suggests polyneuropathy, polymyopathy, or myasthenia gravis.

AGE-RELATED FACTORS

Congenital and familial laryngeal paralysis—onset of clinical signs in the first year of life.

PREGNANCY/FERTILITY/BREEDING

Dogs affected with congenital laryngeal paralysis or laryngeal paralysis/polyneuropathy complex should not be bred.

SEE ALSO

- Brachycephalic Airway Syndrome
- Cyanosis • Myasthenia Gravis

ABBREVIATIONS

- BAS = brachycephalic airway syndrome

LEAD TOXICOSIS

BASICS

DEFINITION

Intoxication (blood lead > 0.4 ppm, although somewhat variable) owing to acute or chronic exposure to some form of lead.

PATHOPHYSIOLOGY

- Cell damage is due to the ability of lead to substitute for other polyvalent cations (especially divalent cations such as Ca and Zn) important for cell homeostasis.
- Diverse biologic processes are affected, including metal transport, energy metabolism, apoptosis, ion conduction, cell adhesion, inter- and intracellular signaling, enzymatic processes, protein maturation, and genetic regulation.

SYSTEMS AFFECTED

- Gastrointestinal—unknown mechanism, likely damage to peripheral nerves.
- Nervous—capillary damage; alteration of membrane ionic channels and signaling molecules.
- Renal/urologic—damage to proximal tubule cells due to enzyme disruption and oxidative damage.
- Hemic/Lymph/Immune—interference with hemoglobin synthesis, increased fragility and decreased survival of RBCs, release of reticulocytes and nucleated RBCs from bone marrow, inhibition of 5'-pyrimidine nucleotidase causing retention of RNA degradation products, aggregation of ribosomes resulting in basophilic stippling.

GENETICS

N/A

INCIDENCE/PREVALENCE

- True incidence unknown.
- Decreasing prevalence in dogs—owing to elimination of sources.
- Steady to increasing prevalence in cats—increased awareness and diagnosis.
- Higher prevalence during warmer months.
- Higher prevalence in young animals—greater bioavailability of lead and more permeable blood-brain barrier.

GEOGRAPHIC DISTRIBUTION

- Low socioeconomic status of pet-owning family associated with high blood lead concentration in pets.
- Areas with older homes/buildings.

SIGNALMENT

Species

Dog and cat: dogs more commonly than cats

Breed Predilections

N/A

Mean Age and Range

Mainly dogs < 1 year of age

Predominant Sex

N/A

SIGNS

General Comments

- Primarily gastrointestinal and neurologic.
- Gastrointestinal—often precede CNS signs; predominant with chronic, low-level exposure.
- CNS—occur more often with acute exposure, more common in younger animals.

Historical Findings

History of renovation of older house or building or ingestion of lead objects.

Physical Examination Findings

- Vomiting
- Diarrhea
- Anorexia
- Abdominal pain
- Regurgitation due to megaesophagus
- Lethargy
- Hysteria
- Seizures
- Blindness
- Cats—central vestibular abnormalities such as vertical nystagmus and ataxia reported

CAUSES

- Ingestion of some form of lead—paint and paint residues or dust from sanding; car batteries; linoleum; solder; plumbing materials and supplies; lubricating compounds; putty; tar paper; lead foil; golf balls; lead object (e.g., shot, fishing sinkers, drapery weights), leaded glass.
- Use of improperly glazed ceramic food or water bowl.
- Lead paint or lead-contaminated dust or soil are common sources for exposure; cats ingest lead as a result of self-grooming.

RISK FACTORS

- Age < 1 year.
- Living in economically depressed areas.
- Living in old house or building that is being renovated.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dogs

- Canine distemper
- Infectious encephalitides
- Epilepsy
- Bromethalin, methylxanthine, or tremorgenic mycotoxin toxicosis
- NSAID toxicosis
- Heat stroke
- Intestinal parasitism
- Intussusception
- Foreign body
- Pancreatitis
- Infectious canine hepatitis

Cats

- Degenerative or storage diseases
- Hepatic encephalopathy
- Infectious encephalitides

- Organophosphate, bromethalin, or methylxanthine toxicosis

CBC/BIOCHEMISTRY/URINALYSIS

- Between 5 and 40 nucleated RBCs/100 WBCs without anemia.
- Absence of nucleated RBC does not rule out the diagnosis.
- Anisocytosis, polychromasia, poikilocytosis, target cells, hypochromasia.
- Basophilic stippling of RBCs; often difficult to detect.
- Neutrophilic leukocytosis.
- Cats—elevated AST and ALP reported.
- Urinalysis—mild nonspecific renal damage; glucosuria; hemoglobinuria.

OTHER LABORATORY TESTS

Lead Concentration

- Toxic—antemortem whole blood: > 0.4 ppm (40 µg/dL); post-mortem liver and/or kidney: > 5 ppm (wet weight).
- Blood lead concentrations fluctuate and do not necessarily correlate with total body burden.
- Lower values—must be interpreted in conjunction with history and clinical signs.
- No normal “background” blood lead concentrations; typically less than 0.05 ppm.
- Blood concentrations—do not correlate with occurrence or severity of clinical signs.
- CaNa₂EDTA mobilization test—collect one 24-hour urine sample; administer CaNa₂EDTA (75 mg/kg IM); collect a second 24-hour urine sample; with toxicosis, urine lead increases 10–60-fold post-EDTA (succimer could conceivably be substituted for CaNa₂EDTA but this has not been evaluated).

IMAGING

May note radiopaque material in gastrointestinal tract; not diagnostic.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Gross—may note paint chips or lead objects in gastrointestinal tract.
- Intranuclear inclusion bodies—may note in hepatocytes or renal tubular epithelial cells; intracellular storage form of lead; considered pathognomonic.
- Cerebrocortical lesions—spongiosis, vascular hypertrophy, gliosis, neuronal necrosis, demyelination.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient—first course of chelation, depending on severity of clinical signs.
- Outpatient—orally administered chelators.

NURSING CARE

- Balanced electrolyte fluids—Ringer's solution; replacement of hydration deficit.

(CONTINUED)

- Gastric lavage or whole bowel irrigation—may be indicated.

ACTIVITY

N/A

DIET

N/A

CLIENT EDUCATION

- Inform client of the potential of adverse human health effects of lead.
- Notify public health officials.
- Determine the source of the lead.

SURGICAL CONSIDERATIONS

Removal of lead objects from the gastrointestinal tract.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Evacuation of gastrointestinal tract—saline cathartics; sodium or magnesium sulfate (dogs, 2–25 g; cats 2–5 g PO as 20% solution or less).
- Control of seizures—diazepam (given to effect; dogs and cats, 0.5 mg/kg IV) or phenobarbital sodium (administer in increments of 10–20 mg/kg IV to effect).
- Alleviation of cerebral edema—mannitol (0.25–2 g/kg of 15% to 25% IV, slow infusion over 30–60 minutes) and dexamethasone (2.2–4.4 mg/kg IV).
- Some evidence that antioxidants or thiol-containing drugs may be useful—vitamins C and E, α -lipoic acid, N-acetylcysteine; optimal doses not determined.
- B vitamins, especially thiamin, may also be useful; optimal doses not determined.
- Reduction of lead body burden: chelation therapy
 - CaNa₂EDTA (dogs and cats, 25 mg/kg SC, IM, IV q6h for 2–5 days); dilute to a 1% solution with D₅W before administration; may need multiple treatment courses if blood lead concentration is high; allow 5-day rest period between treatment courses.
 - Succimer—alternative to CaNa₂ EDTA; orally administered chelating agent; 10 mg/kg PO q8h for 5 days followed by 10 mg PO q12h for 2 weeks; allow 2-week rest period between treatments; may administer per rectum if clinical signs such as emesis preclude oral administration; cats successfully treated with 10 mg/kg PO q8h for 17 days; advantages over other chelators: can be given PO allowing for outpatient

treatment; does not increase lead absorption from the gastrointestinal tract; not reported to be nephrotoxic; chelation of essential elements such as zinc and copper is not clinically significant.

CONTRAINDICATIONS

CaNa₂EDTA—do not administer to patients with renal impairment or anuria; establish urine flow before administration; do not administer orally.

PRECAUTIONS

- CaNa₂EDTA—safety in pregnancy not established; teratogenic at therapeutic doses although in human medicine is recommended over succimer for pregnant patients.
- Succimer—safety in pregnancy not established; fetotoxic at doses much higher (100 to 1,000 mg/kg) than recommended therapeutic dose.

POSSIBLE INTERACTIONS

CaNa₂EDTA—depletion of zinc, iron and manganese with long-term therapy.

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

Blood lead—should be < 0.1 ppm; assess 10–14 days after cessation of chelation therapy.

PREVENTION/AVOIDANCE

- Test paint, dust, soil prior to animal access if likelihood of lead contamination.
- Determine source of lead and remove it from the patient's environment.

POSSIBLE COMPLICATIONS

Occasionally, permanent neurologic signs (e.g., blindness).

EXPECTED COURSE AND PROGNOSIS

- Signs should dramatically improve within 24–48 hours after initiating chelation therapy.
- Prognosis—favorable with treatment.
- Uncontrolled seizures—guarded prognosis.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

Dogs < 1 year of age—more likely to be affected.

LEAD TOXICOSIS**ZOONOTIC POTENTIAL**

None; however, humans in the same environment may be at risk for exposure.

PREGNANCY/FERTILITY/BREEDING

- Transplacental passage—may cause neonatal poisoning.
- Lactation—lead mobilized from bones unlikely to poison nursing animals.

SYNOMYMS

Plumbism

ABBREVIATIONS

- ALP = alkaline phosphatase
- AST = aspartate aminotransferase
- Ca = calcium
- CNS = central nervous system
- NSAID = nonsteroidal anti-inflammatory drug

L

LEFT ANTERIOR FASCICULAR BLOCK

BASICS

DEFINITION

- Conduction delay or block in the anterior fascicle of the left bundle branch (Figures 1 and 2).
- Left ventricle activation then altered or delayed toward the blocked fascicle and corresponding papillary muscle.

ECG Features

- QRS complex—normal duration.
- Left axis deviation—dogs, $< +40^\circ$; cats, $< 0^\circ$

- Small q waves and tall R waves in leads I and aVL—small q not essential.
- Deep S waves (exceeding the R waves) in leads II, III, and aVF.

PATHOPHYSIOLOGY

- Anatomic basis still speculative—anterior fascicle vulnerable because it has a single blood supply, is long and thin, and is located in the turbulent outflow tract of the left ventricle.
- No hemodynamic compromise.

SYSTEMS AFFECTED

Cardiovascular

GENETICS

N/A

INCIDENCE/PREVALENCE

- Most commonly described form of bundle branch block in cats.
- Uncommon in dogs.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog and cat

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

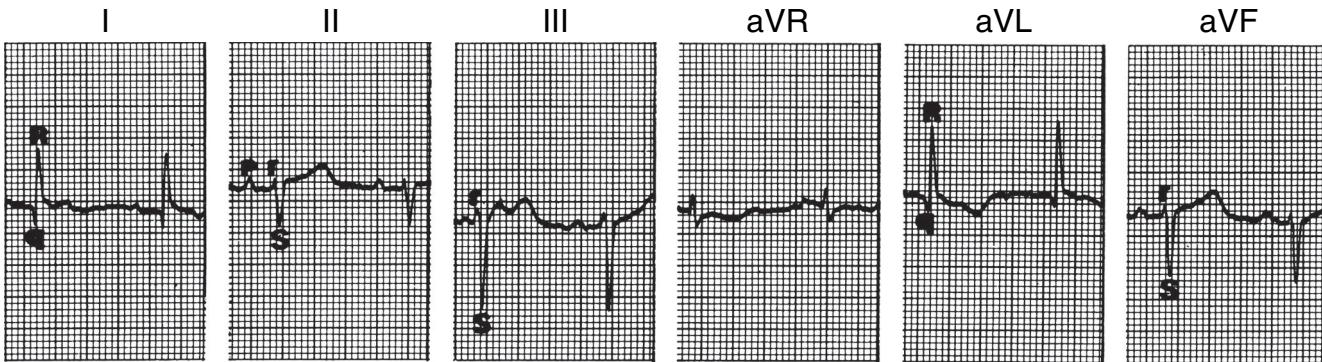

Figure 1.

Left anterior fascicular block in a cat with hypertrophic cardiomyopathy. Severe left axis deviation (-60°) with a qR pattern in leads I and aVL and an rS pattern in leads II, III, and aVF. The QRS complexes are of normal duration. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

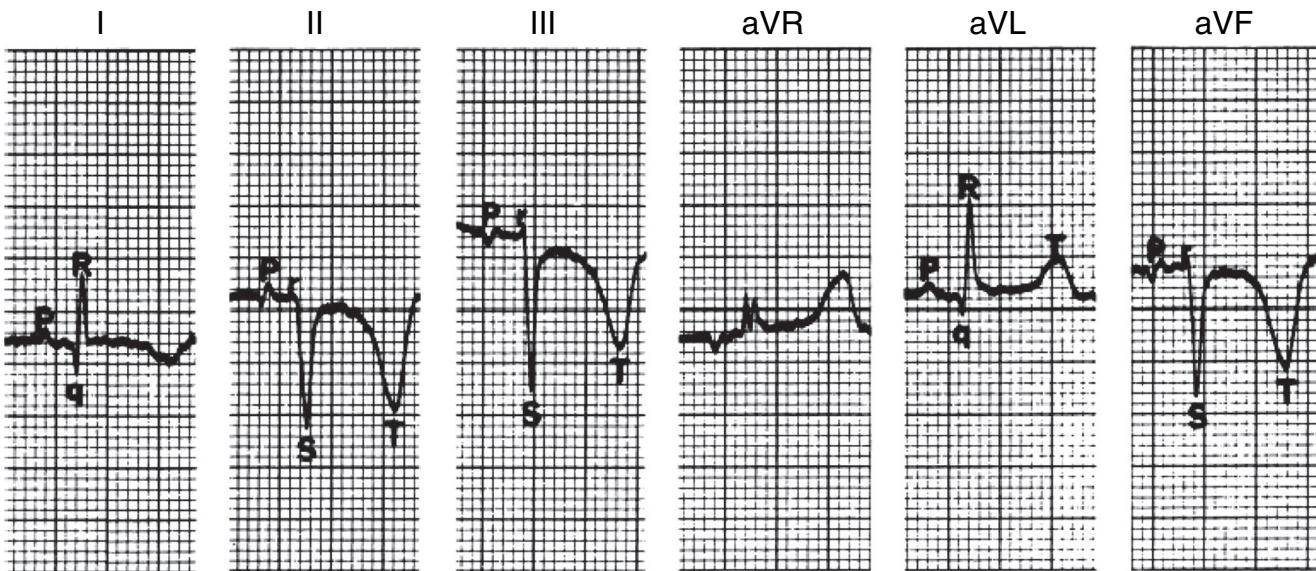

Figure 2.

Left anterior fascicular block in a dog with hyperkalemia (serum potassium, 5.3 mEq/L). There is abnormal left axis deviation (-60°) with a qR pattern in leads I and aVL and an rS pattern in leads II, III, and aVF. The large T waves are compatible with hyperkalemia. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

(CONTINUED)

LEFT ANTERIOR FASCICULAR BLOCK

SIGNS**Historical Findings**

- Signs usually associated with the underlying cause
- Usually an incidental ECG finding

Physical Examination Findings

No associated signs or hemodynamic compromise

CAUSES

- Hypertrophic cardiomyopathy (cats).
- Left ventricular hypertrophy (e.g., mitral insufficiency, aortic stenosis, aortic body tumor, hypertension, and hyperthyroidism).
- Hyperkalemia (e.g., urethral obstruction, acute renal insufficiency, and Addison's disease).
- Ischemic cardiomyopathy (e.g., arteriosclerosis of the coronary arteries, myocardial infarction, and myocardial hypertrophy that obstructs coronary arteries).
- Surgical repair of a cardiac defect (e.g., ventricular septal defect or aortic valvular disease).
- Restrictive cardiomyopathy (cats).
- Fibrosis.

RISK FACTORS

N/A

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

- Left ventricular enlargement—absence of left ventricular enlargement on thoracic radiograph or cardiac ultrasound supports a diagnosis of left anterior fascicular block.
- Right bundle branch block—deep, wide S waves in leads I, II, III, and aVF causing a right axis deviation; in patients with left anterior fascicular block, leads I and aVL are positive and leads II, III, and aVF have deep S waves resulting in a left axis deviation.
- Altered position of the heart within the thorax—thoracic radiographs help identify mass or foreign body that may be displacing the heart.
- Suspect hyperkalemia if signs of urethral obstruction, renal insufficiency, or hypoadrenocorticism (Addison's disease); determine serum potassium concentration.

CBC/BIOCHEMISTRY/URINALYSIS

Hyperkalemia possible

OTHER LABORATORY TESTS

N/A

IMAGING

- Echocardiogram may show structural heart disease.

- Thoracic and abdominal radiographs may show mass, pulmonary metastatic lesion, foreign body, or abnormal cardiac position.

DIAGNOSTIC PROCEDURES

- Electrocardiography.
- Long-term ambulatory monitoring (Holter) may reveal intermittent bundle branch block.

PATHOLOGIC FINDINGS

Possible lesions or scarring on endocardial surface in the path of the bundle branches; applying Lugol's iodine to the endocardial surface within 2 hours post-mortem enables clear visualization of the conduction system.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Treatment unnecessary
- Treat underlying cause

NURSING CARE

Unnecessary

ACTIVITY

Unrestricted unless indicated by underlying condition

DIET

No modifications unless indicated by underlying condition

CLIENT EDUCATION

Fascicular block per se does not cause hemodynamic compromise; combined with right bundle branch block it may develop into second- or third-degree AV block, making treatment essential; need to treat underlying cause.

SURGICAL CONSIDERATIONS

N/A

**MEDICATIONS****DRUG(S) OF CHOICE**

Treatment directed toward the underlying primary disease (e.g., drugs to lower the serum potassium in hyperkalemia).

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

**FOLLOW-UP****PATIENT MONITORING**

ECG regularly

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Causative lesion could progress and lead to a more serious arrhythmia or complete heart block.

EXPECTED COURSE AND PROGNOSIS

No hemodynamic compromise

L

LEFT BUNDLE BRANCH BLOCK

BASICS

DEFINITION

Conduction delay or block in both the left posterior and left anterior fascicles of the left bundle (Figures 1 and 2); a supraventricular impulse activates the right ventricle first through the right bundle branch; the left ventricle is activated late, causing the QRS to become wide and bizarre.

ECG Features

- QRS prolonged—dogs, > 0.08 second; cats, > 0.06 second
- QRS wide and positive in leads I, II, III, and aVF
- Block can be intermittent or constant

PATHOPHYSIOLOGY

- Because the left bundle branch is thick and extensive, the lesion causing the block must be large.
- Usually an incidental ECG finding—does not cause hemodynamic abnormalities.

SYSTEMS AFFECTED

Cardiovascular

GENETICS

N/A

INCIDENCE/PREVALENCE

Uncommon in cats and dogs. In cats with hypertrophic cardiomyopathy, left bundle branch block is not as commonly seen as left anterior fascicular block.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Cat and dog

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

Historical Findings

- Usually an incidental ECG finding—does not cause hemodynamic abnormalities.
- Signs usually associated with the underlying condition.

Physical Examination Findings

Does not cause signs or hemodynamic compromise.

CAUSES

- Cardiomyopathy.
- Direct or indirect cardiac trauma (e.g., hit by car and cardiac needle puncture).
- Neoplasia.
- Subvalvular aortic stenosis.
- Fibrosis.
- Ischemic cardiomyopathy (e.g., arteriosclerosis of the coronary arteries, myocardial infarction, and myocardial hypertrophy that obstructs coronary arteries).

RISK FACTORS

N/A

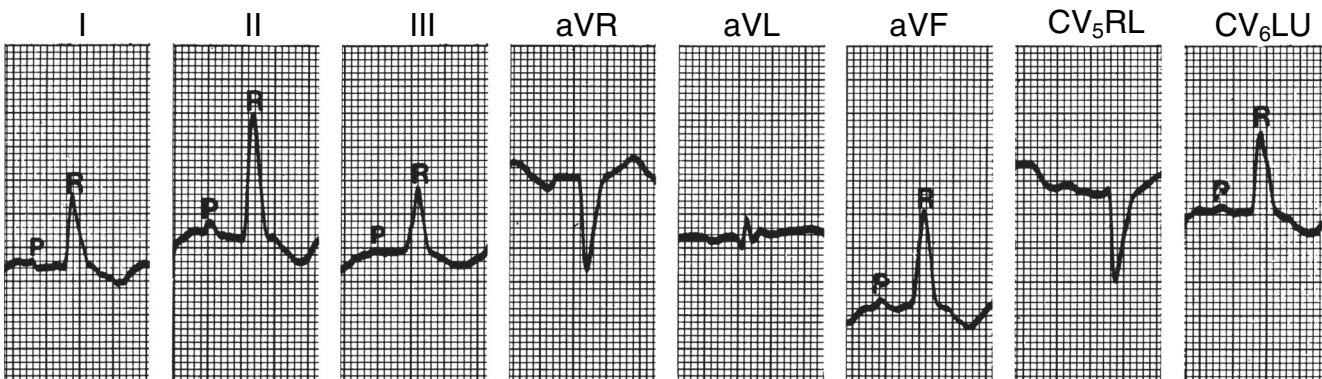

Figure 1.

Left bundle branch block in a cat with hypertrophic cardiomyopathy. The QRS complex is of 0.07-second duration and is positive in leads I, II, III, aVF. Neither a Q wave nor an S wave occurs in these leads. The QRS complex is inverted in lead aVR. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

Figure 2.

Intermittent left bundle branch block in a Chihuahua. QRS complexes are wider (0.07–0.08 second) in the second, third, and fourth complexes and in the last three complexes. Consistent PR interval confirms a sinus origin for the abnormal-appearance QRS complexes (lead II, 50 mm/second, 1 cm = 1 mV). (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

(CONTINUED)

LEFT BUNDLE BRANCH BLOCK**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

- Left ventricular enlargement.
- No left ventricular enlargement on thoracic radiograph or cardiac ultrasound studies supports diagnosis of isolated left bundle branch block.
- Can also be confused with ventricular ectopic beats, but the PR interval is usually constant and left bundle branch block has no pulse deficits.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

- Echocardiography may reveal structural heart disease; absence of left heart enlargement supports a diagnosis of left bundle branch block.
- Thoracic and abdominal radiographs may show masses or pulmonary metastatic lesions; traumatic injuries could result in localized or diffuse pulmonary densities.

DIAGNOSTIC PROCEDURES

- Electrocardiography.
- Long-term ambulatory monitoring (Holter) may reveal intermittent left bundle branch block.

PATHOLOGIC FINDINGS

Possible lesions or scarring on endocardial surface in the path of the bundle branches; applying Lugol's iodine to the endocardial surface within 2 hours post-mortem enables clear visualization of the conduction system.

LEGG-CALVÉ-PERTHES DISEASE

BASICS

DEFINITION

A spontaneous degeneration of the femoral head and neck leading to collapse of the coxofemoral joint and osteoarthritis.

PATHOPHYSIOLOGY

- Precise cause unknown; a specific vascular lesion not identified.
- Histologic evidence—points to infarction of vessels serving the proximal femur.
- Necrosis of subchondral bone—leading to collapse and deformation of the femoral head during normal loading.
- Articular cartilage—becomes thickened; cleft development; fraying of superficial layers.
- Simultaneous osseous degeneration and repair—characteristic of ischemia and revascularization of bone.
- No evidence of hypercoagulability or other blood-clotting abnormalities.

SYSTEMS AFFECTED

Musculoskeletal—causes a hind leg lameness; insidious in onset.

GENETICS

- Manchester terriers—multifactorial inheritance pattern with a high degree of heritability. Miniature poodles and West Highland white terriers—simple autosomal recessive trait.
- Hereditary predisposition likely.

INCIDENCE/PREVALENCE

- Common among miniature, toy, and small-dog breeds
- No accurate estimates available

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog

Breed Predilections

- Toy breeds and terriers—most susceptible.
- Manchester terrier, miniature pinscher, toy poodle, Lakeland terrier, West Highland white terrier, and cairn terrier—higher than expected incidence.

Mean Age and Range

- Most patients are 5–8 months of age
- Range 3–13 months

Predominant Sex

None

SIGNS

General Comments

Usually unilateral; only 12–16% of cases are bilateral

Historical Findings

Lameness—usually gradual onset over 2–3 months; weight-bearing; occasionally leg is carried.

Physical Examination Findings

- Pain on manipulation of the hip—most common
- Crepitation of the joint—inconsistent
- Atrophy of the thigh muscles—nearly always noted
- Patient otherwise normal

CAUSES

- Unknown.
- Tamponade of the epiphyseal intracapsular subsynovial vessels serving the femoral head—suggested cause of ischemia leading to the pathologic changes.

RISK FACTORS

- Small, toy, and miniature breeds—increased risk
- Trauma to the hip region

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Medial patellar luxation—may occur independently; primary differential in young toy breed dogs.
- Rupture of the cranial cruciate ligament—primary differential in older dogs.
- Hip dysplasia—radiographic signs similar.
- Fracture of the femoral head/neck due to trauma.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

- Early radiographic changes—widening of the joint space; decreased bone density of the epiphysis; sclerosis and thickening of the femoral neck.
- Later radiographic changes—lucent areas within the femoral head.
- End-stage radiographic changes—flattening and extreme deformation of the femoral head; severe osteoarthritis—femoral neck fracture.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Femoral head—removed during FHNE or total hip replacement; usually deformed with a thickened irregular articular surface.
- Early disease—histologically characterized by loss of lacunar osteocytes and necrosis of marrow elements; trabeculae surrounded by granulation tissue.
- Later disease—thickened metaphyseal trabeculae; mixture of necrosis and repair tissue typical of revascularization of bone.
- Advanced disease—osteoclastic activity; new bone formation.

TREATMENT

APPROPRIATE HEALTH CARE

- Rest and analgesics—reportedly successful in alleviating lameness in a minority of patients.
- Ehmer sling—successful in one patient; maintained for 10 weeks; increased risk of ankylosis. Not widely recommended.
- Insidious onset often prevents early recognition and possibility of successful conservative treatment.
- FHNE with early and vigorous exercise after surgery—treatment of choice.
- Micro THR has been reported to successfully restore normal ground reaction forces.

NURSING CARE

Post-Surgery

- Physical therapy—extremely important for rehabilitating the affected limb.
- Analgesics, anti-inflammatory drugs, and cold packing—3–5 days; important.
- Range-of-motion exercises—extension and flexion; initiated immediately.
- Small lead weights—attached as ankle bracelets above the hock joint; encourage early use of the treated limb.

ACTIVITY

- Post-surgery—early activity encouraged to improve leg use.
- Conservative therapy—restricted activity recommended.

DIET

Avoid obesity

CLIENT EDUCATION

- Warn owners of Manchester terriers, miniature poodles, and West Highland white terriers of the genetic basis of the disease; discourage breeding affected dogs.
- Warn client that recovery after FHNE may take 3–6 months.

SURGICAL CONSIDERATIONS

FHNE or micro THR—treatment of choice

MEDICATIONS

DRUG(S) OF CHOICE

NSAIDs—preoperative or postoperative; minimize joint pain; reduce synovitis; carprofen (2.2 mg/kg PO q12h), etodolac (10–15 mg/kg PO q24h), meloxicam (0.2 mg/kg PO, IV, or SC first day—then 0.1 mg/kg q24h), deracoxib (1–2 mg/kg PO q24h for OA, 3–4 mg/kg for postoperative pain PO q24h; do not exceed 7 days), firocoxib (5 mg/kg PO q24h), buffered or enteric-coated aspirin (10–25 mg/kg PO q8–12h).

(CONTINUED)

CONTRAINDICATIONS

NSAIDs—gastrointestinal upset may preclude use in some patients.

PRECAUTIONS

NSAIDs—inhibition of platelet activity may increase hemorrhage at surgery; discontinue aspirin for at least 1 week before surgery, if possible; usually cause some degree of gastric ulceration.

POSSIBLE INTERACTIONS

NSAIDs—do not use in conjunction with glucocorticoids; risk of gastrointestinal tract ulceration; consider appropriate wash-out times when switching from one NSAID to another.

ALTERNATIVE DRUG(S)

Chondroprotective drugs (e.g., polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate)—little help in advanced disease; no evidence to suggest that these drugs prevent or reverse the disease process.

**FOLLOW-UP****PATIENT MONITORING**

- Post-surgical progress checks—2-week intervals; necessary to ensure compliance with exercise recommendations.
- Conservative therapy—reevaluate (physical examination, radiographs) to determine if surgery is needed.

PREVENTION/AVOIDANCE

- Discourage breeding of affected animals.
- Do not repeat dam-sire breeding that resulted in affected offspring.

POSSIBLE COMPLICATIONS

Limiting postoperative exercise may result in less than optimal limb function.

EXPECTED COURSE AND PROGNOSIS

- FHNE—good to excellent prognosis for full recovery (84–100% success rate).

- Micro THR—excellent prognosis for full recovery.
- Conservative therapy—reported to alleviate lameness after 2–3 months in about 25% of patients.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

Usually affects juvenile small-breed dogs, but mature dogs may be affected by chronic disease.

ZOONOTIC POTENTIAL

L

LEIOMYOMA, STOMACH, SMALL AND LARGE INTESTINE

BASICS

OVERVIEW

Uncommon benign tumor arising from the smooth muscle of the stomach and intestinal tract; with immunohistochemistry these tumors may be reclassified as a gastrointestinal stromal tumor (GIST) or GIST-like.

SIGNALMENT

- Dog more commonly affected than cat
- Middle-aged to older (> 6 years) dogs and cats
- No breed predisposition

SIGNS

Historical Findings

- Relate to location in the gastrointestinal tract
- Stomach—vomiting
- Small intestine—vomiting; weight loss; borborygmus; flatulence
- Large intestine and rectum—tenesmus; hematochezia; sometimes rectal prolapse

Physical Examination Findings

- Stomach—no specific abnormalities.
- Small intestine—often no abnormal findings; may feel mid-abdominal mass; occasionally distended, painful loops of small bowel.
- Large intestine and rectum—may feel palpable mass per rectum.

CAUSES & RISK FACTORS

Unknown

L

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Foreign body
- Inflammatory bowel disease
- Parasites
- Adenocarcinoma
- Leiomyosarcoma
- GIST
- GIST-like
- Lymphoma
- Pancreatitis

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Hypoglycemia—occasionally associated with paraneoplastic syndrome.

• Stomach and small intestine—may see microcytic hypochromic anemia (iron-deficiency anemia).

OTHER LABORATORY TESTS

N/A

IMAGING

- Abdominal ultrasonography*—may reveal a thickened wall of stomach or bowel; gastric leiomyoma most common at esophageal—gastric junction.
- Contrast radiography* (stomach and small intestine)—may reveal a space-occupying mass.
- Double-contrast radiography* (large intestine and rectum)—reveals a space-occupying mass.

DIAGNOSTIC PROCEDURES

Fine-Needle Aspirates

If mass or thickening seen with ultrasound, FNA with cytology may be performed to rule out other differentials; for leiomyomas cytology is generally low yield.

Upper Gastrointestinal Tract

Perform upper gastrointestinal tract endoscopy and mucosal biopsy; however, frequently non-diagnostic because tumors are deep to the mucosal surface or distal to scope length. Therefore surgical biopsy often required to confirm the diagnosis.

Large Intestine and Rectum

Colonoscopy may reveal a mass; mucosal biopsy may be non-diagnostic because of normal mucosal covering of the tumor; surgical biopsy often required. If mass can be palpated per rectum, transrectal biopsies may be obtained.

TREATMENT

- Surgical resection—treatment of choice; curative if tumor is respectable.
- Even large leiomyomas often can be removed successfully with narrow margins.

MEDICATIONS

DRUG(S)

If reclassified as a GIST (c-KIT positive), may consider a tyrosine kinase inhibitor (toceranib phosphate) as follow-up therapy.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Complete resection—normal postoperative care; no additional follow-up necessary.
- Monitor blood glucose postoperatively if hypoglycemic prior to surgery.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Hypoglycemia—recognized as an associated paraneoplastic syndrome.

ABBREVIATIONS

- FNA = fine-needle aspirate
- GIST = gastrointestinal stromal tumor

LEIOMYOSARCOMA, STOMACH, SMALL AND LARGE INTESTINE

BASICS

OVERVIEW

- Uncommon malignant tumor arising from the smooth muscle of the stomach and intestinal tract.
- Tends to be locally invasive; metastatic rate up to 50%, usually intra-abdominal sites particularly the abdominal lymph nodes and liver.
- Prognosis fair to guarded.
- In the large intestine the cecum is often affected.
- Analyses reclassified many leiomyosarcomas to gastrointestinal stromal tumors (GIST) or GIST-like tumors; need immunohistochemistry to differentiate.
- True leiomyosarcomas occur rarely; however, this chapter will refer to these tumors as LMS as that is how they were characterized in the referenced papers.

SIGNALMENT

- Dog more commonly affected than cat
- Mostly middle-aged to older (> 6 years) dogs and cats
- No breed predisposition

SIGNS

Historical Findings

- Related to gastrointestinal tract.
- Stomach—vomiting; weight loss.
- Small intestine—vomiting; weight loss; diarrhea; borborygmus; flatulence.
- Large intestine and rectum—tenesmus, may lead to rectal prolapse; hematochezia.

Physical Examination Findings

- Stomach—nonspecific.
- Small intestine—may feel mid-abdominal mass; sometimes distended, painful loops of small bowel on abdominal palpation.
- Large intestine and rectum—may feel palpable mass per rectum.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Foreign body
- Inflammatory bowel disease
- Parasites
- Adenocarcinoma
- Leiomyoma
- GIST
- GIST-like
- Lymphoma
- Pancreatitis

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal
- Anemia—may be hypochromic, microcytic (iron-deficiency anemia)
- Leukocytosis
- Hypoglycemia—reported as a paraneoplastic syndrome

IMAGING

- *Abdominal ultrasonography*—may reveal a thickened wall of the stomach or bowel.
- *Positive contrast radiography* (stomach and small intestine)—reveals a space-occupying mass.
- *Double-contrast radiography* (large intestine and rectum)—reveals a space-occupying mass.

DIAGNOSTIC PROCEDURES

Fine-Needle Aspirates

- If mass or thickening seen with ultrasound, FNA with cytology may show mesenchymal cells with features of malignancy supportive of a sarcoma.
- Any enlarged lymph node noted with ultrasound can have FNA and cytology to look for metastasis.

Upper Gastrointestinal Tract

- Endoscopy and mucosal biopsy—can perform, but results are frequently non-diagnostic because in some tumors deep to the mucosal surface, mass may be beyond reach of endoscope.
- Surgical biopsy—often required to confirm diagnosis.

Large Intestine and Rectum

- Colonoscopy—may allow a mass to be seen; mucosal biopsy may be non-diagnostic because of the normal mucosal covering of the tumor.
- Deep biopsy—perform if possible.

TREATMENT

- Surgical resection—treatment of choice.
- Cecal leiomyosarcoma least likely to have metastases.
- Surgery can provide prolonged survival for small intestinal masses.
- Carefully evaluate for metastasis before extensive surgery (e.g., mesenteric lymph nodes, liver, and lungs).

MEDICATIONS

DRUG(S)

If reclassified as a GIST (c-KIT positive), may consider a tyrosine kinase inhibitor (toceranib phosphate) as follow-up therapy.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Leiomyosarcomas often metastasize to the liver and regional abdominal lymph nodes.
- An older case series showed:
 - Small intestinal cases had median survival of 12 months.
 - Cecal cases had median survival of 7.5 months, but most died of other diseases.
 - Gastric cases most rare, but the few reported had high rate of metastasis and short survival times.
 - Even dogs with metastasis can have prolonged survivals, with a median of 21.7 months reported in one study of dogs with metastatic LMS of the GI tract.
 - A recent report found similar survival times between dogs with leiomyoma, LMS, GIST, and GIST-like tumors:
 - 42 dogs with small intestinal tumors treated surgically had 1- and 2-year survivals of 62.6% and 52.3%.
 - 19 dogs with cecal tumors treated surgically

had 1- and 2-year survivals of 84.2% and 66%. • Complete resection—routine physical examination, thoracic radiography, and abdominal ultrasonography at 1, 3, 6, 9, and 12 months after surgery.

• Incomplete resection—symptomatic support to relieve clinical signs.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Hypoglycemia—reported as a paraneoplastic syndrome

ABBREVIATIONS

- FNA = fine-needle aspirate
- GI = gastrointestinal
- GIST = gastrointestinal stromal tumor
- LMS = leiomyosarcomas

LEISHMANIASIS

BASICS

OVERVIEW

- Protozoan—genus *Leishmania*; causes two types of disease: cutaneous; and visceral.
- Affected dogs in the United States invariably acquired infection in another country unless part of the endemic foxhound population.
- *L. donovani infantum*—Mediterranean basin, Portugal, and Spain; sporadic cases in Switzerland, northern France, and the Netherlands.
- *L. donovani* complex or *L. brasiliensis*—endemic areas of South and Central America and southern Mexico.
- Considered endemic in foxhounds in the United States.
- Sandfly vectors—transmit flagellated parasites into the skin of a host. Vector unknown in United States.
- Cats—often localizes in skin.
- Dogs—invariably develop visceral disease; renal failure is the most common cause of death.
- Incubation period—1 month to several years.

SIGNALMENT

- Dogs—virtually all develop visceral (systemic) disease; 90% also have cutaneous involvement; no sex or breed predilection.
- Cats—cutaneous disease (rare); no sex or breed predilection.

SIGNS

Visceral

- Exercise intolerance; weight loss, anorexia, diarrhea, vomiting, epistaxis, and melena; lymphadenopathy and cutaneous lesions (90% of cases); emaciation; signs of renal failure (polyuria, polydipsia, vomiting) possible; neuralgia, polyarthritis, polymyositis, osteolytic lesions, and proliferative periostitis rare; fever and splenomegaly (30%); death is usually due to chronic proteinuric nephritis progressing to end-stage kidney disease, nephrotic syndrome, and/or systemic hypertension.

Cutaneous

- Dogs—hyperkeratosis is the most prominent finding; excessive epidermal scale with thickening, depigmentation, and chapping of the muzzle and footpads; hair coat dry, brittle, hair loss, intradermal nodules and ulcers; abnormally long or brittle nails in some patients.
- Cats—cutaneous nodules (especially on the ears) usually develop.

CAUSES & RISK FACTORS

- Travel to endemic regions (usually the Mediterranean), where dogs are exposed to infected sandflies.
- Transmission by blood transfusion, *in utero*, and direct contact can occur.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Visceral—blastomycosis; histoplasmosis; systemic lupus erythematosus; metastatic neoplasia; distemper; vasculitis.
- Cutaneous—other causes of hyperkeratosis.
- Skin biopsy—hyperkeratotic and nodular lesions; existence of organisms confirms diagnosis.
- Hyperglobulinemia—differentiate from chronic ehrlichiosis and multiple myeloma.

CBC/BIOCHEMISTRY/URINALYSIS

- Hyperproteinemia with hyperglobulinemia—nearly 100% of cases.
- Hypoalbuminemia—95% of cases.
- Proteinuria—85% of cases.
- High liver enzyme activity—55% of cases.
- Thrombocytopenia—50% of cases.
- Azotemia—up to 45% of cases.
- Leukopenia with lymphopenia—20% of cases.

OTHER LABORATORY TESTS

- Serologic diagnosis by IFA or ELISA available—most tests give cross-reaction to *Trypanosoma cruzi*; differentiate based on clinical signs, history, and likelihood of exposure. Rapid in-house immunochromatographic tests are also available.
- PCR—particularly sensitive on bone marrow, lymph nodes, spleen and skin, but also used to assess blood, bodily fluids, conjunctival scrapings, and histopathologic specimens.

DIAGNOSTIC PROCEDURES

- Cultures—skin, spleen, bone marrow, or lymph node biopsies or aspirates; by the Centers for Disease Control and Prevention.
- Cytology and histopathology with immunohistopathology—identify intracellular organisms in biopsies or aspirate specimens (listed above).

PATHOLOGIC FINDINGS

- Cell infiltration (mainly histiocytes and macrophages) and characteristic intracellular amastigote forms especially in skin, lymph nodes, liver, spleen, and kidney.
- Mucosal ulcerations—stomach, intestine, and colon occasionally found.

TREATMENT

- Outpatient.
- Emaciated, chronically infected animals—consider euthanasia; prognosis very poor.
- Diet—high-quality protein; special for renal insufficiency if necessary.
- Cats—single dermal nodule lesions are best surgically removed.
- Advise client of potential zoonotic transmission of organisms in lesions to humans.
- Inform client that organisms will never be eliminated,

and relapse, requiring treatment, is inevitable.

- A canine vaccine is available in Europe and some areas of South America.

MEDICATIONS

DRUG(S) OF CHOICE

- Sodium stibogluconate and meglumine antimonite may only be available from the CDC.
- Allopurinol—produces clinical cures but relapses occur. Best when used in combination with other drugs (meglumine or amphotericin B) as maintenance. Dose: 7 mg/kg PO q8h for 3 months, or 10 mg/kg/day PO for 2–24 months.
- Amphotericin B—0.5–0.8 mg/kg diluted in 50 mL dextrose 5% in water given IV over 1 minute q48h for total dose of 8–15 mg/kg.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Seriously ill dogs—start antimonial drugs at lower doses.
- Renal insufficiency—treat before giving antimonial drugs; prognosis depends on renal function at the onset of treatment.
- Amphotericin B—nephrotoxicity can occur.

FOLLOW-UP

- Treatment efficacy—monitor by clinical improvement and identification of organisms in repeat biopsies.
- Relapses—a few months to a year after therapy; recheck at least every 2 months after completion of treatment; identified by detecting a rise in blood globulin levels or reappearance of clinical signs.
- Prognosis for a cure—guarded.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Leishmaniasis is a notifiable disease reportable to the CDC.
- Advise owner of zoonotic potential.

ABBREVIATIONS

- ELISA = enzyme-linked immunosorbent assay
- IFA = immunofluorescent antibody test
- PCR = polymerase chain reaction

Suggested Reading

Author Stephen C. Barr

Consulting Editor Stephen C. Barr

LENS LUXATION

BASICS

OVERVIEW

- Total dislocation of the lens from its normal location. • Anterior—forward displacement through the pupil into the anterior chamber.
- Posterior—backward displacement into the vitreous. • Occurs when the lens capsule separates 360° from the zonules that hold the lens in place. • Subluxation—partial separation of the lens from its zonular attachments; the lens remains in a normal or near-normal position in the pupil. • Primary (hereditary) luxation—due to a gradual zonular breakdown; usually inherited in dogs; often bilateral. • Congenital luxation—often associated with other congenital anomalies.
- Secondary luxation—due to chronic inflammation, buphthalmia, intraocular neoplasia, senile zonular degeneration or trauma.

SIGNALMENT

- Primary—usually seen in adult dog (typically 3–8 years old); commonly affected breeds include terriers, Chinese crested and Shar-Pei; rare in cats. • Secondary—dog and cat; any age/breed.

SIGNS

- Lens instability and subluxation—fibrils of liquefied vitreous in the anterior chamber; abnormally shallow or deep anterior chamber; abnormal iris curvature; phacodenesis (tremor of the lens with globe movement); iridodonesis (tremor of the iris with globe movement); aphakic crescent (crescent-shaped area of the pupil that is lacking the lens). • Lens luxation—anterior when the lens is in the anterior chamber; posterior when the lens sinks into the vitreous. Can have same signs as lens subluxation. • Acute or chronically painful eye with episcleral injection and diffuse or central corneal edema. • Glaucoma more common in anterior lens luxation.
- Uveitis. • Cataracts. • Retinal detachment.

CAUSES & RISK FACTORS

- Primary—associated with *ADAMTS17* gene mutation in some breeds; inheritance pattern uncertain in others. • Primary luxation and primary glaucoma—may occur simultaneously in some breeds. • Uveitis, especially chronic lens-induced uveitis.
- Intraocular neoplasia—may physically luxate the lens or cause chronic inflammation, leading to zonular degeneration. • Trauma—rarely causes a normal lens to luxate without signs of severe uveitis or hyphema.
- Cataracts—when intumescent or resorptive, can cause tension and breakage of lens zonules.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Uveitis, glaucoma—also cause painful, red eyes with corneal edema and may be concurrent. • Buphthalmia may cause lens luxation. • Corneal endothelial dystrophy or degeneration—may also cause corneal edema.
- Diagnosis made by careful ophthalmic examination and history.

CBC/BIOCHEMISTRY/URINALYSIS

Normal, unless sequela of a systemic disease that causes uveitis or neoplasia.

IMAGING

- Thoracic radiographs and abdominal ultrasonography—may be indicated if secondary to intraocular neoplasia. • Ocular ultrasonography—useful if corneal edema or cloudy ocular media preclude examination.

DIAGNOSTIC PROCEDURES

- Complete ophthalmic examination, including tonometry. • Genetic DNA test is available for some breeds predisposed to lens luxation.

TREATMENT

- Potentially visual eyes—consider referral for surgical removal of the lens. • Manual transcorneal reduction of anterior lens luxation followed by medical management of a posterior luxation has been described.
- Often, topical miotic therapy can keep a posteriorly luxated lens behind the pupil and surgery can be avoided in some cases.
- Irreversibly blind eyes can be treated by enucleation or evisceration with intrascleral prosthesis; if secondary to neoplasia, enucleation is the best choice for therapeutic and diagnostic purposes.

MEDICATIONS

DRUG(S)

- Initiate the following medications, and if the eye has the potential for vision, refer the patient to a veterinary ophthalmologist immediately for possible intracapsular lens extraction. • Topical miotics—demecarium bromide or prostaglandin analogs (latanoprost) q12h; indicated if the lens is primarily subluxated or posteriorly luxated.
- If the pupil is blocked due to anterior lens luxation, tropicamide may allow the pupil to dilate, releasing the lens and decreasing the risk for pupillary block glaucoma. • Mannitol 1 g/kg IV over 20 minutes; indicated for high

IOP (> 40 mmHg). • Carbonic anhydrase inhibitors—topical dorzolamide q8h; indicated for high IOP. • Topical anti-inflammatory—0.1% dexamethasone sodium phosphate or 1% prednisolone acetate (q6–24h) if inflammation is present.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Topical miotics—contraindicated if the lens is in the anterior chamber. • Client must verify location of lens prior to applying a miotic.

FOLLOW-UP

- Medically treated primary posterior luxation—IOP rechecked 24 hours after starting treatment and frequently thereafter; once IOP is stable, re-examine patient 3 or 4 times/year. • Monitor for secondary glaucoma and retinal detachment. • If only one lens is involved at the time of examination, the other lens may eventually become involved; the ophthalmologist may choose to perform prophylactic phacoemulsification in the contralateral eye if not yet luxated.

L

MISCELLANEOUS

ABBREVIATION

- IOP = intraocular pressure

LEPTOSPIROSIS

BASICS

DEFINITION

- Caused by pathogenic members of genus *Leptospira*.
- Acute and chronic diseases of dogs (mainly nephritis and hepatitis) and other animals, including, rarely, cats.
- Dogs—serovars causing disease vary by geographic area; US recent serovars of concern—*L. grippotyphosa*, *L. autumnalis*, and *L. pomona*; vaccines should include representative serovars found in area.

PATOPHYSIOLOGY

- *Leptospira*—penetrate intact/cut skin/mucous membranes; rapidly invade bloodstream (4–7 days); spread to all parts of body (2–4 days).
- Invasion leads to fever, leukocytosis, transitory anemia (hemolysis), mild hemoglobinuria, and albuminuria.
- Fever and bacteremia soon resolve.
- Capillary and endothelial cell damage; occasionally results in petechial hemorrhages.
- Liver—hepatitis and jaundice.
- Kidney—leptospiruria; *Leptospira* localize in damaged renal tubules; organism replicates readily in tubular epithelial cell.
- Early serum antibodies appear about the time bacteremia ceases.
- Death—usually a result of interstitial nephritis, vascular damage, renal failure; may result from acute septicemia or DIC.

SYSTEMS AFFECTED

- Cardiovascular—endothelial cell damage; hemorrhage
- Hepatobiliary—hepatitis; dysfunction; necrosis
- Nervous—meningitis
- Renal/Urologic—focal interstitial nephritis; hemoglobinuric nephrosis; tubular damage/failure
- Respiratory—vasculitis; interstitial pneumonia

Chronic Disease

- Ophthalmic—anterior uveitis
- Renal/Urologic—chronic renal failure
- Reproductive—abortion; weak puppies
- Reproductive—linked to feline stillbirth

INCIDENCE/PREVALENCE

- Reported incidence (dogs)—falsely low; most infections are inapparent and remain undiagnosed.
- Prevalence (dogs)—recent surveys have noted increasing disease in urban dogs; hospital prevalence rates have been increasing since the 1990s.

GEOGRAPHIC DISTRIBUTION

- Worldwide, especially in warm, wet climates/seasons.
- *L. canicola* and *L. icterohaemorrhagiae*—usual serovars; clinical disease in dogs; *L. canicola* most common worldwide; *L. icterohaemorrhagiae* most common in Australia.
- *L. bratislava*—has yet to be confirmed by culture as a serovar in dogs in the United States.
- Standing water and neutral or slightly alkaline soil promote presence in environment.

SIGNALMENT

Species

Dog and rarely cat

Mean Age and Range

- Young dogs without passive maternal antibody—more likely to exhibit severe disease.
- Old dogs with adequate antibody titer levels—seldom exhibit clinical disease unless exposed to a serovar not in the vaccine.

Predominant Sex

Traditionally, male dogs more commonly affected; disputed by recent reports.

SIGNS

General Comments

- Vary with age/immune status, environmental factors that affect *Leptospira* survival, and virulence of infecting serovar.
- Primary reservoir host—may spread particular serovar via urine; may have no clinical signs or less severe disease (acute diffuse to chronic interstitial nephritis, e.g., *L. canicola* in dogs with relatively weak antibody response).
- Incidental (accidental) host—acute severe disease (e.g., *L. icterohaemorrhagiae* in dogs with strong antibody response).

Historical Findings

Peracute to Subacute Disease

- Fever
- Sore muscles
- Stiffness
- Shivering
- Weakness
- Anorexia
- Depression
- Vomiting
- Rapid dehydration
- Diarrhea: with/without blood
- Icterus
- Spontaneous cough
- Difficulty breathing
- PU/PD progressing to anuria
- Bloody vaginal discharge
- Death—without clinical signs

Chronic Disease

- No apparent illness
- Fever of unknown origin
- PU/PD—chronic renal failure

Physical Examination Findings

Peracute to Acute Disease

- Tachypnea
- Rapid irregular pulse
- Poor capillary perfusion
- Hematemesis
- Hematochezia
- Melena
- Epistaxis
- Injected mucous membranes
- Widespread petechial and ecchymotic hemorrhages
- Reluctance to move, paraspinal hyperesthesia, stiff gait
- Conjunctivitis
- Rhinitis
- Hematuria
- Mild lymphadenopathy

CAUSES

- Dogs—*L. canicola*, *L. icterohaemorrhagiae*, *L. pomona*, *L. grippotyphosa*, *L. copenhagenii*, *L. australis*, *L. autumnalis*, *L. ballum*, and *L. bataviae*
- Cats—*L. canicola*, *L. grippotyphosa*, *L. pomona*, and *L. bataviae*

RISK FACTORS

Transmission

- Direct—host-to-host contact via urine, post-abortion discharge, fetus/discharge, sexual contact (semen).
- Indirect—exposure (via urine) to a contaminated environment (vegetation, soil, food, water, bedding) under conditions in which *Leptospira* can

survive.

- Disease agent—*Leptospira* serovar, each with its own virulence factors, infectious dose, and route of exposure.
- Disease in companion animals is often the result of spillover from diseased wildlife (many different types of mammals) that may be maintenance hosts for different serovars.

Host Factors

- Vaccine—protection is serovar-specific; may not prevent kidney colonization and urine shedding; new vaccines available of “subunit” type; research has shown promise of panvalent antigen that cross-protects against many serovars.
- Outdoor animals or hunting dogs—exposure of mucous membranes to water; exposure of abraded or water-softened skin increases risk of infection.

Environmental Factors

- Warm and moist environment; wet season (high rainfall areas) of temperate regions; low-lying areas (marshy, muddy, irrigated); warm humid climates of tropical and subtropical regions.
- Temperature range—7–10°C (44.6–50°F) to 34–36°C (93–96°F).
- Water—organism survives better in stagnant than flowing water; in neutral or slightly alkaline pH.
- Organism survives 180 days in wet soil and longer in standing water.
- Dense animal population—kennels/urban settings; increases chances of urine exposure.
- Exposure to rodents and other wildlife.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Subacute to Acute Disease

- Dogs—heartworm disease; immune-mediated hemolytic anemia; bacteremia/septicemia; infectious canine hepatitis virus; canine herpesvirus; hepatic neoplasia; trauma; lupus; Rocky Mountain spotted fever; ehrlichiosis; toxoplasmosis; renal neoplasia; renal calculi.
- Cats—hemotropic mycoplasmosis; drugs (acetaminophen); bacteremia/septicemia; FIV- and FeLV-associated diseases; cholangitis; toxoplasmosis; FIP; hepatic neoplasia; autoimmune disease; trauma; renal calculi; renal neoplasia.

Reproductive/Neonatal Disease

- Dogs—brucellosis; distemper; herpes.
- Cats—FIP; FeLV; panleukopenia; herpesvirus; toxoplasmosis; salmonellosis.

CBC/BIOCHEMISTRY/URINALYSIS

- PCV and total plasma solids—high owing to dehydration; rarely PCV low (hemolysis)
- Leukocytosis with left shift—leukopenia initially during leptospiremic phase
- Thrombocytopenia
- Increased fibrin degradation products
- BUN and creatinine—high; mainly renal
- Electrolyte alterations—depend on degree of renal and gastrointestinal dysfunction
- Hyponatremia
- Hypochloremia
- Hypokalemia

(CONTINUED)

LEPTOSPIROSIS

hyperkalemia with kidney failure
 • Hyperphosphatemia • Hypoalbuminemia
 • Acidosis—serum bicarbonate low • Alanine aminotransferase, aspartate aminotransferase, lactate dehydrogenase, alkaline phosphatase—high • Proteinuria • Isosthenuria—acute renal failure

OTHER LABORATORY TESTS

Serology (*Microscopic Agglutination Test*)

- Test serum in acute stage and also 3–4 weeks later (convalescent)
- Unvaccinated patients—titers may be low initially (1:100–1:200); may be higher in the convalescent serum (1:800–1:1,600 or higher) if a homologous *Leptospira* serovar is tested; several serovars may cross-react in the MAT test, especially if there are high titers to a single serovar.
- Vaccinated patients, older whole cell bacteria—expect high titers (for up to 12–16 weeks post-vaccination), then drop off to <1:400; new subunit vaccines—titers rise to ≥ 1:1,600 for 12 weeks for serovars *L. canicola* and *L. icterohaemorrhagiae*; titers for other subunit vaccine serovars are more variable (*L. pomona* and *L. grippotyphosa*).
- Run all serum samples (acute and convalescent) at the same time, if possible.

Darkfield Microscopy of Urine

- Often inconclusive • Difficult to read
- Requires fresh urine

Fluorescent Antibody Test of Urine

- More conclusive. • *Leptospira* not need to be viable; submit urine to lab on ice by overnight courier.
- Pretreat with furosemide 15 minutes before urine collection to increase success rate.
- Correlate results with clinical history.

PCR Test of Urine and Tissue

- Promising but still experimental

DIAGNOSTIC PROCEDURES

- Culture of body fluids antemortem (urine, blood, aqueous humor) and tissues post-mortem (kidney, liver, fetus, placenta)—usually not practical due to fastidiousness of *Leptospiras*; contact laboratory for the proper transport medium.
- Fluorescent antibody test—done on tissues submitted for post-mortem workup, especially kidney and liver.
- Special stains (Warthin-Starry silver)—attempt immunohistochemistry with monoclonal antibodies on formalin-fixed sections of kidney, liver, and fetal/placental tissue.
- PCR—some labs have protocols for urine/tissue specimens.

PATHOLOGIC FINDINGS

- Degree of kidney and liver disease depends on serovar and the host's immunity.
- Cats—generally less severe lesions.
- Dogs (acute disease)—lungs may be edematous; kidneys pale and enlarged; liver enlarged, may be friable with multifocal necrosis/hemorrhage; gastrointestinal tract may hemorrhage.

TREATMENT

NURSING CARE

- Dehydration and shock—parenteral, balanced, polyionic, isotonic intravenous solution (lactated Ringer's).
- Severe hemorrhage—blood transfusion may be needed in association with treatment for DIC.
- Oliguria or anuria—initially rehydrate; then give intravenous osmotic diuretics or tubular diuretics; peritoneal dialysis may be necessary.

CLIENT EDUCATION

Inform client of zoonotic potential from contaminated urine of affected dogs and their environment.

MEDICATIONS

DRUG(S) OF CHOICE

- Procaine penicillin G 40,000–80,000 U/kg IM q24h or divided q12h until kidney function returns to normal.
- Dihydrostreptomycin—10–15 mg/kg IM q12h for 2 weeks to eliminate organism from kidney interstitial tissues; try streptomycin if no renal failure; drug not available everywhere.
- Doxycycline 5 mg/kg PO or IV q12h for 3 weeks; use alone to clear both leptospiremia and leptosporuria.

PRECAUTIONS

- Aminoglycoside—carefully monitor patients with renal insufficiency.
- Penicillins (dogs)—adjust doses with renal insufficiency.

ALTERNATIVE DRUG(S)

- Ampicillin or amoxicillin—instead of penicillin (ampicillin 22 mg/kg PO q6–8h for 3 weeks; amoxicillin (22 mg/kg PO q8–12h for 3 weeks).
- Azithromycin—20 mg/kg PO q24h for 3 weeks.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Vaccine (dogs)—whole cell bacterin vaccines contain serovars *L. canicola*/*L. icterohaemorrhagiae* (newer also include *L. pomona*/*grippotyphosa*); promotes immunity to homologous serovars and protection from overt clinical disease; may not prevent colonization of the kidneys, resulting in chronic carrier state; serovar-specific; does not promote protection against other serovars present in nature.
- Newer subunit vaccine contains *L. pomona*, *L. icterohaemorrhagiae*, *L. grippotyphosa*, and *L. canicola*; claims made that subunit provides protection from clinical disease/prevents kidney colonization.
- Vaccines—vaccinate dogs per current label recommendations;

bacteria-induced immunity lasts only 6–8 months and is serovar-specific (no cross-protection outside of the serogroup); revaccinate at least yearly; vaccinate high-risk dogs (hunter, show dogs, dogs with access to water/ponds) every 4–6 months, especially in endemic areas.

- Kennels—strict sanitation to avoid contact with infected urine; control rodents; monitor/remove carrier dogs until treated; isolate infected animals during treatment.
- Activity—limit access to marshy/muddy areas, ponds, low-lying areas with stagnant surface water, heavily irrigated pastures, access to wildlife.
- Environmental contamination: *Leptospira* shedding in urine is intermittent; *Leptospira* survive in urine in the environment but do not multiply; cells survive until either drying, UV light exposure or freeze-thaw has killed the *Leptospira*.

POSSIBLE COMPLICATIONS

- DIC
- Permanent liver/kidney dysfunction
- Uveitis
- Abortion

EXPECTED COURSE AND PROGNOSIS

- Most infections subclinical or chronic
- Prognosis guarded for acute severe disease

MISCELLANEOUS

AGE-RELATED FACTORS

Severe clinical disease in young dogs (non-vaccinated or lacking maternal antibody)

ZOONOTIC POTENTIAL

- High; spread in urine of infected animals.
- Strict kennel hygiene and disinfection of premises (iodine-based disinfectant or stabilized bleach solutions).
- Acutely infected and carrier animals must be treated.

PREGNANCY/FERTILITY/BREEDING

- Possible abortion.
- Antimicrobial therapy—consider effect of drug on developing fetus.

ABBREVIATIONS

- DIC = disseminated intravascular coagulation
- FeLV = feline leukemia virus
- FIP = feline infectious peritonitis
- FIV = feline immunodeficiency virus
- PCR = polymerase chain reaction
- PCV = packed cell volume
- PU/PD = polyuria/polydipsia

L

LEUKEMIA, ACUTE LYMPHOBLASTIC

BASICS

OVERVIEW

• Lymphoproliferative disorder defined as the proliferation of neoplastic prolymphocytes and lymphoblasts in the bone marrow; most are of B-cell origin. • Leads to displacement and/or depression of normal hematopoietic cells (myelophthisis). • Neoplastic lymphoblasts are usually, but not always, circulating in the blood. • May infiltrate other organs including spleen, liver, and lymph nodes.

SIGNALMENT

• Dog—no significant sex predilection; with a mean age in one report 7.4 years old (range, 2–12 years), preponderance of large- and giant-breed dogs. • Rare in cat (also younger animals, especially with FeLV infection).

SIGNS

• Often nonspecific, can include anorexia, weight loss, and lethargy.
• Hepatosplenomegaly. • Mild to moderate lymphadenomegaly. • Petechial or ecchymotic hemorrhages.

CAUSES & RISK FACTORS

• Dogs—genetic factors, ionizing radiation, oncogenic viruses, and chemical agents including alkylating chemotherapy drugs are suspected, but unproven; missense mutations and tandem duplications have been identified in oncogenes such as Flt3, c-kit, and N-ras in dogs with ALL. • Cats—FeLV infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Acute or chronic infection—toxoplasmosis; canine distemper; ehrlichiosis. • Aplastic anemia. • Metastatic neoplasia. • Multicentric lymphoma with bone marrow involvement and circulating lymphoblasts can be difficult to distinguish from ALL. Lymphoma is typically characterized by bulky peripheral disease and minor bone marrow and peripheral blood involvement, whereas ALL has significant bone marrow and peripheral blood involvement and mild to moderate lymphadenopathy. • Other leukemias and myeloproliferative disorders.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC—normocytic, normochromic, nonregenerative anemia (98%); neutropenia (78%); thrombocytopenia (90%); all present in > 75% of cases. • CBC may also show lymphoblastic lymphocytosis, leukopenia, or both. • Serum chemistry profile—elevated liver enzyme activities.

OTHER LABORATORY TESTS

• Careful bone marrow cytopathology—expansion of neoplastic lymphoblasts (> 30%) is the hallmark. Can also see low numbers of myeloid/erythroid precursors and megakaryocytes depending on extent of bone marrow involvement, cell type of origin, and differentiation. • Bone marrow core biopsy with immunohistochemical or enzymatic biochemical studies can be helpful if bone marrow cannot be obtained. • Enzymes include peroxidase and chloroacetate ester. • Flow cytometry using monoclonal antibodies against cell surface antigens on bone marrow aspirates and/or blood is typically used to characterize disease. • Useful antibodies include CD45 (all hematopoietic cells beside erythrocytes), CD34 (progenitor cells), CD18 (leukocytes), CD79a (B cells), and CD3 (T cells). • The majority of ALL cells are CD34+, while the majority of lymphoma cells are CD34-. • PCR for antigen receptor rearrangements (PARR) can confirm a clonally expanded population if bone marrow cytology and/or flow cytometry results are equivocal.

IMAGING

Radiography and ultrasonography often reveal hepatomegaly and splenomegaly.

DIAGNOSTIC PROCEDURES

Bone marrow aspirate and biopsy

TREATMENT

• Usually outpatient, unless supportive care required. • Transfusions—as indicated, to restore RBCs, platelets, or coagulation factors. • Consult a veterinary oncologist for updated treatment approaches. Allogenic bone marrow transplantation (using CD34+ cells harvested from a DLA-matched donor) is an option if initial remission can be achieved using chemotherapy, but is only available at a limited number of veterinary oncology specialty practices.

MEDICATIONS

DRUG(S)

• L-asparaginase (400 IU/kg IM/SC after pre-treating with diphenhydramine); usually used as initial induction agent.
• Combination chemotherapy—prednisone (20–30 mg/m² PO q12h), vincristine (0.5–0.7 mg/m² IV weekly), and cyclophosphamide (200–250 mg/m² divided PO weekly); may result in partial or short-lived complete remission. • Cytosine arabinoside (400–600 mg/m² IV weekly); administer as constant rate infusion over 6–8 hours, can cause thrombocytopenia or

other myelosuppression. • More aggressive chemotherapeutic agents may be used after lymphocytosis has lessened and cytopenias have resolved.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Acute tumor lysis syndrome (life-threatening bradycardia secondary to an acute increase in serum potassium and phosphorus levels following induction chemotherapy) can be seen in ALL dogs with high neoplastic cell counts. Consider high-rate fluid diuresis or peripheral blood leukoreduction using an apheresis machine.

FOLLOW-UP

PATIENT MONITORING

Monitor peripheral blood count and bone marrow—judge success and toxicity of treatment.

POSSIBLE COMPLICATIONS

Hemorrhage from thrombocytopenia—major cause of death in dogs.

EXPECTED COURSE AND PROGNOSIS

Most dogs will have a short-lived complete or partial remission with induction chemotherapy. Prognosis is grave with most dogs succumbing to resistant disease within a few weeks to months.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Chemotherapy—contraindicated in pregnant animals

ABBREVIATIONS

• ALL = acute lymphoblastic leukemia
• FeLV = feline leukemia virus • PCR = polymerase chain reaction • RBC = red blood cell

LEUKEMIA, CHRONIC LYMPHOCYTIC

BASICS

OVERVIEW

- Uncommon, lymphoproliferative disorder.
- Slowly progressive over months to years.
- Circulating neoplastic lymphocytes are mature and well differentiated. • May originate in spleen or bone marrow.

SYSTEMS AFFECTED

- Hematopoietic • Lymphatic

SIGNALMENT

- More frequent in dog than cat. • Dogs—mean age, 10 years (range, 1.5–15 years); male-to-female ratio approaches 2:1. • Cats—median age 12.5 years (range, 5–20); male-to-female ratio 2:1.

SIGNS

- Nonspecific, often no clinical signs of illness
- Lethargy, decreased appetite, chronic weight loss • Lymphadenomegaly, splenomegaly
- Fever • Polydipsia and polyuria

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lymphoma—may have a leukemic phase (stage V). • Acute lymphoblastic leukemia.
- Immune-mediated hematologic diseases.
- Chronic antigenic stimulation (reactive lymphocytosis)—ehrlichiosis, leptospirosis, leishmaniasis. • Acute viral infection associated lymphocytosis.

CBC/BIOCHEMISTRY/URINALYSIS

- Lymphocytosis—range, 5,000–> 500,000 cells/ μ L, typically small, mature lymphocytes.
- In dogs, more than 60% have large granular lymphocyte (LGL) morphology. • Larger cells may be observed, especially with progression to blast crisis (advanced stage). • Mild-to-moderate normocytic, normochromic anemia (nonregenerative). • Normal-to-low platelet count (less than 20% cases). • Normal-to-mildly increased serum globulins.

OTHER LABORATORY TESTS

- Cytologic examination (bone marrow aspirate or core biopsy)—may show high numbers of mature lymphocytes (especially B-cell CLL); crowding out of normal cell lines in advanced stages. • Immunocytochemistry, flow cytometry, PCR for antigen receptor rearrangement (PARR) to determine cell lineage. • If hyperglobulinemia, serum protein electrophoresis to detect monoclonal gammopathy. • Direct Coombs' test—may be positive with secondary immune-mediated hemolytic anemia. • Serology for *E. canis*.

IMAGING

Radiography and ultrasonography may reveal splenomegaly or internal lymphadenomegaly.

DIAGNOSTIC PROCEDURES

- Bone marrow aspiration (cytology) or biopsy (histopathology). • Lymph node and spleen cytology or histopathology.

TREATMENT

- Usually outpatients treated with oral therapy. • Splenectomy may be considered when spleen is involved and appears to be primary site of neoplastic lymphocytes.
- Treatment should be instituted when patient demonstrates clinical signs of illness (including weight loss, lethargy), lymphadenomegaly or organomegaly, cytopenias, or with lymphocyte count above 50,000/ μ L. • Consult a veterinary oncologist for updates in treatment.

MEDICATIONS

DRUG(S)

- Chlorambucil 6 mg/m² PO q24h for 7–14 days; then 6 mg/m² PO q48h and eventually (maintenance) 2–4 mg/m² q48h, adjusted based on response and CBC (dogs); 2 mg q2–4 days (cats). • Prednisone 40 mg/m² PO q12h (dogs); 5–10 mg/cat q24h (cats; use prednisolone); in combination with chlorambucil; may be tapered or discontinued when lymphocyte count normalizes. • Alternative chemotherapy agents and protocols to be considered when resistance or blast crisis develops over time, consult with an oncologist.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Chemotherapy may have toxic side effects; seek advice with oncologist before starting treatment if you are unfamiliar with cytotoxic drugs.

FOLLOW-UP

PATIENT MONITORING

Initially, biweekly examination of CBC—response to treatment and disease progression.

POSSIBLE COMPLICATIONS

Chronic chemotherapy-induced myelosuppression; may need to alter dosage, depending on neutrophil and platelet counts.

EXPECTED COURSE AND PROGNOSIS

- Variable course, but eventually progressive to blast crisis or becomes resistant to therapy.

- Median survival time with therapy approaches 18 months in dogs with B-cell CLL, and surpasses 24 months in dogs with T-cell CLL. • Median survival time with therapy in cats was > 14 months in one study.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Chemotherapy contraindicated in gestating animals

ABBREVIATIONS

- CLL = chronic lymphocytic leukemia
- LGL = large granular lymphocyte • PCR = polymerase chain reaction

LEUKOENCEPHALOMYELOPATHY IN ROTTWEILERS

BASICS

OVERVIEW

- Neurodegenerative disorder that affects the white matter of young adult rottweilers leading to chronic progressive ataxia of the limbs.
- The clinical signs are primarily associated to involvement of the cervical spinal cord, but white matter lesions are also present in the brainstem, cerebellum, and subcortical white matter.
- Occurs worldwide.
- Probably autosomal recessive inheritance.

SIGNALMENT

Rottweiler—either sex; onset in adult dogs 1.5–4 years old

SIGNS

- Insidious, non-painful, progressive onset.
- Cervical spinal cord signs prevail despite widespread demyelinating process.
- Proprioceptive ataxia of the thoracic (delayed protraction with overreaching of the limb) and pelvic limbs, with upper motor neuron weakness.
- Front limbs are more severely affected than hind limbs. Mild asymmetry between right and left limbs may be present.
- Nail scuffing in all limbs.
- Proprioceptive positioning and hopping delayed to absent in all limbs.
- Spinal reflexes normal to exaggerated.

CAUSES & RISK FACTORS

- Autosomal recessive inheritance suspected
- Inbreeding

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cervical compressive lesions such as cervical vertebral spondylomyelopathy (wobbler), cervical subarachnoid diverticula, fibrotic stenosis, spinal cord tumors—difficult to differentiate on clinical signs alone; all can have an insidious onset; MRI necessary for diagnosis.
- Neuroaxonal dystrophy and distal sensorimotor polyneuropathy—neurologic disorders reported in rottweilers; differentiated on the basis of neurologic deficits; neuroaxonal dystrophy: deficits relate to the cerebellum; distal sensorimotor polyneuropathy: tetraparesis associated with lower motor neuron signs.

- Discospondylitis, fracture/luxation, intervertebral disc disease—neck pain; disc disease rarely seen in large-breed dogs at a young age.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

N/A

IMAGING

- Spinal cervical survey radiographs normal.
- MRI—on T2W transverse images of the cervical spine, bilateral and symmetrical well-demarcated, ovoid in shape, intra-axial hyperintensities in the white matter of the dorsolateral funiculi, extending contiguously from the cervicomедullary junction to the sixth cervical vertebral body. Symmetrical hyperintensities also observed in pyramids and ventral aspect of the crus cerebri in the brain. No contrast enhancement.

DIAGNOSTIC PROCEDURES

CSF analysis normal.

PATHOLOGIC FINDINGS

- Although the most severe lesion is located in the white matter of the cervical spinal cord, it extends caudally into the thoracic spinal cord and rostrally into the brainstem.
- Macroscopic examination: in the dorsal aspect of the lateral funiculi of the cervical spinal cord and in the pyramidal tracts of the medulla oblongata, presence of well demarcated whitish opaque foci located bilaterally and symmetrically, corresponding to myelin loss.
- Microscopy: in the cervical spinal cord, the lesion affects the cervical spinal cord white matter in the dorsal portion of the lateral funiculi (dorsal spinocerebellar, lateral corticospinal, reticulospinal, and rubrospinal tracts). In the brain, the lesion affects the pyramidal tracts, crus cerebri, medial lemniscus, caudal cerebellar peduncle, trapezoid body, spinal tracts of the trigeminal nerve, and optic tracts; multifocal lesions are also observed in the cerebellar folia.
- The myelin loss exceeds axon loss with extensive astrogliosis and astrocytosis. Normal appearing axons observed in areas of severe demyelination.
- Lesion bilateral with some asymmetry.

TREATMENT

- Outpatient, unless the severity of neurologic deficits precludes nursing care at home.
- Activity—whatever can be tolerated.

- Diet—ensure proper intake of food; patient may have difficulty reaching the feeding area.
- Neurologic status—slowly and progressively deteriorates; eventually, the patient is unable to walk or get up.

MEDICATIONS

DRUG(S)

N/A

FOLLOW-UP

- Neurologic examination—monitor monthly to assess progression.
- Avoid bed sores and urine and fecal scalding by keeping the patient on a clean, dry, and cushioned pad (e.g., synthetic sheepskin).
- Severe tetraparesis—within 6–12 months after onset of clinical signs.
- Euthanasia—because of severe debility.

MISCELLANEOUS

ABBREVIATIONS

- CNS = central nervous system
- CSF = cerebrospinal fluid
- MRI = magnetic resonance imaging
- T2W = T2-weighted

L-FORM BACTERIAL INFECTIONS

BASICS

OVERVIEW

Caused by bacterial variants with defective or absent cell walls.

L-Form Bacteria

- Isolated from humans, animals, and plants.
- Named for Lister Institute (London), where discovered in 1935.
- Also called L-organisms, cell wall deficient (CWD)-forms.
- Differ from the *Mycoplasma* by lack of sterols in their membranes (similar to bacteria).
- Soft, fragile, pleomorphic, spherical, and osmotically fragile; structurally equivalent to protoplasts and spheroplasts, which cannot divide.
- Can grow and replicate by cell fission in an irregular manner, yielding daughter cells that differ in size, nucleic acid content, and amount of cytoplasm.
- Formed as spontaneous variant of bacteria or when cell wall synthesis is inhibited or impaired by antibiotics (e.g., penicillin), specific immunoglobulins, or lysosomal enzymes that degrade cell walls.
- Can be induced from virtually all gram-positive and -negative bacteria under suitable conditions.
- May revert to normal cell wall strain in a suitable host or favorable medium.
- Encompasses both unstable (can revert to normal walled bacteria) L-forms with reversible loss of cell wall organization due to phenotypic variants of bacteria and stable (not able to revert) L-forms with irreversible loss of cell wall due to genomic mutations.
- Usually no pathogenicity.

SIGNALMENT

- Sporadic in cats and dogs
- Most common in free-roaming cats of all ages

SIGNS

- Dogs—arthritis.
- Cats—penetrating wound (usually cat bite); infected surgical site; cellulitis; fever; arthritis; synovitis.

CAUSES & RISK FACTORS

- Bites, scratches, or trauma may allow organism to enter skin and subcutaneous tissue.
- Environmental reservoir unknown.

- Formation encouraged by antibiotic treatment of host, resistance of host, suitability of in vivo site for establishment of infective locus, and relatively low to moderate virulence of the infecting bacterium.
- Greatly reduced infectivity but may revert and display the pathogenic properties of the original bacterium.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- *Mycoplasma*—differentiate by phase microscopy, electron microscopy, or measuring penicillin-binding proteins.
- Suppurative skin infections caused by mycobacteria, yeast, or fungi.
- Arthritis caused by immune-mediated disease, bacteria, spirochetes, *Mycoplasma*, *Rickettsia*, *Chlamydia*, viruses, or fungus.

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilia with left shift
- Monocytosis
- Lymphocytosis
- Eosinophilia
- Mild normochromic, normocytic anemia
- High serum total protein

OTHER LABORATORY TESTS

- Cytology—exudate from draining lesions contains macrophages and neutrophils.
- Joint fluid—high neutrophil count.
- Culture—difficult; requires special media (Hayflick); “fried-egg” appearance of colonies on solid agar (center portion embedded in agar; thin vacuolated growth on agar surface).
- Light microscopy—difficult to demonstrate.
- Electron microscopy—may show characteristic pleomorphic, cell-wall-deficient organisms in phagocytes.
- Precise characterization and speciation—the organism must revert to the parental cell-walled state (may take years).

IMAGING

Radiographs—periarticular soft tissue swelling; periosteal proliferation.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Biopsy—pyogenic cellulitis; panniculitis; chronic pyogranulomatous arthritis; tenosynovitis.
- Stains—neither conventional (H&E) nor specialized (gram, acid-fast, silver, PAS) reveal organisms.

TREATMENT

- Gentle cleaning degrades fragile organisms.
- Allow open wounds to heal by secondary intention.

MEDICATIONS

DRUG(S)

- Variable antibiotic sensitivity.
- Tetracycline 22 mg/kg PO q8h for at least 1 week after signs disappear.
- Fever usually breaks within 24–48 hours.
- β -lactam antibiotics—inhibit cell wall synthesis; not effective.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

Arthritic changes persist

L

MISCELLANEOUS

- Public health significance unknown
- Ubiquitous; therefore, role in disease questioned
- May play a role in recurrent infections or chronic diseases

ABBREVIATIONS

- H&E = hematoxylin and eosin
- PAS = periodic acid-Schiff

LILY TOXICOSIS

BASICS

OVERVIEW

- Plants in the *Lilium* and *Hemerocallis* genera—widely used ornamental plants; very toxic to cats; *Lilium*—Easter lilies, tiger lilies, Japanese show lilies, rubrum lilies, numerous *Lilium* hybrids; *Hemerocallis*—daylilies.
- Ingestion of leaves or flowers—results in a severe nephrotoxic syndrome; as little as 2–3 leaves reported to be lethal.
- Toxic principle(s) not elucidated, but found to be in the water-soluble plant fraction.

SIGNALMENT

- Cats—systemic poisoning.
- Dogs—only mild gastrointestinal upset, even after ingestion of large quantities of plant material.
- No age or breed predilections noted.

SIGNS

- Sudden onset of vomiting—gradually subsides within 2–4 hours.
- Depression and anorexia—onset about the same time as vomiting; both persist throughout the syndrome.
- Polyuria and dehydration—by 12–24 hours; leads to anuric renal failure.
- Vomiting—recurs by 36 hours; accompanied by progressive weakness.
- Recumbency—by 2–4 days.
- Death—by 4–7 days post-ingestion.

CAUSES & RISK FACTORS

- Plants—Easter lilies; tiger lilies; Asiatic hybrid lilies; Japanese show lilies; *Lilium* hybrids; daylily; primarily when used in cut-flower arrangement or as household potted plants.
- All ingestions by cats of plant material from the *Lilium* and *Hemerocallis* genera should be considered potentially lethal.
- Exclusively indoor cats—predisposed to ingestion of newly introduced plants.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Nephrotoxins

- Aspirin and other NSAIDs
- Zinc
- Boric acid
- Ethylene glycol
- Mercury
- Nephrotoxic antibacterials—aminoglycosides
- Melamine/cyanuric acid poisoning

Systemic Diseases

- Acute presentation of chronic renal failure
- Urinary obstruction
- Immune-mediated renal disease
- Leptospirosis
- Pyelonephritis
- Lymphoma

CBC/BIOCHEMISTRY/URINALYSIS

- Stress leukogram.
- Moderate to severely high BUN, phosphate, and potassium.
- Creatinine—severe increase common; usually 15–29 mg/dL; may be into the 40s.
- Increased AST, ALT, and ALP late in disease.
- Severe proteinuria, glucosuria, and low specific gravity; numerous tubular epithelial casts. Early in the syndrome, tubular cell detail can be seen in the casts.
- Crystalluria—not caused by ingestion of these plants.
- Increased amylase and lipase may occur with very large ingestions.

OTHER LABORATORY TESTS

N/A

DIAGNOSTIC PROCEDURES

- If possible, examine plant to verify that it has been chewed.
- Have plant positively identified by a professional horticulturist or other expert if necessary.

PATHOLOGIC FINDINGS

- Gross—swollen kidneys; empty gastrointestinal tract; moderate to severe perirenal edema.
- Histologic—severe acute renal tubular necrosis with intact basement membranes; mild to severe interstitial edema; severe cast formation in the collecting ducts; later in the syndrome may note evidence of mitotic figures in the remaining tubular epithelium.

TREATMENT

- Early decontamination—lessens duration and severity of signs. Emesis not generally useful as vomiting is common. Endoscopy has been used to remove plant pieces.
- Fluid therapy—initiation within 18 hours of ingestion prevents anuric renal failure; intravenous normal saline at 2–3 times maintenance for 24 hours.
- Anuric renal failure—dialysis is the only effective treatment; 7 days of therapy has resulted in a return of renal function.

MEDICATIONS

DRUG(S)

- Decontamination—activated charcoal (2 g/kg PO).
- Cathartic—sorbitol (2.1 g/kg PO) or magnesium sulfate (0.5 g/kg PO).

CONTRAINdications/POSSIBLE INTERACTIONS

- Avoid fluids containing potassium.
- Avoid drugs eliminated by renal clearance.
- Diuretics (mannitol, hypertonic fluids, furosemide, thiazides) are not effective at initiating urine production once anuric renal failure has occurred.

FOLLOW-UP

PATIENT MONITORING

Periodically follow serum chemistries to ensure normal renal function; especially important after dialysis.

EXPECTED COURSE AND PROGNOSIS

- Dehydration from polyuric renal failure; required for the disease to progress to anuria.
- Prevention of dehydration (early fluids) prevents the progression of the syndrome to anuria. Prevention of anuria generally allows a gradual return to normal over 24–48 hours.

MISCELLANEOUS

Author Jeffery O. Hall

Consulting Editor Lynn R. Hovda

BASICS

OVERVIEW

- Lipomas are benign tumors of adipocytes (fat cells). Their appearance is that of mature adipocytes with no cellular or nuclear atypia, identical to cells that form adult fat.
- These tumors are reported to occur in approximately 16% of dogs and 12% of cats; however, their true incidence is probably higher, since many lipomas are diagnosed by clinical appearance without histology.
- This tumor may occur anywhere on the body, although the subcutaneous areas of the chest, abdomen, limbs, and axillae may be most commonly affected. Lipomas have also been reported within the chest and abdominal cavities, uterus, orbit, and bone.

SIGNALMENT

- Most common in middle-aged to older dogs; rarely seen in cats.
- There is no breed predisposition, although Labrador retrievers, Doberman pinschers, miniature schnauzers, cocker spaniels, dachshunds, and Weimaraners have been reported to be at increased risk.
- Obese animals may be more susceptible.
- Female dogs are predisposed.
- Lipomas in cats may occur more frequently in neutered males.

SIGNS

- Usually solitary, but multiple lipomas may occur in the same individual.
- Variable size, shape (often round), and growth rate (usually slow).
- Animals are often asymptomatic unless the mass becomes large enough to cause functional difficulties commonly with ambulation. Lipomas enlarge by expansion and not invasion. They may compress adjacent organs when they occur in the thoracic or abdominal cavity.
- Lipomas usually feel soft, but those that develop between muscle planes may feel firm and may be mistaken for infiltrative lipomas or soft tissue sarcomas. The caudal thigh region is a common place for intermuscular lipomas (between the semimembranosus and semitendinosus muscles).
- In many cases, the tumor is present for a long period of time (1 year or more) before presentation to a veterinarian.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infiltrative lipoma.
- liposarcoma or other soft tissue sarcomas (e.g., myxosarcoma, fibrosarcoma, hemangiopericytoma).

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

N/A

IMAGING

Radiography—reveals fat density tissue/mass surrounded by soft tissue density structures. Macroscopic fat is also readily identified with CT or MRI techniques.

DIAGNOSTIC PROCEDURES

Fine-needle aspiration cytology—reveals normal, mature adipocytes; fat tends to coalesce into droplets that wash off the slide during staining, leaving a fairly acellular specimen.

PATHOLOGIC FINDINGS

Histologically consistent with normal adipose tissue, which may be subclassified if other tissue elements are present, e.g., cartilage (chondrolipoma), blood vessels (angiolipoma), hematopoietic elements (myelolipoma), or collagen (fibrolipoma); no tumor infiltration into surrounding structures (e.g., muscle).

TREATMENT

- Complete surgical excision is curative as these tumors are well encapsulated, but should only be considered if symptomatic.
- Intermuscular lipomas (most common in caudal thigh and axilla) extend deep between muscle planes but do not invade adjacent structures can be successfully treated with surgical resection.
- Liposuction has also been described with success for tumors up to 15 cm in diameter; however, regrowth occurs in a high proportion of cases.
- Intralesional triamcinolone acetonide has also recently been described, with complete regression in 9 of 15 cases.

MEDICATIONS

DRUG(S)

Medical therapy is unnecessary and unlikely to be effective.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Have owner monitor for recurrence, which is rare and may be addressed successfully with a second surgery. If tumor recurs, consider the possibility of an infiltrative lipoma or soft tissue sarcoma.

PREVENTION/AVOIDANCE

No specific preventive measures, except possibly avoidance of obesity.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Cure with complete surgical excision is expected. Recurrence may occur with incomplete removal. Surgery is best performed before the tumor interferes with function or mobility. Development of other primary lipomas in other locations may occur. Presence of other tissue elements within the tumor, such as cartilage, collagen, or hematopoietic cells, occurs rarely and does not appear to impact surgical outcome or prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Possibly obesity

AGE-RELATED FACTORS

No specific factors, except general predisposition to tumor development with increasing age.

PREGNANCY/FERTILITY/BREEDING

Surgery can likely be delayed until after whelping

Author Anthony J. Mutsaers

Consulting Editor Timothy M. Fan

LIPOMA, INFILTRATIVE

BASICS

OVERVIEW

- Invasive, non-encapsulated, lipoma variant that does not metastasize.
- A benign neoplasm that infiltrates soft tissues, particularly muscles, and including fasciae, tendons, nerves, blood vessels, salivary glands, lymph nodes, and joint capsules, and occasionally bones.
- Muscle infiltration typically extensive.
- Surgical cure—difficult to obtain.
- Occurs much less frequently than does lipoma.

SIGNALMENT

- Usually middle-aged dogs.
- No breed predilection definitively demonstrated; Labrador retrievers—possibly overrepresented.
- May be more common in females than in males.

SIGNS

- Large, diffuse, soft tissue mass.
- Clinically appears as localized muscle swelling and/or distended abdomen if abdominal component.
- Infiltration of pelvic, thigh, shoulder, sternal, and lateral cervical musculature—most common; recent evidence suggests no clear site prediction.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Soft tissue sarcoma, particularly liposarcoma, hemangiopericytoma, myxosarcoma, rhabdomyosarcoma, and fibrosarcoma.
- Lipoma.
- Intermuscular lipoma.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

N/A

IMAGING

- Radiography—reveals fat dense tissue between soft tissue dense structures.

• CT or MRI imaging—allows adequate discrimination of tumor for surgery and/or radiation treatment planning; however, differentiation of normal fat from infiltrative lipoma can be problematic.

DIAGNOSTIC PROCEDURES

- Cytologic examination of aspirate reveals mature adipocytes with no cellular or nuclear atypia, identical to cells that form adult fat.
- Tissue biopsy is required to definitively classify as infiltrative lipoma.

PATHOLOGIC FINDINGS

- Histologic examination—well-differentiated adipocytes; may be indistinguishable from normal adipose tissue.
- Distinctive feature—tumor infiltration into and between muscle bundles and other tissues.

TREATMENT

SURGICAL CONSIDERATIONS

- Characteristic invasiveness makes excision extremely problematic; difficult to distinguish between tumor and normal adipose tissue.
- Poorly defined tumor margins—may contribute to the observed high recurrence rate after surgical excision.
- 36–50% of patients have recurrence within 3–16 months, except with limb amputation for appendicular tumor.
- Amputation of an affected limb is recommended only when quality of life is affected; tumor causes little inconvenience unless it interferes with movement, causes pressure-related pain, or develops in a vitally important anatomic site. However, amputation must be performed before growth of proximal extent of tumor crosses attainable surgical margin.

EXTERNAL BEAM RADIOTHERAPY

- Beneficial for long-term tumor control—median survival 40 months in a retrospective study of 13 dogs, with only 1 dog (7.7%) euthanized owing to tumor-related signs (versus 26.7% with surgery alone).
- Dogs with measurable disease may only have stabilization of the tumor.
- Cytoreductive surgery to microscopic disease prior to radiation may result in long-term disease control.

MEDICATIONS

DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Focus—whether and when to recommend surgery and adjunctive radiation therapy for incomplete surgical margins.
- Reevaluations—schedule as dictated by tumor growth and choice of therapy.

POSSIBLE COMPLICATIONS

Temporary acute side effects (e.g., moist dermatitis and alopecia) expected with radiation therapy, and consultation with a radiation oncologist is recommended regarding specific, anatomic site-related side effects.

EXPECTED COURSE AND PROGNOSIS

- Long-term control of tumor growth may be attained with external beam radiation therapy alone or in combination with surgery.
- Lack of metastatic potential affords a very good prognosis upon control of local tumor growth.
- If liposarcoma diagnosed, behavior is similar to other soft tissue sarcomas, therefore consult relevant literature on these tumors.

MISCELLANEOUS

SYNONYMS

- Lipomatosis
- Has been (mistakenly) referred to as well-differentiated liposarcoma

LIVER FLUKE INFESTATION

BASICS

OVERVIEW

- Platynosomum concinnum* infection occurs in cats in Florida, Hawaii, and other tropical-semitropical areas. One report of infection in a cat from Ohio and 1 from Illinois. Most common trematode infection affecting the liver of companion pets in North America.
- Infestation acquired from ingestion of infected intermediate host (e.g., lizard or frog).
- Estimated 15–85% of cats with intermediate host access are infected in endemic areas.
- Metorchis conjunctus* also may infect the liver and biliary structures of cats.
- Flukes reported in dogs: *Heterobilharzia americana* (North America); raccoon is the natural definitive host and most important reservoir host; *Metorchis conjunctus*; *Clonorchis sinensis* (China), *Schistosoma japonicum* (Philippines), *Metorchis bilis* and *Opisthorchis felineus* (Germany) in sled dogs fed a diet including raw fish.

SIGNALMENT

Platynosomum concinnum: young (6–24 months) cat with access to local fauna.

SIGNS

- Depend on severity of infection.
- Most infested cats lack clinical signs.
- With severe infestation: jaundice, emaciation, anorexia, vomiting, mucoid diarrhea, hepatomegaly, abdominal distention, malaise, fever.

CAUSES & RISK FACTORS

P. concinnum

- Adults reside in bile ducts and gallbladder; life cycle requires two intermediate hosts and tropical or semitropical climate.
- Embryonated eggs—pass in cat's feces; ingested by first intermediate host: a land snail.
- Miracidia—hatch from eggs in the snail penetrating host tissue and develop sporocysts.
- Mature daughter sporocysts—emerge from the snail and thereafter are ingested by a second intermediate host: usually an anole lizard (but also skinks, geckos, frogs, and toads); enter bile ducts where they reside until host ingested as prey by the cat.
- Cercariae—released in the upper digestive tract of the cat; migrate to the bile ducts where they mature and shed eggs within 8 weeks.
- Risk factors for infection—tropical or subtropical climate; appropriate intermediate hosts; access to an outdoor or indoor/outdoor environment; successful hunting skills; consumption of infected intermediate host.

Metorchis conjunctus

- Cats—may infect the liver and biliary structures initially causing watery blood-tinged diarrhea and later evidence of biliary tree invasion; eggs are passed in feces 17 days from initial infection.
- Infection typically associated with increased liver enzyme and may be associated with transient eosinophilia.

Heterobilharzia americana

- Eggs containing fully developed miracidium are passed in feces of final host. In fresh water, eggs hatch, release miracidia that penetrate snail hosts, where sporocysts develop. Cercariae released from snail host 25 days after infection; these infect vertebrate host (dog, human) by skin penetration.
- Adult flukes develop in liver and migrate to mesenteric veins where eggs disseminate to various viscera, including liver, pancreas, mesenteric lymph nodes, spleen, and intestines, where they initiate granulomatous inflammation and sclerotic vascular lesions.
- Eggs appear in feces 68 days after infection.

Schistosoma haematobium

- Adult fluke and eggs disperse to splanchnic organs, including liver and pancreas; in portal or hepatic veins eggs and adults associate with encapsulated fibrotic granulomatous foci.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cholangiohepatitis; hepatic lipidosis; bile duct carcinoma; hepatic lymphoma; choleliths and any disorder causing major bile duct occlusion.
- Identified by finding trematode eggs in feces, rarely observing anechoic ovoid structures with echoic center in biliary tree by ultrasound, cytologic examination of bile or hepatic aspirates; most definitively from histopathology of biopsied liver, biliary structures, or pancreas.

CLINICOPATHOLOGIC FEATURES

Best defined for *Platynosomum concinnum* in cats.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—variable; eosinophilia beginning 3 weeks after infection; persists for months; not all infected cats demonstrate eosinophilia.
- Biochemistry—high liver enzyme activities, especially ALT and AST; ALP may be normal or only slightly increased initially.
- Bilirubin—increased; markedly high in advanced severe disease.
- Urinalysis—bilirubinuria.

OTHER LABORATORY TESTS

- Fasting/postprandial bile acid—increased.
- Fecal examination—noninvasive definitive diagnostic test: *P. concinnum* eggs detected in only 25% of infected cats.

- Fecal egg retrieval—sedimentation most successful; formalin-ether or sodium acetate most reliable (demonstrates eight-fold more eggs than direct fecal examination).

- Patients with few parasites (one to five flukes)—may shed only two to ten eggs/g of feces; thus, may not discover eggs by fecal testing.
- Serial fecal examinations—may be necessary.

IMAGING

- Abdominal radiography—may show mild hepatomegaly.
- Abdominal ultrasonography—differentiates biliary obstruction from hepatocellular disease; shows one or more of the following: (1) biliary obstruction: dilated gallbladder, common bile duct (> 2 mm), and intrahepatic ducts; (2) gallbladder sediment with flukes (oval hypoechoic structures with echoic center), mildly thick gallbladder wall with a double-layered appearance (cholecystitis); (3) hypoechoic hepatic parenchyma with prominent hyperechoic portal areas (ducts) associated with cholangiohepatitis.

DIAGNOSTIC PROCEDURES

- Fecal examination for trematode eggs
- Cholecystocentesis—discloses fluke eggs
- Liver biopsy—reveals signs of infection

PATHOLOGIC FINDINGS

- Gross—liver may appear large and yellow-green with dilated bile ducts; may see flukes in bile ducts or gallbladder; increased size and tortuosity of bile ducts on cut section.
- Histologic lesions—depend on the number of flukes and duration of infestation; *early stage* (4–6 weeks): enlarged bile ducts and periductal areas infiltrated with inflammatory cells, especially eosinophils; *mid-stage* (4 months): severe adenomatous hyperplasia of bile duct epithelium and coincident periductal inflammation; *late stage* (6 months): extensive peribiliary fibrous connective tissue that may cause bile duct stenosis.

TREATMENT

Outpatient versus inpatient—depends on severity of illness

INPATIENT

- Balanced polyionic fluids with supplemental potassium chloride—20–40 mEq/L; as appropriate; based on serum electrolytes.
- Nutritional support—avoid development of hepatic lipidosis; feed high-protein calorically dense food and ensure food intake; use feeding tubes if needed to ensure adequate food intake in inappetent cats; rarely, severe clinical signs may require parenteral nutrition; rarely hepatic encephalopathy necessitates protein restriction.

LIVER FLUKE INFESTATION

(CONTINUED)

- B vitamin supplementation—important for anorectic and ill cats on fluid therapy; 2 mL B-soluble vitamins/L fluids.

MEDICATIONS

DRUG(S)

- Praziquantel 20 mg/kg SC q24h for 3–5 days is treatment of choice for cats; eggs may pass in feces for up to 2 months after treatment. Praziquantel at 30 mg/kg PO once and 50 mg/kg SC once cleared a dog symptomatic for *Heterobilharzia americana*.
- Prednisolone—initial dose for cats showing eosinophilia, significant inflammation on biopsy or having severe clinical signs: 1–2 mg/kg/day for 2–4 weeks; then tapered in 50% decrements every 2 weeks.
- Ursodeoxycholic acid 10–15 mg/kg q24h PO; tablet form and divided dose administered with feeding achieves best bioavailability; avoid if evidence of extrahepatic bile duct obstruction.
- Broad-spectrum antibiotic coverage to protect against retrograde biliary tree infection with enteric organisms introduced by parasite; infection encouraged by fluke death in tissues.
- Antioxidant therapy—suggested by necroinflammatory tissue injury; vitamin E (10 IU/kg day PO) and S-adenosyl-l-methionine (SAMe; Denosyl-SD4 has proven

bioavailability in cats as a GSH donor): 20 mg/kg PO daily, enteric coated tablets, until liver enzymes normalize.

- Antiemetic—metoclopramide (0.2–0.4 mg/kg PO, SC q6–8h or by constant rate infusion 1–2 mg/kg/day); ondansetron (0.5 mg/kg q12h, IV or PO 30 minutes before feeding); maropitant (1.0 mg/kg [5 mg/cat] IV, SC or PO once per day; maximum of 5 days).

CONTRAINDICATIONS

Pregnancy—use caution with drug use.

FOLLOW-UP

PATIENT MONITORING

- Monitor clinical signs, appetite, body condition and weight, liver enzymes, bilirubin, and fecal sedimentation.
- Watch for signs of biliary tree occlusion after administration of praziquantel.

PREVENTION/AVOIDANCE

- Restrict outdoor access if endemic parasite.
- Praziquantel prophylaxis—every 3 months; outdoor cats in endemic, tropical climates.

POSSIBLE COMPLICATIONS

- Death from liver failure; untreated symptomatic disease.
- Biliary tree obstruction.
- Pancreatitis.

- Pancreatic exocrine insufficiency—with chronic infection.
- Cholangitis/cholangiohepatitis (suppurative or nonsuppurative).

EXPECTED COURSE AND PROGNOSIS

Uncomplicated recovery with treatment expected in most patients.

MISCELLANEOUS

ZOONOTIC POTENTIAL

None

SEE ALSO

LIZARD VENOM TOXICOSIS

BASICS

OVERVIEW

- Poisonous lizards—found only in the US Southwest and Mexico; *Heloderma suspectum* (Gila monster—indigenous to Arizona, New Mexico, extreme Southern California, extreme Southern Utah, southwestern Nevada) and *H. horridum* (Mexican beaded lizard—not indigenous to the USA); tenacious bite with considerable mechanical trauma in addition to envenomation; deliver venom from secretory glands on the lower jaw by aggressive chewing action and distributing venom over grooved venom-conducting teeth; non-aggressive; animal envenomations rare.
- Venom components—multiple enzymatic components: kallikrein-like enzymes (helodermatine), acidic neurotoxin (gilatoxin), and phospholipase A₂.
- Envenomation may result in generalized weakness, pain, wound cyanosis, tongue swelling, hypotension, tachycardia, and ventricular arrhythmias. Coagulopathy is rare.

SIGNALMENT

Dogs and cats

SIGNS

Historical Findings

- Sudden onset of pain.
- Bite—usually on the face, especially the lower lip; lizard may still be attached to patient (pathognomonic).

Physical Examination Findings

- Bleeding from bite site
- Hypotension
- Extremely painful bite site
- Localized swelling; edema slower to develop than rattlesnake bite
- Excessive salivation
- Excessive lacrimation
- Frequent urination and defecation
- May note aphonia in cats
- Wound discoloration (bluish appearance)

CAUSES & RISK FACTORS

Outdoor activities in indigenous area

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Trauma; other animal bites or puncture-type trauma.
- Venomous snake bite—single or multiple punctures; pain; local wound discoloration and swelling; lacking (or including) hemolytic, hemorrhagic, and clotting abnormalities.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Electrocardiography—may detect arrhythmias.

TREATMENT

- Remove lizard—place a prying instrument between the jaws; push into the back of the mouth; a flame held underneath the jaw often releases grip; if attached to extremity, completely submerging lizard and limb in warm water may cause release.
- Inpatient—monitor and treat hypotension, as necessary, with crystalloid fluid therapy.
- Bite site—flush with lidocaine; probe to identify and remove fragments of lizard teeth (if not removed, they will become sequestra and abscess); soak with Burrow's solution or similar solution every 8 hours.

MEDICATIONS

DRUG(S)

- Control pain—can use narcotics (if severe)
- Broad-spectrum antibiotics indicated

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Corticosteroids—not generally used by the author; authorities differ on the value of corticosteroids.
- Antihistamines—not useful.

FOLLOW-UP

- Electrocardiogram—monitor for arrhythmias
- Bite site—monitor for infection

LOWER URINARY TRACT INFECTION, BACTERIAL

BASICS

DEFINITION

Adherence and replication of bacteria within the urinary bladder.

PATHOPHYSIOLOGY

Urinary tract defenses against bacterial infection include anatomic and functional barriers that prevent retrograde urethral ascent of pathogens, the inherent antibacterial properties of normal urine, and local (i.e., mucosal) and systemic immune responses. Bacterial colonization and persistence within urine or on urothelial surfaces requires impairment of one or more of these defense mechanisms. The mucosal inflammatory response promotes leukocyte infiltration into the bladder wall, resulting in dysuria, pollakiuria, and hematuria.

SYSTEMS AFFECTED

Renal/Urologic

INCIDENCE/PREVALENCE

- Prevalence of UTIs in animals with predisposing conditions is more clinically relevant than total population frequencies.
- Prevalence of UTIs in dogs:
 - Without urinary tract-associated clinical signs: 2.1%
 - With diabetes mellitus, at initial diagnosis: 7.7%
 - With diabetes mellitus, at any point in time: 37%
 - With hyperadrenocorticism, at initial diagnosis: 46%
 - With thoracolumbar intervertebral disc extrusion: 20.0–38.5%
 - With indwelling urinary catheters while hospitalized: 63.8%
- Prevalence of UTIs in cats:
 - Without lower urinary tract-associated clinical signs: 0.9%
 - With lower urinary tract-associated clinical signs: 3.4–12.0%
 - With ureteral calculi: 8.4%
 - With chronic kidney disease, at any point following diagnosis: 16.9–29.1%
 - With diabetes mellitus, at any point following diagnosis: 12.2–12.8%
 - With uncontrolled hyperthyroidism, referred for I¹³¹ treatment: 12.2%
 - With perineal urethrostomies, at any point following surgery: 22%.

SIGNALMENT

Species

More common in dogs than cats

Breed Predilections

None

Mean Age and Range

- UTIs may occur in any age animal.
- Male dogs: mean, 8.0 ± 0.1 years; female dogs 7.7 ± 0.1 years. Relative risk of UTI diagnosis increases with age.

- Cats: Median, 7.7 yrs (range, 0.2–17 years).

Predominant Sex

- Dogs: female dogs more commonly affected than male dogs.
- Cats: male and female cats affected in approximately equal numbers.

SIGNS

Historical Findings

- Patients may be asymptomatic.
- May have variable severity of:
 - Pollakiuria, dysuria, hematuria, stranguria, urgent need to urinate (which may progress to urinary incontinence), urinating in inappropriate locations, and excessive licking at or discharge from the genitalia.
- Systemic clinical signs (anorexia, generalized discomfort) occur infrequently.

Physical Examination Findings

- Unremarkable in most animals.
- Abnormalities occasionally noted with urinary bladder palpation:
 - Bladder wall thickening or crepitus
 - Stimulation of micturition, regardless of bladder urine volume
 - Pain reactions.

CAUSES

- Commensal skin, mucosal, or gastrointestinal bacteria adhere to the urethral epithelium, and ascend retrograde.
- Urine cultures identify aerobic bacterial species in > 99% of UTIs. A single bacterial species is isolated in 75–95% of cases.
- *Escherichia coli*, *Staphylococcus* spp., or *Proteus* spp. are isolated from approximately 50% of animals.
- Eight species of bacteria (*E. coli*, *Staphylococcus*, *Proteus*, *Streptococcus*, *Klebsiella*, *Enterococcus*, *Pseudomonas*, and *Corynebacterium*) account for approximately 95% of UTIs.

RISK FACTORS

- Systemic immune dysfunction (e.g., suppressed immunity in dogs with hyperadrenocorticism).
- Nidus for bacterial adherence and defense mechanism avoidance (e.g., indwelling urinary catheters, uroliths).
- Altered composition of urine (e.g., persistently dilute urine, glucosuria).
- Compromise of barriers that inhibit retrograde bacterial movement (e.g., loss of urethral tone, ectopic ureters, incomplete bladder emptying).
- Disrupted urinary tract mucosal defenses (e.g., urolith-associated mucosal trauma).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dysuria, pollakiuria, hematuria, and stranguria occur with most lower urinary tract

diseases of dogs and cats. UTI cannot be diagnosed or excluded based on clinical signs.

- Cystolithiasis and lower urinary tract neoplasia commonly induce clinical signs identical to those expected with UTIs. Diagnosis is further complicated by the increased risk of UTIs associated with these conditions. Clinical signs in cats with idiopathic cystitis (i.e., interstitial cystitis) are likewise indistinguishable from those induced by UTIs.
- Diagnostic evaluation and treatment differs for patients with “uncomplicated” vs. “complicated” UTIs. Uncomplicated UTIs are spontaneous infections diagnosed without identifiable breaches in urinary tract defense mechanisms. Complicated UTIs refer to: infections associated with impaired systemic or local urinary tract defenses, or three or more UTIs over a 12-month interval.
- Recurrent infections are subclassified as: reinfection—UTIs resolve with appropriate therapy; bacterial isolates may vary with successive infections; or relapse—UTIs appear to resolve; however, subsequent urine cultures confirm persistence of the original bacterial isolate.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC and biochemistry are unremarkable.
- Urinalysis
 - Pyuria is present in most animals with UTIs; but is not synonymous with infection. Dipstick leukocyte pads are inaccurate in dogs (many false negatives) and cats (many false positives).
 - Hematuria and proteinuria are common.
 - Alkaluria (pH > 7.0) occurs with urea-splitting bacterial UTIs.
 - Magnesium ammonium phosphate (struvite) crystalluria can occur in healthy dogs and cats, and may be absent in patients with UTIs.
 - Presence of “bacteria” in unstained urine sediment preparations incorrectly identifies UTIs in > 20% of cases. Stained sediment preparations improve accurate bacterial identification.

OTHER LABORATORY TESTS

Urine Culture

- Definitive diagnosis requires aerobic culture of a urine sample.
- Cystocentesis is the gold standard method for collecting urine culture specimens. Bacterial growth > 10³ cfu/mL is diagnostic for UTI in cystocentesis-collected urine samples from both dogs and cats.
- Urine samples obtained by catheterization are often contaminated by the normal flora of the distal urethra. Bacterial growth > 10⁴ cfu/mL in male dogs, > 10⁵ cfu/mL in female dogs, and > 10³ cfu/mL in cats, is diagnostic for UTI in catheter-obtained urine samples. Indwelling catheters may be colonized without concurrent UTI; therefore, sample collection from urinary catheters

(CONTINUED)

LOWER URINARY TRACT INFECTION, BACTERIAL

- should be avoided; catheter tip cultures are of questionable value.
- Culturing voided midstream urine samples should be avoided.
- Urine from non-sterile surfaces (i.e., “table top” samples) should not be cultured.

Antibiotic Sensitivity Testing

- Most antibiotics are concentrated and excreted in urine. Antibiotic sensitivity is accurately predicted by use of the isolate’s “sensitive” vs. “resistant” profiles.

IMAGING

Usually unremarkable. May be abnormal with predisposing diseases (ectopic ureters, urolithiasis, urinary tract neoplasia, etc.), or UTI complications (polypoid cystitis, emphysematous cystitis, struvite urolithiasis, pyelonephritis, etc.).

**TREATMENT****APPROPRIATE HEALTH CARE**

Outpatient treatment is appropriate; inpatient treatment may be necessary with UTI complications or associated conditions (e.g., urinary tract obstruction, acute pyelonephritis).

ACTIVITY

Unrestricted.

DIET

Dissolution protocols for infection-induced struvite uroliths include temporary feeding of a calculolytic diet.

CLIENT EDUCATION

Prognosis is excellent with uncomplicated UTIs. Prognosis in patients with complicated UTIs may depend on resolution of any risk factors.

SURGICAL CONSIDERATIONS

Management of struvite uroliths, resistant polypoid cystitis, and infection niduses may require surgical intervention.

**MEDICATIONS****DRUG(S) OF CHOICE**

- “First-line” antimicrobials are excreted in active form at high concentrations, bactericidal, effective against most isolates, and inexpensive. “Second-line” antimicrobials lack some of these characteristics, and should be reserved for resistant isolates.
- When urine culture has not been performed, or pending culture results, then empiric treatment with a first-line antimicrobial is preferred.
- When susceptibility data is available, the lowest-tier antimicrobial should be selected.

- First-line antimicrobials:
 - Amoxicillin (11–15 mg/kg PO q8h)
 - Trimethoprim-sulfadiazine (15 mg/kg PO q12h)
- Second-line antimicrobials:
 - Amoxicillin-clavulanate (12.5–25 mg/kg PO q12h)
 - Enrofloxacin/marbofloxacin/orbifloxacin
 - Cefovecin (8 mg/kg SC)
- Third-line antimicrobials:
 - Amikacin (dogs, 15–30 mg/kg IV or SC q24h; cats, 10–14 mg/kg IV or SC)
 - Chloramphenicol (dogs, 40–50 mg/kg PO q8h; cats 12.5–20 mg/kg PO q12h)
 - Meropenem/imipenem-cilastatin
 - Nitrofurantoin (4.4–5.0 mg/kg PO q8h)
- Antibiotic treatment of uncomplicated infections is recommended for 7–10 days.
- Complicated infections may require treatment for 4–6 weeks.
- Shorter duration treatment (3–4 days) of uncomplicated infections may be sufficient, but cannot yet be routinely recommended.

**FOLLOW-UP****PATIENT MONITORING**

- Uncomplicated UTIs: resolution can be assumed if there is no recurrence of clinical signs after therapy is completed.
- Complicated UTIs: continue therapy for at least 7–10 days beyond resolution of clinical signs, pyuria, and bacteriuria. Resolution should be confirmed by repeating urine culture 7–10 days after end of therapy.

PREVENTION/AVOIDANCE

- Diagnosis and control of predisposing conditions is the most effective method for preventing UTIs.
- Ancillary therapies can be considered with recurrent infections:
 - Methenamine—converted into formalin when urine pH is <7.0. Concurrent administration of ascorbic acid (vitamin C) promotes urinary acidification.
 - Prophylactic antibiotics—once-daily administration of antibiotics may lengthen infection-free intervals; however, multidrug resistance is more likely in subsequent isolates.
 - Cranberry extract—may inhibit *E. coli* attachment to the bladder mucosa.

POSSIBLE COMPLICATIONS

UTIs may lead to pyelonephritis, struvite urolith formation, or polypoid cystitis.

EXPECTED COURSE AND PROGNOSIS

- Prognosis for patients with uncomplicated UTIs is good to excellent. The prognosis for patients with complicated infections is determined by successful control or resolution of predisposing conditions.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Struvite urolithiasis
- Polypoid cystitis
- Pyelonephritis
- Emphysematous cystitis

AGE-RELATED FACTORS

- Juvenile animals with recurrent UTIs should be evaluated for ectopic ureters, urolithiasis, or other urinary tract malformations, regardless of whether urinary incontinence has been reported.
- Adult cats with UTIs should be evaluated for chronic kidney disease, diabetes mellitus, and hyperthyroidism.

SYNONYMS

- Bacterial cystitis
- Urethritis
- Urethrocystitis

SEE ALSO

- Pyelonephritis
- Urolithiasis, Struvite—Cats
- Urolithiasis, Struvite—Dogs

L

ABBREVIATION

- UTI = urinary tract infection

LOWER URINARY TRACT INFECTION, FUNGAL

BASICS

OVERVIEW

- Infecting fungi/yeasts are usually normal commensal flora of the skin and mucosa, or environmentally ubiquitous organisms.
- Candida albicans* is the most common fungal isolate; other *Candida* spp. are less common, and non-*Candida* spp. fungi are least common. • Urinary shedding of fungal organism may occur with systemic fungal infections that have disseminated to the kidneys. This appears to be common in dogs with systemic *Aspergillus* spp. infection, and cats with *Cryptococcus neoformans*. • Organ system affected: renal/urolologic. • Uncommon in dogs and cats.

SIGNALMENT

- Dog and cat • No breed, age, or sex predilection

SIGNS

- Typical signs of lower urinary tract disease: dysuria and pollakiuria; gross hematuria is rare. • Many animals are asymptomatic.

CAUSES & RISK FACTORS

Suspected risk factors: diabetes mellitus, urinary tract stenosis (e.g., perineal urethrostomy, cystotomy tubes, indwelling urinary catheters), lower urinary tract disease (e.g., bladder transitional cell carcinoma, chronic bacterial urinary tract infection), recent or chronic antibiotic or glucocorticoid administration.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Isolated fungal lower urinary tract infections must be differentiated from systemic infections with secondary appearance of fungi in the urine. • Lower urinary tract fungal infections may rarely progress to pyelonephritis.
- Contamination of urine samples during collection may occur in animals with cutaneous or mucocutaneous yeast overgrowth (i.e., ventral abdominal or perivulvar dermatitis or balanoposthitis).

CBC/BIOCHEMISTRY/URINALYSIS

- CBC and biochemistry usually unremarkable. If infection has ascended to the upper urinary tract or has systemically disseminated then abnormalities will reflect those organs involved. • Yeast/fungi may be visible within urine sediment. However, low numbers of organisms may necessitate concentrated sediment preparations for visualization. • Fungal species cannot be determined solely based on cytologic appearance.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Urine Culture

- Candida* spp. usually grow within 3 days on standard blood agar. • Other fungi may grow more slowly and thus will not be detected by standard urine culture protocols. • If fungal urinary tract infection is suspected or confirmed, a fungal culture should be requested. Organism identification is based on growth characteristics and morphologic features on Sabouraud's dextrose agar.

Antifungal Sensitivity Testing

- C. albicans* is usually sensitive to fluconazole; therefore, antifungal sensitivity testing is not necessary at the time of initial diagnosis. • Non-*albicans* species of *Candida* are more commonly resistant to fluconazole, and thus sensitivity testing should be considered. • Susceptibility testing should be performed on non-*Candida* spp. organisms and with *Candida* spp. infections that fail to resolve despite 4–6 weeks of appropriate antifungal therapy.

TREATMENT

- Identify and correct any concurrent risk factors. • Urinary alkalinization has been historically recommended for treatment of funguria, but is of unknown benefit.

MEDICATIONS

DRUG(S)

- Oral fluconazole (5–10 mg/kg PO q12h) is the initial treatment of choice. • Itraconazole or ketoconazole may be effective in some patients, but are not recommended because of poor urinary excretion of active drug. • In patients with persistent infection despite 4–8 weeks of fluconazole, intravesicular (bladder) infusion of 1% clotrimazole (1% solution in PEG 400) may be considered.
- Intravesicular 1% clotrimazole infusion protocol: catheterize and empty the bladder. Infuse 7.5–10 mL/kg of 1% clotrimazole solution (volume should be determined by bladder palpation during infusion). Infused fluid should be retained for a minimum of 15–30 minutes; most cats will retain the infused drug if not allowed access to a litter box or urination area, whereas in dogs, balloon catheters may be required to prevent premature voiding. Repeat infusion q7 days for a minimum of three treatments. Repeat fungal urine culture approximately 1 week after third treatment to determine whether additional infusions are required. Oral

fluconazole therapy should be continued throughout the infusion protocol.

- Amphotericin B (intravenous or intravesicular) treatment has been attempted in sporadic cases, but efficacy is unknown.
- Benign neglect and regular monitoring may be considered in asymptomatic patients with persistent infections despite repeated treatment attempts. However, ascending infection (i.e., fungal pyelonephritis) and systemic dissemination may occur.

CONTRAINdications/POSSIBLE INTERACTIONS

- Intravesicular clotrimazole appears to be safe but has not been fully investigated.
- Intravesicular clotrimazole should be avoided in animals with recent bladder surgery or urethral trauma.

FOLLOW-UP

- Treatment should be continued until two successive urine cultures 14–21 days apart result in no fungal growth. • Fungal urine culture should be repeated approximately 60 days after cessation of therapy and at regular intervals thereafter.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Diabetes mellitus • Transitional cell carcinoma

SEE ALSO

- Aspergillosis chapters • Cryptococcosis

LUMBOSACRAL STENOSIS AND CAUDA EQUINA SYNDROME

BASICS

DEFINITION

- Lumbosacral stenosis refers to narrowing of the lumbosacral vertebral canal and/or L7-sacral intervertebral foramina, causing compression of L7, sacral, or caudal nerves.
- Cauda equina syndrome implies pain or other clinical signs related to dysfunction of these nerves.

PATHOPHYSIOLOGY

- Congenital—abnormal vertebral development causing narrowing of the lumbosacral vertebral canal. Transitional vertebrae and other malformations are common at this site and may contribute to (early) disease progression.
- Acquired—bony and soft tissue degenerative changes, most commonly affecting the L7 intervertebral disc, that cause stenosis of the vertebral canal and/or intervertebral foramina. Specific syndrome of sacral osteochondrosis dissecans recognized in young German shepherds.

SYSTEMS AFFECTED

Nervous—specifically nerves from L7 caudally

GENETICS

No known genetic basis

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

- Reasonably common in dogs
- Uncommonly reported in cats but suspected with increasing frequency

Breed Predilections

- Congenital—small to medium dogs; border collies
- Acquired—any medium-large dog; frequently German shepherds, boxers, rottweilers

Mean Age and Range

- Congenital—3–8 years.
- Acquired—mean age at onset 6–7 years. Sacral osteochondrosis signs often appear ~ 1 year old.

Predominant Sex

- Congenital—none
- Acquired—male

SIGNS

- Lumbosacral pain—salient feature; may be the only clinical sign; may be evident in reluctance to jump or climb stairs. Pain on pressure on, or dorsiflexion of, the lumbosacral vertebral column (often also induced during extension of hip joints).

- Pelvic limb lameness—caused by lumbar 7th and/or sacral nerve dysfunction; may progress to pelvic limb weakness, muscle wasting, and postural reaction deficits.
- Urinary and/or fecal incontinence—caused by S1–3 nerve dysfunction.
- Abnormal tail carriage, tail weakness or paralysis—results from dysfunction of caudal nerves.
- Self-inflicted lesions—most often associated with congenital lesions or cauda equina inflammation.

CAUSES

- Congenital vertebral malformation, including transitional vertebrae, or osteochondrosis of the cranial sacrum.
- Intervertebral disc herniation (types I and II).
- Hypertrophy or hyperplasia of the interarcuate ligament.
- Proliferation of the articular facets and/or peri-articular soft tissues.
- Subluxation at the lumbosacral junction.
- Inflammatory or neoplastic disease of the vertebral canal can produce identical clinical signs (hence “cauda equina syndrome”).

RISK FACTORS

Dogs, especially German shepherds, with lumbosacral transitional vertebrae have increased risk to develop the syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hip dysplasia or other orthopedic disease (notably iliopsoas injury)—distinguish via thorough orthopedic examination ± imaging.
- Chronic discospondylitis, osteomyelitis, neoplastic disease—cannot be differentiated by clinical signs alone.
- Vertebral fractures and subluxations—acute; characterized by more bilateral signs.
- Localized meningo(my)ecephalitis or radiculoneuritis—usually more diffuse pain.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Urinalysis—may reveal lower urinary tract infection secondary to urinary incontinence, or associated with discospondylitis.

OTHER LABORATORY TESTS

If images suggest the need, CSF analysis may aid in diagnosing inflammatory (or infectious or neoplastic) disease.

IMAGING

- Radiology—commonly exhibit spondylosis at the lumbosacral junction; narrowing of the L7–S1 disc space; ventral displacement of the sacrum relative to the lumbar vertebrae; BUT interpret with caution because all these can be observed in clinically normal animals.

- CT and MRI—modalities of choice. Apparent abnormalities must be interpreted with regard to the whole clinical picture because many are also observed in normal animals.

DIAGNOSTIC PROCEDURES

- Electromyography—denervation may be detected in muscles innervated by the nerves L7 to caudal; denervation confirms localization of the lesion but is not specific for compressive lesions.
- Slowed sciatic-tibial nerve conduction or prolongation of F wave latencies may be detected.

PATHOLOGIC FINDINGS

- May see one or more of the following features:
 - Type II disc disease with bulging of dorsal annulus
 - Hypertrophy of the interarcuate ligament
 - Stenosis of the intervertebral foramen by soft tissue or bony proliferation compressing L7 nerve(s)
 - Ventral displacement of the sacrum in relation to lumbar vertebrae
 - Proliferation of articular facets and hypertrophy of joint capsule
 - Congenitally shortened pedicles
 - Thickened and sclerotic laminae and articular processes
 - Various vertebral malformations (not only transitional vertebrae).
- Cauda equina syndrome can also be associated with neoplasia, inflammation, infection.

L

TREATMENT

APPROPRIATE HEALTH CARE

- Urinary incontinence—in-patient for initial management.

NURSING CARE

- Urinary incontinence—manual expression or catheterize the bladder until adequate voluntary control returns; monitor for urinary tract infection and administer appropriate antibiotics following culture and sensitivity.

ACTIVITY

- Nonsurgical treatment—confinement and restricted leash walks, alone or combined with systemic anti-inflammatory drugs or analgesics, or epidural injection of corticosteroids, frequently alleviate pain; clinical signs may return with increasing levels of exercise.
- If treated surgically, restrict for 6–12 weeks; then gradual return to athletic function.

DIET

Avoid obesity; excess weight increases biomechanical stress on the spine.

LUMBOSACRAL STENOSIS AND CAUDA EQUINA SYNDROME (CONTINUED)

CLIENT EDUCATION

- Inform client that there may be progressive neurologic impairment of the pelvic limbs, urinary and fecal incontinence, and paralysis of the tail.
- Inform client that pelvic limb lameness and self-inflicted lesions result from pain associated with nerve root irritation and/or compression.
- Discuss surgical treatment which is appropriate for cases with severe pain and may be suitable for cases with neurologic deficits (especially incontinence, which may be difficult to reverse).
- Medical management is frequently successful for animals with mild pain and/or mild neurologic deficits only.

SURGICAL CONSIDERATIONS

Several options, each focused on alleviating the specific source of the problems defined by imaging—dorsal laminectomy, lateral foraminotomy or fixation-fusion may all be effective in specifically selected cases.

MEDICATIONS

DRUG(S) OF CHOICE

- NSAIDs—e.g., carprofen 2 mg/kg q12h for 5–7 days then reducing doses until used as required.
- Gabapentin—frequently used at ~ 20–30 mg/kg q8h may be effective (side effect: sedation).
- Epidural corticosteroid—methylprednisolone acetate 1 mg/kg (< 0.5 mL total volume).

CONTRAINDICATIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Syndrome progression, increasingly severe neurologic signs.
- Seroma formation—frequent sequela to surgery; can be effectively managed by cage rest and surgical drainage. Prevent by careful soft tissue closure.
- Adhesions between nerves and surrounding soft tissues after surgery.

- Recurrence of clinical signs following medical (commonly) or surgical (uncommonly) intervention.
- Failure of fixation-fusion implant.
- Fracture of articular process after excessive lateral bone excision at surgery.
- Infection (especially if an implant is used for surgery).

EXPECTED COURSE AND PROGNOSIS

- Vary with the severity of neurologic injury.
- Majority are successfully managed medically, but need to ensure outcome matches requirements for dog's way of life; surgery remains an option.
- If low lumbar pain and mild neurologic deficits—good prognosis after surgery; 70–80% have an excellent or good outcome.
- If fecal and urinary incontinence—guarded prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Lower urinary tract infections frequently accompany urinary incontinence.

AGE-RELATED FACTORS

- If a lumbosacral transitional vertebra is present, syndrome may develop 1–2 years earlier than the average dog.
- Older large-breed dogs may have concomitant diseases that also cause neurologic deficits: type II disc protrusions at other sites, degenerative peripheral nerve disease (especially Labradors), degenerative myelopathy (especially German shepherds).

SYNOMYS

- Lumbosacral instability
- Lumbosacral malarticulation or malformation
- Lumbosacral spondylolisthesis
- Lumbosacral spondylopathy

SEE ALSO

- Discospondylitis
- Intervertebral Disc Disease, Thoracolumbar
- Intervertebral Disc Disease—Cats

ABBREVIATIONS

- CT = computed tomography
- MRI = magnetic resonance imaging
- NSAID = nonsteroidal anti-inflammatory drug

LUNG LOBE TORSION

BASICS

OVERVIEW

- Twisting of lung lobe(s) at the hilus with occlusion or narrowing of the bronchus, lymphatics, vein, and (finally) arteries.
- Affected lobes—right middle lobe most commonly affected (especially in large dogs); other lobes can twist singly or in pairs. Occasionally torsion occurs in midlobar area. Pugs—left cranial lobe most common.
- Initially, the lobe becomes engorged with blood and enlarges; infarction and necrosis may follow; hemorrhagic pleural effusion typically develops, chylothorax also possible.
- Chronic survivors—may note shrinkage and fibrosis of the lobe.

SIGNALMENT

- Dogs and less commonly cats.
- More common in large, deep-chested dogs but small breed dogs can be affected.
- Afghans (with chylothorax).
- Any age.
- Spontaneous syndrome in pugs typically ≤ 4 years old.
- More common in males.

SIGNS

- Tachypnea, acute or chronic respiratory distress
- Lethargy
- Anorexia
- Fever
- Pain
- Orthopnea
- Cough, hemoptysis
- Retching
- Ventral thoracic dullness
- Tachycardia
- Pale mucous membranes
- Cyanosis
- Shock

CAUSES & RISK FACTORS

- Inconsistently found with preexisting conditions (e.g., trauma, neoplasia, and chylothorax; asthma/bronchitis in the cat). Atelectasis and/or pleural effusion seem to be predisposing factors.
- Thoracic or diaphragmatic surgery.
- Spontaneous or idiopathic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pulmonary contusion or atelectasis
- Diaphragmatic hernia
- Pulmonary abscess or infarction
- Neoplasia, lymphomatoid granulomatosis
- Coagulopathy
- Pneumonia, embolization or thrombosis
- Congestive heart failure
- Pleural effusion and compression atelectasis

- Fungal or foreign body granuloma
- Lobar consolidation or bronchial obstruction from a foreign body
- Feline steatitis

CBC/BIOCHEMISTRY/URINALYSIS

Neutrophilia and anemia common. Neutropenia may carry poorer prognosis.

OTHER LABORATORY TESTS

Fluid analysis—pleural effusion can be hemorrhagic; with chronicity or preexisting effusions, the effusion may be a modified transudate or chylous.

IMAGING

Radiography

- Opacification of affected lobe with loss of visible lobar vessels and truncation of bronchus.
- Initially may reveal air bronchograms with proximal narrowing or disorientation of the torqued bronchus. Small gas bubbles with “sponge appearance” can be scattered throughout affected lobe (vesicular gas pattern); seen in 87% of one series.
- Progressive pleural effusion—suggested by ventral leafing and interlobar fissure lines.
- Consolidation and occasional swelling of the torqued lobe with possible displacement or rotation of the heart, trachea, or carina. Mediastinal shift can be contralateral or ipsilateral. Other lobes can be displaced.
- Thoracentesis provides therapeutic benefits and can improve visualization of intrathoracic structures.

Ultrasonography

- Thoracic ultrasound prior to fluid removal often allows better resolution of internal structures.
- Hypoechoic periphery with scattered reverberating foci (bronchial cartilage) centrally.
- Rounded edges of lobes.

Computed Tomography

Preoperative computed tomography may be helpful. Requires apnea induced by hyperventilation or breath-hold.

DIAGNOSTIC PROCEDURES

- Thoracentesis—obtain pleural fluid for analysis (modified transudate, exudate, hemorrhage, or chylous effusion possible).
- Bronchoscopy—may reveal occlusion or twist of the associated bronchus.
- Surgical exploration—for definitive diagnosis and treatment.

TREATMENT

- Thoracentesis or chest tube placement as needed.
- Intravenous fluid administration for support.
- Administer oxygen and treat for shock—when indicated.

- Anesthesia—requires adequate ventilatory support; carefully monitor patient.
- Surgical removal of the involved lobe(s)—only effective treatment; do not untwist lobe and attempt to salvage—may lead to recurrence or necrosis; in situ ligation of the vessels or clamping with non-crushing forceps has been advocated to avoid reperfusion problems such as acidosis; consider use of surgical stapling device; closely inspect remaining thoracic structures for any abnormalities; perform culture and pathologic examination of excised specimen.
- Post-surgery—monitoring; supportive care; tube drainage. Torsion of a second lung lobe may occur.

MEDICATIONS

DRUG(S)

- Antibiotics—perioperatively
- Treatment for shock—when indicated
- Pain control

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

L

FOLLOW-UP

- Observe for recurrence of pleural effusion.
- Reexpansion pulmonary edema—can be a serious problem (especially in cats) if large volumes of pleural fluid are withdrawn quickly or if chronically compressed lungs are acutely inflated at surgery.
- Thoracic radiographs—before discharge; as needed thereafter.
- Prognosis—fair to good if no underlying abnormality remains.

Consulting Editor Lynelle R. Johnson

LUPUS ERYTHEMATOSUS, CUTANEOUS (DISCOID)

BASICS

OVERVIEW

- Considered to be a benign variant of systemic lupus erythematosus.
- One of the most common immune-mediated skin diseases in dogs.
- Predominantly involves the nasal planum, face, and ears with rare lesions beyond the head.

SIGNALMENT

- Dogs and cats.
- Very uncommon in cats.
- Predominant breeds—collie, German shepherd dog, Siberian husky, Shetland sheepdog, Alaskan malamute, chow chow, and their crosses.
- No age predilection.

SIGNS

- Initial symptom: depigmentation of nasal planum and/or lips.
- Depigmentation progresses to erosions and ulcerations.
- Loss of normal “cobblestone” architecture of the nasal planum.
- Tissue loss and scarring can occur.
- Chronic lesions are fragile and may easily hemorrhage; rarely severe hemorrhage from arteriole damage.
- May also involve pinnae and periocular region; rarely feet and genitalia.

CAUSES & RISK FACTORS

- Exact mechanism undetermined; actinic radiation may alter antigenic nature of keratinocytes.
- Seasonal and geographic exacerbation—associated with increased actinic radiation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Major Considerations

- Other immune-mediated diseases (PF, PE, SLE)
- Drug reaction
- Dermatomyositis
- Nasal dermatophytosis
- Mucocutaneous pyoderma
- Insect bite hypersensitivity

Other (Rare) Considerations

- Contact allergy
- Zinc-responsive dermatosis
- Trauma
- Superficial necrolytic dermatitis
- Epitheliotropic cutaneous T-cell lymphoma
- Squamous cell carcinoma

CBC/BIOCHEMISTRY/URINALYSIS

Normal unless due to an underlying cause

OTHER LABORATORY TESTS

ANA, LE preparation, and Coombs' tests—usually normal or negative except in SLE.

OTHER DIAGNOSTIC PROCEDURES

- Biopsy and histopathology will differentiate DLE from other disorders.
- Biopsies of early lesions: depigmented areas, mild erosions, or mildly crusted lesions are preferable for diagnosis.

PATHOLOGIC FINDINGS

- Histopathology is characterized by interface-lichenoid dermatitis with prominent basal cell apoptosis, varying degrees of epidermal atrophy, and pigment incontinence.
- Not easily differentiated from mucocutaneous pyoderma by histopathology (treatment with antibiotics prior to sampling is helpful).
- Avoid sampling severely crusted, ulcerative lesions if possible.
- Immunopathologic examination may be done but is usually not necessary.

TREATMENT

- Not life-threatening but may be disfiguring.
- Avoid direct solar exposure; apply waterproof sun blocks.

MEDICATIONS

DRUG(S)

- Topical therapy:
 - Glucocorticosteroids—initially, a potent fluorinated product (e.g., 0.1% fluocinolone) q24h for 14 days; then q48–72h; once in remission switch to less-potent product (e.g., 0.5% or 2.5% hydrocortisone) if possible.
 - Tacrolimus ointment (0.1%) q12–24h initially then taper to q24–72h once in remission.
 - Systemic therapy:
 - Tetracycline and niacinamide—250 mg each PO q8h for dogs < 10 kg; 500 mg PO q8h for larger dogs (alternatives include doxycycline 10 mg/kg PO q24h and minocycline 5 mg/kg PO q12h).
 - Prednisone—consider for severe or non-responsive cases; 2–4 mg/kg/day either solely or in combination with azathioprine 2 mg/kg PO q48h; taper prednisone to 0.5–1 mg/kg PO q48h for long-term maintenance.
 - Cyclosporine—5–10 mg/kg PO q24h as alternative immunosuppressive therapy.
 - Consider systemic antibiotic treatment for a minimum of 3–4 weeks prior to systemic immunosuppressive therapy to differentiate from mucocutaneous pyoderma.
- Vitamin E 10–20 IU/kg PO q12h; may help reduce inflammation and protect the skin.
- Hydroxychloroquine—5 mg/kg q24h; antimalarial drug that has been used in human cases.

FOLLOW-UP

PATIENT MONITORING

- Recheck 2–4 weeks after initiating treatment to evaluate for clinical response.
- CBC and biochemistry—every 12 months if using topical therapy and every 3–6 months if using systemic therapy.
- CBC and platelet

counts—every 2 weeks for the first month; then every 3–6 months while on azathioprine.

PREVENTION/AVOIDANCE

Affected animals should avoid ultraviolet light exposure.

POSSIBLE COMPLICATIONS

- Scarring
- Secondary pyoderma
- Hemorrhage
- Disfigurement

EXPECTED COURSE AND PROGNOSIS

Progressive but not usually life-threatening if left untreated.

- With proper treatment, expect remission in majority of cases.
- Cases requiring chronic immunosuppressive therapy have a more guarded prognosis, but remissions are common with more aggressive therapy.

MISCELLANEOUS

SYNOMYMS

- Collie nose
- Nasal solar dermatitis

BASICS

DEFINITION

A multisystem auto-immune disease characterized by the formation of antibodies against a wide array of self-antigens. Pathogenic antibodies, circulating immune complexes, and auto-reactive T-cells are the primary mediators of tissue injury.

PATOPHYSIOLOGY

- Cause unknown. • Antibodies directed toward a broad range of membrane, cytoplasmic, and nuclear antigens are produced, resulting in Type II hypersensitivity. • Antigen-antibody complexes are formed and deposited in a variety of sites including blood vessels, renal glomeruli, synovial membrane, choroid plexus, and skin, resulting in Type III hypersensitivity. • Production of auto-reactive T-cells causes Type IV hypersensitivity.
- Tissue injury is caused by activation of complement by circulating immune complexes, infiltration of inflammatory cells, and direct cytotoxicity of auto-antibodies against membrane-bound antigens. • Clinical manifestations depend on localization of the immune complexes and specificity of the auto-antibodies. • Genetic, environmental, pharmacologic, and infectious factors may be triggers for disease.

SYSTEMS AFFECTED

- Musculoskeletal—deposition of immune complexes in the synovial membranes. • Skin/Exocrine—deposition of immune complexes in the skin. • Renal/Urologic—deposition of immune complexes in the glomeruli.
- Hemic/Lymphatic/Immune—auto-antibodies against RBCs, leukocytes, platelets, or bone marrow precursors. • Other organ systems—if there is deposition of immune complexes or antibodies (muscle, nerve, eye, for example).

GENETICS

Heritable although not by simple autosomal mechanisms. Breeds that are predisposed include the German shepherd dog, Shetland sheepdog, collie, beagle, and poodle. Several colonies of dogs with a high predisposition toward SLE have been established, and there is an association with MHC (DLA) type. An immune-mediated disease in the Nova Scotia duck tolling retriever characterized by immune-mediated arthropathy and steroid-responsive meningitis-arteritis has been reported and is termed SLE-related disease in this breed.

INCIDENCE/PREVALENCE

Uncommon in dog, rare in cat

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Medium to large breeds. • German shepherd, poodle, and beagle overrepresented.
- German shorthaired pointers are predisposed to exfoliative cutaneous lupus erythematosus. • Rough collies and Shetland sheepdogs are predisposed to vesicular cutaneous lupus erythematosus. • Siamese and Persian cats may be at increased risk of SLE.

Mean Age and Range

The mean age is 5 years, range 6 months to 13 years.

Predominant Sex

Male dogs overrepresented in one study only.

SIGNS

Historical Findings

- Lethargy. • Anorexia. • Shifting-leg lameness. • Skin lesions. • Fever. • Weakness.
- Other findings depend on the organ(s) affected. • Onset of clinical signs may be acute or insidious. • Disease often has a waxing and waning course. • Different clinical manifestations are often sequential rather than concurrent.

Physical Examination Findings

- Swollen and/or painful joints are the major presenting sign in most patients. Joints are often swollen but not deformed (non-erosive).
- Cutaneous lesions may be symmetric or focal—erythema, scaling, ulceration, depigmentation, vesicles, ulcerated or draining nodules, and/or alopecia may be observed. • Ulceration of mucocutaneous junctions and oral mucosa. • Persistent or cyclic fever—especially in the acute phase.
- Lymphadenopathy. • Hepatosplenomegaly.
- Muscle pain or atrophy. • Neurologic signs.

CAUSES

Definitive cause not identified. T suppressor cells may be defective in dogs with SLE.

RISK FACTORS

Exposure to ultraviolet light may exacerbate the cutaneous lesions.

DIAGNOSIS

- Definitive diagnosis—positive ANA or LE test (or both), and two major signs or one major *and* two minor signs. • Probable diagnosis—positive ANA or LE cell test (or both) and one major *or* two minor signs.
- Major signs—polyarthritis, glomerulonephritis, skin lesions, hemolytic anemia, thrombocytopenia, polymyositis.
- Minor signs—fever of unknown origin, oral ulcers, peripheral lymphadenopathy, pleuritis, pericarditis, myocarditis, neurologic signs (seizures, neuropathy).

DIFFERENTIAL DIAGNOSIS

- Neoplastic diseases may be associated with circulating immune complexes; patient may have signs similar to those of SLE.
- Infectious diseases such as ehrlichiosis, leishmaniasis, and bartonellosis. Differentiation is important because SLE is treated with immunosuppressive drugs.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—may reveal anemia, leukopenia, leukocytosis, or thrombocytopenia; anemia may be moderate and nonregenerative (e.g., anemia of chronic disease) or severe and regenerative (e.g., hemolytic).
- Biochemistry—results vary widely, depending on the organ(s) affected.
- Urinalysis—repeatable elevated protein:creatinine ratio (> 1) with benign sediment and negative culture supports pathologic proteinuria due to glomerulonephritis.

OTHER LABORATORY TESTS

- ANA test—detects antibodies directed against nuclear antigens. False-positive results may be seen in normal dogs and cats and in those with infectious, inflammatory, or neoplastic diseases or those being treated with certain drugs (e.g., penicillins, sulfonamides, tetracyclines). Antinuclear antibodies are detected in 10–20% of dogs with seroreactivity to *Bartonella vinsonii*, *Erblichia canis*, and *Leishmania infantum*. False negatives also occur. • LE test—identifies phagocytized nuclear material within neutrophils and macrophages; positive result supports diagnosis of SLE; time-consuming to perform. • Direct antiglobulin (Coombs') test—identifies complement or antibody on the surface of RBCs; test should only be run in patients with anemia.

IMAGING

- Radiographs of affected joints reveal soft-tissue swelling consistent with non-erosive arthritis. • Thoracic and abdominal radiographs may demonstrate hepatomegaly or splenomegaly

DIAGNOSTIC PROCEDURES

- Arthrocentesis—high cell count with nondegenerate neutrophils and monocytes and low viscosity are characteristic findings.
- Bacterial culture of synovial fluid—negative.
- Blood culture in animals with fever—negative. • Skin biopsy—in patients with skin lesions; save specimen in 10% buffered formalin (for histopathologic examination) and Michel's solution (for immunofluorescence testing).

PATHOLOGIC FINDINGS

- Non-erosive polyarthritis with infiltration of synovial membranes by neutrophils and lymphocytes; no pannus formation.
- Membranous or membranoproliferative glomerulonephritis. • Mononuclear interface dermatitis with hydropic degeneration of

LUPUS ERYTHEMATOSUS, SYSTEMIC (SLE)

(CONTINUED)

keratinocytes and eosinophilic round bodies representing apoptotic basal keratinocytes.

- Vasculitis and panniculitis in some patients.
- Immunofluorescence—deposition of immune complexes along the basement membrane of the dermal-epidermal junction.
- Vasculitis may be seen in any organ, especially myocardium, pericardium, and meninges. • Reactive lymphoid hyperplasia in the lymph nodes and spleen.

TREATMENT

APPROPRIATE HEALTH CARE

- Hospitalization—may be necessary for initial management (e.g., in a patient with hemolytic crisis).
- Outpatient management—often possible.

NURSING CARE

Supportive care varies with systems affected.

ACTIVITY

- Enforced rest—during episodes of acute polyarthritis.
- Avoid sunlight if photosensitization suspected.

DIET

Restricted protein, high-quality protein diet with n-3 fatty acid supplementation is recommended in animals with glomerulonephritis.

CLIENT EDUCATION

- Discuss the progressive and unpredictable course of the disease.
- Discuss the need for long-term, immunosuppressive therapy and its side effects.
- Discuss heritability of the disease.

SURGICAL CONSIDERATIONS

None

MEDICATIONS

DRUG(S) OF CHOICE

- Corticosteroids—to control the abnormal immune response and reduce inflammation; e.g., prednisone (1–2 mg/kg PO q12h).
- Cytotoxic immunosuppressive drugs—add when prednisone fails to improve the condition after 7–10 days or if the patient is steroid intolerant.
- Azathioprine (dogs, 2 mg/kg PO q24h until remission, then q48h).
- Chlorambucil (cats, 0.1–0.2 mg/kg PO q24h initially, then q48h).
- Cyclosporine—microemulsion, e.g., Atopica—dogs, 5–10 mg/kg/day PO divided twice daily; cats, 0.5–3 mg/kg PO q12h.

Measurement of trough cyclosporine concentration recommended.

- Gradually taper doses (no more often than every 3–4 weeks) once remission is achieved.

PRECAUTIONS

- Cats are susceptible to azathioprine toxicity and the drug is not recommended for use in this species.
- Azathioprine and chlorambucil may both cause bone marrow suppression.
- Treatment with immunosuppressive drugs can increase the risk of severe infection.
- Cyclosporine may cause gastrointestinal upset, papillomatosis, and gingival hyperplasia.

POSSIBLE INTERACTIONS

Concurrent use of aspirin and prednisone increases the risk of gastrointestinal ulceration.

ALTERNATIVE DRUG(S)

- Levamisole: dogs, 2–5 mg/kg PO every other day for 4 months (max 150 mg per patient) combined with prednisone 0.5–1.0 mg/kg PO q12h. The prednisone is tapered over 1–2 months and the levamisole continued for 4 months.
- Other immunosuppressive drugs can be considered depending upon the clinical manifestations exhibited (mycophenolate mofetil for immune-mediated hemolytic anemia, leflunomide for immune-mediated hemolytic anemia, polyarthritis, and myasthenia gravis).

FOLLOW-UP

PATIENT MONITORING

- Physical examination—weekly.
- CBC and biochemical analysis—to monitor the side effects of cytotoxic immunosuppressive drugs; day 7 then every 2–4 weeks.
- ANA—often remains elevated during remission but may fall as patient improves clinically.

PREVENTION/AVOIDANCE

Do not breed affected animals.

POSSIBLE COMPLICATIONS

- Renal failure and nephrotic syndrome secondary to glomerulonephritis.
- Bronchopneumonia, urinary tract infection, or sepsis secondary to immunosuppression.

EXPECTED COURSE AND PROGNOSIS

Prognosis is guarded. The presence of hemolytic anemia and glomerulonephritis and the development of bacterial infection warrant a poor prognosis.

MISCELLANEOUS

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

The use of cytotoxic immunosuppressive drugs in pregnant animals is contraindicated.

LYME BORRELIOSIS

BASICS

DEFINITION

- One of the most common tick-transmitted zoonotic diseases in the world.
- In man caused by spirochete species of the *Borrelia burgdorferi* sensu lato complex (e.g., *B. burgdorferi* sensu stricto, *B. afzelii*, *B. bavariensis*, *B. garinii*, and others).
- Dominant clinical feature (dogs)—recurrent lameness due to arthritis; sometimes anorexia and depression; may develop renal disease.
- Reported in humans, dogs, horses, and sporadically in cats.

PATHOPHYSIOLOGY

• Arthritis—caused by the presence of migrating spirochetes in tissue and subsequent cellular and humoral immune responses of the host.

- Local skin infection after a tick bite is followed weeks to months later by a generalized infection of predominantly connective tissue in joints, tendons, muscles, and lymph nodes.
- While an *erythema migrans* (EM) may be observed at the site of *Bb* inoculation, this lesion is unique to human. The EM is not seen in dogs.
- Immune complexes with *Bb*-specific antigens have been demonstrated in dogs and can be deposited in the kidneys; viable *Bb* organisms are not found in the kidneys.
- The incubation period in experimentally infected dogs is 2–5 months.

SYSTEMS AFFECTED

- Persisting *Bb* organisms—found in tissues with a high content of collagen (skin, joints, tendons, pericardium, peritoneum, meninges, muscle, heart, and lymph nodes); rarely found in body fluids (blood, CSF, and synovial fluid).
- Pathologic changes—with few exceptions restricted to joints, draining lymph nodes; in rare cases involvement of the kidneys.

GENETICS

Certain dog breeds are reported to develop severe renal failure (e.g., Bernese mountain dogs, Labrador, Golden retriever).

INCIDENCE/PREVALENCE

- Seroprevalence in dogs within a population varies greatly with exposure to infected ticks in endemic areas; in the upper Midwest and northeast of the United States and in central Europe seroprevalence is 2–10%.
- Clinically apparent LB develops in a fraction of infected individuals; mechanisms unclear; however, co-infections with other organisms (e.g., *Anaplasma phagocytophilum*) may impact on clinical outcome.

GEOGRAPHIC DISTRIBUTION

- Northern hemisphere (North America, Europe, Asia).
- United States—the majority of cases have been reported in the Mid-Atlantic to New England coastal states, northeastern states, and upper midwestern states. Ecologic

conditions supporting LB exist in adjacent states and also on the West Coast.

- Europe—absent or less frequent in areas bordering to the Mediterranean basin.

SIGNALMENT

Species

Dog and rarely cat

Mean Age and Range

Experimentally, young dogs (pups) appear to be more susceptible than adult dogs.

SIGNS

- Recurrent lameness due to arthritis.
- Experimentally, acute form lasts for only 3–4 days; reoccurs days to weeks later in the same or other limbs (shifting lameness); one or more joints may be swollen and warm; a pain response is elicited by palpation; responds well to antibiotic treatment.
- Affected dogs may refuse to walk or stand or walk stiffly with an arched back and may be sensitive to touch.
- Chronic non-erosive polyarthritis found in animals with prolonged infection without adequate treatment; may persist despite antimicrobial therapy.
- Fever, anorexia, and depression may accompany arthritis.
- Superficial lymph nodes close to the infecting tick bite may be swollen.
- Kidneys—reported glomerulonephritis with immune-complex deposition in the glomeruli leading to fatal renal disease; patients may present with renal failure (vomiting, diarrhea, anorexia, weight loss, polyuria/polydipsia, peripheral edema or ascites); protein loss (protein-losing nephropathy); hypoalbuminemia.

CAUSES

- *Bb*—transmitted by hard-shelled tick species of the genus *Ixodes* (e.g., *I. scapularis*, *I. pacificus*, *I. ricinus*, *I. persulcatus*).
- Infection—only after a tick (nymph or adult female) has been attached to the host for at least 18 hours.

Ixodes Ticks

- Have a 2- to 3-year life cycle depending on availability of hosts.
- Uninfected eggs are deposited in midsummer.
- Larvae—hatch a few weeks later; become infected by feeding on small mammals or birds that carry *Bb* organisms.
- Nymphs—larvae molt into nymphs in the spring of the following year; stay infected or become infected by feeding again on mammals, birds, or lizards.
- Adults—nymphs molt into adults in summer and stay infected; females mate and feed on larger mammals (e.g. deer); drop off and hide under leaves until the following summer, when they each lay about 2,000 eggs; males usually do not attach and do not feed.

RISK FACTORS

Canine LB is a peri-domestic disease due to expansion of housing into tick habitat; outdoor activities; roaming in and travel to endemic areas places dogs at risk.

DIAGNOSIS

Diagnosis of LB is a clinical conclusion made on the basis of compatible clinical signs, response to antibiotic therapy, exclusion of other diagnoses, appropriate laboratory data (particularly antibody testing), and history of exposure to an epidemiologic environment that provides the opportunity for infection with *Bb*.

DIFFERENTIAL DIAGNOSIS

- Lyme arthritis—differentiate from other inflammatory arthritic disorders.
- Bacteria—anaplasmosis; ehrlichiosis; Rocky Mountain spotted fever; others.
- Immune-mediated diseases—idiopathic, lupus erythematosus, rheumatoid arthritis.
- Specific breed diseases—Akita arthritis, shar-pei fever.
- Rule-out other disorders with serologic assays and immune testing (anticellular antibodies; lupus erythematosus preparations).

CBC/BIOCHEMISTRY/URINALYSIS

- With arthritis only—unremarkable.
- With protein-losing glomerulopathy—uremia, proteinuria, hypercholesterolemia, hyperphosphatemia, and hypoalbuminemia usually occur.

L

OTHER LABORATORY TESTS

- Fluid from affected joints—high WBC counts (up to 75,000/ μ L; up to 97% PMNs).
- Detection of specific antibodies indicates only exposure to *Bb* antigens; Western blotting/line immunoassay/fluorescent bead-based multiplex assay allow differentiation between vaccination and infection; cross-reaction with antibodies induced by other bacterial infections is only problematic in tests with lysate antigen preparations.
- The membrane ELISA in-house test (SNAP 3Dx or 4Dx, IDEXX Labs, Westbrook, ME) detects a subgroup of antibodies against the outer surface protein VlsE of *Bb* using the C6 peptide; convenient test that only indicates infection and does not respond to vaccine-induced antibodies—C6-specific antibodies normally drop or may even disappear approximately 4–6 months after antibiotic therapy. Low to moderate pre-therapy levels do not drop significantly.

IMAGING

Radiographs—help identify effusions in the joint; may help distinguish erosive from non-erosive joint disease; rule out trauma.

DIAGNOSTIC PROCEDURES

- Organisms can be demonstrated regularly in tissue samples taken from skin or synovium after experimental infections with PCR or culture; however, under field conditions these tests are time-consuming and unreliable (not recommended).
- Blood samples particularly are typically negative when tested with PCR or culture.

LYME BORRELIOSIS

(CONTINUED)

PATHOLOGIC FINDINGS

Gross

- Swollen joints with excess synovial fluid.
- Sometimes enlarged lymph nodes.

Histopathology

- Acute, clinically apparent arthritis—fibrinopurulent synovitis.
- Other joints—may have mild synovitis with infiltration of lymphocytes and plasma cells.
- Lymph nodes—may show cortical hyperplasia with multiple enlarged follicles and expanded parafollicular areas.
- Skin near tick bite site—shows perivascular infiltrates of plasma cells, lymphocytes, and some mast cells in the superficial dermis.
- Renal lesions—glomerulonephritis, diffuse tubular necrosis with regeneration, and interstitial inflammation.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient

NURSING CARE

Keep patient warm and dry.

ACTIVITY

Reduced activity until clinical signs improve.

DIET

No change needed

CLIENT EDUCATION

- Inform client of importance of regular application of antibiotics as prescribed.
- A case of diagnosed canine LB should prompt a discussion of the risk to humans living in the same area as the dog.

SURGICAL CONSIDERATIONS

Aspiration of synovial fluid—may be considered for diagnostic purposes.

MEDICATIONS

DRUG(S) OF CHOICE

- Most commonly used antibiotics—doxycycline (5–10 mg/kg PO q12h; with food; vomiting and gastritis possible), amoxicillin (20 mg/kg PO q8–12h) or azithromycin (25 mg/kg PO q24h).
- Doxycycline—preferred when a co-infection with *Anaplasma phagocytophilum* occurs.
- Antibiotics—do not terminate the infection completely; consequently, persistent infection with a very low bacterial burden remains; treatment significantly improves clinical signs and pathology.
- Recommended treatment period—4 weeks.

CONTRAINDICATIONS

Consider potential side effects of applied drugs.

PRECAUTIONS

Doxycycline can be used in young (<6 months old) animals.

ALTERNATIVE DRUG(S)

- Corticosteroids—may initially ameliorate signs; mask effects of antibiotics for diagnostic purposes; enhance clinical signs later by immunosuppression.
- Nonsteroidal pain medications—use judiciously to avoid masking signs.

FOLLOW-UP

PATIENT MONITORING

- Improvement—in acute Lyme arthritis seen within 2–5 days of antibiotic treatment.
- If no improvement or if signs exacerbate—consider a differential diagnosis.

PREVENTION/AVOIDANCE

- Mechanical removal of ticks—groom animals daily.
- Prevention of tick attachment—acaricides and repellents (do not use permethrin on cats) supplied as spot-on, sprays, collars or pills/chewables.
- Vaccines—all vaccines currently available depend predominately on the effect of antibodies against the spirochetes' outer surface protein A (OspA). These antibodies prevent the spirochetes' migration within the feeding tick from the gut into the salivary glands. Commercially available vaccines for dogs contain non-adjuvanted recombinant OspA or OspA and numerous antigens (e.g., OspC) in adjuvants (bacterins) produced from inactivated cultured *Bb* organisms. Studies have shown that the protection rate improves over time due to booster immunizations that induce higher and longer-lasting vaccine antibody titers.
- Tick population control in the environment—restricted to small areas; limited success by reducing deer and/or rodent population.

POSSIBLE COMPLICATIONS

Fatal renal failure

EXPECTED COURSE AND PROGNOSIS

- Recovery from acute lameness expected 2–5 days after initiation of antibiotic treatment.
- Disease may be recurrent with intervals of weeks to months; responds again to antibiotic treatment.

MISCELLANEOUS

AGE-RELATED FACTORS

- Young pups appear to be more susceptible than adult dogs under experimental conditions.
- Disease can occur in dogs of all ages.

ZOONOTIC POTENTIAL

- Occurs in humans; source of infection is infected ticks.
- Dogs can transport unattached ticks, which later attach to humans—however, *Ixodid* are not intermittent feeders; once tick starts feeding on a dog, it usually feeds to repletion and does

not change hosts.

- LB cannot be transmitted directly from dogs to humans.

PREGNANCY/FERTILITY/BREEDING

- Although possible, there is no convincing evidence that *Bb* infection is transmitted *in utero* in dogs.
- Pregnant animals tolerate antibiotic treatment; do not use tetracyclines.
- Maternal C6-specific antibodies can be passed from dams to puppies.

SYNOMYMS

- Lyme arthritis • Lyme disease

available online**

BASICS

DEFINITION

- Inflammation of one or more lymph nodes characterized by active migration of neutrophils, macrophages, or eosinophils into the node.
- Lymphoid hyperplasia is not a form of lymphadenitis.

PATOPHYSIOLOGY

- Usually the result of an infectious agent gaining access to a lymph node and establishing infection; because of the filtration functions of lymph nodes, they are likely to be exposed to infectious agents.
- Many organisms can cause inflammation, but agents such as fungi and mycobacteria that reside within macrophages and elicit a granulomatous inflammatory response are especially prone to establishing infection within lymph nodes.
- Non-infectious—occurs infrequently; an example is eosinophilic lymphadenitis that occurs as an occasional component of eosinophilic inflammatory diseases.

SYSTEMS AFFECTED

- Hemic/Lymphatic/Immune.
- May be a component of a more widespread infectious disease.

GENETICS

- No known genetic basis.
- Exception—rare cases of immunodeficiency; e.g., the familial susceptibility of certain basset hounds to mycobacteriosis, of which lymphadenitis is a frequent manifestation; Rottweilers may be predisposed to idiopathic hypereosinophilic syndromes causing eosinophilic lymphadenitis.

INCIDENCE/PREVALENCE

- Frequent manifestation of a number of infectious diseases.
- Precise incidence is unknown.

GEOGRAPHIC DISTRIBUTION

Same as for systemic fungal infections such as histoplasmosis (central United States) and blastomycosis (central and eastern United States) and, less commonly, leishmaniasis (southern and southwestern United States).

SIGNALMENT

Species

Dogs and cats

Breed Predilections

None

Mean Age and Range

Because of their susceptibility to infection, neonates may have a higher rate of occurrence than older animals.

Predominant Sex

None

SIGNS

General Comments

- Complications of infection in another organ—usually relate to that organ rather than to the inflamed lymph node.
- Component of systemic infection—associated with systemic inflammatory disease: fever, malaise, and anorexia.

Historical Findings

- Seldom causes lymph node enlargement that is severe enough to be observed by owners.
- Systemic signs of inflammatory disease or organ dysfunction.

Physical Examination Findings

- Inflamed lymph nodes are typically large and firm and may be painful.
- Bacterial—animal may develop abscesses within the nodes that may open to the exterior and present as draining tracts.
- Animals may also have fever and other systemic signs of infection.

CAUSES

Bacteria

- Most pathogenic aerobic and anaerobic species have occasionally been reported.
- More likely agents—*Pasteurella*, *Bacteroides*, and *Fusobacterium* spp.
- A few, such as *Yersinia pestis* (bubonic plague) and *Francisella tularensis* (tularemia), have a particular affinity for lymph nodes and are especially likely to be manifest as lymphadenitis, especially in cats.
- Bartonella vinsonii* infection may cause granulomatous lymphadenitis in dogs. *Bartonella* spp. can cause lymphoid hyperplasia in cats; however, organisms are not detected with routine stains.

Fungi

- Infections commonly include lymphadenitis as one manifestation of systemic disease.
- Likely organisms include *Blastomyces*, *Cryptococcus*, *Histoplasma*, *Coccidioides*, and *Sporothrix*.
- Many other mycotic agents have occasionally been reported.

Viruses

- Many viral infections implicated because of lymphoid hyperplasia.
- Coronavirus (FIP).
- Mesenteric lymph nodes are most commonly affected.

Other

- Protozoa—animals with toxoplasmosis and leishmaniasis frequently have lymphadenitis, although it is unlikely to be the most obvious clinical finding.
- Algae—lymphadenitis is often one manifestation of canine protothecosis.
- Non-infectious (e.g., associated with pulmonary or systemic eosinophilic disease)—usually unknown.

RISK FACTORS

- Animals with compromised immune function are susceptible to infection and, therefore, to lymphadenitis.
- FeLV and FIV are among the more common causes of immune compromise in veterinary patients.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Must ascertain that a palpable or visible mass is actually a lymph node and not a neoplastic mass or inflammatory process such as sialoadenitis.
- Frequently cannot be distinguished on the basis of clinical findings from other causes of lymphadenomegaly, such as lymphoid hyperplasia, lymphoma, and metastatic neoplasia.
- Fever and painful lymph nodes are likely to be associated with lymphadenitis.
- Lymphoma and lymphoid hyperplasia are more common causes of generalized lymph node enlargement than is lymphadenitis.

CBC/BIOCHEMISTRY/URINALYSIS

- Although affected animals may have an inflammatory leukogram, the absence of such changes does not exclude the diagnosis.
- Some animals with systemic causes of lymphadenitis (e.g., fungal infections, leishmaniasis) may have marked hyperglobulinemia.
- Circulating eosinophilia, often severe, is a relatively consistent finding in animals with eosinophilic diseases that are extensive and severe enough to cause lymphadenitis.
- Biochemistry results may reflect the degree of organ involvement from the underlying disease process.

OTHER LABORATORY TESTS

Serologic tests for the various systemic fungal diseases and possibly *Bartonella* spp. can be useful for identification, although these tests are best used only when attempts to demonstrate the organisms fail.

IMAGING

Radiography and ultrasonography—involve of internal nodes, such as those in the thoracic and abdominal cavities, in patients with systemic inflammatory disease; valuable in assessing involvement of other organs, e.g., pneumonia in a patient with blastomycosis or histoplasmosis.

DIAGNOSTIC PROCEDURES

- Fine-needle aspiration cytology is sufficient to diagnose most cases; a simple hematologic (Romanowsky) stain (e.g., Diff-Quik) is usually suitable.
- Gram staining can be performed in patients suspected of bacterial infection.

LYMPHADENITIS

(CONTINUED)

- Cytologic findings—high proportion of neutrophils, macrophages, eosinophils, or some combination of those cell types, which are only rarely seen in normal lymph nodes.
- Bacteria, fungal agents, protozoa, and algae—often present in fine-needle aspirates of lymph nodes from animals with those infections; cytologic examination frequently is the most efficient means of detecting and identifying specific infectious agents in animals with either lymphadenitis of an isolated node or systemic infection.
- When a diagnosis is not made by cytologic examination, a lymph node biopsy may be indicated; specimens can be used for both histopathologic evaluation and culture.

PATHOLOGIC FINDINGS

- Although affected lymph nodes may be grossly normal, they are more frequently large and firm; the extent of enlargement varies widely and often distorts the shape of the node.
- Severe lymphadenitis may extend through the capsule of the node into adjacent tissues.
- On cut surface, affected nodes are often hyperemic and may have poorly defined nodules; in extreme examples of purulent lymphadenitis, abscesses may develop.
- Histologic lesions of purulent lymphadenitis include diffuse or multifocal infiltration of the affected node by neutrophils; the normal cortical-medullary architecture of the node may be disrupted.
- Granulomatous lymphadenitis—accumulations of activated macrophages involving the parenchyma of the node.
- Eosinophilic lymphadenitis—large numbers of eosinophils both within sinuses and in the cortical parenchyma.
- Necrosis common in all forms.

TREATMENT

APPROPRIATE HEALTH CARE

- Because lymphadenitis is a lesion rather than a specific disease, no single set of therapeutic recommendations is appropriate.
- The characteristics of the inflammation and the causative agent dictate appropriate treatment.

NURSING CARE

N/A

ACTIVITY

N/A

DIET

N/A

CLIENT EDUCATION

N/A

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

- Effective drug therapy requires identification of the causative agent.
- Purulent lymphadenitis of a single lymph node is likely to be of bacterial cause and can be treated with broad-spectrum systemic antibiotics if no organism is detected on initial cytologic evaluation.

PRECAUTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PREVENTION/AVOIDANCE

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Multiple affected lymph nodes—frequently a manifestation of systemic infection that also affects many other organs.
- Detection of fungi, protozoa, or algae in any inflamed node should alert one to the possibility of systemic infection by that agent.

AGE-RELATED FACTORS

None

ZOONOTIC POTENTIAL

- Bubonic plague, tularemia, and mycotic organisms present some risk of human infection.
- Specimens from affected animals should be handled cautiously.

LYMPHADENOPATHY

BASICS

DEFINITION

Abnormally large lymph nodes, generalized or localized to a single node or group of regional nodes

PATOPHYSIOLOGY

- Can result from hyperplasia and reactivity of lymphoid elements, inflammatory infiltration, or neoplastic proliferation within the lymph node.
- Because of their filtration function, lymph nodes often act as sentinels of disease in the tissues they drain; inflammation of any tissue is often accompanied by enlargement of the draining nodes, which most likely results from reactive lymphoid hyperplasia but may also be caused by extension of the inflammatory process into the nodes (lymphadenitis).
- Reactive hyperplasia involves proliferation of lymphocytes and plasma cells in response to antigenic stimulation; hyperplasia alone involves proliferation of lymphocytes only and is an early stage of reactive hyperplasia.
- Lymphadenitis—implies active migration of neutrophils, activated macrophages, or eosinophils into the lymph node.
- Infectious agents may be involved.
- Neoplastic proliferation may be either primary (malignant lymphoma) or metastatic.

SYSTEMS AFFECTED

Hemic/Lymphatic/Immune

SIGNALMENT

- Dogs and cats
- No breed, sex, or age predilection

SIGNS

- Typically does not cause clinical signs.
- Severe—may cause mechanical obstruction and interference with the function of adjacent organs, signs of which depend on the affected lymph node and may include dysphagia, regurgitation, respiratory distress, dyschezia, and limb swelling.
- Dogs and cats may be systemically ill from the underlying disease process.

CAUSES

Lymphoid Hyperplasia/Reactivity

- Localized or systemic infection caused by infectious agents of all categories (i.e., bacteria, viruses, fungi, protozoa, and algae) when infection does not directly involve the node.
- Some infectious agents may produce lymphadenitis of certain lymph nodes with concurrent hyperplasia of other nodes that are not directly infected.
- Other infectious agents (e.g., rickettsia, *Bartonella* spp., and *Brucella canis*)—hyperplasia without overt lymphadenitis.
- FIV and FeLV infection—generalized hyperplasia, although lymphoid depletion may occur late in the course of the disease;

lymphadenitis can develop with a secondary infection.

- Antigenic stimulation by factors other than infectious agents (e.g., allergens).
- May develop in animals with immune-mediated disease (e.g., SLE and rheumatoid arthritis).

Lymphadenitis

- Bacteria—capable of causing purulent lymphadenitis, which may progress to abscessation; a few (e.g., *Mycobacterium* spp., *Bartonella* spp.) induce granulomatous lymphadenitis; other agents include aerobic and anaerobic organisms, *Pasteurella*, *Bacteroides*, *Fusobacterium*, *Yersinia pestis*, and *Francisella tularensis*.
- Fungi—systemic infections from histoplasmosis, blastomycosis, cryptococcosis, and sporotrichosis.
- Uncommon—protozoa, algae, and metazoan parasites.
- Several involved lymph nodes—frequently a manifestation of systemic infection, such as histoplasmosis or blastomycosis.
- Although primary infection of the lymph nodes does occur, lymphadenitis is usually accompanied by (and often results from) infection of other tissues being drained by the affected node.
- Eosinophilic—may be associated with allergic inflammation of the organ being drained by the affected lymph node (e.g., skin affected with flea allergy dermatitis); may be encountered in a patient with multisystemic idiopathic eosinophilic disease, such as feline and canine hypereosinophilic syndromes, or in a lymph node draining a mast cell tumor.
- Lymphadenitis and reactive hyperplasia often occur together.

Neoplasia

- Cats—neoplastic transformation of lymphocytes by FeLV.
- Dogs—lymphoma, cause unknown.
- Most tumors that metastasize to the lymph nodes—unknown.

RISK FACTORS

- Impaired immune function predisposes to infection and, therefore, to lymphadenitis.
- Animals with allergic diseases are likely to develop lymph node hyperplasia or eosinophilic lymphadenitis.
- Lymphoma (cats)—infection with FeLV, FIV.
- Lymphadenomegaly caused by metastatic neoplasms—vary with the type of primary neoplasm.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- A mass in a location characteristic of a lymph node usually can be assumed to be

one; cytologic evaluation of a fine-needle aspirate usually resolves any doubt.

- Palpable lymph nodes in normal dogs—mandibular, prescapular, axillary, superficial inguinal, and popliteal nodes; facial, retropharyngeal, and iliac nodes are palpable when larger than normal.
- Severe lymph node enlargement (> 5 times normal size)—most likely to develop in patients with abscessation (lymphadenitis) and lymphoma.
- Lesser degrees of enlargement—attributable to reactive hyperplasia, lymphadenitis, or neoplasia.
- Extent of enlargement in patients with metastatic disease varies widely.
- Multiple lymph nodes affected throughout the body—likely the result of lymphoma or systemic infection that causes either lymphadenitis or lymphoid hyperplasia.
- Abscessation and metastatic neoplasms usually affect a single lymph node.

CBC/BIOCHEMISTRY/URINALYSIS

- Cytopenias—seen with lymphoma, anemia of chronic disease, stress, splenic disease, or neoplastic infiltration of the bone marrow; also seen with rickettsial or viral disease.
- Lymphocytosis—suggests rickettsial disease (dogs) and lymphoid neoplasia (dogs and cats); atypical lymphocytes in the blood help establish a diagnosis of lymphoid neoplasia.
- Eosinophilia—may occur in animals with lymphadenopathy due to allergic or parasitic skin disease.
- Neutrophilia, with or without a left shift—may develop in patients with lymphadenitis, lymphoid hyperplasia, or neoplasia.
- Hypercalcemia—relatively common in dogs and rare in cats with lymphoma.
- Hyperglobulinemia—may develop in patients with chronic inflammatory disease or lymphoid neoplasia.

OTHER LABORATORY TESTS

- Cats—test for FeLV antigen and FIV in animals with large lymph nodes; infected animals may have lymphoma, lymphoid hyperplasia, or even lymphadenitis caused by immunosuppression.
- Serologic tests for antibodies against systemic fungal agents such as *Blastomyces* and *Cryptococcus* or bacteria such as *Bartonella* spp. may help establish those diagnoses.

IMAGING

- Radiography and ultrasonography—involve lymph nodes within the body cavity.
- Lesions associated with lymph node enlargement may be detected in other organs (e.g., diffuse pneumonia in dogs with blastomycosis, and primary tumor in animals with lymphadenomegaly caused by metastatic neoplasia).

LYMPHADENOPATHY

(CONTINUED)

DIAGNOSTIC PROCEDURES

Cytologic Examination

- Aspirates from affected lymph nodes help determine the major category of lymphadenomegaly (i.e., hyperplasia, inflammation, or neoplasia) and may provide a specific diagnosis in patients with certain infectious diseases or neoplasms; a standard hematologic (Romanowsky) stain (e.g., Diff-Quik) is suitable in most cases.
- Gram staining can be performed in animals suspected of bacterial lymphadenitis.
- Aspirates from reactive and hyperplastic lymph nodes contain a mixed cell population in which small lymphocytes predominate along with large lymphocytes, plasma cells, occasional neutrophils, and perhaps a few eosinophils and mast cells.
- Aspirates from lymph nodes affected by lymphadenitis contain high proportions of neutrophils, macrophages, and/or eosinophils, depending on the cause of the inflammation; specific infectious agents, such as bacteria and systemic fungi, may be evident.
- Frequently the means of diagnosis in animals with systemic fungal infection, such as blastomycosis and cryptococcosis.
- Aspirates from lymph nodes affected by lymphoma typically contain a high proportion (usually > 50%) of large lymphocytes. These are usually blasts with clearly recognizable nucleoli.
- Aspirates from lymph nodes containing metastatic neoplasia contain populations of cells that are not seen in normal nodes; the appearance of such cells varies widely, depending on the type of neoplasm.

Other

- In cats, severe lymphoid hyperplasia has been misdiagnosed as lymphoma; thus a biopsy is essential for animals with lymphadenomegaly.
- When a diagnosis cannot be made by cytologic examination, a surgical biopsy may be needed; excisional biopsy is preferable to needle biopsy.
- The cytologic diagnosis of lymphoma should be confirmed by histopathologic examination of an excised lymph node for accurate grading and to obtain potential prognostic information.

TREATMENT

- Because of the many disease processes and specific agents that can cause lymphadenomegaly, treatment depends on establishing the underlying cause.
- In animals suspected of lymphoma, corticosteroids should not be administered before completing staging tests if chemotherapy may be instituted.

MEDICATIONS

DRUG(S) OF CHOICE

Appropriate medications vary with the cause of lymph node enlargement.

CONTRAINDICATIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

Lymph node size to assess efficacy of treatment.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Lymph node hyperplasia and lymphadenitis are often components or manifestations of systemic disease.
- Lymphoma may involve other organs (e.g., liver, spleen, intestines, kidneys, and meninges) with a variety of clinical consequences.
- Clinical disease in animals with metastatic neoplasms in the lymph nodes is usually attributable to the primary tumor rather than

to the metastasis; however, exceptions are dogs with tonsillar carcinoma, who may have massively large mandibular lymph nodes, and dogs with adenocarcinoma of the anal sac, who often have dramatically large sublumbar lymph nodes.

AGE-RELATED FACTORS

None

ZOONOTIC POTENTIAL

- Direct transmission of diseases that cause lymphadenitis to humans is unlikely, with the exception of systemic mycotic disease, sporotrichosis, tularemia, plague, and *Bartonella* spp.

- Caution should be exercised when performing fine-needle aspiration in animals that may have systemic fungal disease.

LYMPHANGIECTASIA

BASICS

DEFINITION

An obstructive disorder of the lymphatic system of the gastrointestinal tract resulting in lymphatic hypertension and protein-losing enteropathy.

PATOPHYSIOLOGY

- Lymphatic obstruction results in dilation and rupture of intestinal lacteals with subsequent loss of lymphatic contents (plasma proteins, lymphocytes, and chylomicrons) into the intestinal lumen.
- Although some of the proteins may be digested and reabsorbed, excessive enteric loss of plasma proteins will ultimately result in panhypoproteinemia.
- Hypoproteinemia causes a decrease in plasma oncotic pressure, which, if severe, will lead to edema, ascites, and/or pleural effusion.

SYSTEMS AFFECTED

- Gastrointestinal—diarrhea
- Respiratory—pleural effusion
- Skin—subcutaneous edema
- Systemic—ascites
- Vascular—thromboembolic disease

GENETICS

A familial tendency for protein-losing enteropathy has been reported for soft-coated Wheaten terriers, basenjis, Yorkshire terriers, and Norwegian Lundehunds, but the actual genetic cause has not been identified for any of these breeds.

INCIDENCE/PREVALENCE

Uncommon

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog

Breed Predilections

Increased prevalence in soft-coated Wheaten terrier, Basenji, Norwegian lundehund, and Yorkshire terrier.

Mean Age and Range

Dogs of any age can be affected. Most common in middle-aged dogs.

Predominant Sex

An increased prevalence has been reported in female soft-coated Wheaten terriers; no sex predilection has been reported for other breeds.

SIGNS

- Clinical signs are variable.
- Diarrhea—chronic, intermittent, or continuous, watery to semisolid consistency (typically small bowel type diarrhea); however, not all animals have diarrhea.
- Ascites.
- Subcutaneous edema.

- Dyspnea from pleural effusion.
- Weight loss.
- Flatulence.
- Vomiting.

CAUSES

Primary or Congenital Lymphangiectasia

- Focal—intestinal lymphatics only.
- Diffuse lymphatic abnormalities (e.g., chylothorax, lymphedema, chyloabdomen, thoracic duct obstruction).

Secondary Lymphangiectasia

- Right-sided congestive heart failure
- Constrictive pericarditis
- Budd-Chiari syndrome
- Neoplasia (lymphosarcoma)

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lymphangiectasia must be differentiated from other causes of protein-losing enteropathy.
- PLE must be differentiated from other causes of hypoalbuminemia.

CBC/BIOCHEMISTRY/URINALYSIS

- Hypoalbuminemia and hypoglobulinemia (panhypoproteinemia)
- Hypocholesterolemia
- Hypocalcemia
- Hypomagnesemia
- Lymphopenia

OTHER LABORATORY TESTS

Tests to Differentiate PLE from Other Causes of Hypoalbuminemia

- Serum chemistry profile and pre- and post-prandial serum bile acids concentrations to rule out hepatic failure.
- Urine protein:creatinine ratio to rule out protein-losing nephropathy.
- Occult fecal blood test to rule out gastrointestinal blood loss (requires animal being fed a vegetarian diet for 72 hours to prevent false-positive results from meat protein).
- Fecal α_1 -protease inhibitor concentration to help confirm intestinal protein loss, although this test is not necessary in most dogs with lymphangiectasia.

Tests to Differentiate Other Causes of Excessive Protein Loss into the GI Tract

- Fecal smear and flotation to rule out intestinal parasites.
- Serum cobalamin and folate concentrations to rule out small intestinal dysbiosis or cobalamin deficiency, which could be associated with excessive intestinal protein loss. While cobalamin deficiency does not cause PLE it is an indicator of long-standing and severe distal small intestinal disease,

which in turn could be associated with excessive protein loss.

If an infectious enteritis is suspected, fecal culture for diagnosis of specific enteric pathogens (e.g., *Salmonella* spp.), PCR for enteropathogenic *Campylobacter* spp., and a *Clostridium* enterotoxin test (ELISA) if infectious enteritis is suspected.

Fluid analysis of body cavity effusions—the effusion associated with lymphangiectasia is usually a transudate, but chyloabdomen and chylothorax can occasionally be observed.

IMAGING

- Survey thoracic radiographs to rule out cardiac disease and neoplasia.
- Abdominal radiographs to rule out mechanical intestinal disease (obstruction or partial obstruction) and other causes of PLE.
- Abdominal ultrasound to rule-out mechanical intestinal disease and other causes of PLE.
- Cardiac ultrasound to rule out right-sided congestive heart failure.
- Abdominal ultrasonography can show hyperechoic mucosal striations extending from the lumen to the submucosal layer of the bowel. One study suggested that corn-oil given orally 60–90 minutes before abdominal ultrasonography improves the diagnostic yield.

DIAGNOSTIC PROCEDURES

- Endoscopy allows intestinal mucosal visualization and biopsy. Ileal biopsies should be procured in animals that have hypcobalaminemia.
- Laparotomy allows visualization of dilated intestinal lymphatics and biopsies of intestines (full thickness) and lymph nodes, but may be contraindicated in patients with severe hypoproteinemia.
- An ECG can aid in evaluating the heart in animals suspected of having right-sided congestive heart failure.

PATHOLOGIC FINDINGS

- Gross findings at laparotomy may include dilated lymphatics that are visible as a web-like network throughout the mesentery and serosal surface.
- May see small yellow-white nodules and foamy granular deposits adjacent to lymphatics.
- Histopathology findings include ballooning distortion of villi, caused by markedly dilated lacteals.
- Villi can be edematous; some have a blunted appearance.
- Usually associated with mucosal edema or diffuse or multifocal accumulations of lymphocytes and plasma cells in the lamina propria.

L

LYMPHANGIECTASIA

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

May need hospitalization if complications due to hypoalbuminemia develop.

NURSING CARE

N/A

ACTIVITY

Normal

DIET

- Low-fat diet with high-quality protein. Avoid diets that are excessively high in fiber.
- Dogs with concurrent lymphangiectasia and IBD may benefit from a commercial hypoallergenic hydrolyzed protein diet that is moderately restricted in dietary fat.
- Long-chain triglycerides stimulate intestinal lymph flow and may lead to increased intestinal protein loss.
- Diets fortified with medium-chain triglycerides may be beneficial.
- May feed MCTs to supplement fat and increase caloric intake.
- Commercial sources of MCTs—MCT oil or Portagen (Mead Johnson, Evansville, IN).
- Supplement with fat-soluble vitamins—A, D, E, and K.
- Elemental diets can also be used.

CLIENT EDUCATION

Discuss unpredictable disease progression and response to therapy.

SURGICAL CONSIDERATIONS

- When intestinal lymphangiectasia is secondary to an identifiable lymphatic obstruction, consider surgery to relieve the obstruction.
- Pericardectomy may be indicated in cases of constrictive pericarditis.
- Patients that benefit from surgical intervention are rare.

MEDICATIONS

DRUG(S) OF CHOICE

• Try corticosteroids if dietary therapy alone is unsuccessful (however, such therapy is not intended to treat lymphangiectasia but rather concurrent gastrointestinal inflammation). Oral prednisone or prednisolone at a dose of 1–2 mg/kg q12h for 5–7 days, followed by 1 mg/kg q12h for at least 6 weeks. In large-breed dogs the starting dose should be more conservative than in small-breed dogs. After remission of the disease, dosage can be slowly

tapered to the lowest dose effective at controlling the disease. Alternatively, may consider the use of a locally-effective corticosteroid (e.g., budesonide), or other immunomodulators such as azathioprine or cyclosporine.

- If the patient is cobalamin deficient, cobalamin must be supplemented to achieve therapeutic response: 250–1,500 µg/dog SC once a week for 6 weeks, then one dose 1 month later. Follow with a recheck a month after the last dose to determine the need for continued supplementation.
- If secondary small intestinal dysbiosis is suspected the patient should be treated with tylosin at 10–20 mg/kg q12h for 6 weeks.
- Magnesium sulfate should be supplemented parenterally (IV) at 1 mEq/kg/day in dogs that are hypomagnesemic before oral supplementation with magnesium oxide, magnesium citrate, or magnesium carbonate.
- Diuretics such as furosemide (1 mg/kg q12h) and spironolactone (1 mg/kg q12h) in animals with severe ascites to improve patient comfort.

CONTRAINdications

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Body weight, serum total protein, albumin, and globulin concentrations, and evidence of recurrent clinical signs (pleural effusion, ascites, and/or edema).
- Patients need to be reevaluated depending on the severity of the disease process.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Respiratory difficulty from pleural effusion
- Severe protein-calorie depletion
- Intractable diarrhea

EXPECTED COURSE AND PROGNOSIS

- Prognosis is guarded.
- Some animals fail to respond to treatment.
- Remissions of several months to more than 2 years can be achieved in some patients.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Soft-coated Wheaten terriers may have concurrent protein-losing nephropathy.

Consulting Editor Stanley L. Marks

Client Education Handout
available online

BASICS

OVERVIEW

- Abnormal accumulation of protein-rich lymph fluid into interstitial spaces, especially subcutaneous fat.
- Chronic lymphedema causes tissue fibrosis.
- May be congenital or acquired.

SIGNALMENT

- More common in dog than in cat.
- Congenital in bulldogs and reported to be hereditary/congenital in a family of poodles and whippets; possible breed predilection in Labrador retrievers and Old English sheepdogs.

SIGNS

Historical Findings

- Primary/congenital—usually peripheral limb swelling at birth or develops in first several months.
- Swelling typically starts at distal extremity and slowly advances proximally.

Physical Examination Findings

- Most common in limbs, especially pelvic limbs; may be unilateral or bilateral.
- Less common in ventral thorax, abdomen, ears, and tail.
- Pitting, non-painful; temperature of affected area is normal.
- Pitting quality lost with chronicity as fibrosis occurs.
- Lameness and pain uncommon unless cellulitis develops.

CAUSES & RISK FACTORS

- Hereditary/congenital malformation of the lymphatic system—aplasia, valvular incompetence, and lymph node fibrosis.
- Excessive interstitial fluid production secondary to venous hypertension (associated with congestive heart failure and obstruction of venous drainage) or increased vascular permeability (associated with infection, trauma, heat, and irradiation).
- Secondary damage to lymphatic vessels or lymph nodes—associated with trauma, infection (e.g., *Brugia pahangi* lymphatic filarial infection—Southeast Asia), neoplasia (e.g., lymphoma, lymphangiosarcoma [rare]), and thoracic duct ligation (rare).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Edema caused by venous stasis (e.g., congestive heart failure and cirrhosis); look for varices, hyperpigmentation, and

ulceration.

- Arteriovenous fistulae—listen for machinery murmur; feel for pulsatile vessels; confirm with angiogram.
- Edema caused by hypoproteinemia—protein-losing nephropathy or enteropathy, hepatic failure, serum loss from burns or hemorrhage; check serum protein concentration.
- Trauma—review history; look for bruising and lacerations.
- Neoplasia—if swelling is firm, obtain aspirate for cytologic examination.
- Cellulitis—look for fever, pain, and warm swelling.
- Insect bites.

CBC/BIOCHEMISTRY/URINALYSIS

Results normal

OTHER LABORATORY TESTS

Serologic tests for tick-borne infections, including *Bartonella* spp.

IMAGING

Lymphography useful in documenting abnormalities within the lymphatic system; best results obtained with an injection of water-based contrast media directly into a lymphatic vessel. See "Suggested Reading" for detailed description of the technique.

DIAGNOSTIC PROCEDURES

- Biopsy of affected tissues to rule out lymphangiosarcoma.
- Culture and sensitivity when lymphangitis is present.

TREATMENT

- No curative therapy—a number of surgical and medical treatments may be tried.
- Rest and massage of the affected limbs does not help.
- Conservative care—long-term use of pressure wraps, coupled with skin care and use of antibiotics to treat cellulitis and lymphangitis; may be successful in some patients.
- Surgical procedures—can be attempted when conservative care and medications fail; lymphangioplasty, bridging techniques, lymphaticovenous shunts, superficial and deep lymphatic anastomosis, and excisional procedures; none is consistently beneficial, and excisional procedures have been reported only in dogs.
- In humans—microwave heating of affected areas appears beneficial and adds to the effect of benzopyrones (see "Drugs").
- Diets severely restricted in long-chain triglycerides are being investigated in humans.

MEDICATIONS

DRUG(S)

- Benzopyrones reduce high-protein edema by stimulating macrophages to release proteases; beneficial effects have been recorded in experimental studies in dogs. Rutin, 50 mg/kg PO q8h, may benefit. A study in humans showed combined usage of oral and topical benzopyrones to be more effective than either alone.
- Diuretics, steroids, anticoagulants, and fibrinolytic agents have been used, but no confirmed benefit.
- Treat underlying cause where possible (e.g., ivermectin for *Brugia pahangi* infection).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Diuretics—initially reduce swelling but increase protein content of interstitial fluid, resulting in further tissue damage and fibrosis.

FOLLOW-UP

- Puppies with severe lymphedema may die.
- Resolution seen in some puppies with pelvic limb involvement only.
- Prognosis with lymphangiosarcoma is poor.

LYMPHOMA—CATS

BASICS

DEFINITION

Malignant transformation of lymphocytes

PATHOPHYSIOLOGY

Viral (FeLV) or chemical (tobacco smoke) oncogenesis

SYSTEMS AFFECTED

- Gastrointestinal
- Hemic/Lymphatic/Immune
- Nervous—most common spinal cord tumor in cats
- Ophthalmic
- Renal (high rate of relapse in central nervous system)
- Respiratory—nasal, thoracic cavities

GENETICS

N/A

INCIDENCE/PREVALENCE

- About 90% of hematopoietic tumors and 33% of all tumors in cats.
- Prevalence—41.6–200 per 100,000 cats.

GEOGRAPHIC DISTRIBUTION

Regional differences may relate to differences in FeLV prevalence.

Breed Predilections

Siamese/Oriental breeds overrepresented in some studies

Mean Age and Range

- FeLV-positive cats—3 years.
- FeLV-negative cats—7 years.
- Median age of cats with localized extranodal lymphoma—13 years.
- Most cats with Hodgkin's-like lymphoma are older than 6 years.

Predominant Sex

None

SIGNS

General Comments

Depend on anatomic form.

Historical Findings

- Mediastinal form—open-mouthed breathing; coughing; regurgitation; anorexia; weight loss.
- Alimentary form—anorexia; weight loss; lethargy; vomiting; constipation; diarrhea; melena; hematochezia. SCL typically more chronic signs compared to LCL.
- Renal form—consistent with renal failure.
- Nasal form—nasal discharge or epistaxis, facial swelling, ocular signs, respiratory noise, sneezing, anorexia.
- Multicentric form—possibly none in early stages; anorexia, weight loss, and depression with progression of disease.
- Spinal form—quickly progressing posterior paresis may be seen.
- Cutaneous form—pruritic, hemorrhagic, or alopecic dermal masses may be seen.

Physical Examination Findings

- Mediastinal form—non-compressible cranial thorax, dyspnea, tachypnea.
- Alimentary form—thickened intestines or abdominal masses.
- Renal form—large, irregular kidneys.
- Nasal form—purulent or mucoid nasal discharge, facial deformity, epiphora, exophthalmos, poor globe retropulsion.
- Multicentric form—generalized lymphadenomegaly, possible hepatosplenomegaly.
- All forms—fever; dehydration; depression; cachexia in some patients.

CAUSES

FeLV

RISK FACTORS

- FeLV exposure.
- Exposure to environmental tobacco smoke (relative risk 2.4, increases linearly with duration and quantity of exposure).
- FIV infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mediastinal form—congestive heart failure; cardiomyopathy; chylothorax; pyothorax; hemothorax; pneumothorax; diaphragmatic hernia; allergic lung disease; thymoma; ectopic thyroid carcinoma; pleural carcinomatosis; acetaminophen toxicity.
- Alimentary form—foreign body ingestion; intestinal ulceration; intestinal fungal infection; inflammatory bowel disease; intussusception; lymphangiectasia; other gastrointestinal tumor.
- Renal form—pyelonephritis; amyloidosis; glomerulonephritis; chronic renal failure; polycystic kidneys; feline infectious peritonitis.
- Multicentric form—systemic mycotic infection; immune-mediated disease; toxoplasmosis; lymphoid hyperplasia; hypersensitivity reaction; plague (specifically if prominent cervical lymphadenopathy as with Hodgkin-like form).

CBC/BIOCHEMISTRY/URINALYSIS

- May see anemia (negative prognostic factor), leukocytosis, and lymphoblastosis.
- May find high creatinine, high serum urea nitrogen, high hepatic enzyme activity, hypercalcemia (rare), and monoclonal gammopathy.

OTHER LABORATORY TESTS

FeLV testing: usually negative in older cats and in cats with (LGLL), usually positive in younger cats and those with mediastinal (85%) or CNS lymphoma, renal (45% positive), multicentric (20%), intestinal (15%).

IMAGING

- *Thoracic radiography*—may see mediastinal mass, pleural effusion, abnormal pulmonary parenchymal patterns (rare), perihilar or retrosternal lymphadenomegaly.
- *Abdominal ultrasonography*—may see diffuse echotexture changes in the liver, spleen, and kidneys, focal or diffuse thickening of the intestines and the gastric wall, abdominal lymphadenopathy, intestinal/gastric mass.
 - Hypoechoic subcapsular thickening is associated with renal lymphoma.
 - Despite thickening of intestines, layering may be preserved.
- *Computed tomography*—space-occupying mass effect in affected area, especially used for nasal lymphoma.

DIAGNOSTIC PROCEDURES

- Aspiration or biopsy of a mass or lymph node.
- Aspirate often sufficient to diagnose LCL, biopsy often required for SCL.
- Can be challenging to distinguish SCL from IBD.
- PARR testing can be done to determine if lymphocyte population is monoclonal (consistent with lymphoma) or not; sensitivity for detecting T-cell and B-cell LSA is 78% and 50%, respectively.
- Staging: CBC/Chemistry profile/Urinalysis/FeLV/FIV testing, thoracic radiographs, abdominal ultrasound, regional lymph node aspirates for localized lesions, ± bone marrow aspirate depending on CBC findings serum cobalamin level in SCL.

PATHOLOGIC FINDINGS

- Gross—usually white to gray in color with areas of hemorrhage and necrosis.
- Cytologic—monomorphic population of lymphoid cells, sometimes with prominent, multiple nucleoli and coarse nuclear chromatin.
- Histopathologic—vary; several morphologic classification schemes in use.
 - Nasal lymphoma is most often immunoblastic B-cell origin.
 - Hodgkin's-like lymphoma is characterized by Reed-Sternberg cells and few neoplastic cells in a background of a reactive T-cell population with histiocytes and granulocytes.
 - LGL lymphoma most commonly affects the intestine and mesenteric lymph nodes.
 - B-cell most common in stomach (100%) and large intestine (88%), T-cell most common in small intestine (52%, most common location in gut).
 - In GI lymphoma, LCL more common than SCL when both cytologic and histopathologic samples are evaluated.

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient whenever possible, supportive care if needed.

NURSING CARE

Fluid therapy, antiemetics, appetite stimulants, thoracocentesis, etc. when indicated.

ACTIVITY

Normal

DIET

No change, can add n-3 fatty acids to diet (fish oil origin).

CLIENT EDUCATION

- Emphasize that side effects are treatable and should be addressed promptly.
- Inform client that the goal is to induce remission and achieve a good quality of life for as long as possible.

SURGICAL CONSIDERATIONS

- To relieve intestinal obstructions or perforations and remove solitary masses.
- To obtain specimens for histopathologic examination.

RADIATION THERAPY

Possible option for localized lesions, such as nasal cavity or mediastinum.

MEDICATIONS

DRUG(S) OF CHOICE

- Chemotherapy—there are many variations of similar combination protocols, all with similar efficacy.
- High-grade lymphoma can respond to CHOP-based protocols (cyclophosphamide, doxorubicin, vincristine, prednisone/prednisolone) such as the University of Wisconsin–Madison protocol (alternating drugs in repeated sequence) or COP-based protocols (cyclophosphamide, vincristine, prednisone/prednisolone).
- Vinblastine has similar efficacy but less GI toxicity compared to vincristine.
- SCL can respond to oral chlorambucil (either low dose daily/every other day or high dose pulsed) and prednisone/prednisolone.
- Consult a veterinary oncologist for doses, schedules, and to help assess best option(s) for treatment.

CONTRAINdicATIONS

Avoid doxorubicin in cats with preexisting renal failure as high-cumulative dosages have been demonstrated to potentially be nephrotoxic.

PRECAUTIONS

- Myelosuppression secondary to chemotherapy—more in FeLV-positive cats.

- Seek advice before initiating treatment if you are unfamiliar with cytotoxic drugs. Some drugs such as vincristine and doxorubicin are vesicants and can cause tissue sloughing if leaked outside the vein.

POSSIBLE INTERACTIONS

None

FOLLOW-UP

PATIENT MONITORING

- Physical examination and CBC—before each chemotherapy treatment and 1 week after each new drug is administered, or if there are concerns about low cell counts.
- Diagnostic imaging—as necessary depending on location to assess response to therapy.

PREVENTION/AVOIDANCE

Avoid exposure to or breeding FeLV-positive cats.

POSSIBLE COMPLICATIONS

- Leukopenia/neutropenia.
- Sepsis.
- Anorexia, vomiting, weight loss; may need imaging tests to distinguish between chemotherapy side effects and lymphoma progression.

EXPECTED COURSE AND PROGNOSIS

- Depends on initial response to chemotherapy, anatomic type, FeLV status, and tumor burden.
- Median survival according to treatment (overall 50–70% response rate):
 - Prednisone alone—1.5–2 months.
 - COP/CHOP-based chemotherapy—6–9 months.
 - Doxorubicin-based and lomustine rescue therapy reported for refractory LSA.
 - Median survival according to FeLV status:
 - Negative = 7 months (17.5 months if low tumor burden).
 - Positive = 3.5 months (4 months if low tumor burden).
- Median survival according to anatomic location:
 - Renal—FeLV-negative, 11.5 months; FeLV-positive, 6.5 months.
 - Nasal = 1.5–2.5 years with radiation and chemotherapy.
 - Chemotherapy may not improve survival over radiation alone.
 - Higher radiation doses (> 32 Gy) result in longer survival.
- Mediastinal—about 10% of patients live > 2 years.
- Alimentary—8 months.
- Peripheral multicentric—23.5 months.
- If localized (median remission time)—114 weeks.
- Median survival according to histology (tumor grade or subtype):

LYMPHOMA—CATS

- SCL of gastrointestinal tract with or without additional visceral involvement: 95% overall response to chlorambucil and prednisone for median survival of approximately 2 years (longer in complete vs. partial remission).
- LGLL~30% response for median survival 57 days.
- Cats with Hodgkin-like lymphoma can do well for extended periods of time, even without treatment (months to years).
- Weight loss during first month of treatment of LCL associated with shorter survival.
- Clinical response after 1 cycle of COP chemotherapy associated with longer survival.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Hypoglycemia (rare)
- Monoclonal gammopathy (rare)
- Hypercalcemia (10–15%)

AGE-RELATED FACTORS

Young cats with lymphoma are generally FeLV-positive.

ZOONOTIC POTENTIAL

None

L

PREGNANCY/FERTILITY/BREEDING

Do not use chemotherapy in pregnant animals.

SYNONYMS

- Lymphosarcoma
- Malignant lymphoma

ABBREVIATIONS

- CNS = central nervous system
- FeLV = feline leukemia virus
- GI = gastrointestinal
- IHC = immunohistochemistry
- LCL = large cell lymphoma
- LGLL = large granular lymphocyte lymphoma
- LSA = lymphoma
- PARR = PCR (polymerase chain reaction) for antigen receptor rearrangement
- SCL = small cell lymphoma

LYMPHOMA—DOGS

BASICS

DEFINITION

- Clonal proliferation of B, T, or non-B-/non-T-type (null cell) lymphoblasts found primarily in enlarged peripheral lymph nodes.
- Cells can spread systemically to invade bone marrow, peripheral blood, CNS, and visceral organs.

PATOPHYSIOLOGY

- ~85% of cases are multicentric (involving more than one lymph node).
- ~75% are B-cell in origin and ~25% are T-cell in origin.
- T-cell LSA is usually associated with hypercalcemia.
- Multicentric T-cell LSA includes aggressive (PTCL-NOS) and indolent (TZL, FL) subtypes.
- Multicentric B-cell lymphoma is an aggressive disease.
- Aggressive lymphomas respond to treatment quickly, but have a shorter overall survival.

SYSTEMS AFFECTED

- Lymphatic (~85%)—generalized peripheral lymphadenopathy with or without splenic, hepatic, peripheral blood, and/or bone marrow involvement.
- Gastrointestinal (~5–7%)—focal or diffuse infiltration of intestines, and associated lymph nodes.
- Mediastinal (~5%)—proliferation of neoplastic lymphocytes in mediastinal lymph nodes, thymus, or both.
- Skin—divided into cutaneous non-epitheliotropic B- and T-cell LSA and mycosis fungoides (epitheliotropic T-cell LSA).
- Hepatosplenitis ($\gamma\delta$ T-cell LSA (rare)—liver/spleen sinusoidal infiltration of T-cells with eventual bone marrow infiltration.
- Intravascular LSA (rare)—typically T- or null cell proliferation in lumen or wall of blood vessel.

COMPARATIVE CYTOGENETICS AND GENE EXPRESSION PROFILING

- Some chromosome copy number aberrations are shared between human and canine lymphomas.
- Gene expression profiling can be used to separate distinct subtypes of human and canine lymphoma.
- Canine diffuse large B-cell lymphoma and marginal zone lymphoma may be a continuum of the same disease.

INCIDENCE/PREVALENCE

- 20–107 LSA cases per 100,000 dogs.
- LSA comprises up to 24% of all canine neoplasms and 83% of all canine hematopoietic malignancies.

SIGNALMENT

Breed Predilections

- Boxer, basset hound, golden retriever, Saint Bernard, Scottish terrier, Airedale terrier, and bulldog—reported high-risk breeds.
- Dachshund and Pomeranian—reported low-risk breeds.
- Breed determines relative risk for B-cell or T-cell disease: ~85% of

boxer LSAs are T-cell in origin, while golden retrievers develop both B- and T-cell LSA in a ~50:50 ratio.

Median Age

Historically, 6–9 years

SIGNS

History

- Multicentric—from no clinical signs to anorexia, lethargy, vomiting, diarrhea, weight loss, fever, polydipsia and polyuria secondary to hypercalcemia.
- Gastrointestinal—vomiting, diarrhea, anorexia, weight loss, malabsorption.
- Mediastinal—respiratory distress, pleural effusion, coughing, difficulty swallowing, caval syndrome.
- Skin:
 - Cutaneous LSA—lesions usually generalized or multifocal: nodules, plaques, ulcers, focal alopecia and hypopigmentation.
 - Mycosis fungoides—initial scaling, alopecia, pruritus progressing to thickened, ulcerated, exudative lesions. Later stages include proliferative plaques and nodules with progressive ulceration. Oral mucosa many times involved.
- Extranodal—vary with the anatomic site: ocular—photophobia and conjunctivitis; CNS—neurologic deficits, paresis, paralysis, seizures; hepatosplenitis—lethargy, inappetance, weakness, icterus.

Physical Examination Findings

- Multicentric—generalized, painless, enlarged peripheral lymph node(s) with or without hepatosplenomegaly.
- Gastrointestinal—unremarkable to palpable thickened gut loops and/or abdominal mass, rectal mucosal irregularities, ascites.
- Mediastinal—dyspnea; tachypnea; muffled heart sounds secondary to pleural effusion, pitting edema of head, neck, forelimbs.
- Skin—raised plaques that may coalesce, patch lesions, and erythematous, exudative lesions.
- Extranodal—ocular—anterior uveitis, retinal hemorrhages, and hyphema; CNS—dementia, seizures, and paralysis.

CAUSES

Suggested causes include heritable breed risks, chromosomal aberrations, increased telomerase activity, germline and somatic genetic mutations, epigenetic changes, retroviral infection, Epstein-Barr virus infection, and environmental factors.

DIAGNOSIS

Differential Diagnosis

- Multicentric—disseminated infections, metastatic disease, immune-mediated disorders, other hematopoietic tumors.
- Gastrointestinal—other GI tumors, foreign body, enteritis, GI ulceration, systemic mycosis.
- Mediastinal—other tumors (thymoma, chemodectoma, ectopic thyroid), infectious disease.
- Skin—infestive

dermatitis, pyoderma, immune-mediated dermatitis, histiocytic or mast cell disease.

- Extranodal—depends on affected site.

STAGING

CBC/Biochemistry/Urinalysis

- Anemia of chronic disease, thrombocytopenia, lymphocytosis, lymphopenia, neutrophilia, monocytosis, circulating blasts, hypoproteinemia (gastrointestinal).
- Hypercalcemia, increased liver enzymes with hepatic involvement, increased BUN or creatinine with renal involvement.
- Urinalysis usually normal.

Imaging

- Thoracic radiography—sternal or tracheobronchial lymphadenopathy, widened mediastinum, pulmonary densities, and pleural effusion.
- Abdominal ultrasonography—abdominal lymphadenopathy, hepatosplenic involvement, thickened bowel loops, other visceral organ involvement, ascites.

Diagnostic Procedures

- Fine-needle aspirate cytology of enlarged lymph nodes or other affected organs—for cytopathologic confirmation.
- Lymph node biopsy or resection—for accurate histopathologic classification.
- Bone marrow cytology—for accurate prognosis.
- CSF analysis—if patient has neurologic signs.
- ECG—identify arrhythmias before doxorubicin administration.

Other Laboratory Tests

- Immunohistochemistry (LN biopsy/resection)—to determine immunophenotype.
- Flow cytometry or PCR for antigen receptor rearrangements (PARR) (LN or affected organ fine-needle aspirates)—to determine immunophenotype.

Pathologic Findings

- Multicentric—effacement of LN parenchyma with large, neoplastic CD3+ T cells (PTCL-NOS) or small, CD3+ cell proliferation between fading follicles (indolent TZL). Effacement of LN parenchyma with large, neoplastic CD79a+ B cells (high-grade DLBCL) or perifollicular proliferation of CD79a+ cells (MZL) or CD79a+ cell proliferation that maintains follicle architecture (FL).
- Gastrointestinal infiltration of neoplastic lymphocytes throughout mucosa and submucosa, with occasional transmural infiltration.
- Skin—CD79a+ B-cells infiltrating mucosa and submucosa, but sparing the epidermis (non-epitheliotrophic) LSA or CD3+ T-cells invading the epidermis—Pautrier's microabscesses (mycosis fungoides).
- Hepatosplenitis—sinusoidal infiltration of erythrophagocytic CD3+ T-cells.

Staging

- I—one enlarged LNII—regionally enlarged LNs
- III—generalized LN involvement
- IV—visceral organ involvement
- V—blood

(CONTINUED)

or bone marrow involvement • Substage a—not sick • Substage b—sick

TREATMENT

CURRENT STANDARDS OF CARE

- High-grade LSAs are exquisitely sensitive to both chemotherapy and radiation.
- Systemic multi-agent chemotherapy—therapy of choice.
- Radiation therapy—for refractory lymphadenopathy, large mediastinal masses, and solitary cutaneous areas.
- Surgery—rarely used unless an acutely obstructive gastrointestinal mass is identified or to remove a refractory lymphadenopathy.
- Autologous and allogeneic bone marrow transplantation can be considered.

OTHER TREATMENTS

Fluid therapy—for advanced disease to treat clinically ill, azotemic, and/or dehydrated patients. Also to prevent tumor lysis syndrome and/or reduce calcium levels.

CLIENT EDUCATION

- Canine LSA is a treatable, but rarely curable disease.
- Side effects of chemotherapy drugs include reversible gastrointestinal tract and bone marrow toxicities.
- The vast majority of dogs receiving chemotherapy enjoy an excellent quality of life.

MEDICATIONS

DRUG(S) OF CHOICE

- Always consult a veterinary oncologist to discuss various treatment options, precautions, chemotherapy dosing schedules, and potential side effects.
- Consider combination chemotherapy protocols to treat intermediate and high-grade diseases and single agent protocols to treat indolent diseases.
- Most multi-agent protocols have superior remission and survival times when compared to single agent protocols.
- Corticosteroids alone can induce significant multi-drug resistance.

Intermediate and High-Grade Lymphomas

- L-CHOP—L-asparaginase 10,000 IU/m², vincristine (Onvcovin) 0.7 mg/m² IV, cyclophosphamide (Cytoxan) 250 mg/m² IV or PO, doxorubicin (Adriamycin) 30 mg/m² IV, prednisone 30, 20, 10 mg/m² PO q24h tapering for 3 weeks. Consult a veterinary oncologist concerning the treatment schedule.
- COP—vincristine 0.7 mg/m² IV, cyclophosphamide (Cytoxan) 250 mg/m² IV or PO, prednisone 30, 20, 10 mg/m² PO q24h tapering for 3 weeks. Each drug given weekly.

Single Agent

- Any drug of L-CHOP can be used as a single agent, but expect shorter overall

survival than multiagent.

- Doxorubicin (Adriamycin) 30 mg/m² IV every 3 weeks (1 mg/kg for dog < 15 kg) 5–6 treatments.
- CCNU (lomustine) 70 mg/m² PO every 3 weeks, prednisone 2 mg/kg PO daily.

Low-Grade Lymphomas

- Chlorambucil (Leukeran) 6 mg/m² PO daily for 7–14 days, prednisone 2 mg/kg PO daily. Consider reducing chlorambucil dose to 3 mg/m² for maintenance.
- CCNU (lomustine) as above.

PRECAUTIONS

- Doxorubicin—use dextrazoxane (Zinecard) in conjunction with doxorubicin or substitute epirubicin for dogs with cardiac issues.
- Always use a freshly placed catheter when administering intravenous doxorubicin.
- L-asparaginase and doxorubicin—pretreat with diphenhydramine (1–2 mg/kg SC) 15 minutes before administration.

POSSIBLE INTERACTIONS

Most chemotherapy drugs have overlapping gastrointestinal and bone marrow toxicities. Consider anti-diarrheal (metronidazole, loperamide) and antiemetics (metoclopramide, maropitant, ondansetron) to abrogate these effects.

ALTERNATIVE (RESCUE) PROTOCOLS

- Many published rescue protocols have been reported; therefore always consult with a medical oncologist.
- MOPP—methchlorthamine (Mustargen), vincristine, procarbazine, and prednisone.
- DMAC—dexamethasone, melphalan, actinomycin-D, and cytosine arabinoside.
- CCNU ± L-asparaginase, prednisone, or DTIC (dacarbazine).
- Mitoxantrone alone or Adriamycin/DTIC.

FOLLOW-UP

PATIENT MONITORING

- Weekly physical examination to assess response and CBC to gauge bone marrow toxicities.
- If neutropenia (neutrophils < 1,500 cells/mm³) is noted, reduce dosage (20–25%) of drug when given again.

MOST COMMON COMPLICATIONS

- Reversible neutropenia 4–7 days after chemotherapy.
- Temporary vomiting, diarrhea, and anorexia 2–5 days after chemotherapy.
- Alopecia in certain dog breeds (poodle, Shih Tzu, etc.).
- Febrile neutropenia (treated with broad-spectrum antibiotics).

EXPECTED COURSE AND PROGNOSIS

- > 80% of dogs will go into clinical remission during the first month of induction chemotherapy.
- Stage, substage, and immunophenotype are important prognostic indicators.
- Expect median survivals of ~12–14 months and ~6–9 months in dogs

LYMPHOMA—DOGS

with high-grade multicentric B- and T-cell LSA, respectively, when treated with a multi-agent protocol. Dogs with indolent disease can live years. Gastrointestinal, mediastinal (T-cell ± hypercalcemia), and mycosis fungoides are associated with poorer response to treatment and an overall shorter survival time.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Treatment of pregnant dogs is usually contraindicated.

SYNONYMS

- Lymphosarcoma • Malignant lymphoma

SEE ALSO

- Hypercalcemia • Leukemia, Acute Lymphoblastic • Leukemia, Chronic Lymphocytic

ABBREVIATIONS

- CNS = central nervous system
- DLBCL = diffuse, large B-cell lymphoma
- FL = follicular LSA
- LN = lymph node
- LSA = lymphoma
- MZL = marginal zone lymphoma
- PTCL-NOS = peripheral T-cell lymphoma—not otherwise specified
- TZL = T-zone lymphoma

L

LYMPHOMA, CUTANEOUS EPITHELIOTROPIC

BASICS

OVERVIEW

- Cutaneous epitheliotropic lymphoma (CEL)—most common form of cutaneous T-cell lymphoma.
- An uncommon malignant neoplasia of dogs and cats.
- Sézary syndrome—rare; cutaneous lesions, invasion of peripheral lymph nodes by neoplastic lymphocytes, and leukemia occur simultaneously.
- Pagetoid reticulosis—rare; the lymphoid infiltrate is confined to the epidermis and adnexal structures in the early stages of the disease and extends to the dermis in the late stages.

SYSTEMS AFFECTED

- Hemic/Lymphatic/Immune
- Skin/Exocrine

SIGNALMENT

- Dogs and cats—most common in dogs.
- Age range 6–14 years—mean 8.6 years.
- No apparent breed or sex predilection.

SIGNS

Historical Findings

- Chronic skin disease—months before diagnosis
- Rarely acute
- Mimics other inflammatory dermatoses
- None to severe pruritus

Physical Examination Findings

- Four clinical categories of presentation:
- Exfoliative erythroderma: generalized erythema, scaling, depigmentation, alopecia
- Mucocutaneous: depigmentation, erythema, erosion, and ulceration affecting mucocutaneous junctions
- Tumoral: solitary or multiple erythematous and scaly plaques, nodules, and masses
- Oral mucosal ulceration of gingiva, palate, and/or tongue.
- Lesions—typically throughout the skin; marked tendency for involvement of mucocutaneous junctions or oral cavity; lesions can be limited to the mucocutaneous junctions or oral mucosa.
- Exfoliative erythroderma; progression to the tumor stage is very rapid in dogs compared to humans.
- Mucocutaneous form and oral mucosa form: tend to merge with chronicity.
- Rarely nodules develop without a preexisting patch or plaque stage (d'emblee form).
- Nodular stage may occasionally progress to a disseminated form with lymph node involvement, leukemia, and rarely other organs.

CAUSES & RISK FACTORS

None identified; possible risk of development of chronic antigenic stimulation (including allergy) theorized.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dermatophytosis, demodicosis, feline

thymoma-associated exfoliative dermatitis—alopecia, erythema, scaling.

- Allergic dermatitis and sarcoptic acariasis—generalized pruritus, erythema, scaling.
- Discoid lupus erythematosus, erythema multiforme, mucocutaneous pyoderma—mucocutaneous depigmentation/ulceration.
- Non-neoplastic stomatitis—infiltrative and ulcerative oral mucosal disease.
- Cutaneous neoplasia—nodule or mass formation.

CBC/BIOCHEMISTRY/URINALYSIS

- Laboratory abnormalities—vary depending on the stage and form of CEL, and whether or not the disease has disseminated.
- Generally unremarkable if only the skin or mucosa is affected.
- Sézary cells—neoplastic lymphocytes (8–20 μm) with convoluted nucleus and cerebriform appearance are present in peripheral blood of Sézary syndrome patients.

IMAGING

Radiographs and ultrasound—imaging if signs of systemic disease present and/or for tumor staging.

DIAGNOSTIC PROCEDURES

- Skin scrapings and fungal culture—demodicosis and dermatophytosis.
- Skin biopsy—definitive diagnosis; sample multiple different-appearing lesions, avoid eroded/ulcerated and infected lesions.

PATHOLOGIC FINDINGS

- Infiltrate of neoplastic lymphocytes—into epidermis, hair follicle epithelium, and adnexa; distributed diffusely or as discrete Pautrier microaggregates.
- Dermal infiltrate—polymorphous; malignant lymphocytes may obscure the dermoepidermal junction; patch and plaque stages, limited to the superficial dermis; nodular stage, extends to the deep dermis and subcutis.
- Immunohistochemical tissue staining reveals a predominance of CD8+ cytotoxic T-cells (dogs).

TREATMENT

- Goal is to maintain a good quality of life.
- Therapy is rarely curative.
- Rarely, solitary nodules can be surgically excised.
- Radiation therapy: total skin electron beam therapy or orthovoltage radiation is well tolerated and may be beneficial in some cases.

MEDICATIONS

DRUG(S)

- Chemotherapy—several protocols used with limited to no success.
- Lomustine (CCNU)—overall response rate of 80% with remission achieved in about 25% of cases (60–70 mg/m² PO every 3–4 weeks for a mean of 3 to 5

treatments).

- Dacarbazine—1000 mg/m²; complete and durable remission after 3 cycles in a dog with nodal involvement.
- Pegylated liposomal doxorubicin—44% response rate in dogs (average dose, 1 mg/kg IV every 3 weeks).
- Combination protocol with cyclophosphamide, doxorubicin, vincristine, and prednisolone—partial to complete response in a few dogs that failed lomustine therapy.
- High doses linoleic acid (e.g., sunflower oil)—3 mL/kg orally twice weekly; good improvement in 7/10 dogs for up to 2 years.
- Topical chemotherapy—mechlorethamine (nitrogen mustard); some success in managing early lesions; however, lack of long-term efficacy: carcinogenic potential for owner and veterinary staff.
- Corticosteroids—topical and/or systemic may result in some symptomatic relief.
- Retinoids—isotretinoin (3 mg/kg/day) or acitretin (2 mg/kg/day) may be beneficial; cost can be a limiting factor.
- Imiquimod—a topical immunomodulator with antineoplastic and antiviral effects may be useful for localized disease. No published reports in veterinary literature.

CONTRAINdications/POSSIBLE INTERACTIONS

- Depend on the chemotherapeutic or treatment protocol.
- Seek advice from a veterinary oncologist or dermatologist before initiating therapy if you are unfamiliar with cytotoxic drugs and/or to learn about the most recent treatment protocols.

FOLLOW-UP

- Prognosis grave.
- Average survival time for dogs depends upon stage of disease at diagnosis, therapeutic choice, and response to therapy; varies from a few weeks to longer than 18 months.
- Rarely, dogs and cats may live for longer than 2 years after the diagnosis is made.
- Death is usually the result of euthanasia.

MISCELLANEOUS

SYNONYMS

- Lymphoma, epidermotropic
- Mycosis fungoïdes

LYMPHOMATOID GRANULOMATOSIS

BASICS

OVERVIEW

- Lymphomatoid granulomatosis is a rare lymphoproliferative disorder predominantly involving the lungs.
- Rare pulmonary disease of dogs and cats characterized by angiocentric and angiodestructive proliferation and infiltration by atypical lymphoid cells.

SIGNALMENT

- Dog and cat
- Median age—5.75 years (range, 1.5–14 years) in dogs
- No breed predilection but more common in large breeds and pure breeds
- No gender predisposition

SIGNS

- Progressive respiratory signs including cough and dyspnea
- Serous nasal discharge
- Exercise intolerance
- Weight loss
- Anorexia
- Fever in 50% of patients
- Duration—days to weeks

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mycotic, bacterial, or aspiration pneumonia
- Primary or metastatic pulmonary neoplasia
- Atypical pulmonary lymphoma

CBC/BIOCHEMISTRY/URINALYSIS

- No consistent abnormalities
- Neutrophilic leukocytosis, eosinophilia, and basophilia may be common

OTHER LABORATORY TESTS

Some dogs have concurrent heartworm disease and/or test positive for heartworms.

IMAGING

- Radiography—reveals lobar pulmonary consolidation (e.g., mass lesions), hilar lymphadenomegaly, and pleural effusion.
- Lesions—unilateral or bilateral.

DIAGNOSTIC PROCEDURES

- Biopsy—for definitive diagnosis (adequate tissue sample size required for accurate diagnosis).
- Immunohistochemistry is required on the biopsied tissue (CD3, CD20, CD79).

PATHOLOGIC FINDINGS

- Gross—multiple pulmonary nodules with a predilection for the caudal lung lobes with metastasis or involvement of hilar lymph nodes.
- Histologic—characterized by sheets of atypical lymphoid and plasmacytoid cells admixed with fewer eosinophils and small lymphocytes in the pulmonary blood vessels. The lymphocytes can be of B-cell and T-cell lineage, with Reed-Sternberg-like cells reported.
- Cytologic—may appear as sterile eosinophilic and neutrophilic inflammation with reactive macrophages.
- Systemic spread is possible—to liver, heart, kidneys, spleen, pancreas, adrenal gland, and other organs.

TREATMENT

- Cytotoxic drugs combined with surgical excision when appropriate.
- Always consult a veterinary oncologist.

MEDICATIONS

DRUG(S)

Combination protocol—CHOP or other combination protocol suitable for lymphoma. No standard treatment protocol has been systemically evaluated.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Myelosuppression—caused by cytotoxic drugs
- Hemorrhagic cystitis—caused by cyclophosphamide

FOLLOW-UP

PATIENT MONITORING

Same as for lymphoma treated by chemotherapy

POSSIBLE COMPLICATIONS

- Dyspnea as disease progresses
- Depression
- Anorexia
- Myelosuppression caused by chemotherapy

EXPECTED COURSE AND PROGNOSIS

Median survival in dogs with systemic chemotherapy has been reported to be approximately 12 months; however, range for survival may be broad based upon initial response to therapy. The reported survival is compounded by the difficulty of accurately diagnosing the disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS

No known definitive associations

SYNOMYMS

- Eosinophilic pulmonary granulomatosis
- Granulomatosis
- Lymphoid granulomatosis
- Lymphoproliferative angiitis

ABBREVIATION

CHOP = cyclophosphamide, hydroxydaunorubicin (doxorubicin), vincristine (Oncovin), and prednisone

L

LYSOSOMAL STORAGE DISEASES

BASICS

OVERVIEW

- Inherited disorders caused by partial or complete deficiency of a lysosomal enzyme or an enzyme-activator protein, which leads to intracellular accumulation (storage) of the substrate of that enzyme.
- Storage products—proteins, carbohydrates, lipids, or a combination.
- Classes of diseases—proteinoses, glycoproteinoses, oligosaccharidoses, sphingolipidoses, mucopolysaccharidoses.
- Many different types reported in dogs and cats.
- Inheritance is autosomal recessive.

SIGNALMENT

- Dog—German shepherd, German shorthaired pointer, English setter, beagle, cairn terrier, bluetick hound, West Highland white terrier, Sydney silky terrier, English springer spaniel, Portuguese water dog, Japanese spaniel, Labrador retriever, American bulldog, Irish setter, mixed-breed dogs, many others.
- Cats—Persian, Siamese, Korat, Balinese, domestic shorthair.
- Most affected animals <1 year old; a few adult-onset diseases described, with onset as late as 2 years old, or older.

SIGNS

General Comments

- Vary with severity of the enzyme deficiency.
- In certain diseases, carrier animals can be affected with a milder form of the disease.
- Many organ systems are affected, but neurologic signs tend to predominate.

Historical Findings

- Affected animals are normal at birth.
- Fail to thrive and may manifest skeletal malformations, particularly in the mucopolysaccharidoses.
- Neurologic signs within the first few months of life suggest multifocal neurologic disease.

Physical/Neurologic Examination Findings

- Cerebellar dysfunction common—intention tremor, nystagmus, dysmetria.
- Peripheral neuropathy occurs in some diseases—weakness, hyporeflexia or areflexia, wasting.
- Other neurologic signs—ataxia; exercise intolerance; seizures; behavioral changes; visual deficits, deafness, stereotypical behaviors, proprioceptive deficits, tremors.
- Non-neurologic signs—may see organomegaly or skeletal malformations.
- Ocular pathology in some diseases—corneal opacification, cataract formation.

CAUSES & RISK FACTORS

- Genetic—deletion or mutation involving a single gene that causes an absolute or partial deficiency of a lysosomal enzyme or activator protein; deficient production of enzymes that

do not have normal biologic activity.

- Susceptible breed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Metabolic encephalopathy—usually episodic clinical signs; results of CBC, biochemistry, and urinalysis often diagnostic.
- Toxicities—acute onset of clinical signs; history of exposure.
- Cerebellar hypoplasia—onset at 3–6 weeks of age; non-progressive.
- Cerebellar abiotrophy—deficits limited to the cerebellum; may be difficult to differentiate in the early stages without specific tests.
- Prenatal or neonatal infections (especially viral) resulting in meningoencephalomyelitis—differentiated by CSF analysis; may be other signs, such as chorioretinitis.
- Metabolic diseases—especially organic and amino acidurias.

CBC/BIOCHEMISTRY/URINALYSIS

- Regular blood smears and CSF analysis—cytoplasmic vacuolation of leukocytes caused by accumulation of storage products is present in some cases.
- Urine—may find abnormal accumulation of substances (e.g., oligosaccharide in a-mannosidosis).

OTHER LABORATORY TESTS

N/A

IMAGING

- Radiography—bony malformation may be present in diseases in which skeletal pathology is a feature (e.g., mucopolysaccharidoses).
- Magnetic resonance imaging—used in one case to reveal diffuse white matter pathology in the brain of a dog with globoid cell leukodystrophy.

DIAGNOSTIC PROCEDURES

- Molecular genetic testing—available for the diagnosis of many lysosomal storage diseases; may be used to identify potential carriers.
- Aspirates or biopsies of parenchymal organs, particularly the liver and spleen, may reveal intracellular storage material.
- Biochemical tests—diagnosis may be made by demonstrating low enzyme activity or presence of accumulated substrate or metabolic intermediates in preparations of serum, brain, viscera, leukocytes, or skin fibroblasts.
- Electromyography and nerve conduction studies—abnormal in diseases in which peripheral neuropathy or myopathy is a feature.
- Biopsy of peripheral nerve or skeletal muscle may demonstrate specific pathology.

TREATMENT

- Outpatient—unless severe deficits preclude nursing care at home.
- Activity—restrict to

safe areas; avoid stairs.

- Diet and fluids—ensure proper intake in patients often debilitated; parenteral fluid therapy and enteral or parenteral nutritional support may be needed with severe disease.
- Bone marrow transplantation—used experimentally with some success.
- Gene therapy—area of intense research that may offer hope for specific treatment.
- Enzyme replacement therapy—intrathecal enzyme replacement has shown some efficacy in an experimental setting.
- Primary treatment—preventive; control of breeding; genetic counseling.
- Patients may be at risk of developing secondary infection; initiate appropriate treatment if infection develops.

MEDICATIONS

DRUG(S)

N/A

FOLLOW-UP

- Progressive; ultimately fatal.
- Pedigree analysis—useful in diagnosis; important for identification of potential carrier animals.

MISCELLANEOUS

ABBREVIATION

- CSF = cerebrospinal fluid

MALASSEZIA DERMATITIS

BASICS

OVERVIEW

- *Malassezia pachydermatis* (syn. *Pityrosporum canis*)—yeast; commensal of the skin, ears, and mucocutaneous areas; can overgrow causing dermatitis, cheilitis, and otitis externa.
- *M. pachydermatis* is lipid-loving, others are lipid-dependent. • Yeast numbers in diseased areas are usually excessive, although this is a variable finding. • The transformation from harmless commensal to pathogen related to allergy, seborrheic conditions, and congenital and hormonal factors.

SYSTEMS AFFECTED

Skin/Exocrine

SIGNALMENT

- Dog—any breed; West Highland white terrier, poodle, basset hound, cocker spaniel, and dachshund predisposed. • Cat—less common; associated with internal neoplasia in aged cats; affects all breeds; however, young Rex cats are predisposed. • No gender predilection. • *Malassezia* dermatitis and *Malassezia*-associated seborrheic dermatitis—common worldwide.

SIGNS

- Pruritus variable; erythema, alopecia, scale, and greasiness of lips, ears, feet, axillae, inguinal area, and ventral neck; malodor.
- Hyperpigmentation and lichenification—chronic cases. • Concurrent black waxy to seborrheic otitis—frequent. • Frenzied facial pruritus—uncommon but characteristic.
- Often an allergy history that worsens and develops glucocorticoid tachyphylaxis.
- Concurrent bacterial folliculitis, hypersensitivity, endocrine and seborrheic dermatitis.

CAUSES & RISK FACTORS

- High humidity and temperature—may increase the frequency. • Concurrent hypersensitivity disease (particularly atopy, flea allergy, and some food allergy/intolerances)—may be a predisposing factor.
- Seborrheic dermatitis (young dogs)—in predisposed breeds. • Endocrinopathy—suspected predisposing factor. • Genetic factors—in predisposed dog breeds and Rex cats. • Concurrent increase in cutaneous *Staphylococcus pseudintermedius* and bacterial folliculitis—confirmed finding; in some cases, canine seborrheic dermatitis with overgrowth of both; treatment of one produces partial resolution and unmasks the other; antiyeast treatment only resolves signs of *Malassezia* dermatitis. • Cats have a young and an adult-age disease, and can be allergy-associated. In Rex cats, genetic factors of the skin and/or their predisposition to a mast cell

abnormality called urticaria pigmentosa are speculative risk factors. Aged cats: *Malassezia* dermatitis associated with thymomas and carcinomas of the pancreas and liver.

DIAGNOSIS

Diagnosis by demonstrating excessive numbers of the organism on diseased skin, and a significant improvement in clinical signs following removal of the yeast.

DIFFERENTIAL DIAGNOSIS

- Allergic dermatitis—including flea allergy, atopy, and cutaneous adverse reaction to food
- Superficial bacterial folliculitis • Primary and secondary seborrhea (keratinization defect)
- Acanthosis nigricans—dachshund

CBC/BIOCHEMISTRY/URINALYSIS

Normal unless affected by underlying cause

OTHER LABORATORY TESTS

- Fungal culture—use contact plates (small agar plates made from bottle lids and filled with Sabouraud agar or modified Dixon agar, especially in the cat); press plates onto the affected skin surface; incubate at 32–37°C for 3–7 days; count the distinctive yellow or buff, round, domed colonies (1–1.5 mm); provides semi-quantitative data. • Non-quantitative culture methods—no value because *Malassezia* is a normal commensal.

DIAGNOSTIC PROCEDURES

- Skin cytology—touch, cotton swab, or cellophane tape preparation stained with Diff-Quik; apply stain as a drop directly onto the slide (yeast may wash off during staining); pass a flame under the slide to improve stain penetration and visualization. • Greasy and/or scaly areas are most likely to produce positive results.

TREATMENT

- Identify and treat any predisposing factors or diseases. • Topical therapy—yeast is principally located in the stratum corneum.
- Shampoo treatment—to remove scale and exudation. • Topical therapies (based on trial data)—miconazole and chlorhexidine shampoo most effective; selenium sulfide shampoo less effective but useful; twice-weekly treatments. • Other topical antifungal and antibacterial shampoo treatments (e.g., ketoconazole) also of value if given with suitable systemic medications.
- Alternative combinations—topical keratolytic shampoo treatment with systemic antiyeast and antibacterial drugs.

MEDICATIONS

DRUG(S)

- Localized cases—may respond to creams and lotions containing imidazole compounds.
- Ketoconazole 10 mg/kg q24h for 2–4 weeks in widespread or chronic lichenified cases. Fluconazole 10 mg/kg q24hr. Itraconazole 5 mg/kg q24hr. • Other imidazoles also effective. • Chronic lichenified cases—ketoconazole (7–10 mg/kg q24h) as a short diagnostic for 7–10 days with effective topical antimycotic shampoo treatment; a good response confirms the diagnosis; response may be slow in chronic cases in which yeasts are buried deep in epidermal folds. • Topical antimicrobial antibacterial shampoo—to maintain remission in chronic cases.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Ketoconazole—rarely may cause hepatic reaction; masks signs of hyperadrenocorticism and interferes with adrenal function tests due to blocking of cortisol production (via inhibition of P450) in the adrenal gland; contraindicated in cats with hepatic and severe debilitating internal malignancy as they may not be able to metabolize the drug.

FOLLOW-UP

- Physical examination and skin cytology—after 2–4 weeks, to monitor therapy. • Treat until only rare organisms can be demonstrated or 7 days after a complete response is achieved. • Pruritus and odor—usually noticeably improved within 1 week.
- Recurrences—common when underlying dermatoses are not well controlled; regular bathing with antifungal antibacterial shampoo combinations helps decrease recurrence.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Ketoconazole contraindicated

Consulting Editor Alexander H. Werner

MALIGNANT FIBROUS HISTIOCYTOMA

BASICS

OVERVIEW

- Name based on histologic features of fibroblast- and histiocyte-like cells.
- A group of primitive pleomorphic mesenchymal neoplasms, but definitive cellular origin unknown; likely possibilities include fibroblasts, histiocytes, and undifferentiated mesenchymal cells.
- Several histologic variants.
- Storiform-pleomorphic and giant cell—two major variants; both locally invasive; firm, subcutaneous, or visceral masses on examination.
- Despite previous reports to the contrary, metastatic potential in dogs appears to be moderate to high.
- Have been reported as injection site-related sarcomas of cats.

SIGNALMENT

- More commonly reported in cat than in dog.
- Similar biologic behavior in both species.
- Mean age—cats: 9 years (range, 2–12 years); dogs: 8 years (range, < 1–10 years).
- No proven breed or sex predilection, although flat-coated retrievers, rottweilers and golden retrievers appear overrepresented and may be predisposed.

M

SIGNS

Historical Findings

- Anorexia, weight loss, and lethargy may occur.
- Dependent upon on site of involvement.

Physical Examination Findings

- Firm, invasive tumor arising in subcutaneous tissue.
- May exhibit deep extension into underlying skeletal muscle.
- May develop adjacent to bone and induce bone destruction and proliferation.
- Most common sites—dorsal thoracic and scapular area, limbs, and pelvic region.
- May also be a primary splenic tumor in dogs; palpable splenomegaly may be found.
- Distant metastasis—common.

CAUSES & RISK FACTORS

- Unknown
- Can be induced with carcinogens in laboratory animal species
- Injection sites in cats

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other soft tissue sarcoma (e.g., fibrosarcoma, leiomyosarcoma)
- Chondrosarcoma
- Osteosarcoma (extraskeletal)
- Liposarcoma
- Peripheral nerve sheath tumors
- Histiocytic diseases, such as histiocytic sarcoma or systemic histiocytosis
- Mast cell neoplasia

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—may vary; may be normal; may see regenerative or nonregenerative anemia.
- Biochemistry—variably abnormal.
- Urinalysis—usually normal.

OTHER LABORATORY TESTS

Cytologic examination of aspirate—may reveal histiocyte- and fibroblast-like cells.

IMAGING

- Radiography—reveals soft tissue dense mass; may note bone proliferation or destruction.
- Three-view thoracic radiography to check for lung metastasis.
- MRI or CT may be superior for delineating extent of tumor invasion into surrounding tissues.
- Ultrasonography may detect abnormalities consistent with abdominal metastasis (most common in lymph nodes and liver).

DIAGNOSTIC PROCEDURES

Histologic examination of biopsy specimen—necessary for definitive diagnosis.

PATHOLOGIC FINDINGS

- Classification—considerable debate exists among pathologists, which may account for the apparent differences in behavior reported in the literature.
- Storiform-pleomorphic (may be called inflammatory) and giant cell (also called osteoclast-like) are the two major variants reported. Myxoid variant also described.
- Many are histologically high grade.
- Specialized immunohistologic stains, such as CD18, vimentin, desmin, alpha-smooth muscle actin, extra domain 1 (ED1), and/or azan (for collagen) may aid classification. Definitive staining patterns have not been clearly identified.
- Recent report of considerable overlapping histopathologic characteristics with histiocytic diseases in the splenic form.

TREATMENT

- Surgical excision—difficult owing to local invasive nature; recurrence rate is high.
- Amputation of an affected limb—may be appropriate; thoracic and abdominal radiographs and abdominal ultrasound critical for evaluating detectable metastasis before amputation.
- Radiotherapy may be helpful as adjuvant treatment for localized tumor not amenable to complete surgical resection. Expected local tumor control rates may be similar to other high-grade soft tissue sarcomas.

MEDICATIONS

DRUG(S)

Chemotherapy—may be helpful in residual, high-grade tumor or metastatic disease setting; doxorubicin-based protocols are most commonly instituted (dose for canine patients > 10 kg, 30 mg/m² IV every 3 weeks; patients < 10 kg, 1 mg/kg IV every 3 weeks).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Reexamination—metastatic potential would suggest physical examination and possible imaging; monthly for 3 months, then every 3 months thereafter.

POSSIBLE COMPLICATIONS

Temporary acute side effects (e.g., moist dermatitis and alopecia) may be expected with radiation therapy, and consultation with a radiation oncologist is recommended regarding specific, anatomic site-related side effects.

MALOCCLUSION—SKELETAL AND DENTAL

BASICS

DEFINITION

- **Malocclusion:** any deviation from normal occlusion due to abnormal positioning of a tooth (dental malocclusion) or due to asymmetry or deviation of bones that support the dentition (skeletal malocclusion).
- **Ideal occlusion:**
 - Maxillary incisors positioned rostral to the mandibular incisors.
 - Mandibular canine is inclined labially and bisects the space between the opposing maxillary third incisor and canine.
 - Maxillary premolars do not contact the mandibular premolars; mandibular premolar crowns are positioned lingual to the maxillary premolars; mandibular premolar crown cusps bisect the interdental spaces rostral to the corresponding maxillary premolar.
 - Maxillary fourth premolar mesial cusp is lateral to the space between the mandibular fourth premolar and first molar.

Terms of Malocclusion (American Veterinary Dental College Nomenclature)

- Neutroclusion (Class 1): a normal rostral-caudal relationship of the maxillary and mandibular dental arches with malposition of one or more individual teeth (dental malocclusion); rostral (anterior) crossbite; mesioversion ("lance tooth") linguoversion ("base-narrow mandibular canine) and caudal (posterior).
- Mandibular distoclusion (Class 2): an abnormal rostral-caudal relationship in which the mandibular arch occludes caudal to its normal position relative to the maxillary arch (skeletal malocclusion).
- Mandibular mesioclusion (Class 3): an abnormal rostral-caudal relationship in which the mandibular arch occludes rostral to its normal position relative to the maxillary (skeletal malocclusion).
- Asymmetrical skeletal malocclusion: maxillary-mandibular asymmetry that can occur in a rostro-caudal direction (unilateral abnormal relationship), in a side-to-side direction (loss of midline alignment), or in a dorso-ventral direction with abnormal vertical space between opposing dental arches (open bite).
- "Wry bite": a nonspecific term used to describe a variety of unilateral occlusal abnormalities.

SIGNALMENT

Species

Dogs and cats

Breed Predilections

Breed predilection for certain malocclusions

Mean Age and Range

Malocclusion usually apparent after eruption of teeth (permanent or deciduous).

SIGNS

- Vary greatly according to type, extent, and consequent injuries caused by the

malocclusion.

- May be associated with open or closed bites or overcrowding of the teeth.
- Periodontal disease—from crowding or misalignment of teeth.
- Soft tissue defects—from traumatic tooth contact; may be seen in the floor of the mouth and palate; palatal trauma may eventually result in oronasal fistula formation.
- Fractures or attrition (wear) of teeth—may result from improper tooth contact.

Class 1 Malocclusions

- Rostral (anterior) crossbite—palatally displaced maxillary incisors or labially displaced mandibular incisors; level bite—maxillary and mandibular cusps contact directly.
- Base-narrow canines—tips of mandibular canines touch palate lingual to normal contact point, just labial to the diastema between corner incisor and maxillary canine (linguoversion).
- Lance teeth—mesioversion of maxillary canine(s); the diastema between the corner incisor and this canine is often diminished and may force the mandibular canine into an abnormal position. dolichocephalic breeds (e.g., shelties and collies).
- Caudal (posterior) crossbite—most are due to reversal of the relationship (labial/lingual) between the upper and lower carnassial teeth; more common in dolichocephalic breeds (e.g., collies, shelties, some sight hounds).

CAUSES

- Congenital or hereditary factors—skeletal malocclusions (Classes 2, 3, and 4) and breed predilection.
- Impediment to tooth eruption—operculum; retention of soft tissue covering.
- Delayed eruption of deciduous or permanent teeth.
- Retention (persistent) or delayed loss of deciduous teeth; permanent mandibular canines will erupt lingual to persistent deciduous teeth.
- Traumatic injury affecting the jaws or teeth.

RISK FACTORS

Hereditary predispositions

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Tooth displacement—due to trauma, oral masses, or other causes.
- Mechanical block—due to jaw fractures, luxated or subluxated teeth, or foreign bodies causing open bite.
- Examine breed standards to determine what might be acceptable for the breed.

CBC/BIOCHEMISTRY/URINALYSIS

Generally normal

IMAGING

- Oral photography—pre-, peri-, and post-therapy.
- Intraoral radiography—to evaluate roots and abnormalities, jaw anatomy, root maturity

DIAGNOSTIC PROCEDURES

- Complete oral examination to assess other oral abnormalities, including persistent deciduous teeth.
- Impressions and models—for evaluation and appliance manufacture.

TREATMENT

APPROPRIATE HEALTH CARE

- The accurate assessment of abnormalities of occlusion will help determine if treatment is warranted and what treatment is appropriate.
- Extraction of offending teeth can many times be an effective alternative to more classic orthodontic treatments.
- Not every malocclusion needs orthodontic correction. If the bite is functional and non-traumatic to the animal, treatment may not be necessary.
- Additionally, extraction (or crown reduction with pulp capping) of offending teeth often can be an effective alternative to more classic orthodontic treatments.
- Orthodontic treatment is usually based on prevention of improper contact trauma, wear, or injury to hard or soft tissues, and should only be performed by a trained individual.

DIET

Soft diet with appliances

CLIENT EDUCATION

Home Care with Appliance

- Examine the appliance twice daily.
- Flush the mouth with an oral hygiene solution or gel.
- Prevent chewing of items and provide a soft diet until the appliance is removed.

SURGICAL CONSIDERATIONS

Permanent Tooth Class 1 Malocclusion

- Treatment primarily involves tipping movements of the teeth, although extrusion may be required to provide proper retention.
- Rostral crossbite—arch crowding; may require odontoplasty to thin teeth (to allow room for movement).
 - Movement can be accomplished but is likely complicated and should be handled by a specialist.
- Base-narrow canine teeth—treatment is aimed at prevention of contact trauma, pain and discomfort, and oronasal fistula formation.
 - The diastema (space between the maxillary third incisor and canine) must be sufficient for the mandibular canine to fit; once occluding correctly in the diastema, the closed bite serves as a natural retainer.
 - If the mandibular canines have just started to erupt into a lingual position, manual manipulation or "ball therapy" may influence a more buccal eruption sequence; the deciduous teeth and roots must be completely absent.
 - A hard rubber ball (hand ball, etc.) can be placed in the mouth and of a size that will help "slide" the canines laterally; apply the ball with gentle

MALOCCLUSION—SKELETAL AND DENTAL

(CONTINUED)

mouth closing pressure two to three times daily, a few minutes at a time, and encourage play with the ball. • If the tip of the mandibular canine barely touches the edge of the maxillary mucosa, gingivoplasty or gingivectomy in the diastema may release the contact. • Moderate cases may be easily managed by building a false crown extension with composite material that will splay the false tip lateral to the gingival margin, with eventual correction of the positioning. • More severe cases (extreme linguoversion, inadequate diastema or rostral or distal deviation of the mandibular canine) may require an orthodontic appliance (incline plane): • Movement can be accomplished but is likely complicated and should be handled by a specialist. • Mandibular canine extraction or crown reduction with vital pulpotomy can provide the patient with a comfortable bite. • Maxillary canine mesioversion (Lance tooth): • Movement can be accomplished but is likely complicated and should be handled by a specialist. • Caudal (posterior) crossbite—in most cases, no treatment is necessary, as the bite is typically functional; in traumatic situations, extraction of one of the offending teeth; orthodontic correction is long and tedious and requires more advanced orthodontic appliances and blocking the bite open.

M

Permanent Tooth Class 2, 3, and Asymmetrical Malocclusion

- Based on providing a functional, non-traumatic occlusion for the animal's medical health; treatment may not be necessary.
- May require advanced orthodontic and surgical procedure and is generally best handled by a specialist.

Deciduous Tooth Class 1 Malocclusion

Careful and gentle extraction of the maloccluded deciduous tooth (interceptive orthodontics) to remove inappropriate physical impediment in hopes that the permanent tooth will erupt in the appropriate position; when performed at least 4 weeks prior to permanent tooth eruption, success rate > 80% is not uncommon.

Deciduous Tooth Class 2, 3, and 4 Malocclusion

Careful and gentle extraction of the maloccluded deciduous tooth in hopes that the short jaws will be released from the bite interlock, allowing it to grow (if the genetic potential is present), prior to eruption of permanent teeth and reestablishment of bite interlock; performed at least 6 weeks prior to permanent tooth eruption, success rate < 20% is common.

FOLLOW-UP

PATIENT MONITORING

- For the corrected occlusion to be stable, it needs to be self-retaining or it may tend to revert to malocclusion; examine at 2 weeks, 2 months, and 6 months after the treatment is complete to see if desired outcome is stable.
- It is advisable at around 6 months post-therapy for radiographs to be taken and compared to the pretreatment films to determine if all teeth still appear vital (alive) and to evaluate any root changes that may have occurred due to the pressures of tooth and root movement during orthodontics.

PREVENTION/AVOIDANCE

- Careful selection of puppies, with oral and general examination, as well as examination and history of sire and dame, prior to purchase.
- Selective breeding based on preferred breed characteristics.
- Careful monitoring of deciduous and permanent tooth eruption for early detection and treatment, if required.

POSSIBLE COMPLICATIONS

- Selective extraction of deciduous tooth—potential for injury to underlying permanent tooth buds either by direct injury with extraction instruments or subsequent traumatic inflammation affecting tooth growth and maturity; injuries may result in tooth buds dying, teeth becoming non-vital as they erupt, root dysplasia or dilaceration, crown hypoplasia, or hypomineralization.
- Orthodontic movement of permanent teeth—several conditions may result, including root resorption, root ankylosis, or non-vitality of the tooth; these conditions are uncommon in properly managed orthodontic procedures.

EXPECTED COURSE AND PROGNOSIS

- Course of treatment may vary with the type of malocclusion and the animal's nature and habits (e.g., inappropriate chewing).
- Generally, most cases take 1–7 months for movement and retention phase, depending on severity and if extrusion of tooth/teeth is required for stabilization of the bite. Prognosis is good to excellent in most treated patients.
- Prognosis is fair to good in most untreated malocclusions.
- Complications in untreated cases—periodontal disease; attrition or fractures of teeth; trauma to soft tissues;

oronasal fistula formation; drying or desiccation of exposed tooth surfaces, resulting in beige to brown discoloration.

- Some cases DO NOT need or require orthodontic intervention; only routine observation for early detection and treatment of any secondary complications (e.g., periodontal disease, worn or chipped teeth) is advised.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Lack of head symmetry
- Oral soft tissue trauma
- Chipped teeth
- Desiccation of exposed tooth surfaces
- Periodontal disease

PREGNANCY/FERTILITY/BREEDING

Although animals have the medical right to as functional and correct an occlusion as can be reasonably provided by therapy, animal club rules, professional association principles, and state and national laws may conflict with an animal's right to proper medical therapy. Some kennel club rules disqualify animals with modification to natural appearance (with certain exceptions), and owners should be made aware of this. If hereditary involvement is suspected, inform the owner. If treatment is being considered, the owner or agent should acknowledge his or her responsibility to inform anyone who has the right to know of such alterations. Additionally, the possibility of removing the animal from the genetic pool by appropriate methods should be discussed.

MAMMARY GLAND HYPERPLASIA—CATS

BASICS

OVERVIEW

Benign enlargement of one or more mammary glands

SIGNALMENT

- Young, intact, cycling, or pregnant queens.
- Cats of either gender after gonadectomy (rare in tom).
- Cats of either gender that are receiving exogenous progestagen (e.g., megestrol acetate).
- Less often in older (9–12 years) pregnant queens.

SIGNS

- Localized or diffuse rapid (2–5 weeks) enlargement of one or more mammary glands.
- Firm and non-painful masses in uncomplicated cases.
- No concurrent signs of systemic illness; tachycardia, lethargy and anorexia possible with complications.

CAUSES & RISK FACTORS

- Exaggerated proliferation secondary to an endogenous progesterone influence (pregnancy, pseudopregnancy) or exogenous progestagens (megestrol or medroxyprogesterone acetate).
- May develop after gonadectomy; pathogenesis may involve progesterone, growth hormone, prolactin, insulin-like growth factors. Suspect ovarian remnant syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mastitis—lactating queen; mammary glands erythematous and painful; systemic illness with fever and immature neutrophilia; inflammatory cells and bacteria in fluid expressed from the affected gland(s).
- Mammary neoplasia—old queens (> 6 years); gross appearance may be indistinguishable; irregular shape and margins, heterogeneous echogenicity on ultrasound; differentiated by biopsy of affected tissue.

CBC/BIOCHEMISTRY/URINALYSIS

Normal; leukocytosis possible with secondary mastitis.

OTHER LABORATORY TESTS

Progesterone analysis—confirm exposure or ovarian remnant syndrome.

IMAGING

- Transabdominal ultrasonography—rule out pregnancy.

- Ultrasonography of affected gland(s)—homogeneous parenchyma, round or oval with regular margins.

DIAGNOSTIC PROCEDURES

- Cytologic examination of fluid expressed from affected glands—non-inflammatory.
- Excision biopsy—benign fibroglandular proliferation with no inflammation or necrosis.

TREATMENT

- Hyperplasia owing to high endogenous progesterone—regresses when progesterone falls at the end of false pregnancy or gestation; consider ovariohysterectomy if preservation of fertility is not desired.
- Hyperplasia owing to exogenous progestagens—regresses when medication is withdrawn.
- Hyperplasia developing after gonadectomy—suspect ovarian remnant; surgical removal of ovarian remnants.
- In uncomfortable animals, may attempt progesterone receptor blockers (aglepristone), prolactin inhibitors (bromocriptine, cabergoline), testosterone.
- Mastectomy, systemic antibiotics or supportive care may be needed with complications.

MEDICATIONS

DRUG(S)

- Bromocriptine mesylate 0.25 mg (per cat) PO q24h for 5–7 days; not approved for use in cats; may cause nausea.
- Cabergoline 5 µg/kg PO q24h for 5–7 days.
- Nausea—metoclopramide (0.2 mg/kg PO q6–8h) or divided bromocriptine dose (give twice daily).
- Aglepristone (10–15 mg/kg SC on 2 consecutive days or 20 mg/kg SC once a week until resolution); not approved for use in cats, not readily available in the United States (mifepristone, a related compound, available in United States as human product; dose for cats undefined).
- Testosterone cypionate or testosterone enanthate (2 mg/kg IM once); not approved for use in cats.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Aglepristone—pregnant animals will abort. May see dermatitis at the site of injection.
- Dopamine agonists—pregnant animals will abort; may cause vomiting.

FOLLOW-UP

AGE-RELATED FACTORS

Young queens

EXPECTED COURSE AND PROGNOSIS

- Remission within 4 weeks after the end of pseudopregnancy or gestation, withdrawal of progestins, ovarioectomy, or aglepristone treatment.
- Likelihood of recurrence in cats left intact—unknown.
- Correlation with other abnormal conditions of the reproductive tract—unknown.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Fertility not affected after aglepristone treatment.

SYNOMYS

- Benign mammary hyperplasia
- Fibroglandular mammary hyperplasia
- Mammary fibroadenomatosis
- Fibroepithelial mammary hyperplasia
- Fibroadenomatous hyperplasia

MAMMARY GLAND TUMORS—CATS

BASICS

DEFINITION

Malignant and benign tumors of the mammary glands in cats

PATHOPHYSIOLOGY

- 5–15% of tumors are histologically benign.
- 85–95% of tumors are malignant, and most are carcinomas; sarcomas are rare (see "Pathologic Findings").
- Inflammatory carcinomas are rarely diagnosed. These are anaplastic carcinomas with considerable inflammatory cell infiltrates, and are associated with extensive local ulceration, edema, and pain, as well as rapid metastasis.
- Pulmonary metastasis is identified in up to 80% of cats, and regional lymph node metastasis in up to 50%. Other sites for metastasis include the liver, spleen, kidney, adrenal gland, pleura, peritoneum, heart, thyroid gland, and bone. At necropsy, metastasis is identified in > 90% of cats.

SYSTEMS AFFECTED

- Reproductive—mammary glands.
- Metastasis can affect any organ system, especially the respiratory and lymphatic systems.

M

GENETICS

The high incidence of mammary tumors in Siamese cats suggests a genetic component to this disease, but specific genes have not been identified to date.

INCIDENCE/PREVALENCE

- Third most common neoplasia in cats (after hematopoietic and skin tumors).
- The estimated incidence is 12.8–25.4 per 100,000 cats.

SIGNALMENT

Species

Cat

Breed Predilections

- Domestic shorthair and longhair breeds are affected most commonly, but this likely reflects the popularity of these breeds rather than a true predilection.
- Siamese cats have twice the risk of other breeds for developing mammary tumors.

Mean Age and Range

- Mean—10–12 years.
- Range—9 months to 23 years; most are > 5 years of age.
- Siamese cats tend to develop mammary tumors at a younger age, and the incidence begins to plateau around 9 years of age.

Predominant Sex

- Females predominate.
- While being intact increases the risk of mammary tumors (see "Risk Factors"), most cats diagnosed with mammary tumors are spayed.
- 1–5% of mammary carcinomas occur in male cats.

SIGNS

Historical Findings

- Most cats present for evaluation of a palpable ventral abdominal mass.
- Cats with advanced metastatic disease may present for general signs of illness (e.g., lethargy or anorexia) or for signs attributable to a specific site of metastasis (e.g., dyspnea due to pulmonary metastasis or pleural effusion).
- The duration of clinical signs can vary from days to several months.

Physical Examination Findings

- Mammary masses can be discrete or infiltrative, soft or firm. Smaller masses often are freely moveable, whereas larger masses can adhere to the underlying abdominal musculature.
- The overlying skin can be intact, but frequently it is ulcerated.
- The associated nipple may be inflamed and exude serous fluid.
- Any gland can be affected, although the caudal two glands are affected more commonly. Left and right sides are affected with equal frequency.
- Up to half of cats will have multiple tumors affecting glands on the same and/or opposite sides.
- Axillary or inguinal lymphadenopathy (reactive or metastatic) may be present.
- As tumor cells spread via the lymphatics, linear beaded chains of tumor nodules can form in lymphatic vessels within the mammary tissue.
- Cats with inflammatory carcinomas present with severe ulceration, erythema, pain, and edema in the ventral abdomen and pelvic limbs.

CAUSES

Unknown

RISK FACTORS

- Compared to intact cats, those spayed at < 6 months of age are 11 times less likely to develop mammary carcinomas, and those spayed at 6–12 months are 7 times less likely, suggesting that hormonal influence is significant in the pathology of mammary gland carcinoma.
- There is no obvious protective effect when cats are spayed at > 12 months of age.
- Exogenous progestins (e.g., medroxyprogesterone acetate) increase the risk of benign and malignant mammary tumor development in female and male cats. In one study, 8 of 22 male cats with mammary carcinomas had a history of exogenous progestin therapy.
- Parity has not been shown to affect mammary tumor development.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fibroepithelial hyperplasia—especially in young (< 2 years) intact female cats, and older or spayed cats receiving exogenous progestins.

- Mastitis.
- Other cutaneous or subcutaneous tumors.
- Inguinal or axillary lymphadenopathy (reactive or neoplastic).
- Inguinal hernia.
- Large/prominent inguinal fat pad.

CBC/BIOCHEMISTRY/URINALYSIS

Usually unremarkable

OTHER LABORATORY TESTS

Coagulation profile recommended for cats with suspected inflammatory carcinomas due to the high incidence of secondary disseminated intravascular coagulopathy.

IMAGING

- Three-view thoracic radiographs are recommended to screen for pulmonary metastasis and/or pleural effusion. Pulmonary metastases are most commonly associated with ill-defined interstitial nodules or a diffuse pulmonary pattern, although well-defined interstitial nodules are seen occasionally. Malignant pleural effusion is common, and can obstruct adequate visualization of pulmonary parenchyma.
- Abdominal ultrasound is recommended to screen the medial iliac lymph nodes and other abdominal visceral organs for metastases.
- Ultrasound also can be used to try to visualize non-palpable axillary or inguinal lymph nodes, as well as to look for additional small masses within the mammary glands.

DIAGNOSTIC PROCEDURES

- Cytology can be useful for ruling out other non-mammary malignancies. However, it is not useful for distinguishing between benign and malignant mammary masses.
- Histopathologic evaluation is needed to reach a definitive diagnosis. Since most mammary tumors are malignant, this is usually performed on tissue removed during radical mastectomy (see "Treatment"). While not contraindicated, incisional biopsies are routinely recommended only for cats with advanced-stage disease that are not candidates for aggressive local surgery.
- All tissue removed must be submitted for histopathologic evaluation. This allows for the most accurate diagnosis, and also allows for evaluation of surgical margins for completeness of excision.
- The ipsilateral draining lymph nodes (axillary and inguinal) should be removed whenever possible and submitted separately for histopathologic evaluation, even if grossly normal.
- Cytology of pleural fluid can be useful for confirming intrathoracic metastasis.

PATHOLOGIC FINDINGS

- The most common histologic subtypes are tubulopapillary, cribriform, and solid carcinomas.
- Histologic subtype has not consistently been shown to affect prognosis, but there is some evidence that tubulopapillary carcinomas carry a better

(CONTINUED)

prognosis. • Tumor grade, based on degree of tubule formation, nuclear and cellular pleomorphism, and mitotic index, is predictive of survival after surgery. • Vascular and lymphatic invasion is associated with more advanced clinical stage and shorter disease-free interval after treatment.

- Mammary sarcomas are rare but potentially slow to metastasize.

TREATMENT

APPROPRIATE HEALTH CARE

- Surgery is recommended for cats with gross disease confined to the mammary glands with or without regional lymph node involvement.
- Adjuvant chemotherapy is recommended after the cat has recovered from surgery.
- Chemotherapy can be used as a sole treatment modality for cats with non-surgical local disease and/or distant metastasis, although long-term control would not be expected to be durable. • Radiation therapy has not been evaluated. • Palliative pain therapy is recommended for cats with non-resectable local disease or gross metastasis, or when definitive therapy is declined.

CLIENT EDUCATION

- Stress the benefits of early ovariohysterectomy (< 6 months of age) in non-breeding cats. • Stress the importance of early detection and aggressive treatment.

SURGICAL CONSIDERATIONS

- Radical mastectomy of the affected mammary chain(s) is recommended. This significantly reduces the risk of local tumor recurrence as well as recurrence in the lymphatic vessels coursing through the mammary tissue. • Bilateral radical mastectomies are usually staged 2–4 weeks apart; however, some studies suggest that unilateral radical mastectomy is sufficiently effective to control local disease in a subset of patients. • The inguinal and (if possible) axillary lymph nodes should be removed at the same time, regardless if they are normal in size. • In cats with advanced metastatic disease, palliative local mastectomy can be considered to remove an ulcerated or infected tumor.

MEDICATIONS

DRUG(S) OF CHOICE

- Doxorubicin (25 mg/m² IV q3 weeks) alone or in combination with cyclophosphamide (100 mg/m² IV or PO divided over 4 days).
- Mitoxantrone, carboplatin, and docetaxel might have activity. • Consult with an oncologist for current chemotherapy recommendations.
- Palliative analgesics and antibiotics should be considered for cats with tumors that are painful and/or ulcerated.

CONTRAINdications

Use doxorubicin with caution in cats with renal or hepatic insufficiency.

PRECAUTIONS

If you are unfamiliar with chemotherapy, consult an oncologist before administering.

FOLLOW-UP

PATIENT MONITORING

- Thorough physical examination conducted monthly for the first 3 months, then every 2–3 months thereafter is recommended. Palpation of the previous incision line, the remaining mammary glands, and regional lymph nodes should be emphasized during examination. • Three-view thoracic radiographs every 2–3 months for detection of metastases.

PREVENTION/AVOIDANCE

Ovariohysterectomy prior to 6 months of age can reduce the risk of developing mammary carcinoma by 11 times.

POSSIBLE COMPLICATIONS

Malignant pleural effusion may develop rapidly causing life-threatening dyspnea.

EXPECTED COURSE AND PROGNOSIS

- Most cats die from local recurrence and/or metastasis. • Tumor size is strongly predictive of prognosis. For tumors ≤ 2 cm in diameter median survival is > 4.5 years (14 months in males), for tumors 2–3 cm it is 1–2 years (5–6 months in males), for tumors > 3 cm it is 4–6 months (1–2 months in males).
- Radical mastectomy significantly reduces the risk for local tumor recurrence. The impact on survival is not as consistent because

of the high metastatic rate associated with this tumor. • In retrospective studies, adjuvant chemotherapy (doxorubicin with or without cyclophosphamide) has not consistently improved disease-free interval or survival. However, chemotherapy has proven efficacy against nonresectable and metastatic feline mammary tumors (gross disease), and given the high metastatic rate of these tumors adjuvant chemotherapy is still strongly recommended. • For cats with advanced-stage disease treated with chemotherapy alone, response rates are around 50%. Survival times are 6–12 months for cats that do have a positive response to treatment, < 6 months for those that do not.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- Given the possible genetic contribution to this disease, particularly in Siamese cats, breeding affected cats is not recommended.
- Chemotherapy is not recommended in pregnant queens, particularly during the early stages of pregnancy.

M

MAMMARY GLAND TUMORS—DOGS

BASICS

DEFINITION

Benign or malignant tumors of the mammary glands in dogs

PATHOPHYSIOLOGY

- Estrogen can exert direct genotoxic effects on mammary epithelium leading to mutations and aneuploidy.
- Progesterone may increase growth hormone and growth hormone receptor expression by the mammary gland leading to increased insulin-like growth factor-1 (IGF-1) which is associated with proliferation and survival.
- Most dogs develop multiple tumors due to entire mammary tissue exposed to sex hormones during puberty, i.e., "field carcinogenesis."
- Mammary gland tumors are a continuum from benign to malignant.
- Obesity decreases sex hormone-binding globulin leading to increased concentration of free estrogen.

SYSTEMS AFFECTED

- Reproductive
- Metastasis—lymphatic, respiratory, skeletal, nervous, and other systems

M

GENETICS

Germline mutations of *BRCA-1* and -2 genes reported in English springer spaniels.

INCIDENCE/PREVALENCE

50–70% of all tumors in female dogs. 71% of all female Beagles developed at least one mammary neoplasm.

SIGNALMENT

Breed Predilections

Toy and miniature poodle, English springer spaniel, Brittany spaniel, cocker spaniel, English setter, boxer, English pointer, German shepherd, Maltese, Doberman, and Yorkshire terrier

Mean Age and Range

Uncommon in dogs < 5 years; mean age 9–11 years (malignant) and 7–9 years (benign).

SIGNS

- 70% of patients have multiple tumors.
- Caudal mammary glands more commonly affected.
- Discrete, well-circumscribed mass in systemically healthy patient.
- Inflammatory carcinoma: diffuse edematous, warm, painful mammary chains.
- Inflammatory carcinoma associated with distant metastasis and systemic illness.

CAUSES

Unknown; likely hormonal

RISK FACTORS

- Age
- Breed: small breeds more common than large breeds

- Hormone influence (see "Prevention")
- Obesity during puberty increases risk. Underweight at 9–12 months of age associated with protective effect.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lipoma
- Mast cell tumor
- Mammary hyperplasia
- Mastitis

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

IMAGING

- Thoracic radiography may detect metastasis and three views are advised.
- CT is more sensitive for detection of pulmonary metastasis than are plain radiographs.
- Abdominal radiography may detect metastasis to regional lymph nodes or vertebrae.
- Abdominal sonography to evaluate for regional or distant metastasis.

DIAGNOSTIC PROCEDURES

- Fine-needle aspirate cytology: 67.5–93% correlation with histopathology; 88% sensitivity and 96% specificity for malignancy.
- Fine-needle aspirate cytology of local lymph node(s).
- Histologic evaluation for definitive diagnosis. Request margin evaluation.

PATHOLOGIC FINDINGS

- There is a wide histologic spectrum of mammary tumors. Dogs may have concurrent benign and malignant tumors. Histologic examination of all excised masses is indicated.
- Histologic grading 1 (well-differentiated) to 3 (poorly differentiated) based on tubule formation, nuclear pleomorphism, and mitotic index valid for epithelial tumors only.
- Stromal invasion, vascular/lymphatic invasion, and lymph node status important.

TREATMENT

APPROPRIATE HEALTH CARE

- Surgery—primary mode of treatment.
- Chemotherapy—may be effective and indicated for patients with high risk of metastasis or recurrence: histologic high-grade, lymphatic/vascular invasion, stage III or higher.

CLIENT EDUCATION

- Advise client that a mammary lump should be evaluated by a veterinary health professional.

- Inform client that early surgical intervention is best.

- Advise ovariohysterectomy before first estrus.

SURGICAL CONSIDERATIONS

- Type of surgery determined by therapeutic intent. Curative intent with wide excision, preventative with chain mastectomy, palliative intent for advanced disease.
- Consider age, tumor size, number of tumors, history of prior tumors, and clinical stage.
- Most patients with inflammatory carcinoma are poor surgical candidates due to profound diffuse microscopic disease, advanced stage, systemic illness, and local coagulopathies.
- 58% of dogs treated with regional mastectomy will develop a new tumor in the ipsilateral chain. Increased risk if initial tumor is malignant (> 70%).
- Current recommendations for single tumor of unknown histology: wide excision to achieve complete removal is the adequate surgical "dose," i.e., 2-cm lateral margins and 1 fascial plane deep.
- Ovariohysterectomy (OHE) within 2 years prior to or concurrent with tumor removal may have survival benefit.
- Remove tumor following abdominal closure if performing concurrent OHE to avoid tumor seeding of abdomen or incision.

MEDICATIONS

DRUG(S) OF CHOICE

- Always consult a veterinary oncologist for updated information.
- Doxorubicin 30 mg/m² IV (dogs > 15 kg) every 21 days.
- NSAID ± chemotherapy for inflammatory carcinoma.

CONTRAINDICATIONS

Doxorubicin—myocardial failure

PRECAUTIONS

Chemotherapy may be toxic; seek advice before treatment if you are unfamiliar with cytotoxic drugs.

POSSIBLE INTERACTIONS

Doxorubicin—potential side effects include myelotoxicity, vomiting, diarrhea, and cardiac damage.

ALTERNATIVE DRUG(S)

- Carboplatin, gemcitabine, 5-FU, cyclophosphamide have been reported with varying impact on clinical outcome.
- Perioperative desmopressin for grade 2–3 carcinoma may improve survival.
- Tamoxifen—helpful in some humans with breast cancer; ineffective in dogs and has serious side effects (e.g., pyometra); do not use in dogs.

(CONTINUED)

FOLLOW-UP

PATIENT MONITORING

Physical examination, abdominal sonography, and thoracic radiographs—1, 3, 6, 9, and 12 months after treatment.

PREVENTION/AVOIDANCE

- Spayed before first estrous cycle—0.5% lifetime risk of developing tumor.
- Spayed before second estrous cycle—8.0% lifetime risk.
- Spayed after second estrus—26% lifetime risk.
- Spayed after 2.5 years of age—no sparing effect on risk.

POSSIBLE COMPLICATIONS

- Infection or dehiscence with surgery
- Myelosuppression with chemotherapy
- DIC with some (especially inflammatory carcinomas) types

EXPECTED COURSE AND PROGNOSIS

- 50% of canine mammary tumors are malignant.
- 50% of malignant tumors metastasize.
- 58–70% of dogs will develop another tumor in the ipsilateral chain.
- Tumor size, lymph node status, and proposed WHO clinical stage (I–V) are most consistent prognostic factors.
- Presence of lymphatic invasion, incomplete surgical margins may be independent prognostic factors.
- Mammary sarcoma carries worse prognosis.

- Inflammatory carcinoma median survival time < 3 months.
- WHO clinical stage may be applicable to non-inflammatory epithelial tumors.
- Stage I: Tumor size < 3 cm, no regional or distant metastasis—complete excision has excellent prognosis.
- Stage II: Tumor 3–5 cm, no regional or distant metastasis—complete excision has excellent prognosis.
- Stage III: Tumor > 5 cm, no regional or distant metastasis—median survival 10 months with surgery alone.
- Stage IV: Any tumor size, lymph node metastasis, no distant metastasis—median survival time 5–10 months with surgery.
- Stage V: Any tumor size, any lymph node status, evidence of distant metastasis—median survival time < 6 months.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Hypertrophic osteopathy
- Metastasis to lymph nodes, lungs, and CNS

PREGNANCY/FERTILITY/BREEDING

- Treatment with progestin increases the chance of tumor development at a younger age.
- Treatment with progestin increases risk of development of benign tumor.
- Treatment with progestin and estrogen increase risk of malignant tumor development.

M

MARIJUANA TOXICOSIS

BASICS

OVERVIEW

- Marijuana (*Cannabis sativa*) is the most common illicit drug exposure in companion animals.
 - The major psychoactive agent, δ -9-tetrahydrocannabinol (THC), is most concentrated in the leaves and buds. Dried plants are much more potent than fresh.
 - THC binds two cannabinoid receptors, CB1 (CNS) and CB2 (peripheral), resulting in clinical signs.
 - The minimum lethal dose of THC is greater than 3 g/kg for dogs.
 - The THC content in marijuana can range from 0.4% to 20% depending upon the cultivation techniques.
- Commonly affected organ systems
- Cardiovascular • Gastrointestinal • Nervous
 - Ophthalmic • Respiratory • Renal/Urologic

SIGNALMENT

Younger animals may be overrepresented due to an increased tendency to ingest foreign items.

SIGNS

- M**
- Often begin 1–2 hours after ingestion. May begin in minutes following inhalation.
 - Ataxia and incoordination, hypersalivation, vomiting, glazed eyes, mydriasis, depression, hypothermia, trembling, urinary incontinence.
 - Higher doses may cause bradycardia, hypotension, and coma. Nystagmus, vocalization, sinus tachycardia, seizures, and hyperthermia may also occur.

CAUSES & RISK FACTORS

- Intoxication occurs via ingestion (most often) or inhalation of marijuana smoke. Pets in homes of recreational or medical marijuana users are at greater risk for exposure.
- Ingestion of plant material is most common but homemade or commercial foods laced with concentrated marijuana ("medibles") are gaining popularity. Examples include brownies, cookies, gummy candy, soda/other drinks, pizza, ice cream, caramel corn, chocolates, bread, snack mixes, and more.
- Regions with medical marijuana dispensaries may correlate to increased exposures.
- Police dogs may be at higher risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other illicit drugs—LSD, PCP, hallucinogenic mushrooms.

- Opioids (greater cardiac/respiratory depression, miosis, reversed with naloxone), benzodiazepines, muscle relaxants, ethanol, ethylene glycol (metabolic acidosis, crystalluria), methanol, diethylene glycol, propylene glycol, tranquilizers, depressants, xylitol (hypoglycemia).

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities but should be used to rule out other causes.

OTHER LABORATORY TESTS

- Human urine drug tests are unreliable and may result in false negatives. A positive result can be considered a true positive.
- Stomach contents and/or urine may be submitted to veterinary diagnostic lab for confirmatory testing.

IMAGING

No specific abnormalities but abdominal radiography is useful if an obstruction is suspected (e.g., ingestion of a baggie containing marijuana, packaging of a food product).

DIAGNOSTIC PROCEDURES

None

TREATMENT

- Mildly affected patients may not require intervention and can be kept in a low-stimulatory, protective environment.
- Treatment is focused on decontamination and supportive care. Induce emesis following recent (< 2 h) ingestion in asymptomatic patients only if they have not already vomited. If symptomatic, gastric lavage should be considered for very large ingestions or if concentrated products (i.e. butter, foods) were ingested.
- Activated charcoal q8h for 2–3 doses if severe signs.
- Warming/cooling measures as needed.
- IV fluid support if poor perfusion parameters or dehydration.
- Oxygen if respiratory depression.
- Provide ocular lubricant and rotation to comatose animals.

MEDICATIONS

DRUG(S)

- Antiemetics (e.g., maropitant 1 mg/kg SQ q24h for dogs or cats) as needed.
- Diazepam (0.25–0.5 mg/kg IV PRN for dogs or cats) for CNS stimulation, anxiety, agitation.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Use acepromazine cautiously due to risk of hypotension.
- Use phenobarbital cautiously due to the risk of severe sedation and respiratory depression.

FOLLOW-UP

PATIENT MONITORING

Monitor temperature, pulse, and respiration q2–3h until normal. Monitor blood pressure in severe cases (hypotension).

PREVENTION /AVOIDANCE

- Educate pet owners about the risks of leaving marijuana or laced food products accessible to pets. Stress that pets will readily consume such products.
- Keep pets confined during parties.
- Keep police dogs muzzled if indiscriminate eaters.

EXPECTED COURSE AND PROGNOSIS

- Clinical signs may last up to 24 hours in mild cases and may be monitored at home.
- Clinical signs may persist for several days in severe cases, especially if a large dose were ingested.
- The prognosis is excellent with appropriate care.
- Death is rare but has been reported in dogs ingesting foods made with marijuana butter.

MISCELLANEOUS

ABBREVIATIONS

- CNS = central nervous system
- THC = δ -9-tetrahydrocannabinol

MARKING, ROAMING, AND MOUNTING BEHAVIOR—CATS

BASICS

OVERVIEW

Urine Marking

- Depositing of urine on vertical (spraying) or horizontal (novel items) surfaces for communication purposes (territorial, sexual, or agonistic situations).
- Marking can account for 30% of feline behavior problems.

Roaming

- Escape or wandering activity for the purpose of seeking mates, defining territory, obtaining food, or sensory stimulation/enrichment.
- Urine marking and roaming behavior are normal but undesirable feline behaviors in companion cats.

Mounting

- Mating behavior
- Mounting of inanimate objects for the purpose of masturbation.

SIGNALMENT

- Common in intact males, especially if estrus females are present.
- Can also occur in intact females or neutered individuals of either gender.
- No age or breed predilection for marking or roaming.
- Mounting can also be seen in sexually deprived, intact male cats mounting other males, females, kittens, people, and inanimate objects.

SIGNS

- Urine marking is characterized by the cat backing up to object with an erect and quivering tail and projecting a stream of urine backward and upward toward the object.
- May also occur with the cat assuming a squatting posture and depositing urine on horizontal surfaces, notably personal or novel items in the environment.
- Urine marking is thought to be characterized by the deposition of small amounts of urine, on multiple surface types, in conjunction with normal litter box use for toileting of urine and fecal material.
- Mounting of other cats, people, or objects.

CAUSES AND RISK FACTORS

- Urine marking may function to delineate territory, aggressive intent, or reproductive goals between cats or may be a response to anxiety.
- Likelihood of urine marking within the household appears to increase with density of cats in the household; however, urine marking may occur in households with only 1 or 2 cats.
- Agonistic (aggressive) relationships between cats in the same household and the presence of outdoor cats are correlated with an increase in the likelihood of marking behavior.

- Roaming is a normal feline exploratory behavior with cats seeking environmental enrichment, food, or sexual activity.
- Roaming is more likely with outdoor cats being housed indoors, in intact male cats, and in cats with a barren indoor environment (resulting in increased motivation to explore the outdoors).
- Mounting can be seen in deprived males or isolated males or if males are housed in pairs.
- Roaming, marking, and mounting may be seen in 5–10% of neutered males.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rule out causes of lower urinary tract disease.
- Urine marking must be distinguished from inappropriate urination for the purpose of emptying the bladder. The latter problem is characterized by elimination on a consistent surface or location, may involve feces, and is usually associated with a decrease in litter box use. Cats can continue to use the litter for fecal elimination while avoiding it for urination, and the reverse is also possible. Cats that urine mark will continue to use the litter box for toileting of urine and feces.
- Roaming behavior may occur due to any disease process that might cause a cat to seek isolation due to illness.
- For marking and mounting also consider neonatal testosterone exposure, treatment with anabolic steroids or testosterone or retained or residual testicular tissue.

CBC/BIOCHEMISTRY/URINALYSIS

- Rarely do cats with roaming or mounting behaviors display abnormalities in lab work.
- CBC/biochemistry tests can provide helpful information to rule out coexisting conditions and provide baseline data prior to initiating drug therapy.
- Urine marking may be associated with underlying urinary tract disorders.

OTHER LABORATORY TESTS

- Unless indicated from baseline data, no further lab tests are necessary.
- In neutered and spayed females, rule out potential hormonal effects from retained or residual testicular tissue which might be associated with secondary sexual characteristics such as penile barbs and elevated testosterone in males or estrus like behaviors in females.
- Urine marking may be associated with medical conditions that might contribute to increased irritability such as hyperthyroidism.

IMAGING

Radiographs and ultrasound if laboratory data indicates a need to further explore the urinary tract.

DIAGNOSTIC PROCEDURES

None indicated

TREATMENT

FOR URINE MARKING

- Neuter and spay intact animals. When possible, reduce numbers of cats in the household to reduce density if overcrowding a factor.
- Provide alternate marking options such as scratching posts, scratch boxes, facial marking combs (Cat-A-Comb). Given that urine marking is a normal behavior, for some cats the use of a urine marking station (empty litter box placed vertically at location where marking occurs) may be appropriate.
- Multiple feeding stations and litter stations in multiple locations (one litter box per cat plus one additional).
- Manage litter hygiene so that boxes are scooped daily and completely cleaned weekly (clay litters) or monthly (clumping type litters) using hot water only (no cleansers).
- Increase perching and hiding opportunities (especially elevated locations) in each room of the home.
- Isolate cat from area being marked.
- Make urine marked areas aversive by using double-stick tape, mothballs, bubble wrap, etc.
- Manage stress factors in household (alter routine in home, address relationship issues between cats in the home, manage interactions between cats and people in home to increase positive relationships by encouraging play and positive reinforcement-based training).
- Reduce exposure to outdoor cats by blocking visual access, decrease number of cats in yard (use of fencing, motion-activated sprinkler, remove bird feeders, etc.).
- Increase (or decrease) time allowed outdoors.
- Use of synthetic facial pheromone (F3 fraction).

FOR ROAMING BEHAVIOR

- Neuter if intact.
- Use double barriers at exits (for example, screen doors) or confine away from doors (e.g., room).
- Alternately, allow controlled access to outdoors using cat fencing or screened areas or outdoor access while walked on a leash and harness.
- Enrich home environment with increased food access, random treats, and increased play opportunities. Feed the cat as soon as it returns home.
- Remove outdoor reinforcements such as outdoor cats through the use of fencing, motion-activated water sprinklers, removing

MARKING, ROAMING, AND MOUNTING BEHAVIOR—CATS

(CONTINUED)

bird feeders, and insuring neighbors not feeding.

- ID cat (tags, tattoo, or microchips).

FOR MOUNTING BEHAVIOR

- Neuter if intact.
- Interrupt the behavior and redirect to more desirable behaviors such as play.
- Identify and remove any triggers which initiate the behavior.
- Provide alternative outlets for play/enrichment.

**MEDICATIONS****DRUGS****For Urine Marking**

- Fluoxetine 0.5–1.0 mg/kg PO q24h; Side effects: sedation, anorexia, irritability, urine retention, constipation.
- Clomipramine 0.5–1.0 mg/kg PO q24h; Side effects: sedation, anticholinergic effects, arrhythmias, and GI disturbances.

For Roaming Behavior

No medications are recommended for roaming behavior

For Mounting Behavior

- Medications might be a consideration if a stress/anxiety component identified.
- Fluoxetine or clomipramine as in urine marking.
- Lorazepam 0.25–0.50 mg per cat PO q12–24h; Side effects sedation, hyperphagia and possible hepatic disease.

M

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Use caution when prescribing clomipramine in cats with seizures.
- Do not use fluoxetine or clomipramine with MAO inhibitors such as selegiline.
- Caution in using TCAs, such as clomipramine, when treating cats with diabetes, glaucoma, or cardiac disease.
- Do not combine a TCA and an SSRI; serotonin syndrome possible.

**FOLLOW-UP****PATIENT MONITORING**

- Telephone follow-up within 2 weeks after consultation, repeat as needed to monitor progress and assess response to treatment.
- Electrocardiogram if concerns about cardiac status.
- CBC and biochemistry profile 3–4 weeks after initiating medical therapy and then q6–12 months while on medication.

EXPECTED COURSE AND PROGNOSIS

- Response to therapy by diminished urine marking within 4 weeks.
- Continue drug therapy for a minimum of 8 weeks if response noted; continue 1 month beyond resolution.
- When the behavior is stable, wean dose by 25% per week.
- If behavior reoccurs, reinstitute lowest effective dose.
- Some animals may need to be maintained on medication indefinitely.

**MISCELLANEOUS****SEE ALSO**

Housesoiling—Cats

ABBREVIATIONS

- GI = gastrointestinal
- MAO = monoamine oxidase
- SSRI = selective serotonin reuptake inhibitor
- TCA = tricyclic antidepressant

MARKING, ROAMING, AND MOUNTING BEHAVIOR—DOGS

BASICS

DEFINITION

- Marking, roaming, and mounting behavior fall within the normal behavioral repertoire for the dog. However, they are objectionable to owners if the behavior is shown to excess, in an inappropriate context, or in a sexually altered dog.
- Normal behaviors with multiple causes—may be maladaptive owing to stimuli in the dog's environment.
- Marking—generating a signal for conspecifics with either a visual mark or leaving scent (urine, feces, anal sacs, or sebaceous glands) on an object or to define territory.
- Roaming—free wandering for exploration or in search of potential mates, food, or social contact.
- Mounting—primarily a component of mating behavior but also shown in social contexts and play (especially in pre-pubertal dogs).

GENETICS

None known but objectionable expression of these behaviors may be more common in familial lines.

INCIDENCE/PREVALENCE

Not known

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog

Breed Predilections

- Seen in any breed

Mean Age and Range

- Age at onset—sexual maturity (around 1 year of age)
- Mounting may occur in prepubertal puppies

Predominant Sex

- Males
- Most common in intact males, or intact females in estrus
- Also exhibited by castrated males and spayed females

SIGNS

Historical Findings

- Marking—deposition of urine and/or fecal matter in locations unacceptable to owners; occurs inside and outside of the home.
- Roaming—wandering behavior that takes the dog away from its home.
- Mounting—a behavior in which a dog raises the cranial part of its body onto other dogs, animals, people or objects while wrapping forelimbs around the target with or without pelvic thrusting.

Physical Examination Findings

- Physical examination findings are typically unremarkable unless a medical etiology is suspected (especially for marking behavior).
- For inappropriate mounting of other dogs, it is advisable to also perform a physical examination of the target of the mounting.

CAUSES

- Normal dog behaviors. Urine marking occurs most commonly in novel areas rather than in the home environment. Female dogs rarely mark in the home.
- Hormonally regulated; intact males likely to roam, mark, and mount.
- Learned components possible; reproductive status not sole variable.

Roaming

- Anxiety • Curiosity • Reproduction • Social contact and play

Marking

- Medical. • Communication with conspecifics; communicates social rank, sexual status, territorial boundaries, or general information, not related to the need to empty the bladder or bowel. • Anxiety

Mounting

- Sexual (including courtship and masturbation) • Play • Social status or cohesion • Attention-seeking • Anxiety
- Compulsive disorder

RISK FACTORS

- Intact males more likely to roam, mark, and mount.
- Marking on walks; learned behavior.
- Mounting only in front of owners; attention-seeking.
- Intact bitches, or females spayed after first heat.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Define the cause of the behavior as either normal or a sign of another diagnosis.

Roaming

- Sexually motivated behavior • Testosterone-producing tumors • Hunger/searching for food • Separation anxiety • Noise phobias
- Territorial behavior • Social facilitation
- Predatory behavior • Escaping from enclosure—play/investigative behavior

Marking

- Sexually motivated behavior • Testosterone-producing tumors • Territorial behavior
- Social status behavior • Conflict behavior
- Anxiety • Housesoiling; incomplete or loss of housetraining • Urinary tract disease • Any medical condition that causes PU/PD
- Constipation or diarrhea • Anal sac disease

Mounting

- Sexually motivated behavior • Testosterone-producing tumors • Social status behavior
 - Endocrine disease • Urinary tract disease
- If target of mounting is another dog, look at target for:
- Estrogen-producing tumors
 - Infections of anal sacs, uterus, vagina, or urinary tract

CBC/BIOCHEMISTRY/URINALYSIS

If abnormal, address medical issues.

OTHER LABORATORY TESTS

As indicated:

- Thyroid testing if roaming due to hunger
 - Blood testosterone levels in neutered animals showing intact male behaviors
 - Urine culture and sensitivity
 - Vaginal cytology to determine estrus status
- If target of mounting is another dog, exam target for:
- Blood estrogen levels (reproductive tumors)
 - Urine culture and sensitivity
 - Vaginal cytology, culture and sensitivity

IMAGING

Radiographs or ultrasound if a medical etiology is suspected.

DIAGNOSTIC PROCEDURES

As applicable if a medical etiology is suspected

PATHOLOGIC FINDINGS

N/A

M

TREATMENT

APPROPRIATE HEALTH CARE

N/A

NURSING CARE

N/A

ACTIVITY

See "Client Education"

DIET

No special dietary considerations

CLIENT EDUCATION

Roaming

- Secure enclosure to prevent escape
- Leash walk
- Adequate exercise, attention, supervision, stimulation
- Doggie daycare

Marking

- Restrict access to targeted areas and provide adequate indoor supervision when the owner is home.
- Confinement if tolerated when home alone.
- Remove stimuli or triggers.
- Express anal sacs if necessary.
- Use Bellyband (male) or Puppy Pants (female).
- Clean marked areas with effective enzymatic cleaners.

MARKING, ROAMING, AND MOUNTING BEHAVIOR—DOGS (CONTINUED)

- Command-/reward-based interaction with dog.
- Consider counter-conditioning or systematic desensitization to trigger stimuli or for anxiety conditions.
- Consider remote punishment for marking (such as water sprayer, alarm, citronella spray).

Mounting

- Obedience training
- Command-/reward-based interaction with dog
- Consider counter-conditioning or systematic desensitization to trigger stimuli or for anxiety conditions
- Adequate exercise, attention, and stimulation
- Ignore behavior if an attention-seeking component
- Consider remote punishment

SURGICAL

- Neuter intact males.
- Spay females. For marking spay early before first estrus to prevent hormone effects.

MEDICATIONS

DRUG(S) OF CHOICE

- M**
- Medication is not necessary for roaming unless the primary problem (separation anxiety or noise phobias) warrants its use. Medical etiologies should be treated accordingly.
 - No drug is approved for the treatment of marking or mounting; informed owner consent is advised. Medication use is *only* appropriate if persistent anxiety is strongly suspected as a contributing motivation.
 - Medication should *only* be used in combination with a sound behavior modification plan.

Tricyclic Antidepressants (TCA)

- Amitriptyline 2–4 mg/kg PO q12h
- Clomipramine 1–3 mg/kg PO q12h
- Side effects include sedation, anticholinergic effects, cardiac conduction disturbances, and GI signs.

Selective Serotonin Reuptake Inhibitors (SSRI)

- Fluoxetine 0.5–2 mg/kg PO q24h
- Paroxetine 1–2 mg/kg PO q24h
- Sertaline 1–3 mg/kg PO q24h
- Side effects include sedation, inappetence, lethargy, irritability, urine retention, constipation.

Azapirone

- Buspirone 0.5–2 mg/kg PO q8–12h
- Side effects: GI signs

Benzodiazepines

In dogs with concurrent anxiety diagnoses—alprazolam 0.01–0.1 mg/kg PO q8–12h

CONTRAINDICATIONS

- TCAs are contraindicated in animals with cardiac conduction disturbances or glaucoma.
- TCAs and SSRIs are contraindicated for dogs with a history of seizures.

PRECAUTIONS

- When dispensing clomipramine and fluoxetine, clients should be advised that occasional cases of increased aggression have been reported.
- Use caution with all drugs if dog has hepatic or renal compromise.
- Use benzodiazepines with caution in aggressive dogs because of potential for disinhibition.

POSSIBLE INTERACTIONS

- TCAs and SSRIs should not be used together.
- Do not use TCAs or SSRIs with monoamine oxidase inhibitors, including amitraz products and selegiline

ALTERNATIVE DRUG(S)

Megestrol Acetate

- Outdated treatment used as a last resort only.
- Side effects include obesity, pyometra, polyuria/polydipsia, diabetes mellitus, mammary hyperplasia, and carcinoma.

FOLLOW-UP

PATIENT MONITORING

Follow-up is variable depending on the severity of the problem and whether medication is prescribed. Help may be needed implementing changes to the environment and behavior modification. Owners should be encouraged to keep logs or journals detailing episodes of marking, roaming, or mounting to assess treatment success or non-response. If medication is prescribed, follow-up and journals are essential to assess response. In urine marking, owners should be encouraged to supervise the dog indoors and to inspect areas daily for urine marks.

PREVENTION/AVOIDANCE

- Neutering males and spaying females reduces likelihood of marking, roaming, and mounting behavior.
- Client education via proper husbandry techniques is helpful.

POSSIBLE COMPLICATIONS

- Roaming—becoming lost or picked up by animal control; possible injury from car accidents or fighting with other animals.
- Marking—property damage when it occurs inside the home.
- Mounting—disruption of relationship with familiar dogs; possible fighting with other animals
- Pet relinquishment.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is good if the correct cause is determined and the owner is compliant with the behavior protocols.
- Castration will decrease house marking by 90% or better in 40% of male dogs, while 80% of dogs will decrease marking by at least 50%. Castration has little to no effect on urine marking in outdoor areas.
- Castration decreases mounting in more than 65% of dogs but relatively few stop completely. Castration has its greatest effect when the target of mounting is human rather than dog-dog mounting.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Intact animals older than sexual maturity.

ZOONOTIC POTENTIAL

Roaming exposes pet to other animals, including wildlife—rabies exposure possible.

PREGNANCY/FERTILITY/BREEDING

Listed medications should be avoided in pregnant animals.

SYNONYMS

N/A

MAST CELL TUMORS

BASICS

DEFINITION

- Malignant round cells derived of hematopoietic origin containing granules packed with many vasoactive substances including histamine, heparin, serotonin, dopamine, tryptase, and chymase.
- Most common malignant skin tumor in the dog, representing approximately 7–21% of all canine skin tumors.
- Second most common malignant skin tumor in the cat, representing approximately 20% of all feline skin tumors.
- Tumors may affect dermis, subcutis, spleen, liver, and intestines.

PATOPHYSIOLOGY

- Histamine release from MCTs affects a multitude of tissues.
- Histamine (H₂) receptors are primarily located within the stomach and histamine is thought to be one of the most significant stimulants of gastric acid secretion.
- In extreme cases, perforation of the gastrointestinal tract may occur, leading to peritonitis.
- Histamine release around a tumor leads to the production of wheals, hives, and erythema.
- Local release of heparin is also common, resulting in bleeding and subsequent bruising, which can be seen around the tumor.

SYSTEMS AFFECTED

- Skin—MCTs are the most common malignant cutaneous tumor of the dog.
- Gastrointestinal—on necropsy evaluation, 35–83% of dogs with MCTs have evidence of gastrointestinal ulceration.
- Hemic/Lymph/Immune—lymph node metastasis is common in high-grade tumors. Bone marrow metastasis is rare but can occur.
- Hepatobiliary—the liver and spleen are common distant sites of metastasis for high-grade MCTs.

GENETICS

The specific breed predilections indicate that a genetic predisposition exists.

INCIDENCE/PREVALENCE

- Most common malignant skin tumor in the dog, representing approximately 7–21% of all canine skin tumors.
- Primary visceral and intestinal MCTs are rare in the dog.
- Second most common skin tumor in the cat, accounting for 20% of cutaneous tumors.
- Most common splenic tumors of cats, comprising half of the MCTs diagnosed in cats.

SIGNALMENT

Species
Dog and cat

Breed Predilections

- Dogs—brachycephalic breeds, as well as golden retriever, Labrador, Rhodesian ridgeback, beagle, Staffordshire terrier, Weimaraner, Shar-Pei, and Australian cattle dog.
- Cats—Siamese.

Mean Age and Range

- Dogs—middle-aged, range 4 months–18 years.
- Cats—middle-aged (8–9 years for cutaneous mastocytic types) and older cats (intestinal and splenic); however, the histiocytic form of cutaneous MCTs affects young cats with a mean age of 2.4 years.

Predominant Sex

- Dogs—no predilection
- Cats—male Siamese

SIGNS

Dogs

- Mass is found in the subcutis or on the skin and may also be present within lipomas.
- Regional edema or a Darier's sign may be seen in the region around a tumor that has degranulated.
- Lymphadenopathy of regional lymph nodes may be seen in dogs with metastatic disease.
- History of intermittent progression and regression in size.
- Systemic illness with advanced local or systemic disease; vomiting, anorexia, weight loss, and melena.

Cats

- Visceral disease manifests as chronic weight loss, anorexia, diarrhea, and lethargy.
- Focal mass lesion may be palpated with primary intestinal MCT.

CAUSES

- Up to 30% of canine MCTs have been shown to contain a mutation in the c-kit oncogene, leading to constitutively activated receptor and unchecked cell division.
- Up to 56% of feline MCTs have a c-kit mutation, though these mutations do not appear to have any bearing on prognosis nor on protein expression.

RISK FACTORS

See above under "Breed Predilections" and "Causes"

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cutaneous forms—adenexal tumors, basal cell tumors, histiocytoma, lipoma, and soft tissue sarcoma.
- Visceral forms—lymphoma, histiocytic tumors, malignant fibrous histiocytomas, multiple myeloma, hemangiosarcoma, hemangioma, and erythroid myeloid hyperplasia.
- Intestinal forms—lymphoma, adenocarcinoma, leiomyoma,

leiomyosarcoma, gastrointestinal stromal tumors, and fungal infections.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia (regenerative secondary to gastrointestinal blood loss).
- Eosinophilia, mastocytosis, and thrombocytopenia.
- Identification of circulating mast cells is more common in the cat with visceral MCT than the dog.
- Increased BUN secondary to gastrointestinal bleeding and increased liver values secondary to metastasis.

OTHER LABORATORY TESTS

- Regional lymph node aspiration and cytology
- Liver and splenic aspiration and cytology
- Mast cell tumor prognostic panel
- C-kit PCR and immunohistochemistry staining

IMAGING

- Thoracic radiographs—intrathoracic or sternal lymph node metastasis
- Abdominal ultrasound—viscera assessment with emphasis on liver, spleen, and mesenteric lymph nodes

DIAGNOSTIC PROCEDURES

- Fine-needle aspirate and cytology for definitive diagnosis.
- Biopsy (incisional or excisional) for definitive diagnosis and histologic grading.

M

PATHOLOGIC FINDINGS

- Dogs—Patnaik grading scale:
 - Grade I (low-grade) tumors have a mostly benign behavior and represent ~36%.
 - Grade II (intermediate-grade) MCTs are the most common form and represent ~43%.
 - Grade III (high-grade) MCTs are the most aggressive form, are metastatic, and represent ~20%.
- Cats—Histologic forms of cutaneous MCTs:
 - Mastocytic form—single tumor and is the most common (compact or diffuse). There are two histologic varieties of mastocytic MCTs in the cat, compact and diffuse: compact—more benign behavior; diffuse—more undifferentiated and aggressive.
 - Histiocytic form—multiple lesions on the head and neck with relatively benign behavior.

TREATMENT

ACTIVITY

Limit for animals with heavy tumor burdens (such as cats with visceral MCTs or dogs with large tumors) until the mass has been treated appropriately.

MAST CELL TUMORS

(CONTINUED)

DIET

N/A

CLIENT EDUCATION

Owners of dogs with MCTs should be informed that 14–17% of dogs will develop additional MCTs. All new masses should be evaluated by a veterinarian.

SURGICAL CONSIDERATIONS

- Conventional recommendations (dogs)—2–3 cm margins and one fascial plane deep, maybe unnecessary with grade II MCTs in dogs as majority (70%) of “dirty” margins fail to locally regrow.
- Narrow margins (cats)—majority of tumors will not regrow following narrow surgical margins.
- Splenectomy (cats)—recommended in cats with massive visceral tumor burden despite the presence of metastases.

RADIATION THERAPY

- For incompletely excised mast cell tumors in locations that are not amenable to surgical re-excision or in cases where another surgery is not possible (dogs).
- Can be used in a gross disease setting, but severe systemic reactions (including death) are possible.

MEDICATIONS

DRUG(S) OF CHOICE

Dogs

- Vinblastine (2.0 mg/m² IV q7 days × 4, then q14 days × 4) and prednisone (1 mg/kg PO q24h).
- Vinblastine only (3.5 mg/m² IV q14 days).
- Lomustine (50–70 mg/m² PO q 21 days).
- Torceritinib (2.75 mg/kg PO MWF).
- Masitinib (12.5 mg/kg PO q24h).

Cats

- Lomustine (32–60 mg/m² PO q4–6 weeks).
- Vinblastine (2 mg/m² IV q7 days × 4, then q14 days × 4) and prednisone (1 mg/kg PO q24h).

CONTRAINDICATIONS AND PRECAUTIONS

- Vinblastine—use with caution in animals with liver disease; drug is also myelosuppressive and possesses vesicant properties.
- Lomustine is hepatotoxic and should be avoided in dogs with underlying liver disease; drug is extremely myelosuppressive and associated with refractory thrombocytopenia. Administer with Denamarin.
- Torceritinib and masitinib can cause gastrointestinal ulcers, myelosuppression, muscle pain, hypertension, proteinuria and gastrointestinal upset.

POSSIBLE INTERACTIONS

- Torceritinib and masitinib should be used with caution with other drugs that induce

gastric ulcers such as prednisone or NSAIDs, or in patients with gastric ulceration secondary to mast cell tumor.

- Lomustine should be used with caution with other hepatotoxic drugs such as NSAIDs.

ALTERNATIVE DRUG(S)

Symptomatic treatment—benadryl, prednisone, famotidine or other H₂ inhibitors, omeprazole, and sucralfate should be considered for any dog or cat with gross mast cell disease.

FOLLOW-UP

PATIENT MONITORING

Dogs

- Grade I or II—complete surgical resection should be curative in the majority of patients.
- Grade II (high)—complete surgical resection evaluated every 3 months for 1 year with physical examination, abdominal ultrasound, and lymph node assessment.
- High-grade tumors (grade III or those in a location associated with a negative prognosis)—physical examination, blood work, and abdominal ultrasound every 3 months for 1 year and then every 6 months for an additional 2 years.

Cats

Visceral or intestinal—abdominal ultrasound every 3 months for 1 year.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Chemotherapy-related myelotoxicity or hepatotoxicity

EXPECTED COURSE AND PROGNOSIS

- Complete excision of low-grade mast cell tumors in most locations is curative.
- Complete excision of high-grade mast cell tumors or those located in areas associated with a poor prognosis (mucocutaneous junctions, ± inguinal regions) often require adjuvant therapy with chemotherapy. Median survival times average approximately 11–12 months.
- Incomplete excision of a low-grade mast cell tumor may require additional local therapy with another surgery (often cured) or radiation therapy (93% disease-free at 3 years).
- Incomplete excision of a high-grade mast cell tumor requires additional local therapy in addition to systemic chemotherapy. Median survival times range from 6 to 12 months.
- Regional metastasis to a lymph node should be treated with surgical excision at the time of the primary tumor removal. Systemic chemotherapy is necessary. Median survival times are typically less than 9 months.
- Evidence of distant metastasis is often treated with systemic chemotherapy or

ancillary therapies alone with a median survival of 4 months or less.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Progressive and metastatic disease has the potential to cause excessive parietal cell production of hydrochloric acid with associated gastric ulceration, melena, and iron-deficiency anemia and gastric perforation.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

While on chemotherapy dogs should not be bred. There are no long-term studies regarding fertility in dogs or cats previously treated with lomustine, vinblastine, or RTKIs.

SYNONYMS

- Mastocytoma
- Systemic mastocytosis

ABBREVIATIONS

- MCT = mast cell tumor
- NSAID = nonsteroidal anti-inflammatory drug
- RTK = receptor tyrosine kinase
- RTKI = receptor tyrosine kinase inhibitor

Client Education Handout
available online

MASTITIS

BASICS

OVERVIEW

- Bacterial infection of one or more lactating glands.
- Result of ascending infection, trauma to the gland, or hematogenous spread.
- *Escherichia coli*, *Staphylococci*, and β -hemolytic streptococci—most commonly involved. *Mycobacterium* and blastomycosis reported.
- Potentially life-threatening infection; may lead to septic shock.
- Sepsis—direct effect of mammary glands with systemic involvement.

SIGNALMENT

- Postpartum bitch and queen
- Pseudopregnant lactating bitch or queen (rare)

SIGNS

Historical Findings

- Anorexia
- Lethargy
- Neglect of puppies or kittens
- Failure of puppies or kittens to thrive

Physical Examination Findings

- Firm, swollen, warm, and painful mammary gland(s) from which purulent or hemorrhagic fluid can be expressed.
- Fever, dehydration, and septic shock—with systemic involvement.
- Abscessation or gangrene of gland(s) can result.

CAUSES & RISK FACTORS

- Ascending infection via teat canals.
- Trauma inflicted by puppy or kitten toenails and teeth.
- Poor hygiene.
- Systemic infection originating elsewhere (e.g., metritis).
- Rarely secondary to fibroadenomatous hyperplasia in queens.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Galactostasis—no systemic illness; cytologic examination and culture of milk help with differentiation.
- Inflammatory mammary adenocarcinoma—affected gland does not produce milk; differentiated by biopsy.

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis with left shift
- Leukopenia—with sepsis
- Mildly high PCV, total protein, and BUN—with dehydration

IMAGING

- Ultrasonography reveals loss of distinct layering of normal tissue in glands, decreased echogenicity, increased heterogeneity, and altered blood vessel density on color Doppler.
- Color Doppler can assist in prognosis—loss of blood vessels in inflamed areas predicts progression to gangrene.

OTHER LABORATORY TESTS

Culture—identification and sensitivity of microorganisms from milk of affected glands;

screening for methicillin-resistant *Staphylococcus aureus* recommended.

DIAGNOSTIC PROCEDURES

- pH of milk—normally slightly more acidic than serum, may become alkaline with infection.
- Cytology—neutrophils, macrophages, and other mononuclear cells can be observed in normal milk; the presence of large numbers of free and phagocytosed bacteria and degenerative neutrophils is noted with septic disease; bacterial culture to identify the organism and sensitivity pattern.

TREATMENT

- Inpatient until stable.
- Puppies and kittens—neonates may be allowed to continue nursing unless glands are necrotic or dam is systemically ill; affects choice of antibiotics; monitor weight gain in neonates: pups should gain 10% of birth weight per day, kittens should gain a minimum of 7–10 g/day.
- Dehydration or sepsis—intravenous fluid therapy.
- Correct electrolyte imbalances and hypoglycemia.
- Treat shock, if present.
- Apply warm compress and milk out affected gland(s) several times daily.
- Cover glands with friable tissue to prevent excoriation if nursing is allowed.
- Application of cabbage leaf wraps to affected glands may speed resolution.
- Abscessed or gangrenous glands—require surgical debridement, with or without negative pressure wound therapy.
- Open wound management may be needed after surgery in some cases; negative pressure wound therapy useful adjunctive modality postoperatively and for conservatively managed cases.

MEDICATIONS

DRUG(S)

- Acidic milk—weak bases; erythromycin (10 mg/kg PO q8h), lincomycin (15 mg/kg PO q8h), or trimethoprim-sulphadiazine (15–30 mg/kg PO q12h), for 21 days.
- Alkaline milk—weak acids; amoxicillin or cephalosporin (20 mg/kg q8h, dogs and cats); amoxicillin/clavulanic acid (13.75 mg/kg PO q12h, dogs; 62.5 mg/cat PO q12h, cats) for 21 days.
- Either alkaline or acidic milk—chloramphenicol (40–50 mg/kg PO q8h) or enrofloxacin (2.5 mg/kg PO q12h) for 21 days.
- May infuse affected gland(s) with 1% betadine solution by lacrimal cannula.
- Cabergoline (5 μ g/kg PO q24h, 5–7 days) to suppress lactation in unaffected glands in patients with sepsis; neonates must be hand reared.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Patient allowed to nurse—avoid tetracycline, enrofloxacin, and chloramphenicol; may use cephalosporins, amoxicillin, and amoxicillin with clavulanic acid.

FOLLOW-UP

PATIENT MONITORING

- Physical examination and CBC.
- Repeated ultrasonographic evaluation helps assess healing—normal distinct layering of tissues will appear with recovery.

PREVENTION/AVOIDANCE

- Clean environment
- Hair shaved from around mammary glands
- Toenails of puppies and kittens clipped
- Ensure neonates nurse from all glands.

POSSIBLE COMPLICATIONS

- Abscessation or gangrene—may cause loss of gland(s).
- Hand-raising puppies and kittens—requires considerable commitment by the owner, may affect behavioral outcome of offspring.

EXPECTED COURSE AND PROGNOSIS

Prognosis—good with treatment

M

MISCELLANEOUS

ABBREVIATION

PCV = packed cell volume

MATERNAL BEHAVIOR PROBLEMS

BASICS

DEFINITION

Abnormal maternal behavior is either excessive maternal behavior in the absence of neonates or deficient maternal behavior in the presence of the dam's own neonates. The latter is more common in dogs, the former in cats.

PATHOPHYSIOLOGY

The pathophysiology of one type of excessive maternal behavior, pseudocyesis, appears to be elevated progesterone levels following estrus in unbred bitches followed by an abrupt drop in progesterone levels. The pathophysiology of refusal to accept puppies by females after caesarean section is the waning of factors, including oxytocin, needed during the sensitive period for acceptance of the neonate. The pathophysiology of other types of deficient maternal behavior is unknown.

SYSTEMS AFFECTED

Behavioral

GENETICS

There is no identified genetic predisposition, but a breed disposition for deficient maternal behavior in Jack Russell terriers indicates that there may be a genetic component. There are genetic models in mice. The genes responsible for deficient maternal behavior in mice are paternally imprinted. If this is true in dogs and cats, one would expect that rejecting mothers were normally mothered themselves, but their grandmother may have been deficient. The genetic basis should be investigated in dogs and cats.

INCIDENCE/PREVALENCE

The incidence of deficient maternal behavior has not been determined but seems to be low, less than 1% of cases in a behavior practice. Maternal behavior in cats and dogs that do not have offspring is more common.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dogs and cats

Breed Predilections

Poor maternal behavior may be more common in Jack Russell terriers and cocker spaniels, but there has been no quantitative study.

Mean Age and Range

There is no particular age at risk, but primiparous females and older bitches seem to be at risk of deficient maternal behavior.

Predominant Sex

Female generally, but some males may allow suckling behavior.

SIGNS

Deficient Maternal Behavior

Absent maternal behavior; the mother simply abandons her offspring. This is most apt to occur after caesarean section.

Poor Maternal Behavior

- The mother stays with her offspring but will not allow them to nurse.
- In other cases the mother may show inadequate retrieval of young, insufficient cleaning of the young, or failure to stimulate elimination.
- In another form of poor maternal behavior, the bitch carries the puppies from place to place without settling down or, in the most extreme form, kills some or all of her litter.

Abnormal Maternal Behavior

- The bitch or queen may allow her offspring to suckle but kills her offspring either at birth or over a period of days. Occasionally the bitch, or more rarely the queen, will abandon or attack her offspring if it has changed in odor or appearance. A female may be disturbed by another animal or by people and can redirect her aggression to her offspring.
- A bitch may accidentally disembowel or even consume offspring completely while eating the fetal membranes and umbilical cord. This should be distinguished from normal licking, which can be quite vigorous, even dislodging the pup from a teat.

Maternal Aggression

Cats with kittens may be aggressive to other animals, especially dogs in the same household. Bitches may be aggressive to unfamiliar humans or even to familiar humans, especially if they are hypocalcemic.

Excessive Maternal Behavior

- The pseudopregnant bitch or bitch spayed during the late luteal phase of the estrous cycle adopts, attempts to nurse, and guards inanimate objects (stuffed animals or even leashes). The pseudopregnant bitch may have mammary development and may be lactating.
- The newly spayed queen may steal kittens from a lactating queen. Queens post-spaying may also lactate if suckled.

CAUSES AND RISK FACTORS

- The presence of kittens in the environment of the recently spayed cat is a risk factor for excessive maternal behavior and kitten stealing.
- The risk of excessive carrying of pups, redirected aggression, or even cannibalism is increased if there are other dogs or too many people present in the nest area.
- Primiparous females or those subjected to caesarian section are at higher risk than multiparous or naturally delivering females.
- A large litter of kittens or sick offspring.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The most important differential is between primary abnormal maternal behavior and poor maternal behavior secondary to mastitis or metritis.
- Lactation tetany can result in aggressive behavior, although this behavior is rarely directed at the puppies and occurs later in lactation, not at parturition.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal unless other medical conditions are present. Blood calcium levels will be low if the bitch is suffering from lactation tetany.

OTHER LABORATORY TESTS

Only as indicated by metabolic conditions of the bitch or queen.

IMAGING

Only as indicated by other problems.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Presence of milk in the mammary glands of females with excessive maternal behavior.

TREATMENT

APPROPRIATE HEALTH CARE

Normal health care

NURSING CARE

N/A

ACTIVITY

N/A

DIET

- Adequate diet for nursing bitches and queens to meet energy and calcium demands.
- Restricted diets for pseudocyesis to discourage lactation and diminish milk production.
- In the case of deficient maternal behavior, the bitch or queen should be fed ad libitum to encourage lactation.

CLIENT EDUCATION

Abnormal or Poor Maternal Behavior

- The bitch that is carrying her pups or exhibiting redirected aggression to them should be isolated in a quiet, dark area. The bitch that bites her pups should be muzzled. The owner must stimulate elimination of the puppies or kittens because the muzzled female cannot. An Elizabethan collar inhibits cannibalism in queens.
- The bitch should be attended at parturition and the pups removed temporarily if she is biting the pups themselves in addition to the umbilical cord.

(CONTINUED)

MATERNAL BEHAVIOR PROBLEMS

- Bitches and queens with poor maternal behavior may exhibit the same behavior with subsequent litters.

Excessive Maternal Behavior

- Cats that have stolen kittens should be separated from the biologic mother and kittens.
- The mothered objects should be removed from the pseudopregnant bitch.
- Food intake should be restricted to inhibit lactation.

Maternal Aggression toward Animals or Humans

The best treatment for excessive maternal aggression is to separate the kittens; weaning alone may not suffice because the presence of the kittens alone may sustain or even reinstate maternal aggression in a queen separated from her kittens for several weeks.

SURGICAL CONSIDERATIONS

- Delay spaying for 4 months post-estrus to avoid post-spaying maternal behavior and its accompanying aggression.
- Spaying avoids future excessive maternal behavior in the absence of young.

**MEDICATIONS****DRUG(S) OF CHOICE****Excessive Maternal Behavior**

- Mibolerone (Cheque Drops) was the drug of choice for pseudopregnant bitches or those exhibiting maternal behavior and lactation following spaying. The dose is 16 µg/kg PO once daily for 5 days. Mibolerone inhibits prolactin and thereby inhibits lactation. The drug is no longer available except at some compounding pharmacies.
- Bromocriptine (Parlodel) can be used to inhibit prolactin. The dose is 10 micrograms/kg for 10 days. Should not be administered to pregnant animals.
- Cabergoline is a prolactin antagonist shown to be effective for the treatment of pseudopregnancy in dogs. Dosage is 5 µg/kg PO q24h for 4–6 days. Some animals may require more than one course of treatment. Not commercially available in North America.

CONTRAINDICATIONS

Do not use mibolerone in cats because it has a narrow margin of safety in that species. It should not be administered to Bedlington terriers.

PRECAUTIONS

Mibolerone can cause masculinization that may include male sexual behavior, clitoral

hypertrophy, vulvovaginitis, and urinary incontinence in females. Bromocriptine can cause gastrointestinal vomiting, sedation, and hypotension as well as abortion.

POSSIBLE INTERACTIONS

- If tranquilizers are administered, care must be taken that the puppies or kittens are not sedated.
- Do not use estrogen or progesterones at the same time as mibolerone.

ALTERNATIVE DRUG(S)

Drugs are usually not needed.

Deficient Maternal Behavior

- Oxytocin may be administered either parenterally 1–5 units or by nasal spray (Syntocinon).
- Because prolactin appears to be necessary for maternal behavior in other species, a dopamine blocker, acepromazine (0.55–2.2 mg/kg PO), can be used. Dopamine inhibits prolactin release; therefore, a dopamine blocker would increase prolactin.

CONTRAINDICATIONS

Do not give oxytocin to pregnant animals or in combination with sympathomimetic agents.

**FOLLOW-UP****PATIENT MONITORING**

The puppies or kittens of females with deficient or poor maternal behavior should be monitored daily to be sure that they are gaining weight.

PREVENTION/AVOIDANCE

- Place a nursing female in quiet, comfortable quarters away from noise and disturbances by other animals or people.
- Do not rebreed females with poor maternal behavior. Determine whether any female offspring of the female with abnormal behavior have also exhibited poor maternal behavior. In other species, poor maternal behavior is a paternally imprinted gene; the father must contribute the gene for poor maternal behavior. The daughters of rejecting mothers will not reject, but the daughters of their sons may.
- Deficient maternal behavior can occur with each litter; do not rebreed.

POSSIBLE COMPLICATIONS

- Loss of offspring.
- Hand-reared puppies and kittens frequently have abnormal or deficient social behavior. This is due in part to insufficient suckling

time and to the consequences of lack of maternal licking, which adversely affects response to stress and reproductive behavior.

EXPECTED COURSE AND PROGNOSIS

- Excessive maternal behavior usually wanes around the time of normal weaning (6–8 weeks).
- Poor and deficient maternal behavior can occur with each litter.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

- Consider especially drug use and effect of disease on the fetus.
- Do not breed dogs with history of poor maternal behavior.

MAXILLARY AND MANDIBULAR FRACTURES

BASICS

DEFINITION

Fractures of the mandibles, maxillae, and associated structures are classified as to location, severity (i.e., tooth involvement, soft tissue tears, and type of bone fracture), and effects of the muscles of mastication on reduction.

PATHOPHYSIOLOGY

Effects of the Muscles of Mastication

- The muscles opening the mouth (e.g., digastric muscle) may help reduce or displace a fracture.
- Favorable—fracture reduced by muscles of mastication.
- Nonfavorable—fracture displaced by muscles of mastication.

Classification of Sympyseal Injury

- Type I—separation; no break in soft tissue.
- Type II—separation; break in soft tissue.
- Type III—separation; break in soft tissue and comminution of bone; broken teeth not unusual.
- Teeth involved may be maintained during osseous process (i.e., with endodontics or restoration). If required, they can be extracted following bone healing.
- Note: symphyseal laxity is a common clinical finding in geriatric cats and toy breed dogs.

Classification of Jaw Fracture by Location

- A—central incisors (mesial midline) to canine teeth (a symphysis is a common jaw fracture site in the cat)
- B—from canine to second premolar
- C—second premolar to first molar (carnassial tooth)
- D—from first molar to the angle of the mandible
- E—angle of the mandible
- F—coronoid process
- G—condylar process
- H—midline palate
- I—non-midline palate
- J—massive or combination of fractures

SIGNALMENT

Species

Dog and cat

SIGNS

- Vary greatly according to the location, type, extent, cause, and underlying risk factors resulting in the injury.
- Facial deformity, malocclusion, fractured teeth, oral or nasal bleeding, and inability to properly close the jaw are common signs.

CAUSES

Injury, trauma, and predisposing factors

RISK FACTORS

- High-risk environment or temperament.
- Oral infections (e.g., periodontal disease, osteomyelitis), neoplasia, or certain metabolic diseases (e.g., hypoparathyroidism)—may result in weaker jaws that are more prone to injury.
- Traumatic injury affecting the jaws or teeth.
- Congenital or hereditary factors resulting in weakened or deformed jaw bone.

DIAGNOSIS

A thorough and complete physical examination is very important in traumatic jaw injuries as many unseen or multiple injuries and complications are possible.

DIFFERENTIAL DIAGNOSIS

- Based on visualization, palpation, and radiographic findings.
- TMJ conditions—see Temporomandibular Joint Disorders.
- Tooth subluxation or luxation (i.e., interference with jaw closure).
- Endodontic disease (e.g., tooth abscess).
- Foreign body lodged in or near the oral cavity.
- Maxillary or mandibular nerve injury or disease.
- Eosinophilic myositis.
- Craniomandibular osteopathy.
- Neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

As required—to assess and treat shock from initial injury; to assess animal prior to surgery.

IMAGING

Radiography—*intraoral and extraoral; CT and MRI*

DIAGNOSTIC PROCEDURES

- Oral examination
- Neurologic examination
- Biopsy for histopathology, if indicated

PATHOLOGIC FINDINGS

- Non-unions
- Neoplasia
- Osteomyelitis
- Periodontal and/or endodontic disease

TREATMENT

SURGICAL CONSIDERATIONS

- Based on type of fracture, available equipment, supplies, and the doctor's knowledge, experience, and comfort level.
- Treatment selection is based on four major points: (1) Reduction of fracture and reasonable contact of fracture ends, if possible.
- (2) Reestablishment of natural occlusion, and avoidance of causing a malocclusion when the fracture is reduced.
- (3) Stabilization sufficient for proper healing.
- (4) Salvage condition (nonrepairable or non-stabilizable condition).

TYPICAL TYPES OF TREATMENTS FOR CLASSES OF FRACTURES

Interarch Stabilization (Typically for Classes D, E, F, G, and J)

- Tape muzzle
- Cross-arch wiring (maxilla to mandible)
- Composite fixation of cross-arch teeth; sometimes used in combination with dental pins (e.g., TMS, Whaledent, New York, NY)
- Bimaxillary encircling and retaining device (BEARD)
- Cross-arch buttons

Intra-Arch Stabilization (Typically for Classes H and I)

- Pin and wire combination
- Dental wiring
- Acrylic or composite splint

Intraoral Stabilization with Splint

(Typically for Classes A, B, C, H, I, and J)
Composite or acrylic splint

Intraoral Stabilization with Wire

(Typically for Classes A, B, C, H, I, and J)

- Interdental wiring—Ivy loop, Stout's multiple loop, Essig, and Risdon wiring techniques.
- Dental wiring—circumferential used for anchorage for composite and acrylic splints (pig tails, cerclage, or twists).
- Osseous wiring—circumferential; transosseous; transcircumferential.

Internal Fixation (for Most Classes of Fractures, but Must Be Used Selectively with Consideration of Teeth and Roots)

- Orthopedic wire; IM pins; plates; screws.
- Note: do NOT place an IM pin within the mandibular canal.

External Fixation (for Most Classes of Fractures, but Must Be Used Selectively with Consideration of Teeth and Roots)

IM pins with bars (stainless steel or carbon) or tubing (e.g., Penrose) reinforced with composite or acrylic.

Salvage Surgery (Typically for Class J Fractures)

- Condylectomy—non-repairable fractures of the TMJ.
- Cheiloplasty—salvage procedure to maintain reasonable mandibular support in certain nonunion conditions.
- Rostral (or other) mandibulectomy—used in certain non-union cases or with massive injury.

TECHNIQUES

Below are more commonly used techniques; more advanced options are beyond the scope of this chapter (see "Suggested Reading").

Initial Treatment

- Awareness of occlusion, tooth roots, and anatomy during treatment is critical.
- Patient should be intubated, and a pharyngostomy tube aids in occlusal checks intraoperatively.
- Teeth in the fracture line should be assessed and maintained by appropriate treatment until the fracture heals, if possible, as removal may result in instability.
- Bone graft—to re-establish structural stability: autograft (harvested from individual); allograft—(same species); Alloplast (artificial material).
- Treatment with composite/acrylic splints in association with wiring (Ivy loop, Stout's multiple loop) is generally very effective; may allow for improved occlusal reestablishment and less dental trauma.
- Assess soft tissue damage, debride and suture where appropriate.

Procedure

- Disinfect with chlorhexidine and clean and polish teeth (flour pumice without fluoride).
- Reduce fracture in proper occlusion.
- Coat adjacent teeth and soft tissue with petroleum jelly.
- Acid etch the teeth with a 37% phosphoric acid gel; leave on for 30–60 seconds; rinse off thoroughly and air dry the teeth.
- Apply splint.

(CONTINUED)

MAXILLARY AND MANDIBULAR FRACTURES**Materials****Acrylics**

Warning: Acrylics give off vapors that can be hazardous and should be used in well-ventilated areas. They also generate heat during the thermochemical reaction during setting that can result in thermal injury to the teeth (pulpitis).

- Place the powder and liquid in a salt-and-pepper fashion in small increments (to avoid hyperthermic reaction) until the desired shape and density of splint attained.
- Finish and smooth with acrylic bur on high-speed handpiece.

Composites (ProttempGarant-ESPE)

- Little exothermal reaction and fumes; more expensive.
- After acid-etching, use a dentinal bonding agent and apply a separator agent to opposing arcade to prevent composite from bonding to these teeth during occlusion check.
- With a new mixing tip, apply product to splint area, shaping it as it hardens.
- Finish and smooth with white stone bur and place a final layer of unfilled resin.

Circumferential Osseous Wiring or Suturing

- Wiring around the bone—used most commonly for symphyseal separations.
- 20- or 18-gauge needle—to pass wire.
- 24- to 28-gauge wire—in neonates, small dogs or cats, absorbable (long-acting—e.g., PDS) or non-absorbable 1- to 2-0 suture material can sometimes be substituted for wire.
- Run wire from stab incision (ventral intermandibular space) to vestibule; pass behind canines, down through vestibule on opposite side, and back down through the ventral incision.
- Tighten wire to reduce fracture, but do not overtighten the wire ends or the teeth may be pulled too far medially (base narrow, lingually displaced) and hit the palate.
- If teeth go base narrow, either loosen the wire ends or place a figure-8 wire looped around the canine teeth and under the jaw.

HOMECARE

- Orthodontic wax—soft, pliable wax sent with owner to periodically cover irritating wires.
- Oral irrigants—use twice daily for oral hygiene and to reduce bacteria; chlorhexidine solutions help reduce bacteria; zinc and ascorbic acid solutions (Maxi-Guard Gel, Addison Biological) help reduce bacteria and stimulate soft tissue healing.
- Diet—soft food or gruel may be required during healing.
- Nutritional and fluid maintenance required.
- Chewing exercise—avoid hard chew items during healing process.

**MEDICATIONS****DRUG(S)****Pain Management**

- Local anesthesia— intraoral local blocks; regional nerve blocks: mental n., mandibular

n., infraorbital n., palantine n., and maxillary n.

- Injectables—butorphanol tartrate; buprenorphine; nalbuphine.
- Transdermal patches—fentanyl.
- Oral—carprofen; butorphanol tartrate; hydrocodone.

Antibiotics

- Broad-spectrum based on history, health, and chemical profile.

**FOLLOW-UP****PATIENT MONITORING**

- Physical—recheck 2 weeks postoperative.
- Radiographic—recheck 4–6 weeks postoperative, then every 2 weeks until fracture is healed and/or appliance is removed.
- Fracture site may temporarily (1–2 weeks) be more at risk to refracture after the support of the appliance is removed.
- Once the fracture line is stable, compromised teeth may need additional endodontic treatment (e.g., root canal) or careful extraction.
- If the healing process results in a malocclusion—orthodontics, endodontics, and/or selective exodontia (extraction) may be required.
- Other considerations—stability of fracture and appliance; oral hygiene; oral intake of food and water; maintenance of weight; appropriate urination and defecation; indications of pain or swelling.

PREVENTION/AVOIDANCE

Try to minimize risk of trauma.

POSSIBLE COMPLICATIONS

- Malocclusion • Endodontic disease
- Osteomyelitis • Non-union • Sequestrum
- Dehiscence • Neurologic defects • Facial pain syndrome • Impaired mastication
- Temporary weight loss • Soft tissue trauma due to appliance or wires

POSSIBLE SEQUELAE**Impaired Mastication**

- TMJ arthritis—chronic or intermittent TMJ pain; may require condylectomy.
- Malocclusion—dental attrition; may require extractions.
- Non-union—may require partial or complete mandibulectomy or maxillectomy.
- Ankylosis of mandible at the TMJ or zygomatic arch area.

Facial Pain Syndrome

- Acute or chronic.
- Due to nerve trauma from injury or as a complication of surgery.

Nerve Damage

Affecting motor function

EXPECTED COURSE AND PROGNOSIS

- Generally good; however, predisposing factors, initiating force, location, type of fracture, quality of homecare, and selection of treatment modality all affect the healing outcome.
- 4–12 weeks to bony union.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Malocclusion • Mastication difficulty
- Lack of head symmetry • Soft tissue trauma
- Periodontal disease • Chipped, broken, luxated, or avulsed teeth

AGE-RELATED FACTORS

Fracture healing may be faster in younger animals.

M

MEDIASTINITIS

BASICS

OVERVIEW

- The mediastinum occupies the central portion of the chest and is defined anatomically by the thoracic inlet cranially, the diaphragm caudally, the mediastinal pleura laterally, the paravertebral gutters and ribs dorsally, and the sternum ventrally. It is lined on both sides by parietal pleura, contains the major organs in the central thorax, and separates these organs from the left and right lung lobes.
- Mediastinitis—an inflammatory process involving the mediastinal space, usually the result of bacterial or fungal infection.
- Acute disease—severe infection may be life-threatening and can spread to the pleural space; sepsis can occur.
- Chronic—mediastinal granuloma or abscess can develop and result in cranial vena cava syndrome or chronic smoldering internal abscessation.
- Systems affected—cardiovascular system through interference with venous return; respiratory system secondary to intrathoracic mass effect or pleural effusion; gastrointestinal system through esophageal obstruction.

M SIGNALMENT

Rare in dogs and cats

SIGNS

- Lethargy and weakness.
- Dysphagia and regurgitation.
- Edema of head, neck, and forelimbs.
- Polypnea, respiratory difficulty or obstructed breathing, and cough.
- The presence of a fever should raise the suspicion for an infectious process.

CAUSES & RISK FACTORS

- Acute disease—usually result of esophageal perforation, tracheal tear, foreign body migration, or neck wound; mediastinal abscesses can develop subsequent to infections or neoplastic disorders arising in the mediastinum or adjacent tissues.
- Chronic disease—usually result of a bacterial (e.g., *Actinomycetes* and *Nocardia* spp.) or fungal (e.g., *Coccidioides*, *Cryptococcus*, *Blastomyces*, and *Histoplasma* spp.) infection. *Spirocercus lupi* infection possible in certain geographic regions.
- Predisposing factors—esophageal foreign body; cervical or thoracic trauma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Isolated pericarditis, pyothorax, and pneumonia.
- Cranial mediastinal mass—lymphosarcoma; thymoma, thyroid, or parathyroid tumor; neurogenic tumor; mesenchymal tumor; mediastinal cyst.

- Esophageal motor dysfunction, sliding hiatal hernia.
- Gastroesophageal disorders, causing gastroesophageal reflux, chronic vomiting, and other upper GI conditions.

CBC/BIOCHEMISTRY/URINALYSIS

- High WBC count with left-shift.
- PCV and total protein—may be high owing to volume depletion/dehydration.

OTHER LABORATORY TESTS

Additional laboratory tests to rule-out other possible causes of clinical signs.

IMAGING

- Thoracic radiographs—usually demonstrate a focal or diffuse widening of the mediastinum; can be accompanied by pneumothorax or bilateral pleural effusion, depending upon the underlying disease process.
- Esophageal contrast study—investigate esophageal perforation or other abnormality; use a water-soluble contrast medium with suspected perforation (i.e., iohexol or iopamidol).
- Thoracic ultrasonography—differentiate between mediastinal fluid accumulation (e.g., cyst and abscess), inflammatory reaction, and tumor.
- Computed tomography—more definitive than ultrasound.

DIAGNOSTIC PROCEDURES

- Cytology—thoracocentesis of any pleural effusion; transthoracic fine-needle aspirate or cutting-needle biopsy of a mediastinal mass that is not cardiac or vascular in origin.
- Ultrasound-guided aspirate or biopsy most helpful in accurate sampling of tissues.
- Submit samples for aerobic and anaerobic bacterial culture and sensitivity testing.

TREATMENT

- Antibiotic or antifungal therapy as indicated.
- Drainage and debridement of abscessed material.
- Inpatient therapy with restricted activity until infection is controlled and condition is stable.
- Pleural effusion of marked quantity or pyothorax of any degree—managed by tube thoracostomy or possibly surgery.
- Intravenous fluid therapy, parenteral nutrition or esophageal feeding tube—until oral water and food intake returns to normal or near normal.
- Esophageal perforation—surgical emergency; after surgery, use either parenteral nutrition or gastric tube feeding for 3–5 days.
- Chronic disease—surgical exploration needed when associated with an abscess or a granuloma.
- Tube thoracostomy—maintain post-surgery by continuous water seal suction or intermittent lavage and suction for 5–7 days or until negligible fluid is removed.

MEDICATIONS

DRUG(S)

- Broad-spectrum bactericidal antibiotic—based on bacterial culture and sensitivity testing; should be administered parenterally for at least the first week of treatment, then orally.
- Antifungal treatment—indicated for mycotic infection. Recommended agents include itraconazole, fluconazole, and amphotericin B; treatment usually required for 3–6 months.

FOLLOW-UP

PATIENT MONITORING

- Daily temperature recording.
- Hemogram—every 2–3 days during hospitalization (usually 7–10 days).
- Thoracic radiographs—at 7- to 10-day intervals (more often if drainage is needed).
- Antibiotics—generally continue for 1 week after hemogram and radiographs return to normal; with abscessation, continue an additional 4–6 weeks.

POSSIBLE COMPLICATIONS

- Pyothorax
- Sepsis
- Mediastinal fibrosis

EXPECTED COURSE AND PROGNOSIS

- Advise clients of guarded prognosis.
- With early diagnosis and aggressive treatment—prognosis fair to good.
- With mediastinal fibrosis—long-term prognosis guarded to poor.
- Recognized complications—esophageal dysmotility; compression of the cranial or caudal vena cava; phrenic or recurrent laryngeal nerve paralysis.

MISCELLANEOUS

ABBREVIATIONS

- GI = gastrointestinal
- PCV = packed cell volume
- WBC = white blood cell

MEGACOLON**BASICS****DEFINITION**

A gastrointestinal disorder characterized by persistently increased large bowel diameter associated with chronic constipation/obstipation and low-to-absent colonic motility.

PATHOPHYSIOLOGY

- Acquired megacolon results from chronic colonic fecal impaction that leads to excessive absorption of fecal water and solidified fecal concretions.
- Prolonged distension of the colon results in irreversible changes in colonic motility that leads to colonic inertia.
- Congenital absence of colonic ganglionic cells (Hirschsprung's disease) is not clearly documented in small animals.
- The pathogenesis of idiopathic megacolon in cats likely involves a disturbance of normal colonic smooth muscle function.

SYSTEMS AFFECTED

Gastrointestinal

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT**Species**

- Idiopathic megacolon—cat
- Acquired megacolon—cat and dog

Breed Predilections

Some evidence for increased risk in Manx cat

Mean Age and Range

- Idiopathic megacolon—middle-aged to older cats (mean age, 4.9 years; range, 1–15 years).
- Acquired megacolon—none.

Predominant Sex

None

SIGNS**Historical Findings**

- Idiopathic megacolon—typically a chronic/recurrent problem; signs often present for months to years.
- Acquired megacolon—signs may be acute or chronic.
- Constipation/obstipation.
- Tenesmus with small or no fecal volume.
- Hard, dry feces.
- Infrequent defecation.
- Small amount of diarrhea (often mucoid) may occur after prolonged tenesmus.
- Occasional vomiting, anorexia, and/or lethargy with chronic fecal impaction.
- Weight loss.

Physical Examination Findings

- Abdominal palpation reveals an enlarged colon with hard feces.
- Digital rectal examination may indicate an underlying (obstructive) cause and confirms fecal impaction.
- Dehydration.
- Scruffy, unkempt hair coat.

CAUSES

- Idiopathic—cats.
- Mechanical obstruction—pelvic fracture malunion, foreign body or improper diet (especially bones), stricture, prostatic disease, perineal hernia, neoplasia, anal or rectal atresia.
- Causes of dyschezia—anorectal disease (anal sacculitis, anal sac abscess, perianal fistula, proctitis), trauma (fractured pelvis, fractured limb, dislocated hip, perianal bite wound or laceration, perineal abscess).
- Metabolic disorders—hypokalemia, hypocalcemia, severe dehydration.
- Drugs—vincristine, barium, antacids, sucralfate, anticholinergics.
- Neurologic/neuromuscular disease—congenital abnormalities of the caudal spine (especially Manx cats), paraplegia, spinal cord disease, intervertebral disc disease, dysautonomia, sacral nerve disease, sacral nerve trauma (e.g., tail fracture/pull injury), trauma to colonic innervation.

RISK FACTORS

- Conditions leading to inability to posture (limb and pelvic fractures, neuromuscular disease, etc.) or rectoanal pain.
- Prior pelvic fractures.
- Possible association with low physical activity and obesity.
- Perineal hernias.

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

- Other causes of palpable colonic masses (e.g., lymphoma, carcinoma, intussusception)—distinguish on the basis of texture, rectal examination, imaging, and mucosal biopsy.
- Dysuria/stranguria—exclude by palpation of the bladder and colon, and by urinalysis.
- Tenesmus due to inflammation of the colonic mucosa (colitis)—exclude by palpation, rectal examination, and endoscopic imaging with mucosal biopsy.

CBC/BIOCHEMISTRY/URINALYSIS

- May show evidence of dehydration (elevated packed cell volume, total protein) and stress leukogram.
- Electrolyte abnormalities may develop depending on duration of obstipation; may be prerenal azotemia with dehydration.
- Urinalysis—no consistent changes; important to confirm normal renal function

in dehydrated animals and to rule out lower urinary tract disease as a differential diagnosis.

OTHER LABORATORY TESTS

N/A

IMAGING

- Abdominal/pelvic radiographs to identify any underlying causes.
- Can easily see the enlarged, fecal-filled colon on survey abdominal radiographs.
- Abdominal ultrasound may identify mural or obstructive masses.

DIAGNOSTIC PROCEDURES

May need colonoscopy to rule out mural or intraluminal obstructive lesions.

PATHOLOGIC FINDINGS

- The most severe dilation typically occurs in the transverse and descending colon, although the entire length of the colon can be involved.
- The colon is usually histologically unremarkable with megacolon.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Inpatient medical management; surgery may be indicated if recurrent/severe problem.
- Medical therapy—restore normal hydration, followed by anesthesia and manual evacuation of the colon using warm water enemas, water-soluble jelly, and gentle extraction of feces with a gloved finger or sponge forceps; do not traumatize the colonic mucosa.
- Continue long-term therapy at home.

NURSING CARE

- Most patients require parenteral fluid support to correct dehydration.
- Intravenous administration of balanced electrolyte solutions is the preferred route.

ACTIVITY

- Encourage activity and exercise.
- Restriction indicated in the postoperative period if surgery is performed.

DIET

- Many patients require a low-residue producing diet; bulk-forming fiber diets can worsen or lead to recurrence of colonic fecal distension.
- A high-fiber diet is occasionally helpful.
- A more palatable, maintenance-type diet can be supplemented with fiber-enriched foods (pumpkin) or products containing fermentable fiber such as Metamucil.

CLIENT EDUCATION

- In idiopathic disease or with severe colonic injury, medical therapy is often life-long and can be frustrating to clients.
- Increased activity of the cat with daily or alternate-day subcutaneous fluid therapy can help minimize recurrences in many cats.
- Recurrence of megacolon is common.

MEGACOLON

(CONTINUED)

- Surgery (subtotal colectomy) is indicated if medical therapy fails.

SURGICAL CONSIDERATIONS

- An underlying obstructive cause requires surgical correction.
- Avoid enema administration/colonic evacuation prior to subtotal colectomy.
- Subtotal colectomy with ileorectal or colorectal anastomosis—treatment of choice for idiopathic megacolon refractory to medical management.
- Colectomy may also be required with obstructive megacolon caused by irreversible changes in colonic motility.

MEDICATIONS

DRUG(S) OF CHOICE

- Can improve colonic motility in less severe cases with cisapride, a prokinetic gastrointestinal drug (dogs, 0.3–0.5 mg/kg PO q8–12h; cats, 2.5–10 mg/cat q8–12h). Metoclopramide does not affect colonic motility and should not be used in cats with megacolon.
- Stool softeners (e.g., lactulose, 1 mL/4.5 kg PO q8–12h to effect) are recommended in conjunction with cisapride and diet.
- Broad-spectrum antibiotics are recommended prior to surgery to reduce the potential for bacterial sepsis.

M

CONTRAINDICATIONS

- Sodium phosphate retention enemas (e.g., Fleet; C.B. Fleet Co., Inc.)—because of their association with severe hypocalcemia.
- Mineral oil and white petrolatum—because of danger of fatal lipid aspiration pneumonia due to lack of taste.

PRECAUTIONS

Common hairball laxatives (e.g., Laxatone, Cat-a-Lax) are typically ineffective.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Docusate sodium can be used as a stool softener in place of lactulose.

FOLLOW-UP

PATIENT MONITORING

- Following colonic resection and anastomosis—for 3–5 days check for signs of dehiscence and peritonitis.
- Clinical deterioration warrants abdominocentesis and/or peritoneal lavage to detect anastomotic leakage.
- Continue fluid support until the patient is willing to eat and drink.

PREVENTION/AVOIDANCE

- Repair pelvic fractures that narrow the pelvic canal.
- Avoid exposure to foreign bodies and feeding bones.

POSSIBLE COMPLICATIONS

- Recurrence or persistence—most common.
- Potential surgical complications include peritonitis, persistent diarrhea, fecal incontinence, stricture formation, and recurrence of obstipation.
- Traumatic perforation of the colon is a serious complication of overzealous fecal evacuation.

EXPECTED COURSE AND PROGNOSIS

- Historically, medical management has been unrewarding for the long term.
- Cisapride appears to improve the prognosis with medical management in some patients, but may not suffice in severe or long-standing cases.
- Postoperative diarrhea—expected; typically resolves within 6 weeks (80% of cats with idiopathic megacolon undergoing subtotal colectomy) but can persist for several months; stools become more formed as the ileum

adapts by increasing reservoir capacity and water absorption.

- Subtotal colectomy is well tolerated by cats; constipation recurrence rates are typically low.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Perineal hernia

AGE-RELATED FACTORS

Concurrent medical conditions (e.g., chronic renal insufficiency, hyperthyroidism) may occur with idiopathic megacolon, because many cats are old.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

- The effect of cisapride on the fetus is unknown.
- Patients would be at increased risk for dystocia if they carried a pregnancy to term.

SEE ALSO

- Constipation and Obstipation
- Dyschezia and Hematochezia
- Perineal Hernia

MEGAESOPHAGUS

BASICS

DEFINITION

A focal or generalized, diffuse dilation of the esophagus with decreased to absent peristalsis.

PATHOPHYSIOLOGY

- In the normal esophagus, the presence of a food bolus in the proximal esophagus stimulates afferent sensory neurons.
- Signals are transferred centrally, via the vagus and glossopharyngeal nerves to the tractus solitarius and nucleus ambiguus.
- Motor impulses travel back via the efferent neurons of the vagus nerve to stimulate striated muscle (canine) and striated and smooth muscle (feline) esophageal contraction.
- Lesions anywhere along this pathway may lead to megaesophagus and resultant retention of food and liquids.
- There is evidence that afferent nerve dysfunction is the most common lesion in idiopathic cases of megaesophagus. Focal megaesophagus is typically caused by esophageal obstruction distal to the dilated portion of esophagus.

SYSTEMS AFFECTED

- Gastrointestinal—dysphagia, regurgitation, weight loss.
- Musculoskeletal—weakness, weight loss, exercise intolerance, dysphonia.
- Nervous—possible manifestation of systemic neurologic/neuromuscular disorder.
- Respiratory—aspiration pneumonia, coughing.

GENETICS

- Congenital form—megaesophagus can be inherited in wirehaired fox terriers (autosomal recessive) and miniature schnauzers (autosomal dominant or 60% penetrance autosomal recessive).
- Other breeds reported include dachshund, German shepherd, Great Dane, Irish setter, Labrador retriever, pug, and Chinese shar-Pei.
- Myasthenia gravis may be congenital in Jack Russell terriers, springer spaniels, smooth fox terriers, dachshunds, and Samoyeds.
- Acquired form—many diseases, especially neuromuscular diseases, may have an association with megaesophagus. Genetic predispositions for such diseases are listed under each disease separately.

INCIDENCE/PREVALENCE

- Congenital forms—rare
- Acquired disease—uncommon in the dog and rare in the cat.

SIGNALMENT

Species

Dogs are more commonly affected than cats

Breed Predilections

- Dogs—see “Genetics”
- Cats—Siamese and Siamese-related cats

Mean Age and Range

- Congenital cases present soon after birth or at weaning during transition from liquid diets to solid foods.
- Acquired cases may be seen at any age, depending on the etiology.

SIGNS

Historical Findings

- Owners often report vomiting; the veterinarian must differentiate vomiting from regurgitation.
- Regurgitation (considered the hallmark sign); dysphagia; coughing/nasal discharge with aspiration pneumonia; ravenous appetite or inappetence; weight loss or poor growth; ptalism, and halitosis.
- Dysphonia may occur secondary to neuromuscular disease.
- Other signs depend upon underlying etiology.

Physical Examination Findings

- Cervical swelling may be noted, representing a distended cervical esophagus; ptalism; halitosis; increased respiratory noises, nasal discharge, and fever (if concurrent pneumonia); cachexia; weakness; weight loss.
- Assess for concurrent neurologic deficits that may indicate generalized disease. Special attention should be paid to cranial nerves IX, X, and XI. Muscle atrophy (if present) may be focal or generalized.

CAUSES

Congenital

Idiopathic megaesophagus; congenital MG (rare)

Acquired/Adult Onset

- Idiopathic (most common).
- Neuromuscular disease—MG, focal or generalized (25% of cases in dogs); SLE; myositis/myopathic disease; dysautonomia (more common in cats); botulism; vagal dysfunction/damage (bilateral); a possible association between laryngeal paralysis and esophageal dysmotility secondary to polyneuropathy has been identified.
- Brainstem disease—disease involving CN IX, X nuclei or peripheral nerves.
- Esophageal obstruction—vascular ring anomaly; esophageal or periesophageal neoplasia (e.g., lymphoma, leiomyoma); stricture; foreign body; granuloma.
- Toxicity—lead, thallium, anticholinesterase; acrylamide.
- Endocrine disease—hypoadrenocorticism, hypothyroidism (controversial). Thymoma is associated with MG and megaesophagus in approximately 25% of cats.
- Miscellaneous—gastric dilatation volvulus, hiatal hernia, gastroesophageal intussusception; esophagitis (gastroesophageal reflux, parasitic infection).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Must distinguish regurgitation from vomiting.
- Regurgitation—passive; little to no abdominal effort; no prodromal phase; regurgitated material has increased amounts of thick mucus.
- Vomiting—active process; prodromal phase; vomited material may have increased bile staining.
- The shape of the

expelled material, presence of undigested food, and length of time from ingestion to regurgitation or vomiting are less helpful to differentiate.

CBC/BIOCHEMISTRY/URINALYSIS

- May be normal.
- Inflammatory leukogram may be seen with pneumonia.
- Other changes may identify underlying etiology—basophilic stippling on red blood cells with lead toxicity; electrolyte disturbances with hypoadrenocorticism; hypercholesterolemia with hypothyroidism; elevated creatine kinase with myopathic disease.

OTHER LABORATORY TESTS

- Acetylcholine receptor antibody titer in all cases of megaesophagus (screen for MG). Approximately 2% of dogs with generalized MG are seronegative; testing should be repeated 2–3 months later, particularly if initial antibody titer is only slightly below the reference interval.
- ACTH stimulation test or baseline cortisol level for hypoadrenocorticism.
- Thyroid panel for hypothyroidism (may be affected by concurrent disease).
- Blood and urine lead levels.
- ANA titers for SLE.
- Blood cholinesterase levels for organophosphate toxicity.

IMAGING

Survey Thoracic Radiographs

- Dilated esophagus filled with air, fluid, or food. Interpret thoracic radiographs in anesthetized animals and anxious or painful animals with caution in light of aerophagia that can cause distention of the esophagus with air.
- Evidence of aspiration pneumonia.
- Ventral displacement of the trachea on lateral radiographs.
- Ventrodorsal radiographs may show lateral tracheal displacement.
- Evidence of underlying etiology: mediastinal mass (thymoma), hiatal hernia, neoplasia, etc.
- Radiographs do not differentiate dogs with megaesophagus due to MG from dogs with megaesophagus due to other etiologies.

Contrast Esophagram and Video-Fluoroscopy

- Barium liquid and barium meal may demonstrate abnormal pooling, poor motility, or structural lesions. Iohexol may be used if perforation is a concern.
- Use with caution in animals with megaesophagus due to risk of aspiration of contrast material.
- Exercise extreme caution in animals with radiographic evidence of pneumonia.
- Monitor animals closely after radiographs for signs of aspiration.
- Videofluoroscopy—may be used to assess primary and secondary esophageal peristalsis. May help determine the best food consistency for long-term management.

DIAGNOSTIC PROCEDURES

- Esophagoscopy—may be used for foreign body retrieval, evaluation of suspected obstructive lesions, neoplasia, or esophagitis.

MEGAESOPHAGUS

(CONTINUED)

Distal esophageal neoplasia may mimic idiopathic megaesophagus and may require endoscopy for diagnosis.

- Electrophysiology—in cases of suspected neuromuscular disease, may be used in conjunction with muscle and nerve biopsies.
- Additional tests—may be indicated in cases of CNS disease: CSF analysis, distemper titers, brain CT or MRI. • Fecal exam—may indicate *Spirocerca lupi* infection.

PATHOLOGIC FINDINGS

Depend upon underlying etiology and presence of complicating factors.

TREATMENT

APPROPRIATE HEALTH CARE

- Treat underlying etiology (when applicable).
- Most important aspects are meeting nutritional requirements and treating or preventing aspiration pneumonia.

NURSING CARE

• Aspiration pneumonia may require oxygen therapy, nebulization/coupage, fluid therapy with balanced electrolyte solution. • These animals may be recumbent and require soft bedding and should be maintained in sternal recumbency or turned to alternate down side every 4 hours.

ACTIVITY

Depending on etiology, restricted activity is not necessary.

DIET

- Calculate precise nutritional requirements, including degree of debilitation.
- Experimentation with different food consistencies is essential (e.g., liquid gruel, small meatballs, blenderized slurries). • Many cases benefit from gastrostomy tube placement for feeding; however, this does not prevent gastroesophageal reflux and potential aspiration or aspiration of saliva. • Feeding and drinking should be from an elevated position (45–90° from floor) and the upright position should be maintained for 10–15 minutes after eating or drinking. An upright position may be easier to attain with the use of a specific "chair" (e.g., Bailey chair).

CLIENT EDUCATION

- Most cases of megaesophagus require life-long therapy. Even if an underlying etiology is found and treated, prognosis for resolution of megaesophagus is guarded. Client dedication is important for long-term management. • Most animals succumb to or are euthanized because of aspiration pneumonia or progression of underlying disease.

SURGICAL CONSIDERATIONS

- Surgery is indicated for vascular ring anomalies, bronchoesophageal fistula, some foreign bodies and other obstructive lesions,

or thymectomy. • Balloon dilation is indicated for cases of esophageal stricture. • Surgical resection of megaesophagus is not recommended.

MEDICATIONS

DRUG(S)

- Antibiotics for aspiration pneumonia (ideally based on culture and sensitivity from transtracheal wash or bronchoalveolar lavage).
- Therapy for underlying etiology if indicated—immunosuppressives (use with caution if pneumonia present) for immune-mediated disease; pyridostigmine for MG, prednisone supplementation for hypoadrenocorticism • H₂ blockers for esophagitis—ranitidine (1–2 mg/kg PO, IV q12h), famotidine (0.5–1 mg/kg PO, SC, IM, IV q12–24h). Proton pump inhibitors may be used in severe cases—omeprazole (1 mg/kg PO q24h) or pantoprazole (1 mg/kg IV q24h).

Prokinetics

- The use of prokinetics in dogs and cats with diffuse megaesophagus is controversial and should be avoided because they will tighten the lower esophageal sphincter and possibly increase the risk of aspiration pneumonia. Prokinetics such as metoclopramide (1.0–2.0 mg/kg/day IV CRI or PO q6–8h) or cisapride (0.5 mg/kg PO q8–12h) are more effective for minimizing gastroesophageal reflux and esophagitis. Cisapride is more potent and effective than metoclopramide for increasing lower esophageal tone and enhancing gastric emptying, and can be used in animals with evidence of esophagitis but no evidence of megaesophagus, or in cats with esophageal dysmotility affecting the smooth muscle in the distal 1/3 of the esophagus.

PRECAUTIONS

- Absorption of orally administered drugs may be compromised. • Injectable forms should be used when applicable.
- Immunosuppression, if indicated, must be used with caution due to risk of aspiration pneumonia.

FOLLOW-UP

PATIENT MONITORING

- Thoracic radiographs when aspiration pneumonia is suspected (fever, cough, lethargy). • Cases of pneumonia may require CBC, blood gas analysis, and bronchoalveolar lavage. Repeat thoracic radiographs in animals with congenital megaesophagus as spontaneous resolution may occur. • Examine and weigh patients regularly to evaluate disease progression and ensure adequate nutritional intake.

PREVENTION/AVOIDANCE

If an esophageal foreign body is identified, remove as quickly as possible.

POSSIBLE COMPLICATIONS

- Aspiration pneumonia • Others, depending on etiology

EXPECTED COURSE AND PROGNOSIS

- Congenital cases have a guarded prognosis (20–40% recovery). • Miniature schnauzers may have better prognosis. • Prognosis may be improved with identification and treatment of specific etiology (e.g., hypoadrenocorticism, vascular ring anomaly).
- Roughly 50% cases of MG respond to therapy; however, megaesophagus may persist even if other signs of MG resolve. • Prognosis for idiopathic, adult onset disease is poor.
- Owner dedication is crucial.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Aspiration pneumonia

AGE-RELATED FACTORS

- Signs of regurgitation in very young animal or at weaning may indicate congenital lesion.
- Prognosis may be better in young animals.

ZOONOTIC POTENTIAL

- None for megaesophagus. • Rabies vaccination status should be determined in any animal with possible neurologic disease.

SYNOMYMS

- Esophageal aperistalsis • Esophageal dilatation

SEE ALSO

- Dysphagia • Esophageal Foreign Bodies
- Myasthenia Gravis • Pneumonia, Aspiration
- Pneumonia, Bacterial • Regurgitation

ABBREVIATIONS

- ACTH = adrenocorticotrophic hormone
- ANA = antinuclear antibody • CNS = central nervous system • CSF = cerebrospinal fluid • CT = computed tomography • MG = myasthenia gravis • MRI = magnetic resonance imaging • SLE = systemic lupus erythematosus

MELANOCYTIC TUMORS, ORAL

BASICS

DEFINITION

Tumor of melanocytes arising in the oral cavity (gingiva, palate, tongue), most frequently malignant.

PATHOPHYSIOLOGY

- Locally invasive.
- Metastatic in > 75% cases in dogs (lymph nodes, lungs, other).
- When malignant, may invade into the underlying bone.

SYSTEMS AFFECTED

- Oral cavity (gingiva, palate, tongue)
- Metastatic sites—lymph nodes, lungs, bones, other

GENETICS

Unknown

INCIDENCE/PREVALENCE

- Dogs—most common malignant oral tumor, accounting for ~ 40% of neoplasms.
- Cats—third most common oral malignancy.

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dog more than cat

Breeds

- Dogs—cocker spaniel, miniature poodle, retriever breed, chow chow (tongue)
- Cats—none

Mean Age and Range

- Dogs—11 years (5–18 years)
- Cats—12 years (11–15 years)

Predominant Sex

- Dogs—male predisposed (in some studies)
- Cats—not reported

SIGNS

Historical Findings

- Excessive salivation
- Halitosis
- Dysphagia
- Bloody oral discharge
- Weight loss

Physical Examination Findings

- Oral mass (up to one-third are poorly pigmented or amelanotic), often friable
- Loose teeth
- Facial deformity (including exophthalmos)
- Regional lymphadenomegaly
- Pain or discomfort

CAUSES & RISK FACTORS

Overrepresented breeds

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other oral tumors (squamous cell carcinoma, fibrosarcoma)
- Epulides
- Gingival hyperplasia
- Tooth root abscess

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

Immunohistochemical markers—may help differentiate melanoma (especially amelanotic) from other tumors; may stain positive with vimentin, S-100, neuron-specific enolase, HMB-45 and Melan A (most specific, but somewhat less sensitive marker).

IMAGING

- High-detail skull radiography or dental radiographs—evaluate for osteolytic changes.
- Advanced imaging such as contrast-enhanced CT or MRI—better detail (especially maxilla) and helps with therapeutic planning (surgery or radiation therapy).
- Thoracic radiography or CT—evaluate lungs for metastasis.
- Abdominal ultrasonography—to complete clinical staging, occasional distant metastasis in abdominal visceral organs.

DIAGNOSTIC PROCEDURES

- Large and deep tissue biopsies—required to obtain definitive diagnosis via histopathology. Biopsies always taken from inside the mouth, not through the skin (would compromise local control with surgery).
- Fine-needle aspiration and cytology of regional lymph nodes (mandibular and retropharyngeal) recommended to evaluate for regional metastases, regardless of their size and consistency upon palpation.

PATHOLOGIC FINDINGS

Gross

- Masses—may be ulcerated and friable, often bleed when large and malignant.
- Amelanotic to dark brown, gray, or black.
- Varies greatly in size, often invasive in surrounding tissues.

Cytologic Findings

- Brown, rod-like intracellular granules (melanin) of various size and shapes.
- Pigment may be absent with amelanotic tumors.
- May see melanophages (phagocytic macrophages) with large intracytoplasmic vacuoles containing melanin, especially in lymph nodes.
- More cellular atypia observed in malignant tumors.

Histopathologic Findings

- Cells may vary in shape (e.g., epithelioid, fusiform, dendritic, and mixed), degree of pigmentation, and cytoplasmic morphology.
- Malignant—generally high mitotic index; nuclear and nucleolar pleomorphism (more atypia, less differentiation); invasive into surrounding tissues; amelanotic may pose a diagnostic challenge; immunohistochemistry and special stains may be particularly useful. Proliferation markers may help predict behavior.
- Immunohistochemistry (e.g., Melan-A, S100, HMB-45, vimentin)—may help confirm a diagnosis, especially if amelanotic (approximately one-third of cases).
- Histopathology report should include mitotic index (mitoses per 10 high-power field), degree of atypia/differentiation, invasiveness, and surgical margins if excisional biopsy.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient if undergoing aggressive oral surgery.

NURSING CARE

Pain management—multimodal analgesia (preemptive, intra- and postoperative) is mandatory with aggressive surgeries.

ACTIVITY

Restrict until sutures are removed and all surgical wounds are healed.

DIET

- Normal, but soft food recommended after aggressive oral surgery.
- Avoid toys and hard treats until oral tissues healed completely.

CLIENT EDUCATION

- Discuss importance of clinical staging.
- Discuss need for early aggressive approach with surgical removal.
- Warn caretaker that malignant melanoma frequently metastasize early in the course of the disease, resulting in a guarded prognosis.
- Adjuvant therapy is recommended to improve survival time and delay metastasis.
- Repeat clinical staging recommended after therapy.

SURGICAL CONSIDERATIONS

- Goal should be to remove all macroscopic tumor burden and obtain complete margins, in order to improve overall prognosis.
- Radical en bloc surgical excision—required (e.g., mandibulectomy or maxillectomy); well tolerated by most patients; surgical margins of at least 2 cm; improved survival when margins are free of neoplastic cells.

MELANOCYTIC TUMORS, ORAL

(CONTINUED)

- Surgical removal of the draining lymph node(s) is recommended when metastasis confirmed or suspected and no evidence of distant (e.g., lung) metastatic disease.

RADIATION THERAPY

CONSIDERATIONS

Three to six, weekly to twice weekly, large fractions of megavoltage radiation therapy—good response rate (> 80%) and may offer long-term control with inoperable tumors.

MEDICATIONS

DRUG(S)

- Carboplatin has been described for oral melanoma in dogs, with a response rate approximating 30% on measurable disease, but no clear survival advantage was demonstrated when used in the adjuvant setting.
- No effective chemotherapy described in cats.
- Multimodal analgesia recommended to control pain and discomfort.

IMMUNOTHERAPY

- Many immunotherapies have been attempted with varied success.
- A therapeutic vaccine is available that involves the injection of human cDNA (xenogeneic) coding for a melanocyte-specific protein, tyrosinase, and results in a measurable immune response in some patients.
- The tyrosinase vaccine is approved for the postoperative treatment of stage II and III oral malignant melanomas and results in improved survival times in comparison with historical control studies.

CONTRAINDICATIONS

Avoid the use of cisplatin in cats.

PRECAUTIONS

Seek advice from an oncologist before initiating treatment if you are unfamiliar with cytotoxic drugs (myelosuppression, specific toxicities, etc.).

POSSIBLE INTERACTIONS

Drug with overlapping toxicities should be avoided.

ALTERNATIVE DRUGS

Piroxicam may play a minor role for alleviating pain and slowing tumor progression.

FOLLOW-UP

PATIENT MONITORING

- Evaluate for local recurrence and regional metastasis—every 2–3 months following surgery or earlier if the owner believes the mass is returning; or if the patient is otherwise not normal.
- Thoracic radiography—at the time of rechecks and periodically thereafter.

PREVENTION/AVOIDANCE

None.

POSSIBLE COMPLICATIONS

- Poor wound healing, dehiscence, infection possible after aggressive surgery.
- Early radiation side effects, such as mucositis or dermatitis, may result from hypofractionated protocols.

EXPECTED COURSE AND PROGNOSIS

- Poor prognosis when untreated (median 2 months).
- Depends upon disease stage; better prognosis with stage I.
- Complete surgical excision (local and regional lymph node when positive) is essential to improve the prognosis. Median survival time with surgery alone varies with stage:
 - Stage I—over 18 months.
 - Stage II and III—5–12 months; prognosis of stage II and III canine oral melanoma may be improved to over 18 months with the adjuvant use of the recombinant xenogeneic tyrosinase vaccine.
 - Stage IV—less than 3 months.
- Survival with radiotherapy treatment alone (dogs)—6–10 months.
- Most common causes of death in dogs are metastatic disease and local tumor recurrence.
- Overall prognosis in cats—poor; most tumors are locally invasive and diagnosed late in the course of the disease; cause of death is often due to local disease progression. Median survival time of 146 days in 5 cats treated with hypofractionated radiation therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

None

AGE-RELATED FACTORS

Older age at diagnosis (> 12 years) might predict a poorer prognosis in dogs.

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

Cytotoxic chemotherapy agents should not be used in pregnant or breeding animals.

SYNONYMS

Malignant—melanosarcoma (rarely used)

SEE ALSO

Melanocytic Tumors, Skin and Digit

ABBREVIATIONS

- CT = computed tomography
- MRI = magnetic resonance imaging

Author Louis-Philippe de Lorimier

Consulting Editor Timothy M. Fan

MELANOCYTIC TUMORS, SKIN AND DIGIT

BASICS

OVERVIEW

- Benign or malignant neoplasm arising from melanocytes in the epidermis or the nail bed.
- Localized growth behavior with potential invasive characteristics.
- When malignant—occasionally invades bone (e.g., third phalanx) and metastasizes (lymph node, lungs, and other sites).

SIGNALMENT

- Dogs—around 10% of all skin tumors.
- Cats—< 5% of all skin tumors.
- Dogs, mean age 9 years, certain breeds more common—terriers (Scottish, Boston, and Airedale) schnauzers, cocker and springer spaniels, boxer, Irish setter, chow chow, Chihuahua, retriever breeds, and Doberman pinscher.
- Cats, mean age 10–12 years, no breed predilection.

SIGNS

- Skin mass with variable growth rates, pigmented or not (amelanotic), usually solitary.
- Lameness and pain if digit is involved.
- Develops anywhere; in dogs more common on face, trunk, feet, and scrotum, while in cats more common on head, digit, pinna, and nose.
- Draining regional lymph nodes—may be enlarged.
- Advanced disease—may cause respiratory signs secondary to diffuse pulmonary metastasis.

RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Distinguish amelanotic melanoma from poorly differentiated discrete cell tumors (mast cell tumors, lymphoma), various sarcomas (e.g., histiocytic), and carcinomas (especially basal cell).

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

Immunohistochemical markers—may help differentiate melanoma (especially amelanotic) from other tumors; may stain positive with vimentin, S-100, neuron-specific enolase, HMB-45, and Melan A.

IMAGING

- Thoracic radiography recommended for the detection of metastasis.
- Advanced imaging (CT scan) is more sensitive to detect smaller metastases.

- With digit melanoma, radiography of the lesion is recommended to determine if underlying bone (P3) is involved. Bone lysis is less common with nailbed melanoma (approximately 10%) than with squamous cell carcinoma (approximately 75%).

DIAGNOSTIC PROCEDURES

- Cytologic examination of fine-needle aspirates (primary mass, draining lymph node, other).
- Draining lymph nodes should be evaluated with cytology independently of their size or clinical appearance.

PATHOLOGIC FINDINGS

Gross

- Masses—may be ulcerated and friable when malignant.
- Benign—brown to black; varies from macules and plaques to firm, dome-shaped nodules, 0.5–2 cm in diameter, well demarcated.
- Malignant—amelanotic to dark brown, gray, or black, often > 2 cm in diameter and more invasive in surrounding tissues.
- Melanomas of the digit and mucocutaneous junctions tend to be malignant.

Cytologic findings

- Brown, rod-like cytoplasmic granules (melanin) in cells of various sizes and shapes.
- Pigment may be absent with amelanotic melanoma.
- May see macrophages (melanophages) with large intracytoplasmic vacuoles containing phagocytosed melanin.
- More atypia observed (e.g., large single nucleolus, mitotic figures) in malignant tumors.

Histopathologic Findings

- Both benign and malignant lesions may have cells that vary in shape (e.g., epithelioid, fusiform, dendritic, and mixed), degree of pigmentation, and cytoplasmic morphology.
- Malignant—generally high mitotic index; nuclear and nucleolar pleomorphism (more atypia, less differentiation); invasive into surrounding tissues; amelanotic may pose a diagnostic challenge; immunohistochemistry and special stains may be particularly useful. Proliferation markers may help predict behavior.

TREATMENT

SURGICAL CONSIDERATIONS

- Wide surgical excision—treatment of choice.
- Amputation of digit with nailbed localization.
- Lymphadenectomy of the draining lymph node indicated when metastasis confirmed or suspected and no evidence of detectable distant dissemination.

MEDICATIONS

DRUG(S)

- Adjunctive therapy—recommended with malignant melanoma, when surgical excision is incomplete, when the mass is non-resectable, or if metastasis is present.
- A study showed a xenogeneic murine tyrosinase vaccine, similar to the commercially available therapeutic vaccine approved for canine oral malignant melanoma, to be safe and potentially effective in the treatment of digit melanoma.
- In dogs and cats, the cytotoxic drugs with some reported efficacy include carboplatin (dogs and cats), cisplatin (dogs only), and doxorubicin. In general response rate is below 30%.
- Piroxicam may play a minor role in pain control and tumor control.
- Multimodal analgesia recommended to control pain and discomfort.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Drugs with overlapping toxicity should be avoided. Cisplatin is absolutely contraindicated in cats.

PRECAUTIONS

Veterinarians administering chemotherapeutics should follow published guidelines on the safe use of these drugs and should be familiar with potential side effects.

FOLLOW-UP

PATIENT MONITORING

- Evaluate for local recurrence and regional metastasis—every 2–3 months following surgery or earlier if the owner believes the mass is returning; or if the patient is otherwise not normal.
- Thoracic radiography—at the time of rechecks and periodically thereafter.

EXPECTED COURSE AND PROGNOSIS

Dogs

- Approximately 25% of cutaneous melanocytic tumors are reported to be malignant. Melanomas on the digit, footpad, scrotum, and mucocutaneous junctions are more frequently malignant.
- Prognosis with benign cutaneous melanomas is excellent.
- Median survival with malignant cutaneous or digit melanoma is 12 months.
- Breed differences in prognosis in some studies—majority of cutaneous melanomas in Doberman pinschers and miniature schnauzers behave in a benign fashion, and a majority of cutaneous melanomas in miniature poodles behave in a malignant fashion.

MELANOCYTIC TUMORS, SKIN AND DIGIT

(CONTINUED)

Cats

- 35–50% of melanomas reported to be malignant.
- Median survival with melanoma of the skin or digit not well documented and reported to be 4.5 months after surgery in one study of 57 cats.

MISCELLANEOUS

ASSOCIATED CONDITIONS

None

AGE-RELATED FACTORS

None

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

N/A

available online

BASICS

DEFINITION

Presence of digested blood in the feces, causing a black, tarry appearance.

PATHOPHYSIOLOGY

Usually results from upper GI bleeding (esophagus, stomach, small intestine), but can be associated with ingested blood from the oral cavity or respiratory tract.

SYSTEMS AFFECTED

- Gastrointestinal
- Respiratory
- Coagulation

SIGNALMENT

- More common in dog than cat

SIGNS

Historical Findings

- Patients with upper GI tract hemorrhage may demonstrate vomiting (blood or “coffee grounds” appearance), inappetence, weight loss, weakness, and/or mucous membrane pallor.
- Patients with respiratory tract hemorrhage may demonstrate epistaxis, sneezing, hemoptysis, mucous membrane pallor, weakness, and/or dyspnea.
- Patients with abnormal coagulation may demonstrate petechia, ecchymosis, mucous membrane pallor, epistaxis, hematuria, hyphema, and/or weakness.

Physical Examination Findings

Depends on the underlying cause.

CAUSES

Primary GI Ulceration/Erosion

- Neoplasia—lymphoma, adenocarcinoma, sarcoma
- IBD (lymphoplasmacytic, eosinophilic, granulomatous, and/or histiocytic gastritis/enteritis)
- Benign polyps
- Infectious—Bacterial (*Salmonella* spp., *Clostridium perfringens*, *C. difficile*, *Helicobacter* spp.); fungal or fungal-like (pythiosis, histoplasmosis), parasitic (hookworms), viral (parvovirus, circovirus, distemper).
- Mechanical—foreign body
- Inflammatory—acute and chronic gastritis; hemorrhagic gastropathy,
- Drugs—NSAIDs, corticosteroids.

Metabolic/Other Diseases That Cause GI Ulceration

- Renal failure
- Hepatic disease/failure
- Pancreatitis
- Hypoadrenocorticism
- Neoplasia—gastrinoma, mast cell tumor
- Shock, poor perfusion

Ingestion of Blood

- Diet (raw foods)
- Esophageal lesion—neoplasia, esophagitis
- Oral or pharyngeal lesion—neoplasia, abscess
- Nasal lesion—neoplasia, fungal rhinitis, inflammatory rhinitis
- Respiratory lesion—lung lobe torsion, neoplasia, pneumonia, trauma (causing hemoptysis)

Coagulopathy

- Thrombocytopenia
- Thrombocytopathy—von Willebrand disease, thrombasthenia, thrombopathia, NSAIDs
- Clotting factor abnormalities—anticoagulant rodenticide ingestion, clotting factor deficiency
- Disseminated intravascular coagulation

RISK FACTORS

Arthritis or other conditions requiring use of NSAIDs or corticosteroids

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Medications that cause dark stool—bismuth subsalicylate, oral iron therapy, sucralfate
- Must distinguish intestinal from extraintestinal disease

CBC/BIOCHEMISTRY/URINALYSIS

- Microcytic, hypochromic, poorly regenerative anemia if chronic blood loss.
- Regenerative anemia in early blood loss—may be poorly regenerative if < 3–5 days.
- Panhypoproteinemia if significant blood loss.
- Thrombocytopenia, neutrophilia in some patients; pancytopenia in some.
- Biochemistry analysis may reveal extra-intestinal cause of melena—renal failure, hepatic disease, hypoadrenocorticism. Discordant increase in the BUN:creatinine ratio can be seen secondary to GI bleeding.
- Urinalysis may demonstrate hematuria in patients with coagulation defects.

OTHER LABORATORY TESTS

- Coagulation profile may reveal clotting abnormality.
- Buccal mucosal bleeding time may be prolonged and tests primary hemostasis.
- Fecal centrifugation flotation may reveal parasites.
- Diarrhea PCR panels for bacterial DNA and toxin genes in combination with ELISA testing for *C. perfringens* enterotoxin and *C. difficile* toxins A and B should be done judiciously in patients when indicated based on history, physical examination findings, environment, and risk factors.

- Rectal scraping may demonstrate fungal organisms (*Histoplasma* spp.).
- Resting cortisol and/or ACTH stimulation test abnormally low with hypoadrenocorticism.
- Gastric and intestinal histopathology, PCR, and urease testing for *Helicobacter* spp.

IMAGING

- Abdominal radiography may reveal a mass or foreign body, or abnormalities in renal or hepatic size/shape.
- Abdominal radiographs can be unremarkable with hepatic, and gastrointestinal dysfunction. Thoracic radiographs may identify pulmonary, tracheobronchial lesions.
- Nasal CT may demonstrate intranasal lesions.
- Ultrasonography may reveal a GI mass, loss of intestinal layering, alterations in hepatic echotexture and size, pancreatic changes suggestive of pancreatitis, or changes supportive of renal disease.
- Upper GI barium series may delineate gastric or upper small intestinal masses, ulceration, or filling defects; however, upper GI series is insensitive for detection of gastric and intestinal ulceration.

DIAGNOSTIC PROCEDURES

- Endoscopy allows visualization of masses and/or ulcers (esophageal, gastric, and/or duodenal), retrieval of GI foreign bodies, and procurement of biopsy samples.
- Rhinoscopy may allow visualization of nasal lesions (retroflexion of scope and choanal evaluation is helpful).
- Bronchoscopy allows visualization of airway lesions.
- Bone marrow aspiration and cytology indicated if pancytopenia is present.

TREATMENT

- Inpatient—most patients admitted for workup and management with exception of animals with melena secondary to intestinal parasites.
- Treat underlying disease—renal failure, hepatic disease, hypoadrenocorticism, respiratory disease, etc.
- Fluid replacement with balanced electrolyte solutions and potassium supplementation.
- Whole blood or packed red cell transfusions if anemia is severe.
- Whole blood or plasma transfusion if the patient has a coagulopathy.
- Temporarily discontinue oral intake if vomiting is intractable. Antiemetics may be needed in select cases with intractable vomiting.
- Surgery may be required for severe gastroduodenal ulceration, neoplasia, or foreign bodies.

MELENA

(CONTINUED)

**MEDICATIONS****DRUG(S) OF CHOICE**

- Mucosal protectants for gastroduodenal ulceration/erosion—H₂-receptor antagonists (e.g., ranitidine 1–2 mg/kg IV, SC, or PO q12h or famotidine 0.5–1 mg/kg IV, SC, or PO q12h); sucralfate 0.5–1 g PO q6–8h; misoprostol 3–5 µg/kg PO q8h.
- Triple therapy if *Helicobacter* suspected or confirmed (see *Helicobacter* spp.).

CONTRAINDICATIONS

Avoid corticosteroids and NSAIDs in patients with gastroduodenal ulceration/erosion.

ALTERNATIVE DRUG(S)

Proton pump inhibitors (omeprazole 0.7–1.5 mg/kg PO q12–24h) are superior to

H₂-receptor antagonists in animals with severe esophagitis or gastroduodenal ulceration.

**FOLLOW-UP****PATIENT MONITORING**

- PCV daily until anemia stabilized, then weekly.
- Hydration daily if patient vomiting.

POSSIBLE COMPLICATIONS

- Gastric or duodenal perforation resulting in peritonitis.
- Hypovolemic shock and death if severe, acute blood loss.

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

Helicobacter spp. and *Salmonella* spp. are potentially zoonotic.

SEE ALSO

Individual causative diseases

MENINGIOMA—CATS AND DOGS**BASICS****DEFINITION**

- Tumors of the meninges, most commonly found over the cerebrum.
- Most common tumor of the canine brain and spinal cord.
- Most common tumor of the feline brain, and second most common tumor of the feline spinal cord after lymphoma.

PATHOPHYSIOLOGY

- Primary tumor arising from the arachnoid cap cells.
- Intradural-extramedullary tumors.
- Usually solitary masses; occasionally multiple (cats > dogs).
- May occur as plaque-like masses on the floor of the calvaria, paranasally, or (rarely) in a retrobulbar location in dogs more than cats.
- Neurologic deficits secondary to the slow compression of the adjacent tissue, most commonly causing vasogenic edema, and occasionally obstructive hydrocephalus or infarction.
- Most are cytologically benign. In dogs, tend to be more invasive into brain parenchyma or surrounding vasculature, and can be considered *biologically* malignant, unless aggressive surgical resection is possible.

SYSTEMS AFFECTED

Nervous—primary effects (e.g., infiltration and compression of adjacent structures), and secondary effects (e.g., edema, increased ICP, brain herniation).

INCIDENCE/PREVALENCE

- Reported incidence of brain tumors is 14.5/100,000 dogs and 3.5/100,000 cats. Meningiomas account for approximately 22% of all canine brain tumors, and 59% of all feline brain tumors.
- 17% of cats with intracranial meningioma have > 1 tumor of the same type.
- Incidence of spinal tumors in dogs and cats—unknown; considerably less than that of brain tumors. Spinal meningiomas account for 14% of all canine meningiomas, and 4% of all feline meningiomas.

SIGNALMENT

Dog and cat

Dogs

- Boxers and golden retrievers most commonly affected; dolichocephalic breeds may have an increased risk of intracranial meningioma; mesocephalic breeds may have a higher incidence of paranasal meningioma.
- Most > 7 years of age; median 9 years, range 11 weeks–14 years; a spinal meningelial sarcoma was diagnosed in an 11-week-old rottweiler; slight predominance for females.
- Cystic meningiomas reported.

Cats

- No breed predilection.
- Most > 9 years of age; mean 12 years, range 1–24 years; slight predominance for males.

SIGNS**General Comments**

- Vary with tumor location.
- Typically chronic and insidiously progressive over weeks to months.
- May be acute if vascular invasion results in focal ischemia or if edema develops rapidly.
- Lateralizing deficits predominate.
- Elevated ICP, cerebral edema, or brain herniation may make localization of a focal lesion difficult.

Historical Findings

May be prolonged history of vague signs until compensatory mechanisms (e.g., decreased CSF and blood volume) are exhausted, followed by rapid progression of clinical signs.

Intracranial

- Dogs—late-onset seizures most common presenting sign.
- Cats—abnormal behavior and mentation most common presenting signs; nonspecific signs include lethargy, inappetence, and anorexia; seizures less common than in dogs.

Intraspinal

- Neck or back pain.
- Progressive incoordination and weakness—may worsen with exercise.

Physical Examination Findings**Intracranial**

- Cerebral disease is most common—abnormal behavior and mentation; circling or head-pressing; contralateral hemi-neglect, hemianopsia, facial paresis, facial and thoracic hypesthesia and conscious proprioceptive deficits; seizures.
- Brainstem—alterations of consciousness; abnormal gait; ipsilateral proprioceptive and cranial nerve deficits in CN III to XII; central vestibular abnormalities.
- Cerebellum—ataxia and dysmetria; intention tremors; truncal sway; broad-based stance; lack of menace responses with normal vision, and pupillary light and palpebral reflexes.
- Orbital—exophthalmos, orbital swelling, prolapsed globe; blindness in the affected eye; fundic abnormalities.

Intraspinal

- Paraspinal or radicular pain reflecting region of spinal column involved.
- Ataxia and paresis caudal to the lesion.

CAUSES

- Uncertain.
- Documentation in young cats with mucopolysaccharidosis type I suggests a causal relationship.

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

- Metabolic or toxic encephalopathy—may also present with seizures or mentation changes and normal neurologic exam; differentiate with brain imaging.
- Other primary CNS (e.g., glioma, pituitary, nephroblastoma) or secondary (e.g., lymphoma, extensional, metastatic) tumors—may have more rapid onset and progression of signs; differentiate with brain or spinal imaging.
- Granulomatous meningoencephalitis—may cause progressive focal deficits in dogs; differentiate based on age; imaging and CSF analysis may be helpful.
- Nerve sheath tumors, gliomas, lymphoma, focal meningoencephalitis, type II intervertebral disc disease, degenerative myelopathy—differentiate by spinal cord imaging.
- *Cryptococcus* granuloma—reported to have same appearance on CT as a meningioma in a cat.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

M

IMAGING

- MRI—preferred imaging modality for intracranial and spinal disease.
- MRI—often hyperintense on T2WI, isointense on T1WI, and uniformly contrast-enhancing mass lesion of the brain or spinal cord; broad-based, with extra-axial attachment; a “dural tail” is a characteristic feature. If present, “dural tail” helps to differentiate an intraventricular meningioma from a choroid plexus tumor; spinal cord swelling may make the distinction between intradural-extramedullary and intramedullary difficult.
- CT—often homogeneous contrast enhancement of well-circumscribed mass lesion.
- Skull radiography and CT—may reveal hyperostosis of the calvaria adjacent to the meningioma and increased tissue density if the tumor is calcified; hyperostosis more commonly seen in cats.
- Spinal radiography—usually normal with intraspinal meningioma; can be helpful to rule out bony lesions.
- Myelography—typically reveals an intradural-extramedullary mass and interruption of the normal flow of contrast at the tumor; “golf tee” appearance makes differentiation from a nerve sheath tumor difficult without biopsy.

MENINGIOMA—CATS AND DOGS

(CONTINUED)

DIAGNOSTIC PROCEDURES

- CSF analysis—infrequently performed because of the characteristic results of diagnostic imaging; normal or high protein, sometimes with a neutrophilic or mixed pleocytosis. Should not be considered unless CT or MRI have been performed; if increased ICP is suspected, CSF collection is contraindicated; may increase risk of neurologic decompensation from brain herniation.
- Electroencephalography—reveals slow-wave, medium- to high-voltage activity indicating cortical depression; may show paroxysmal waveforms characteristic of seizure activity.
- Biopsy—remains necessary for definitive diagnosis; during surgery or using a CT-guided stereotactic system for intracranial tumors.

TREATMENT

APPROPRIATE HEALTH CARE

- M**
- Inpatient—necessary if dehydration, anorexia, disequilibrium, and/or frequent or life-threatening seizures.
 - Surgical excision—for definitive management; usually successful if the tumor is accessible; incomplete excision more common in intracranial meningiomas in dogs due to invasiveness, in intraspinal meningiomas in cats, and in tumors ventral to the spinal cord.
 - Fractionated conventional radiation therapy consisting of 15–20 treatments over 3–4 weeks—after incomplete excision, if excision not possible, or if a less invasive approach is desired; when combined with surgery, radiation is associated with prolonged survival time in canine intracranial and intraspinal meningiomas compared to surgery alone, and may contribute to prevention or delay of local recurrence. Feline intracranial meningiomas are believed to be radiation sensitive, but data are lacking due to the success of surgery.
 - SRS—delivers high dose of radiation to tumor with sub-millimeter accuracy; steep dose gradient limits exposure of normal tissue and reduces side effects of radiation; can be conducted on an outpatient basis in 1–5 treatments delivered on consecutive days; best candidates are those that are able to be stabilized with steroids prior to the procedure; shown to significantly decrease tumor volume, but occurs slowly. IMRT delivered in 3–5 fractions (hypofractionated IMRT) is sometimes mistakenly referred to as SRS; it is not as exact as SRS.
 - Chemotherapy—may be associated with prolonged survival after incomplete excision, post-radiation, or as sole agent. Hydroxyurea inhibits DNA synthesis, leading to cell death during the S phase of the cell cycle; shows

effectiveness in humans with intracranial meningiomas; commonly used in veterinary medicine, but controlled studies are lacking.

- Medical management—antiepileptic drugs and corticosteroids are only palliative; neither radiation nor chemotherapy aid in control of seizures or edema.

NURSING CARE

- Fluids—avoid overzealous administration; may exacerbate cerebral edema and neurologic deficits.
- Use caution with jugular compression during venipuncture or when positioning for surgery to avoid increases in ICP.

MEDICATIONS

DRUG(S)

Cerebral Edema

- Corticosteroids—improve neurologic deficits associated with vasogenic edema.
- Stuporous, severely ataxic, or showing signs of herniation—methylprednisolone sodium succinate (30 mg/kg IV) or dexamethasone sodium phosphate (0.25 mg/kg IV).
- Continued deterioration or no improvement—20% mannitol solution (0.5 g/kg IV over 15–20 minutes). Furosemide (2 mg/kg IV), has synergistic effects with mannitol and can be added if needed; hypertonic saline (3–5 mL/kg) may be used as an alternative to mannitol; dexamethasone (0.05–0.1 mg/kg q24h IV).
- Once patient is stable—dexamethasone (0.05–0.1 mg/kg q24h or in divided daily doses PO) or prednisone (0.25–0.5 mg/kg PO q12h); then taper to lowest effective dose.

Seizures

- Antiepileptic drugs—mandatory if isolated seizures > 1/month, cluster seizures, or status; recommended if any seizure activity in animal with meningioma, and possibly as preventive measure in animals with forebrain meningioma.
- Maintenance treatment—phenobarbital (first choice in dogs and cats) 2–3 mg/kg IV or PO q12h; or zonisamide 5–10 mg/kg q12h PO (dogs or cats); or levetiracetam 20–30 mg/kg q8h IV or PO; if extended release levetiracetam q12h PO (dogs or cats).
- Cluster seizures or status—diazepam 0.5 mg/kg/h CRI; or phenobarbital 4 mg/kg IV q2–6h until 12–16 mg/kg total loading dose; or midazolam 0.2–0.4 mg/kg/h CRI; or levetiracetam 60 mg/kg IV.

Chemotherapy

Hydroxyurea—150 mg/kg/week (dogs) and 75 mg/kg/week (cats).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Mannitol—monitor serum osmolality and electrolytes with repeated use; maintain osmolality at or below 320 mOsm/L to reduce risk of renal failure due to renal vasoconstriction.
- Corticosteroids—perform serial neurologic examinations; marked neurologic improvement possible within 24–48 h after initiation of corticosteroids.
- Antiepileptic drugs—evaluate serum phenobarbital levels 3 weeks after initiation of therapy; evaluate liver enzymes every 6 months while on phenobarbital.
- Hydroxyurea—monitor CBC with platelet count before starting, at 2 weeks, 6 weeks then CBC, chemistry profile every 3–4 months. May lead to GI effects, stomatitis, sloughing of nails, alopecia, and dysuria; most serious effects are bone marrow depression and pulmonary fibrosis.

EXPECTED COURSE AND PROGNOSIS

Cats

Intracranial

- Surgical excision—prognosis good; 75–80% of patients that undergo surgical excision are cured; reported mean survival time 22–27 months; seizure activity may persist despite successful excision. Recurrence usually occurs in same location.

- Medical management—neurologic deficits become more severe; may occur slowly over many months because meningiomas tend to be slow growing.

Intraspinal

- Surgical excision—survival time is shorter than that of cats with cerebral meningiomas; reported median survival times of 14.2 months in 16 cats, and 17.3 months in 26 cats.

- Corticosteroids—thoracolumbar disease progresses to paralysis and inability to control urination with urinary retention and possibly bladder atony and cystitis.

Dogs

Intracranial

- Surgical excision—outcome depends on surgical technique; reported median survival time is 7 months; increased with regional cerebral resection (16.5 months in 6 dogs), or with the use of a surgical aspirator (41.8 months in 17 dogs) or with endoscopy-assisted tumor removal (70.1 months with forebrain and 23.4 months with caudal brain meningioma in 33 dogs).

- Surgical excision with postoperative fractionated radiation therapy—reported median survival times of 16.5–30 months.

(CONTINUED)

MENINGIOMA—CATS AND DOGS

- Radiation therapy alone—reported median survival times of 5–12.5 months with conventional radiation.
- Chemotherapy using hydroxyurea—reported mean survival time of 7–8 months.
- SRS e.g., Frameless SRS, Varien Trilogy, Cyberknife—reported mean survival time of 16.4 months in 38 dogs, and 19.8 months in 20 dogs.
- Medical management—reported mean survival time of 3 months in dogs treated with palliative therapy alone.

Intraspinal

- Surgical excision—reported mean survival time of 19 months in 8 dogs.
- Surgical excision with postoperative radiation therapy—reported median survival time of 13.5 months in 6 dogs.

**MISCELLANEOUS****AGE-RELATED FACTORS**

Suspect brain tumor in dogs and cats > 5 years with recent onset of seizures and unremarkable extracranial diagnostic workup for seizures.

ABBREVIATIONS

- CN = cranial nerve
- CNS = central nervous system
- CSF = cerebrospinal fluid
- CT = computed tomography
- GI = gastrointestinal
- ICP = intracranial pressure
- IMRT = intensity modulated radiation therapy
- MRI = magnetic resonance imaging
- SRS = stereotactic radiosurgery
- T1WI = T1-weighted images
- T2WI = T2-weighted images

MENINGITIS/MENINGOENCEPHALITIS/MENINGOMYELITIS, BACTERIAL

BASICS

DEFINITION

- Meningitis—inflammation of the meninges.
- Meningoencephalitis—inflammation of the meninges and brain.
- Meningomyelitis—inflammation of the meninges and spinal cord.

PATHOPHYSIOLOGY

- Bacterial infection of the CNS can occur by direct extension from an infected extraneuronal site or less commonly when bacteria are introduced by penetrating trauma or a migrating foreign body.
- Hematogenous spread of bacteria to the CNS from mucous membrane colonization or a distant pyogenic focus can also occur. This is the most common cause in septicemic neonates and severely immunocompromised patients.
- Inflammation of the meninges commonly leads to secondary inflammation of the brain or spinal cord parenchyma, resulting in neurologic deficits.
- Inflammatory debris and scarring can obstruct CSF flow, leading to secondary hydrocephalus.

SYSTEMS AFFECTED

- Nervous—meninges, brain, or spinal cord.
- Multisystemic signs—may be present when the infection originates in an extraneuronal site or when the systemic inflammatory response is severe.

INCIDENCE/PREVALENCE

Rare

SIGNALMENT

Species

Dog and cat

Mean Age and Range

Any age

Predominant Sex

Males and females affected equally

SIGNS

General Comments

- Patients are often systemically ill.
- Depression, shock, hypotension, and DIC are often found in septicemic patients.
- CNS signs may be profound and rapidly progressive.

Physical Examination Findings

- Pyrexia in approximately 50%.
- Cervical rigidity and hyperesthesia—especially with meningitis.
- Neurologic deficits—reflect the location of the involved spinal cord or brain parenchyma (e.g., altered mentation, cranial nerve deficits, postural reaction deficits, ataxia, paresis, seizures).
- May find an extraneuronal site of underlying bacterial infection.
- Vomiting.
- Bradycardia with systemic hypertension suggests increased intracranial pressure.

CAUSES

- Meningoencephalitis—can be secondary to local extension from otitis media/interna or infection of the eye, retrobulbar space, sinuses, or nasal passages or due to direct inoculation by traumatic skull fractures or migrating grass awn or porcupine quill foreign bodies.
- Meningomyelitis—can be secondary to discospondylitis or vertebral osteomyelitis.
- Hematogenous spread of bacterial infection to the CNS can occur in neonates with omphalophlebitis, immunocompromised patients, or in dogs with bacterial endocarditis, prostatitis, discospondylitis, pneumonia, or severe gastroenteritis.
- The point of origin is not always found.

RISK FACTORS

- Untreated bacterial infection
- Immunocompromised state
- Injury involving the CNS or adjacent structures

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Infectious Meningitis (Non-bacterial)

- Canine distemper, toxoplasmosis, neosporosis, cryptococcosis, blastomycosis, neuroborreliosis, rickettsial organisms, West Nile virus, and feline infectious peritonitis all cause meningitis/meningoencephalitis that can be difficult to distinguish from bacterial disease.
- CSF—inflammatory with a variable lymphocytic, mixed mononuclear or neutrophilic pleocytosis depending on the specific infectious etiology.
- Antemortem diagnosis suspected based on typical clinical findings and identification of affected extraneuronal sites.
- Diagnosis is by identifying organisms in the CSF or in extraneuronal sites (using cytology, culture, or PCR) and by serology.

Steroid Responsive Meningitis-Arteritis (Aseptic Meningitis)

- Observed mainly in young (6–19 months) adult large-breed dogs but middle-aged and older dogs occasionally affected.
- Beagles, boxers, Bernese mountain dogs, German shorthaired pointers, Weimaraners, and Nova Scotia duck tolling retrievers are predisposed; any breed can be affected.
- Cervical pain without neurologic deficits is most common.
- Fever occurs in 60–80% of affected dogs.
- Signs may wax and wane initially.
- Affected dogs are systemically normal.
- Neurologic deficits may occur in chronically affected or inadequately treated dogs.
- CSF—increased nucleated cell count and protein.
- Neutrophilic pleocytosis in acute cases, mononuclear cells may predominate in chronic cases.
- Negative bacterial culture.
- Serum and CSF IgA increased.
- Dramatic response to corticosteroid administration.

Granulomatous

Meningoencephalomyelitis

- Idiopathic non-infectious inflammatory disease of the brain, spinal cord, and meninges in dogs.
- Meningoencephalitis of unknown origin (MUE) may be a more correct name for all of the non-infectious inflammatory disorders, because definitive diagnosis is not possible without post-mortem examination.
- Young adult and middle-aged dogs most often affected—poodles and terriers predisposed; any breed can be affected.
- Neurologic abnormalities reflect the location of the lesion(s).
- Cervical pain/fever in some dogs with disseminated form that involves the cervical spinal cord and meninges.
- CSF—mixed mononuclear pleocytosis with lymphocytes, monocytes, plasma cells, and large macrophages; may include 20% non-toxic neutrophils.
- CSF culture—negative.

Necrotizing Meningoencephalitis/Necrotizing Leukoencephalitis

- Breed-related idiopathic inflammatory disorders of the brain characterized by regional necrosis forming areas of cavitation.
- Signs reflect cerebral cortical damage (seizures, behavior change, circling) in pugs, Maltese terriers, Chihuahuas, Pekingese, Shih Tzus, and Lhaso apsos with NME.
- Yorkshire terriers with NLE have lesions in the cerebrum and in the brainstem resulting in seizures and abnormal mentation as well as abnormal gait, head tilt and cranial nerve abnormalities.
- No systemic signs.
- CSF—increased protein content and total nucleated cell count (NME and NLE).
- Small lymphocytes predominate in NME, while a mixed mononuclear pleocytosis is common in NLE.

Primary CNS Neoplasia

- History protracted; neurologic signs limited to the CNS; standard laboratory tests normal.
- Diagnosis by CT, MRI, CSF analysis, and biopsy.

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis is common; left-shift or toxicity may be seen. Thrombocytopenia may be present in septicemic patients.
- Biochemical evidence of other organ involvement (e.g., liver and kidney) may be seen in septicemic patients.
- Hyperglobulinemia may reflect chronic extraneuronal infection.
- Pyuria and bacteriuria occur in patients with underlying urinary tract or prostatic infection and in some bacteremic animals.

OTHER LABORATORY TESTS

- Serologic tests—may differentiate fungal, protozoal, rickettsial, and viral from bacterial disease; in cats, toxoplasma titer may be positive without clinical disease.
- Cytology of infected tissues—skin, eyes, nasal discharge, lymph node, tracheal wash; helps

MENINGITIS/MENINGOENCEPHALITIS/MENINGOMYELITIS, BACTERIAL

identify non-bacterial causative organisms, especially in patients with fungal disease.

- Blood culture—positive in 30% of dogs with bacterial meningitis.

IMAGING

- Thorax/abdominal radiography and abdominal ultrasound—to identify underlying infection or other significant disease.
- Spinal radiography—discospondylitis may be identified as a focus of infection.
- Head CT—may identify infected sinus, nasal cavity, or middle and inner ear as initiating site. Inflamed regions of brain parenchyma and meninges usually enhance with contrast.
- Echocardiography—performed when valvular endocarditis suspected based on murmur/arrhythmia.
- MRI with contrast—documents brain, spinal cord and meningeal inflammation and can identify extraneurial sites of infection (sinus, nasal, ear).

DIAGNOSTIC PROCEDURES

CSF Analysis

- Collection—a concern in animals with diminished mentation suggesting high intracranial pressure, because the procedure may precipitate brain herniation—pretreat with mannitol.
- Analysis—neutrophilic pleocytosis with high protein concentration; neutrophils may appear toxic or degenerated and intracellular bacteria are occasionally seen; often difficult to differentiate aseptic from bacterial meningitis cytologically.
- Culture—aerobic or anaerobic; may be positive (< 40%)—inoculation of CSF into broth enrichment media improves diagnostic yield.
- Universal bacterial PCR assay of CSF can be used to identify DNA from causative organisms when bacterial culture is negative.

PATHOLOGIC FINDINGS

- May note subdural empyema, or purulent material on the surface of the brain or spinal cord.
- Asymmetric diffuse or multifocal brain or spinal cord and meningeal suppurative inflammation common.
- Culture of affected neurologic tissue—positive in > 75% of patients.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—treat aggressively; intensive care monitoring often necessary.

NURSING CARE

Fluid therapy and supportive care

ACTIVITY

Restricted

CLIENT EDUCATION

Inform client that rapid and aggressive treatment is important and that the prognosis for recovery is guarded.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics

- Bactericidal agents that achieve therapeutic concentrations within CSF are most desirable—lipid-soluble drugs with small molecular size, low protein binding, and a low degree of ionization at physiologic pH recommended.
 - Cultures—CSF, blood, urine, primary site; determine drug sensitivity; until cultures identify the organism choose a broad-spectrum agent that penetrates the blood-brain barrier.
 - Recommended drugs include third-generation cephalosporins (moxalactam, ceftriaxone, cefotaxime), fluoroquinolones, trimethoprim-sulfonamides, doxycycline and metronidazole.
 - Penicillin, ampicillin, amoxicillin-clavulanate and carbapenems enter the CNS when there is inflammation and are a good choice to use in combination with another antibiotic that will continue to cross the BBB as inflammation resolves such as trimethoprim-sulfonamides. Ampicillin may achieve high CSF concentrations even without inflammation.
 - Metronidazole reaches high levels in CSF, brain parenchyma, and brain abscesses and demonstrates the best bactericidal activity against anaerobes.
 - Clindamycin is lipid soluble but does not readily cross the blood-brain barrier.
- Concentrations in brain and spinal cord are adequate for treatment of *Toxoplasma* and *Neospora* infections but insufficient for treating most CNS bacterial infections.
- Administer antibiotics intravenously for 3–5 days to achieve high CSF concentrations rapidly, then maintain on oral therapy.
 - Immediate IV therapy can be based on cytology; penicillin for Gram-positive infections, fluoroquinolone (enrofloxacin or ciprofloxacin) or third-generation cephalosporin for Gram-negative infections.

Antiepileptic Drugs

- Indicated for seizures • Diazepam initially and then phenobarbital

Corticosteroids

- Most CNS damage is due to inflammation.
- May administer dexamethasone (0.2 mg/kg) prior to antibiotic therapy and then every 12 hours for 2 days.

CONTRAINdicATIONS

- Aminoglycosides and first-generation cephalosporins—do not penetrate the blood-brain barrier even in the presence of inflamed meninges.
- Chloramphenicol reaches high CSF concentrations but is associated with a high relapse rate; do not use.

FOLLOW-UP

PATIENT MONITORING

Monitor for nervous system signs, fever, leukocytosis, and systemic signs.

PREVENTION/AVOIDANCE

Treat local infections adjacent to the CNS (e.g., infections of the eyes, ears, sinuses, nose, and spine) early and aggressively to prevent extension to the CNS.

POSSIBLE COMPLICATIONS

Damage to the brain and spinal cord may be irreversible.

EXPECTED COURSE AND PROGNOSIS

- Response to antibiotics—variable; prognosis guarded.
- Many patients die despite treatment.
- Some patients will have residual neurologic deficits.
- Treatment for at least 4 weeks after resolution of all signs is recommended.

MENINGOENCEPHALOMYELITIS, EOSINOPHILIC

BASICS

OVERVIEW

Although eosinophilic meningoencephalomyelitis (EME) can be associated with meningitis, encephalitis, and myelitis as a result of CNS infection or parasitic migration, in most cases, no underlying cause can be found. Idiopathic EME occurs in young to middle-aged large-breed dogs and resolves in many cases following steroid treatment.

SIGNALMENT

- Dog and rarely cat. • Idiopathic EME—often larger dogs (> 25 kg); Rottweilers and golden retrievers predisposed. • Mean age—4 years (2 months–13 years).

SIGNS

- Vary with CNS location and severity.
- Neurologic deficits—most frequently associated with cranium, infrequently with spinal cord and rarely with cranial nerve involvement.

CAUSES & RISK FACTORS

- Idiopathic EME (unknown cause)—majority of reported cases. • Infectious—*Dirofilaria immitis* and cuterebral myiasis in cats; *Toxoplasma gondii*, *Neospora* spp., *Prototheca* spp., *Cryptococcus* spp., and nematode migration with *Baylisascaris procyonis* in dogs. • *Angiostrongylus*—dogs in Australia. • Intervertebral disc disease probably as allergic response to disc material.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cannot be differentiated from other encephalitides solely on clinical signs; CSF analysis must be done. • Idiopathic EME—negative serologic test results; marked CSF eosinophilic pleocytosis (20–95%); usually steroid-responsive. • Infectious diseases—identified on presence of systemic signs, blood work, fecal sample, CSF, serum/CSF serology, and imaging.

CBC/BIOCHEMISTRY/URINALYSIS

- Peripheral eosinophilia—may or may not be present. • Biochemistry and urinalysis—usually normal with idiopathic disease; eosinophilia, liver enzyme activity, and creatine kinase may be elevated in infectious diseases.

OTHER LABORATORY TESTS

- Serology—to rule out suspected infectious diseases. • Fecal flotation and sedimentation—to rule out migratory parasite.

IMAGING

- Thoracic radiography and abdominal ultrasound—to rule out systemic involvement. • MRI—variable; focal mass lesions, diffuse parenchymal abnormalities, post-contrast diffuse meningeal enhancement; abnormalities depend on cause and location of lesion.

DIAGNOSTIC PROCEDURES

CSF Analysis

- Eosinophilic pleocytosis significant when > 10%. • Presence of eosinophilic pleocytosis by itself cannot differentiate idiopathic EME from infection causing CSF eosinophilic pleocytosis. • Idiopathic EME—total nucleated cell count 4–3,880 cells/ μ L (median 99 cells/mL; reference < 0.003) with 22–95% eosinophils. • Infections—62–4,740 cells/mL (median 875 cells/mL) with 30–95% eosinophils.

CSF Serologic Testing

- If CSF eosinophils > 10%, look for parasitic and fungal disease. • Test for heartworm, *N. caninum*, *T. gondii*, and *C. neofmans*.

PATHOLOGIC FINDINGS

- CSF eosinophilic pleocytosis does not necessarily correlate with eosinophils observed in CNS parenchyma. • Wide variety of pathologic findings may indicate multiple causes, or the same disease taken at different times.

TREATMENT

- Usually inpatient, because of severity of clinical signs. • Activity—as tolerated.
- Regular diet.

MEDICATIONS

DRUG(S)

- Idiopathic disease—steroid administration; dexamethasone (0.2 mg/kg q24h for 1 day; then 0.15 mg/kg q24h for 6 days); follow with prednisone (0.5 mg/kg q24h for 8 weeks); then slowly wean patient off prednisone over 8 weeks–6 months depending on clinical response. • Protozoal disease—clindamycin, sulfonamides, and pyrimethamine. • Heartworm—microfilarial migration to the CNS is rare; no available treatment other than supportive.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Important to differentiate idiopathic EME from infection as treatment greatly differs—immunosuppressive dose of steroids versus anti-organism treatment. • Steroid should be used with caution if diagnosis has not been substantiated.

FOLLOW-UP

PATIENT MONITORING

Inpatient—repeat neurologic examination every 6 hours to monitor progress.

PREVENTION/AVOIDANCE

Steroid treatment should not be stopped even if the animal is back to normal within a few days. A minimum of 8 weeks followed by tapering of the medication over as many weeks is mandatory.

POSSIBLE COMPLICATIONS

- Recurrence may occur following cessation of medication. • Ensure treatment dosage is adequate and reinstate for a longer period.

EXPECTED COURSE AND PROGNOSIS

- Idiopathic disease—good prognosis in most cases with early treatment; improvement usually seen in the first 72 hours; full recovery in 2–6 months. Some patients continue to deteriorate despite steroids, and die.
- Protozoal and fungal diseases—poor-to-grave prognosis. • Larval migration—prognosis guarded to poor and depends on location of the lesion; signs may resolve, but larvae often continue to migrate and death may ensue. • Degradation of eosinophils is toxic to nervous tissue; patient may have permanent deficits from not only the primary disease but also cell death.

MISCELLANEOUS

AGE-RELATED FACTORS

Idiopathic EME is more frequent in young to middle-aged larger dog breeds (> 25 kg).

SEE ALSO

Encephalitis

ABBREVIATIONS

- CNS = central nervous system • CSF = cerebrospinal fluid • EME = eosinophilic meningoencephalomyelitis • MRI = magnetic resonance imaging

MENINGOENCEPHALOMYELITIS OF UNKNOWN ORIGIN (MUO)

BASICS

DEFINITION

Meningoencephalomyelitis of unknown origin (MUO) refers to a broad term to describe inflammatory disorders that affects the CNS focally, diffusely, or multifocally. In the past, the majority of CNS inflammatory disorders were categorized as GME. As a result, multiple less serious viral and idiopathic disorders were frequently erroneously diagnosed as GME. The appropriate clinical term to describe cases in which CNS inflammation is suspected is now considered MUO or MUE.

PATOPHYSIOLOGY

- Unknown. Although a specific etiologic agent is not recognized, in the majority of cases, viral and immune causes are strongly suspected.
- Three clinicopathologic forms recognized—ocular, multifocal (brain or brain and spinal cord), and focal (single focus in the brain or spinal cord).

SYSTEMS AFFECTED

- Nervous
- Ophthalmic

GENETICS

Not proven

INCIDENCE/PREVALENCE

Unknown. Since brain biopsies are rarely obtained, a presumptive diagnosis is made in most cases. The condition is diagnosed and treated successfully with increasing frequency.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Breed Predilections

Any breed can develop MUO. Smaller toy breeds may be overrepresented and can be less responsive to therapy. However, the condition also occurs in medium and large-breed dogs.

Mean Age and Range

- Mean—5 years
- Range—6 months–10 years

Predominant Sex

Slightly higher prevalence in females

SIGNS

- Depend on the form of the disease and neuroanatomic localization.
- Cerebral form—frequently results in seizure activity.
- Ocular form—acute onset of blindness with dilated, unresponsive pupils.
- Focal form—*cerebral lesion*: disorientation, behavioral changes, seizures, cortical blindness, compulsive circling, head pressing; *brainstem lesion*: somnolence, cranial nerve deficits (most commonly facial and vestibular dysfunction), ipsilateral hemiparesis; *spinal cord*: neck pain, tetraparesis (C1–C5 or C6–T2 lesions) or paraparesis (T3–L3 or L4–S2 lesions) and proprioceptive ataxia.

CAUSES

Unknown

RISK FACTORS

- Unknown.
- Some dogs develop clinical signs within 5–15 days of vaccination.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The combination of history, neurologic examination, CSF analysis, and MRI results usually lead to a presumptive diagnosis of inflammatory disease, but defining the cause of the inflammation can be problematic.
- Definitive diagnosis only by histopathologic studies. Some dogs with CNS inflammatory disease are successfully treated but data on these cases are lacking. Brain biopsies rarely performed to confirm the diagnosis. It is possible that some dogs surviving inflammatory CNS disease have lesions compatible with GME, but post-mortem studies not available to prove it. Alternatively, dogs who survive CNS inflammatory disease could have been suffering from other type of less serious viral or idiopathic inflammatory disease. Therefore the current accepted medical term to group these categories is MUO.
- Infectious inflammatory diseases—viral (distemper virus, other viruses); fungal (*Blastomycetes dermatitidis*, *Coccidioides* spp., *Cryptococcus neoformans*); rickettsial (*Rickettsia rickettsii*); bacterial (*Ehrlichia* spp., *E. coli*, *Streptococcus*); protozoal (*Neospora caninum*, *Toxoplasma gondii*).
- Other inflammatory disease—necrotizing encephalitis of the Yorkshire terrier, Maltese, and pug; immune-mediated steroid-responsive meningitis (beagles, Bernese mountain dogs, Nova Scotia duck tolling retrievers, Weimaraners, boxers).
- Sudden acquired retinal degeneration.
- Brain tumor—meningioma, glioma, choroids plexus papilloma, lymphoma.
- Subatlantoaxial luxation.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- CBC—stress leukogram (elevated white blood cell count and segmented neutrophilia with lymphopenia) may be present.

OTHER LABORATORY TESTS

Serologic testing to rule out infectious CNS diseases.

IMAGING

MRI—method of choice; abnormalities are variable and consist of solitary, multiple, or circumscribed mass lesions. Multiple areas of heterogeneous contrast enhancement are frequent in the multifocal form of the disease. Other findings include mass effect with midline shift, obstructive hydrocephalus, white matter edema, and effacement of the

sulci. Usually MRI lesions are characterized as hypointense in T1-weighted and hyperintense in T2-weighted images. Necrotic lesions are recognized by a center of hypointensity with a peripheral ring of enhancement.

DIAGNOSTIC PROCEDURES

CSF Analysis

- Reference range—white cell count (0–3 cells/ μ L); protein concentration (0–30 mg/dL).
- Helps confirm presence of inflammatory disease but rarely demonstrates a definitive cause. The following are only guidelines, as significant overlap exists regarding CSF cytology of different inflammatory disorders.
- Inflammatory diseases—white cell count and protein concentration usually increased. Even with a normal cell count, presence of an abnormal cell population (e.g., macrophages) should be taken into consideration as evidence of pathology.
- Usually, mononuclear pleocytosis; however, polymorphonuclear pleocytosis, or a normal CSF can be present.
- Bacterial (rare in dogs)—marked polymorphonuclear pleocytosis.
- Fungal, protozoal infections—mixed pleocytosis (mononuclear and polymorphonuclear); rarely a fungal organism (*Cryptococcus neoformans* or *Blastomycetes dermatitidis*) is identified.
- Viral infections—mononuclear pleocytosis.

Brain Biopsy

Brain biopsy is the only procedure that can confirm conclusively a diagnosis of MUO. Due to morbidity, mortality, and cost associated with brain biopsy the test is not performed routinely. It is important to note that GME is NOT a clinical diagnosis but a term to describe findings at post-mortem. The term should not be used as clinical diagnosis, to avoid confusion.

PATHOLOGIC FINDINGS

- Hallmark feature—dense perivascular distribution of mononuclear infiltrates (lymphocytes, monocytes, and plasma cells).
- Macroscopically, discoloration and softening of affected tissue sometimes evident.

TREATMENT

APPROPRIATE HEALTH CARE

- Stable patients can be discharged with recommended treatment.
- Inpatient—for severely affected dogs; monitor patient closely for progression of neurologic deficits.
- In severe cases, sequential assessment of pupil size and reaction to light, and mentation are helpful to determine risk of herniation.

NURSING CARE

- Intravenous fluids for the anorexic patient. Take care not to overhydrate to exacerbate cerebral edema.
- Provide a padded cage for

MENINGOENCEPHALOMYELITIS OF UNKNOWN ORIGIN (MUO) (CONTINUED)

dogs with vestibular ataxia, severe dementia, or seizure activity. • Recumbent patients should be turned frequently (every 4 hours).

ACTIVITY

- Depends on severity of disease and lesion localization.
- Ataxic patients should be confined to a padded cage to avoid injury.

DIET

Ensure adequate caloric intake.

CLIENT EDUCATION

- Explain to the client that there is significant overlap of clinical signs among different inflammatory diseases. Insist on the importance of a diagnostic workup.
- Mortality rate is variable but clearly biased by older literature describing the severe cases that went to post-mortem as suffering from GME. Brain biopsies are rarely conducted. Clinical experience suggests that up to 70% of patients can respond to therapy, especially if initiated early in the course of the disease. However, treatment may be prolonged or could be required for life.
- Corticosteroid therapy may be necessary indefinitely.

MEDICATIONS

DRUG(S) OF CHOICE

- Dexamethasone 0.25 mg/kg IV or PO q24h for 4 days followed by prednisone 0.5–1.0 mg/kg PO q24h for 2 weeks. Dose is adjusted according to response and side effects. The goal is to find dosage that keeps the clinical signs controlled with minimal side effects. If deterioration of clinical signs noted when tapering steroids, immediately go back to previous dose that controlled the signs or consider adding other immunosuppressant listed below.
- To prevent gastrointestinal ulceration, combine steroid therapy with omeprazole 0.5 mg/kg PO q24h, famotidine 0.5–1 mg/kg IV or PO q12h. • If there is seizure activity—phenobarbital 2 mg/kg PO q12h, levetiracetam 20 mg/kg PO (ideally q8h but may be attempted q12h), or zonisamide 5–10 mg/kg PO q12h.
- Gabapentin 2–5 mg/kg PO q8–12h if compulsive circling is present.

CONTRAINDICATIONS

- Fungal, bacterial, and protozoal conditions can be exacerbated by the use of steroids. It is important to rule out these infectious disorders with proper diagnostic workup.
- Steroid should not be used in a patient treated or recently treated with NSAIDs.

PRECAUTIONS

Reduction in corticosteroid therapy can result in recrudescence of clinical signs that may not be controlled again as initially.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

- Azathioprine 2 mg/kg PO q24h.
- Cytosine arabinoside 50–100 mg/m² body surface area q12h for 2–3 days SC or IV. Repeat treatment every 3 weeks to 8 weeks pending clinical response.
- Cyclosporine 3–7 mg/kg PO q12h.
- Leflunomide 4 mg/kg PO q24h.
- Radiation therapy—alternative treatment in focal form of disease when other therapies have failed. Confirm diagnosis with histopathology before starting radiation therapy.

FOLLOW-UP

PATIENT MONITORING

- Repeat neurologic examination periodically (every 2–4 weeks).
- Evaluate CBC and biochemical profile regularly to monitor for leukopenia, thrombocytopenia, and liver and kidney function if alternative drugs are used.
- Monitor urine in patients on long-term steroid treatment—proteinuria or infection are frequent consequences. Patients receiving zonisamide may be at risk for KCS and immune-mediated conditions—hemolytic anemia, immune thrombocytopenia, and polyarthritis.

POSSIBLE COMPLICATIONS

- Deterioration of clinical signs despite aggressive treatment.
- Status epilepticus, dementia, brain herniation, and death.

EXPECTED COURSE AND PROGNOSIS

- Not all patients with CNS inflammatory disease have a poor prognosis.
- GME has been stereotyped as fatal without enough evidence. Uncertain if surviving dogs had GME as brain biopsies are rarely done.

BASICS

OVERVIEW

- Rare tumor in dogs and cats arising from the mesothelial cells of the serosal lining of the pleural, pericardial, or peritoneal cavities.
- Also has been reported in dogs to arise from the tunica vaginalis of the testes.

SIGNALMENT

- Older animals—dog and cat
- Sclerosing subtype more common in males
- German shepherds overrepresented

SIGNS

- Pleural effusion—dyspnea, tachypnea, exercise intolerance, coughing, gagging, cyanosis.
- Pericardial effusion—lethargy, anorexia, weakness, collapse, respiratory distress, exercise intolerance, distended abdomen, vomiting.
- Ascites—distended abdomen, anorexia, vomiting, lethargy, abdominal discomfort.
- Swollen testes.
- Sclerosing subtype signs are secondary to restriction around affected organs—vomiting, urinary issues.

CAUSES & RISK FACTORS

- Increased risk with asbestos exposure.
- Possible increased risk in golden retrievers with idiopathic hemorrhagic pericardial effusion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of effusions—hypoproteinemia, vasculitis, neoplasia (e.g., lymphoma, chemodectomas, hemangiosarcoma, carcinomatosis), idiopathic, congestive heart failure, liver disease, infectious/inflammatory.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

IMAGING

- Thoracic radiography—identification of pleural effusion, evaluation of cardiac silhouette (i.e., globoid heart consistent with pericardial effusion).

- Echocardiography—identification of pericardial effusion, rule out primary cardiac neoplasia.
- Thoracic and abdominal ultrasonography—evaluation of effusions.
- CT—identification of mass lesions and evaluation of lungs in the face of pleural effusion.

DIAGNOSTIC PROCEDURES

- Cytology of effusions to rule out infectious causes or lymphoma—difficult to diagnose mesothelioma on cytology as mesothelial cells are typically shed into effusions and can be highly reactive.
- Exploratory surgery (open or via thoracoscopic or laparoscopic examination) with biopsies.
- Fibronectin levels in effusions—not specific for mesothelioma but typically elevated in neoplastic effusions.

TREATMENT

- Pericardectomy or mass removal if possible.
- Symptomatic pericardiocentesis or thoracocentesis.

MEDICATIONS

DRUG(S)

- Intracavitary chemotherapy.
 - Cisplatin (dog only) 50–70 mg/m² every 3 weeks with saline diuresis.
 - Carboplatin (cat) 180–200 mg/m² every 3–4 weeks.
 - Carboplatin (dog) 300 mg/m² (dog) every 3 weeks.
 - Mitoxantrone (dog) 5.0–5.5 mg/m² every 3 weeks.
- Intravenous chemotherapy—doxorubicin 30 mg/m² (dog > 10 kg) or 1 mg/kg (dog < 10 kg or cat), or mitoxantrone (4.5–5.5 mg/m² dog and cat) once every 3 weeks.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Chemotherapy can cause gastrointestinal, bone marrow, cardiac, and other toxicities—seek advice if unfamiliar with cytotoxic drugs.
- Cisplatin in particular is nephrotoxic. Do not use in cats; causes fatal pulmonary edema.

FOLLOW-UP

PATIENT MONITORING

- Blood tests—especially CBC to monitor for bone marrow suppression secondary to chemotherapy and renal values to monitor for renal toxicity if treating with cisplatin.
- Serial thoracic radiography and/or ultrasounds of heart, thoracic cavity, or abdominal cavity to monitor for recurrence of effusions and to monitor tumor response.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—variable and anecdotal.
 - Intracavitary cisplatin (dogs)—range 8 months to > 3 years.
 - Intracavitary carboplatin (cats) with piroxicam—6 months.
 - Surgery and intracavitary cisplatin and IV doxorubicin—> 27 months.
 - Reported survival with surgery alone—4–9 months.

M

MISCELLANEOUS

It is not recommended to breed animals with cancer. Chemotherapy is teratogenic—do not give to pregnant animals.

ABBREVIATION

- CT = computed tomography

METALDEHYDE TOXICOSIS

BASICS

DEFINITION

- Metaldehyde is a polymeric form of acetaldehyde and primarily affects the nervous system. It is an ingredient of slug and snail baits, and sometimes found in solid fuel for camp stoves.
- Metaldehyde crosses the blood-brain barrier and disrupts GABAergic inhibitory action, facilitating neuronal excitation and increasing potential for convulsions.

SYSTEMS AFFECTED

- Neuromuscular—seizures and muscle tremors.
- Hepatobiliary—delayed hepatotoxicosis occasionally reported in dogs.
- Multiple organ failure may occur secondary to convulsions and hyperthermia.

INCIDENCE/PREVALENCE

Depends on presence and accessibility of toxicant.

GEOGRAPHIC DISTRIBUTION

More frequent in coastal and low-lying areas, where snails and slugs are common.

SIGNALMENT

Species

Dogs and cats (less often).

SIGNS

- So-called “shake and bake” toxicant due to characteristic tremors, seizures, and hyperthermia
- Signs typically develop within 4 hours of ingestion
- Anxiety and restlessness
- Salivation, vomiting, diarrhea
- Tachycardia
- Tachypnea
- Hyperthermia, often 106°F (41°C) or greater, leading to DIC and multi-organ failure if uncontrolled
- Ataxia
- Tremors
- Seizures, initially intermittent, progressing to continuous
- Hyperesthesia
- Depression
- Mydriasis
- Nystagmus (particularly in cats)

CAUSES

Ingestion of metaldehyde

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Strychnine - intermittent seizures that can often be evoked by external stimuli.
- Tremorgenic mycotoxins – tremors and seizures.
- Lead - seizures, behavior changes, blindness, vomiting, diarrhea.
- Zinc phosphide rodenticide—seizures and hyperesthesia.
- Bromethalin rodenticide—ataxia, tremors, seizures.
- Organophosphate and carbamate insecticides - seizures; often accompanied by excessive salivation, lacrimation, urination, defecation, GI upset, emesis.

CBC/BIOCHEMISTRY/URINALYSIS

- No specific diagnostic features
- Metabolic acidosis
- Increased serum muscle enzyme activity
- Changes in hepatic or renal values, likely secondary to uncontrolled hyperthermia

OTHER LABORATORY TESTS

Metaldehyde testing—gastric contents, serum, urine, brain, or liver. Testing capabilities vary widely among labs - contact your lab of choice to see what samples are recommended.

PATHOLOGIC FINDINGS

- Lesions neither consistent nor pathognomonic on gross and histologic examination.
- Gastric contents may have a formaldehyde-like odor.

TREATMENT

APPROPRIATE HEALTH CARE

Emergency evaluation, followed by inpatient intensive care management until convulsions, tremors, and hyperthermia are controlled.

NURSING CARE

- Control hyperthermia with cool intravenous crystalloids, ice packs, fans, enemas, etc.
- Monitor to prevent aspiration of vomitus.
- Crystalloids to correct dehydration or acidosis.
- Monitor CNS status.

DIET

Do not feed patients that are vomiting, convulsing, or heavily sedated.

MEDICATIONS

DRUG(S) OF CHOICE

- No specific antidote available.
- Removal of toxicant via gastric lavage (preferred with large toxicant ingestions and patients that are symptomatic) or emetics.
- Reduce absorption via single dose of activated charcoal with cathartic, if patient is not at risk for aspiration.
- Control convulsions with benzodiazepines (first choice), barbiturates, propofol, or inhalant general anesthetics.
- Methocarbamol or 5% guaifenesin for control of tremors.
- Consider hepatoprotectants in dogs ingesting large doses of metaldehyde.

CONTRAINdicATIONS

Do not induce vomiting or give activated charcoal to a patient that is convulsing or heavily sedated.

PRECAUTIONS

Use depressant drugs very cautiously in an already depressed patient, and only if other options are unavailable or ineffective. Use anticonvulsants at lowest effective doses.

FOLLOW-UP

PATIENT MONITORING

- Periodically allow anticonvulsants to wear off to reevaluate seizure condition.
- Recheck liver enzymes 72 hours post-discharge in dogs that have ingested large amounts of metaldehyde.

PREVENTION/AVOIDANCE

- Do not apply metaldehyde in areas accessible to pets.
- Some manufacturers dye these products green or blue to assist with identification.
- Bittering agents are sometimes added to metaldehyde products but do not reliably discourage ingestion.

POSSIBLE COMPLICATIONS

- Liver or renal dysfunction possible several days after recovery from the initial signs, probably as sequelae to convulsions and hyperthermia.
- Aspiration pneumonia is a concern with any convulsing patient.
- Hyperthermia may lead to DIC or multiple organ failure.
- Temporary blindness has been reported in rare cases.

EXPECTED COURSE AND PROGNOSIS

- Prognosis usually good to excellent if treated early and aggressively.
- Guarded to poor prognosis with delayed or inadequate treatment, especially with large ingestions.
- Fatalities most often occur within 24 hours of ingestion. Survival beyond the first 24 hours is a positive prognostic indicator.

MISCELLANEOUS

ABBREVIATION

DIC = disseminated intravascular coagulation

METFORMIN TOXICOSIS

BASICS

OVERVIEW

- Metformin (Glucophage) is a biguanide antihyperglycemic prescription medication labeled for the treatment of non-insulin-dependent (type 2) diabetes mellitus in humans.
- Available as single or extended release formulation (Glucophage XR).
- Formulated as a single ingredient and in combination with other antidiabetic medications.
- The agent potentially could be useful in the adjunctive treatment of non-insulin-dependent diabetes mellitus in cats; use is controversial.
- Toxicity causes gastrointestinal signs and lethargy.
- 243 exposures to metformin were reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. Of these, 231 were dogs with 27 showing clinical signs and 12 cases were cats with 2 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting and diarrhea.

SIGNALMENT

- Dogs and cats
- No breed, age, or sex predilections

SIGNS

Dogs

- Common sign: vomiting
- Possible signs: lethargy, depression, anorexia, and hypothermia

Cats

- Frequent sign: vomiting
- Possible signs: lethargy, diarrhea, and vocalization

CAUSES & RISK FACTORS

Ingestion of metformin in single ingredient preparations as well as in combination with other antidiabetic agents.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other gastrointestinal tract irritants

CBC/BIOCHEMISTRY/URINALYSIS

- Azotemia reported in humans due to acute renal failure in cases of biguanide lactic acidosis; not reported in animal toxicities.
- Hypoglycemia not reported.

OTHER LABORATORY TESTS

- Blood gases—lactic acidosis rare but possible with large ingestions (a Shih Tzu ingesting 167.2 mg/kg of metformin developed lactic acidosis, vomiting, and hypothermia. No hypoglycemia developed and the dog fully recovered with treatment).
- High performance liquid chromatography may identify presence of metformin in plasma; drug levels are not clinically useful.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

N/A

TREATMENT

- Induce emesis within the first 2–3 hours of exposure.
- Activated charcoal should only be considered with very large exposure.
- Treat gastrointestinal signs supportively.
- Treat lactic acidosis if present.

MEDICATIONS

DRUG(S)

- Metoclopramide 0.1–0.4 mg/kg PO, SC, or IM q6h.
- Sucralfate 0.5–1 g PO q8–12h for dogs and 0.25–0.5 g PO q8–12h for cats.
- Famotidine 0.5 mg/kg orally, subcutaneously, or intramuscularly q12–24h for dogs and cats.
- Ranitidine 0.5–2 mg/kg PO, SC, or IM q8–12h for dogs and 2.5 mg/kg IV q12h or 3.5 mg/kg PO q12h for cats.
- Omeprazole 0.5–1 mg/kg PO q24h for dogs and 0.7 mg/kg PO q24h for cats.
- Bicarbonate: if serum bicarbonate or total CO₂ is unavailable: 2–3 mEq/kg IV over 30 minutes if patient has decreased tissue perfusion or renal failure and does not have diabetic ketoacidosis. Must be used judiciously.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Concurrent administration of cimetidine may reduce the urinary excretion of metformin by competing for renal tubular organic cationic transport systems.

- The manufacturer states that other cationic drugs that undergo substantial tubular secretion (e.g., amiloride, digoxin, morphine, procainamide, quinidine, quinine, ranitidine, triamterene, trimethoprim, and vancomycin) may possibly decrease the urinary excretion of metformin.

METHEMOGLOBINEMIA

BASICS

DEFINITION

- Methemoglobin content in blood > 1.5% of total hemoglobin.
- Methemoglobin differs from hemoglobin in that the iron moiety of heme groups has been oxidized from the ferrous (+2) to the ferric (+3) state.

PATHOPHYSIOLOGY

- About 3% of hemoglobin is oxidized to methemoglobin each day in normal animals as a result of autoxidation of hemoglobin or secondary to oxidants produced in normal metabolic reactions.
- Methemoglobin usually accounts for < 1% of total hemoglobin, because it is constantly reduced back to hemoglobin by an NADH-dependent cytochrome b_5 reductase (methemoglobin reductase) enzyme reaction within RBCs.
- Caused by either increased production of methemoglobin by oxidants or decreased reduction of methemoglobin associated with a deficiency of the RBC cytochrome b_5 reductase enzyme.

SYSTEMS AFFECTED

- Hemic/Lymphatic/Immune—reduced oxygen-carrying capacity of blood, because methemoglobin cannot bind oxygen; if methemoglobin content reaches high values (e.g., > 50% of total hemoglobin), various organs may suffer hypoxic injury.
- Hepatobiliary—in addition to hypoxic injury, the liver may be damaged directly by oxidant drugs that it metabolizes.
- Renal/Urologic—in addition to hypoxic injury, the kidneys may be damaged if intravascular hemolysis occurs.

SIGNALMENT

- Dogs and cats.
- Deficiency in RBC cytochrome b_5 reductase has been recognized in Chihuahuas, borzois, English setters, terrier mixes, cockapoos, coonhounds, poodles, corgis, Pomeranians, pit bull mixes, and toy Eskimo dogs and in domestic shorthair cats.

SIGNS

Caused Directly

- Possibly none in animals with mild to moderate methemoglobinemia.
- Cyanotic-appearing mucous membranes—may be difficult to recognize in heavily pigmented animals.
- Lethargy, tachycardia, tachypnea, ataxia, and stupor caused by hypoxia when methemoglobin content exceeds 50%.
- Coma-like state and death when methemoglobin content reaches 80%.

Caused by Associated Diseases

- Vomiting, anorexia, and diarrhea possible in patients with drug toxicity.

- Hemoglobinuria secondary to severe intravascular hemolysis in some patients with concomitant Heinz body hemolytic anemia.
- Subcutaneous edema, especially involving the face, and salivation in cats with acetaminophen toxicity.

CAUSES

- Toxicity—acetaminophen, benzocaine, phenazopyridine, and skunk musk also cause Heinz body hemolytic anemia; excess nitrite in pet food and hydroxycarbamide toxicity are reported to cause methemoglobinemia without Heinz body hemolytic anemia.
- Deficiency in RBC cytochrome b_5 reductase.

RISK FACTORS

- Application of benzocaine to traumatized skin or mucous membranes increases the likelihood of systemic absorption and methemoglobinemia.
- Cats are much more likely to develop clinically significant methemoglobinemia than are dogs after acetaminophen administration; this drug is not recommended for use in cats.
- Methemoglobinemia secondary to cytochrome b_5 reductase deficiency is an inherited disorder.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Both low blood oxygen tension and methemoglobinemia can cause cyanotic-appearing mucous membranes and dark-colored blood samples.
- Hypoxemia is documented by measuring low Po_2 in an arterial blood sample.
- Methemoglobinemia is suspected when arterial blood with normal or high Po_2 is dark-colored.

LABORATORY FINDINGS

Drugs That Alter Laboratory Results

None

Disorders That May Alter Laboratory Results

Hemolysis in the sample may raise the methemoglobin value, especially if the methemoglobin assay is not conducted soon after sample collection.

Valid if Run in Human Laboratory?

- Valid, as long as the method to lyse RBCs does not cause methemoglobin formation in the animal being tested.
- Saponin should not be used to lyse RBCs, because it raises the methemoglobin value in some species.

CBC/BIOCHEMISTRY/URINALYSIS

- Chronic methemoglobinemia secondary to cytochrome b_5 reductase deficiency can result in a slightly high HCT; in contrast, anemia

may accompany methemoglobinemia caused by oxidant drugs.

- If severe or induced by oxidant drugs, evidence of injury to various organs (e.g., high BUN and ALT) may be seen.

OTHER LABORATORY TESTS

- Spot test—determine if the patient's methemoglobin content is clinically important: one drop of blood from the patient is placed on a piece of absorbent white paper and a drop of normal control blood is placed next to it. If the methemoglobin content is ≥ 10%, the patient's blood will be noticeably browner than the bright red of the control blood.
- Co-oximetry is the method of choice for accurate measurement of methemoglobin content in whole blood samples.
- Methemoglobin content in dogs with cytochrome b_5 reductase deficiency varies from 13 to 51%; the methemoglobin content in six deficient cats was 44–52%.
- A definitive diagnosis of cytochrome b_5 reductase deficiency is made by measuring enzyme activity in RBCs; this assay is done in a few research laboratories and requires that arrangements be made before blood samples are submitted.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Blood should be stained for Heinz bodies if evidence of toxicity is present.
- The presence of Heinz bodies indicates exposure to an oxidant drug that may also cause hemolytic anemia.

TREATMENT

- Mild to moderate—does not require specific treatment to reduce the methemoglobin content.
- Drug induced—the use of the drug should be discontinued; RBCs can convert much of the methemoglobin back to hemoglobin within 24 hours after elimination of drug exposure.
- Inherited cytochrome b_5 reductase deficiency—animals have normal life expectancy and generally do not require treatment, although veterinarians may wish to give a single IV injection of methylene blue (see below) 1 hour before a deficient animal is anesthetized for surgery to maximize the amount of hemoglobin that is capable of binding oxygen.
- Whole blood transfusions should be given to patients with severe anemia and those with rapidly decreasing HCT and clinical signs suggesting a deteriorating condition.
- Severe intravascular hemolysis—IV fluid administration recommended.

(CONTINUED)

- Treatment of electrolyte or acid-base imbalances may also be indicated in patients with severe vomiting or diarrhea, concomitant renal injury, or impending shock.
- Administration of oxygen is of limited value because methemoglobin cannot bind oxygen, and an increase in dissolved oxygen results in only a small increase in blood oxygen content.

MEDICATIONS

DRUG(S) OF CHOICE

- Methylene blue—given slowly over several minutes as a 1% solution (1 mg/kg IV), may be administered in patients with severe methemoglobinemia; a dramatic response should occur during the first 30 minutes of treatment; caution: although this dose can be repeated if necessary, methylene blue can cause Heinz body hemolytic anemia in cats and dogs.
- N*-acetylcysteine is efficacious in the treatment of acetaminophen toxicity in cats if given within a few hours after exposure; recommended dosage is 140 mg/kg PO followed by 70 mg/kg q6h for seven treatments.

CONTRAINDICATIONS

None

PRECAUTIONS

In patients that have been given drugs that cause substantial Heinz body formation and methemoglobinemia, methylene blue treatment can potentiate the formation of Heinz bodies and anemia; consequently, it is prudent to measure the HCT for 3 days after methylene blue treatment to ensure that clinically important anemia does not develop.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

None

FOLLOW-UP

PATIENT MONITORING

- The cyanotic appearance of skin and mucous membranes should disappear after reduction of methemoglobin to an amount that does not produce clinical signs.
- Blood on the spot test should appear bright red after reduction of methemoglobin to values < 10% of total hemoglobin.
- If methylene blue treatment is given or Heinz bodies are present within RBCs, the HCT should be monitored closely, because it usually does not reach its lowest point until approximately 3 days after initial oxidant exposure.

METHEMOGLOBINEMIA

POSSIBLE COMPLICATIONS

Coma and death can occur if methemoglobin content reaches 80% of total hemoglobin.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Heinz body anemia

M

METRITIS

BASICS

OVERVIEW

- Bacterial uterine infection that develops in the immediate postpartum period (usually within the first week); occasionally develops after an abortion or non-sterile artificial insemination—rarely after natural breeding.
- Bacteria—ascend through the open cervix to the uterus; a large, flaccid, postpartum uterus provides an ideal environment for growth; gram-negative bacteria (e.g., *Escherichia coli*) commonly isolated.
- Potentially life-threatening infection; may lead to septic shock.
- Directly affects uterus; systemic involvement as sepsis develops.
- Can become chronic and lead to infertility.

SIGNALMENT

- Postpartum bitch and queen
- No age or breed predilection

SIGNS

Historical Findings

- Malodorous, purulent, sanguinopurulent, or dark green vulvar discharge
- Depression
- Anorexia
- Neglect of puppies and kittens
- Reduced milk production
- Polyuria/polydipsia due to endotoxin effect on renal tubules.

Physical Examination Findings

- Fever
- Large uterus on abdominal palpation
- Dehydration
- Injected mucous membranes
- Tachycardia—with sepsis

CAUSES & RISK FACTORS

- Dystocia
- Obstetric manipulation
- Retained fetuses or placentas
- Prolonged delivery (large litter)
- Post-abortion, and post-natural or artificial insemination (rare)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Subinvolution of placental sites—no sign of infection on cytologic examination of vagina.
- Eclampsia—differentiated by serum calcium concentration.
- Mastitis—differentiated by physical examination findings.

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilia with left shift.
- Leukopenia—occasionally with endotoxic shock.
- High PCV, total protein, creatinine, BUN, and urine specific gravity—secondary to dehydration. Normocytic, normochromic nonregenerative anemia may also occur.
- High liver enzyme—with endoxemias.
- Low urine specific gravity—may see with endoxemias.
- Hypoalbuminemia, elevation of C-reactive protein, and acute phase proteins may occur.
- Urinalysis may reveal isosthenuria, bacteruria (obtain via U/S guided cystocentesis).

OTHER LABORATORY TESTS

N/A

IMAGING

- Radiography—reveals a large uterus and possibly retained fetus(es).
- Ultrasonography—reveals intrauterine fluid accumulation and increased horn width, retained placenta(s), and retained fetus(es); shows abdominal effusion secondary to uterine rupture.

DIAGNOSTIC PROCEDURES

- Vaginal cytologic examination—detect degenerative neutrophils with intracellular and extracellular bacteria.
- Guarded anterior vaginal or transcervical culture—aerobes and anaerobes; identify organism and its antibiotic sensitivity pattern.

TREATMENT

- Inpatient until systemic signs resolve.
- Dehydration—intravenous balanced electrolyte solution.
- Treat shock.
- Electrolyte imbalances and hypoglycemia—correct; identified by serum chemistry profile.
- Ovariohysterectomy—treatment of choice for retained fetus(es) or placenta(s), uterine rupture, or severe infection, and if future breeding is not desired.
- Chronically affected patient that does not respond to medical treatment—may perform hysterotomy and lavage as long as the uterus has no friable areas.
- Friable uterus—pack off and handle gently at surgery.

MEDICATIONS

DRUG(S)

- Antibiotics—start with broad-spectrum agents (oral if patient is stable; intravenous if patient is in shock); choice confirmed by bacterial culture and sensitivity; continued at least 14 days. Give at separate time from PGF_{2α} administration due to risk of vomiting.
- Nursing planned—amoxicillin-clavulanic acid (dogs, 12.5–25 mg/kg PO q12h; cats, 62.5 mg/cat PO q12h); can administer q8h with Gram-negative infections; or oxacillin (22–40 mg/kg PO q8h) to start.
- Nursing not planned—enrofloxacin (2.5–10 mg/kg PO q12h) to start.
- Oxytocin 0.5–1 U/kg IM (do not exceed 20 IU total); then repeat in 1–2 hours; may note inadequate response if > 48 hours since parturition.
- PGF_{2α} 10–50 µg/kg SC q3–5h for 3–5 days or 100 µg/kg SC q12h for 3–5 days; to evacuate uterus, ultrasound prior to cessation of treatment to ensure resolution of fluid accumulation in uterine lumen.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Prostaglandin—may induce uterine rupture if the tissue is devitalized.
- Oxytocin—not effective beyond 48 hours postpartum.
- Uterine flushing—may cause rupture of devitalized wall.

FOLLOW-UP

PATIENT MONITORING

- CBC, temperature, vaginal cytologic examination, and clinical signs.
- Ultrasonography—monitor evacuation of uterine fluid.

POSSIBLE COMPLICATIONS

- Ovariohysterectomy—necessary when medical treatment is ineffective.
- Uterine rupture and peritonitis—may occur with medical treatment.
- Owners may need to foster or hand-raise puppies and kittens, monitor daily weight gain to ensure adequate nutrition: pups should gain 10% of birth weight per day; kittens should gain a minimum of 7–10 g/day.

EXPECTED COURSE AND PROGNOSIS

- Ovariohysterectomy—prognosis for recovery good; recommended for older patients.
- Medical treatment—prognosis for recovery dependent on early recognition of problem by owner—good if early, may adversely affect future reproduction.

MISCELLANEOUS

ABBREVIATIONS

- PCV = packed cell volume
- PGF_{2α} = prostaglandin F_{2α}

MICROSPORIDIOSIS (ENCEPHALITOZOONOSIS)

BASICS

OVERVIEW

- Encephalitozoonosis is now called microsporidiosis.
- Obligate intracellular spore forming parasite found in a wide array of domestic mammals.
- Infection with the parasites *Encephalitozoon cuniculi* and other species.
- *Encephalitozoon cuniculi* has been divided into three strains—I rabbit type, also detected in man, II mouse type, and III dog type.
- Affects brain, kidney, liver, intestine, eye, lungs.
- Uncommon in the United States but may be more prevalent in other countries.
- Organ systems affected:
 - Neurologic ◦ Renal/Urologic
 - Hepatobiliary ◦ Gastointestinal ◦ Ocular
 - Hemic/lymphatic/immune

SIGNALMENT

- Dogs and cats
- No sex or breed predilection
- Young animals

SIGNS

- Appears a few weeks postpartum
- Stunted growth
- Ill-thrift
- Depression
- Inappetance and weight loss
- Nephritis progressing to renal failure
- Neurologic abnormalities—convulsions, viciousness, biting, vocalization, ataxia, circling, hypermetria
- Ocular abnormalities—including cataracts, uveitis, and blindness

CAUSES & RISK FACTORS

- Transmitted through ingestion, inhalation, transplacentally or rarely through epithelium after trauma.
- Infectious spores are excreted in urine, feces, and mucus.
- Can be ingested from tissues of infected rabbits or mice.
- Kennel housing is a risk factor.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rabies
- Canine distemper
- Canine herpesvirus
- Neosporosis
- Toxoplasmosis
- Hydrocephalus
- Feline panleukopenia
- Septicemia

CBC/BIOCHEMISTRY/URINALYSIS

- Normochromic, normocytic anemia
- Lymphocytosis and monocytosis

- High serum ALT and ALP expected
- Azotemia—variable
- Hyperproteinemia
- Urinalysis—haematuria and proteinuria

OTHER LABORATORY TESTS

- Serology (immunofluorescent antibody staining, complement fixation, ELISA, and Western immunoblot assays)—blood and CSF (IFA > 100 or ELISA > 800).
- PCR—highly specific and sensitive but not routinely available in veterinary diagnostic labs.
- Histopathology—brain, lung, kidney, placenta, eye. Difficult to identify parasites by light microscopy with H&E stains. Trichrome stain, Calcofluor white fluorescent stain or Fungi-Fluor stain can be used to identify organisms.
- Cytology—aqueous humor and lens material (low sensitivity).
- Urine sediment—special stains may identify parasite spores.

IMAGING

May be contributory but not diagnostic.

DIAGNOSTIC PROCEDURES

CSF—pleocytosis, increased protein. May see organisms with special stains.

PATHOLOGIC FINDINGS

- Urogenital—lymphocytic-plasmacytic interstitial nephritis, hemorrhagic cystitis, renal cortical cysts, or infarcts.
- Neurologic—lymphocytic-plasmacytic meningoencephalitis, thrombosis and encephalomalacia, perivascular cuffing with occasional intracellular parasitic cysts containing Gram-positive spores.
- Hepatic—multifocal microgranulomatous hepatitis.
- Respiratory—interstitial pneumonia.
- Cardiac—fibrous pericarditis.
- Gastrointestinal—regional enteritis.
- Other—reticuloendothelial hyperplasia of the spleen and hyperplasia of the bone marrow. Necrotic, tortuous medium-sized to small arteries (polyarteritis nodosa).

TREATMENT

- Inpatient with supportive therapy.
- Poor understanding of the disease progression exists. Most diagnosed post-mortem. Asymptomatic infections likely occur.
- Euthanasia—when severe neurologic signs occur.

MEDICATIONS

DRUG(S)

- No treatment has been reported. Try benzimidazoles, particularly albendazole

(400 mg q12h for > 3 weeks), because they work in mice and humans.

- Trimethoprim or pyrimethamine and sulphonamides, alone or in combination, with albendazole have been effective in humans with disseminated infections.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PREVENTION/AVOIDANCE

- Sanitation—important; accomplish with 70% ethanol, hydrogen peroxide, 10% formalin and 10% bleach.
- Spores survive in humid environments at ambient temperatures.

EXPECTED COURSE AND PROGNOSIS

A number of patients recover without further signs if neither the renal nor the cerebral manifestation becomes severe.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Potential risks to humans, especially the immunosuppressed and children.
- Single report of possible direct transmission between dog and child.

ABBREVIATIONS

- ALP = alkaline phosphatase
- ALT = alanine aminotransferase
- CSF = cerebrospinal fluid
- PCR = Polymerase chain reaction

MOVEMENT DISORDERS

BASICS

OVERVIEW

• Movement disorders—CNS disorders characterized by the occurrence of continuous or episodic involuntary movements with dystonia, ballism, chorea or athetosis in a fully conscious animal; unrelated to epileptic activity. Movements restricted to one body part, e.g. one, two limbs or the whole body. Hyperkinetic movement disorders often occur as paroxysmal dyskinesias with episodes of abnormal movements or increased muscle tone alternating with normal neurologic function. • Abnormal CNS neural transmission, ion channelopathy, neurotransmitter dysfunction.

SIGNALMENT

• Dog; less common in cat. • Breed-related syndromes. • Age of onset variable. Often < 3 years.

SIGNS

• Physical examination—unremarkable. • *Paroxysmal dyskinesia*—in Bichon frises, Bolonkas, border terriers (*canine epileptoid cramping*), Chinooks, soft-coated Wheaten terriers: repeated flexion or kicking of one hind limb, difficulty walking, extensor rigidity with resulting ataxia, kyphosis or scoliosis, some with backward gait; no autonomic signs; normal mentation; some border terriers prone to vomiting and diarrhea; minutes to hours; triggered by excitement, stress. • *Episodic falling*—in CKCS, Scotty cramp in Scottish terriers: muscle hypertonicity with temporary inability to relax trunk and limb muscles, stiffness, kyphosis, lateral or forward collapse. Triggered by excitement, stress. • *Neuromyotonic collapse* in JRTs—with hereditary ataxia, myokymia, facial rubbing; lateral recumbency, rigidity; conscious, severe hyperthermia, lasts hours; triggered by hot weather; also in a dachshund. • *Startle disease*—in Irish wolfhound puppies: extensor rigidity when handled, relaxed when sleeping, cyanotic; suspected in Labrador retriever puppies with *reflex myoclonus*. • *Episodic head tremor or head bobbing*—Doberman, English bulldogs, boxer, others: rapid yes or no head excursions, triggered by stress, interruptible, variable duration, non-predictable occurrence.

CAUSES & RISK FACTORS

• Genetic defects in neural transmission—CKCS (brevican), Irish wolfhounds (glycine receptor), Russell terrier (KCNJ10), soft-coated Wheaten terrier. • Metabolic. • Drugs—phenobarbital-induced dyskinesia, propofol. • Toxins—herbicides, mycotoxins, chlorinated hydrocarbons, bromethalin. • Triggered by excitement, stress, exercise; heat in JRT.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- *Epilepsy*—impaired mentation during the episode unless simple focal seizure limited to one limb; short duration < 5 minutes, autonomous signs (urination, salivation, mydriasis). • *Obsessive compulsive behavior*—complex behavior, normal mentation and muscle tone, interruptible. • *Pain episodes*—spinal pain. • *Myoclonic epilepsy*—stimulus-induced repetitive shock-like contractions; miniature wire-haired dachshund, beagle, basset. • *Myotonic myopathy*—muscle stiffness or collapse, worse after rest and myotonic dimpling: Chow-chows, miniature schnauzer. Hyperadrenocorticism: myotonic discharges on EMG. • *Potassium-aggravated muscle stiffness*—cats. • *Exercise-induced collapse*—Labrador and other dog breeds. • *Constant repetitive myoclonus*—following encephalomyelitis (distemper), lead, persists in sleep.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

- Genetic testing. • Electrolytes, CK, liver function tests, fasting glucose, T4/TSH, ACTH test. • Neurometabolic screen—lactate/pyruvate, urinary organic acids/amino acids.

IMAGING

MRI brain, spinal cord—exclude structural disease.

DIAGNOSTIC PROCEDURES

- Video documentation. • Scotty cramp—methysergide 0.3 mg/kg IV provokes episodes. • Video electroencephalography. • Electromyography. • CSF—exclude inflammatory CNS disease.

PATHOLOGIC FINDINGS

Unremarkable. Stiff Labradors—astrogliosis.

TREATMENT

- Control environment—many episodes triggered by stress, excitement, exercise; heat in JRT. • Dietary change in Border terriers.

MEDICATIONS

DRUG(S)

- No evidence-based treatments. • Stiff Labradors—positive response to NSAIDs. • Diazepam 0.5 mg/kg q8h; clonazepam 0.5 mg/kg q8–12h; acetazolamide 4–8 mg/kg q8–12h (side effects: abdominal pain,

lethargy, weakness); 4-aminopyridine 0.25–0.5 mg/kg q12h; fluoxetine 1–2 mg/kg q24h.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Clinical signs do not usually respond to antiepileptic drugs.

FOLLOW-UP

PATIENT MONITORING

Acetazolamide—hypokalemia, acidosis

PREVENTION/AVOIDANCE

Avoid potential triggers. Avoid heat in JRTs.

POSSIBLE COMPLICATIONS

Hyperthermia (death) in JRT neuromyotonia

EXPECTED COURSE AND PROGNOSIS

Unpredictable frequency

MISCELLANEOUS

AGE-RELATED FACTORS

Often appears in dogs < 3 years old

PREGNANCY/FERTILITY/BREEDING

Breeding not recommended. Genetic testing recommended.

MUCOPOLYSACCHARIDOSES

BASICS

OVERVIEW

Mucopolysaccharidosis should be considered as a differential diagnosis for young dogs and cats with stunted growth, progressive skeletal malformations, and neutrophil and lymphocyte inclusions. The mucopolysaccharidoses are characterized by the accumulation of GAG and result from the impaired function of 1 of 11 enzymes required for normal GAG degradation. Almost all of these disorders have been described in animals. Undegraded GAGs are stored in lysosomes, resulting in progressive tissue and organ dysfunction, including CNS (usually clinically insignificant), skeleton, eye, cardiovascular system and liver.

Types of MPS Reported in Dogs and Cats

- MPS I— α -l-iduronidase deficiency; dermatan and heparan sulfate stored.
- MPS II—iduronate sulfatase deficiency; dermatan and heparan sulfate stored; first MPS recognized in humans.
- MPS IIIA—heparan N-sulfatase deficiency; heparan sulfate stored.
- MPS IIIB— α N acetyl glucosaminidase deficiency; heparan sulfate stored.
- MPS VI—arylsulfatase B deficiency; dermatan sulfate stored; first MPS recognized in an animal.
- MPS VII— β -glucuronidase deficiency; dermatan, heparan, and chondroitin sulfate stored.

SIGNALMENT

- Cats—MPS I and VII, domestic shorthair; MPS VI, Siamese and domestic shorthair.
- Dogs—MPS I, Plott hounds; MPS II, Labrador retrievers; MPS IIIA, wire-haired dachshunds and Huntaway dogs, Rotweiler dog, Boston terrier dog; MPS IIIB, skipper dog; MPS VI, miniature pinschers, miniature schnauzers, Welsh corgis, and a Chesapeake Bay retriever dog; MPS VII, mixed breeds and German shepherds.
- Both sexes equally affected by MPS I, III, VI, and VII; primarily males affected by MPS II.

SIGNS

- Dwarfism (except cats with MPS I), small ears, wide-spaced eyes, flattened face with possible protuberant tongue.
- Severe bone disease (dysostosis multiplex).
- Degenerative joint disease, including hip subluxation.
- Facial dysmorphia—more evident in Siamese cats, which normally have an elongated face, than in other cats.
- Hepatomegaly (except cats with MPS VI).
- Corneal clouding—a result of fine granular opacities in the corneal stroma, first apparent at approximately 8 weeks of age.

- Large tongue.
- Thickening of the heart valves.
- Excess urinary excretion of GAG.
- Metachromatic granules (Alder-Reilly bodies) in blood leukocytes.
- Disease progresses; clinical signs apparent at 2–4 months of age.
- Affected animals may live several years, but locomotor difficulty is progressive.
- Skeletal abnormalities more severe in cats with MPS VI than in those with MPS I; some MPS VI cats develop posterior paresis owing to spinal cord compression.
- Manipulation of the head or neck usually painful.

CAUSES & RISK FACTORS

- MPS transmission is autosomal recessive, except MPS II, which is X-linked recessive.
- In-breeding increases risk if the defective gene is present in the family.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Metachromatic granules within neutrophils and lymphocytes—suggest MPS; also observed with GM₂ gangliosidosis, a lysosomal storage disease that, unlike MPS, is characterized by progressive neurologic disease and early death; granules may also be observed in neutrophils of some Burmese cats that have normal lymphocytes and have no clinical abnormalities; very rarely, toxic granulation of neutrophils can have a similar appearance.
- Corneal clouding—also observed with numerous other lysosomal storage diseases, including acid lipase deficiency, GM₁ and GM₂ gangliosidosis, and mannosidosis; lysosomal enzyme panels can be performed to definitively diagnose the type of storage disorder; corneal edema and corneal dystrophy may have a similar appearance.
- Whereas the radiographic appearance of MPS is characteristic, other disorders with similarities include congenital hypothyroidism, epiphyseal dysplasia, and hypervitaminosis A.

CBC/BIOCHEMISTRY/URINALYSIS

- Examination of Wright's-stained blood films reveals neutrophils and monocytes containing numerous distinctive metachromatic granules.
- Granules quite indistinct in animals with MPS I.
- Granules usually not apparent when stained with Diff-Quik.
- Occasional lymphocytes have vacuoles that contain metachromatic granules.

OTHER LABORATORY TESTS

- Wright's-stained cytologic preparations of lymph node, liver, bone marrow, and joint fluid specimens reveal characteristic metachromatic granules within cells.

- Presence of excess GAG in urine usually indicates MPS. Screening tests (Berry spot test) and quantitative analysis are available.
- Definitive diagnosis made by measuring lysosomal enzyme activity in serum, leukocyte pellets, or frozen liver.
- DNA testing on blood samples or cheek swabs is now available for most of the MPS disorders in dogs and cats.

IMAGING

- Radiography—low bone density with thin cortices.
- Epiphyseal abnormalities—vary from slight irregularities to large scalloped defects in subchondral bone.
- Joint changes—acetabular flattening and periaricular osteophyte formation.
- In some cats, proliferative bone is present around all articular facets of vertebrae, causing fusion of cervical vertebrae.

DIAGNOSTIC PROCEDURES

- Specialized laboratories can measure lysosomal enzyme activity in leukocyte pellets and detect specific gene mutations in some disorders.
- DNA testing for most of the mucopolysaccharidosis disorders is available through Penngen (research.vet.upenn.edu) or email penngen@vet.penn.edu.

PATHOLOGIC FINDINGS

Distended lysosomes seen in cells of many tissues examined by light and electron microscopy.

TREATMENT

DEFINITIVE TREATMENT

- BMT—after successful engraftment, donor-derived normal leukocytes provide missing enzyme to various tissues; when performed at a very early age, affected animals lead near-normal lives; not as helpful when performed after skeletal maturity; expensive, life-threatening, and a normal sibling is needed as a donor.
- Enzyme-replacement therapy (ERT), using recombinant enzyme, has been quite effective in animal models of MPS. The major limitations are inability of intravenously injected enzyme to reach the CNS (and synovial joints in some diseases), the cost, an immune response in some patients and the need for frequent, life-long injections.
- Both BMT and enzyme replacement are expensive and have been employed primarily in animal models to determine the potential success in children; very few privately owned animals have been treated.
- Gene therapy has been very effective in some animal models and is the primary treatment modality that is currently being evaluated. The basic premise is to provide some autologous cells with the relevant

MUCOPOLYSACCHARIDOSES

(CONTINUED)

normal cDNA to produce and secrete normal enzyme for uptake by abnormal cells. The major difficulties are obtaining adequate levels of gene product in the specific cell types in which they are needed (e.g., in the CNS), maintaining expression over long periods of time *in vivo*, and regulating the levels of gene expression.

**MEDICATIONS****DRUG(S)**

Affected animals are susceptible to viral and bacterial respiratory infection; antibiotics may be indicated.

**FOLLOW-UP****PREVENTION/AVOIDANCE**

- Avoid in-breeding in family with history of disease.
- Enzyme assays should be performed to diagnose heterozygotes.

EXPECTED COURSE AND PROGNOSIS

- Prognosis reasonably good in animals treated at a young age. However, treatment is very expensive, possibly life-threatening, and usually only performed experimentally.
- Untreated animals usually develop severe skeletal and joint disease and may become non-ambulatory at 3–5 years of age.

**MISCELLANEOUS****ABBREVIATIONS**

- BMT = bone marrow transplant
- CNS = central nervous system
- GAG = glycosaminoglycan
- MPS = mucopolysaccharidoses

MULTIPLE MYELOMA

BASICS

DEFINITION

- Malignant plasma cells in the bone marrow.
- Diagnosis requires constellation of pathologies including bone marrow plasmacytosis, osteolytic bone lesions, and serum or urine myeloma proteins (M-component).

PATHOPHYSIOLOGY

- Proliferation of malignant plasma cells that produce immunoglobulins or subunits.
- Immunoglobulins may polymerize and increase serum viscosity. • Bleeding disorders due to paraprotein coating of platelets, thrombocytopenia, hyperviscosity, or interference with coagulation factors.
- Nephrotoxicity due to protein deposition of amyloid or direct effect of the protein on renal tubular epithelial cells. • Hypercalcemia due to osteoclast activation and bone lysis.

SYSTEMS AFFECTED

- Musculoskeletal: multiple punctate areas of bone lysis in the absence of bony proliferation.
- Nervous, cardiovascular, and respiratory: abnormalities secondary to hyperviscosity.
- Soft tissues—neoplastic infiltration.

INCIDENCE/PREVALENCE

- Dogs: 1% of all malignancies; < 8% of hematopoietic malignancies; 3.6% of all bone tumors. • Cats: < 1% of hematopoietic tumors.

SIGNALMENT

Dog and cat, 6–13 years

SIGNS

Due to bone infiltration and lysis, immunoglobulins produced, and infiltration of organ(s).

Physical Examination Findings

Dogs

- Lethargy, weakness (62%) • Lameness (47%) • Bleeding diathesis (37%): gingiva and epistaxis • Funduscopic abnormalities including retinal hemorrhage or detachment and tortuous vessels (35%)

Cats

Anorexia, weight loss, malaise, polydipsia, polyuria

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ehrlichiosis, leishmaniasis • Metastatic bone lesions • Rheumatoid arthritis

CBC/BIOCHEMISTRY/URINALYSIS

Dogs

- Hemogram: nonregenerative anemia (66%); neutropenia (25%); thrombocytopenia (33%)
- Chemistry: hyperglobulinemia, hypercalcemia (10–25%), azotemia (33%)

- Urinalysis: proteinuria, isosthenuria, cylindruria, pyuria, hematuria, or bacteriuria

OTHER LABORATORY TESTS

- Serum protein electrophoresis: monoclonal gammopathy in the beta or gamma region, and occasionally a biclonal gammopathy will be present. • Urine protein electrophoresis: Bence-Jones proteins in 25–40%
- Coagulation profile: ~50% will have abnormal coagulation values.

IMAGING

- Radiography (dogs): 25–66% have multifocal, lytic lesions or diffuse osteoporosis.
- Radiography (cats): bony lesions rare, more common for visceral organ infiltration (myeloma-related disorder). • Ultrasonography: detect changes in visceral organs.

DIAGNOSTIC PROCEDURES

- Diagnosis depends on identifying at least 3 of 4 pathologies:
 - Monoclonal gammopathy
 - Lytic bone lesions
 - Bence-Jones proteinuria
 - Bone marrow cytology: > 20% plasma cells or > 5% malignant plasma cells. • For cats—bone marrow involvement is rare, and hence diagnosis is based upon the identification of malignant plasma cells within the visceral organs (myeloma-related disorder).

TREATMENT

APPROPRIATE HEALTH CARE

- Hospitalization if azotemia, hypercalcemia, bleeding disorder, or bacterial infection
- Plasmapheresis lowers protein burden: for symptomatic patient, withdraw a volume of venous blood, centrifuge, discard plasma, and return RBCs to patient in IV crystalloid fluids
- Phlebotomy for hyperviscosity, replace with an equal volume of isotonic fluids IV
- Always consult a veterinary oncologist for latest information regarding treatment.

CLIENT EDUCATION

- Inform client that chemotherapy is palliative but long remissions are possible. • Warn client that relapse will occur. • Discuss side effects, which depend on the drugs used.

SURGICAL CONSIDERATIONS

Areas non-responsive to chemotherapy or solitary lesions can be removed surgically.

RADIATION THERAPY

Radiation therapy can be palliative and highly effective for managing osteolytic bone cancer pain. Indications include painful bone lesions, spinal cord compression, pathologic fractures (after fracture stabilization), or a large soft tissue mass. Consult with a radiation oncologist.

MEDICATIONS

DRUG(S) OF CHOICE

- Dogs—melphalan and prednisone;

cyclophosphamide can be used in addition to or in place of melphalan. • Cats—melphalan and prednisone • Intravenous aminobisphosphonate drugs for management of hypercalcemia and palliation of bone pain. • Consult a veterinary oncologist or reliable drug resource for dosages.

PRECAUTIONS

- Melphalan—delayed thrombocytopenia
- Cyclophosphamide—sterile hemorrhagic cystitis

FOLLOW-UP

PATIENT MONITORING

- CBC and chemistry every 2 weeks for 2 months, then monthly. • Serum electrophoresis and/or Bence-Jones proteinuria monthly until at least 50% decrease in baseline values, then once every 2–3 months.

POSSIBLE COMPLICATIONS

Chemotherapy may cause leukopenia or thrombocytopenia, anorexia, alopecia, hemorrhagic cystitis, and/or pancreatitis.

EXPECTED COURSE AND PROGNOSIS

- Improvement in clinical signs and laboratory abnormalities expected within 3–6 weeks. • Radiographic abnormalities could take longer and be partial.

Dogs

- Median survival with alkylating agents and prednisone: 18 months Overall response rate > 90% • Hypercalcemia, extensive bone lysis, or Bence-Jones proteinuria may have shorter survival • Death typically due to kidney failure, secondary infections, or bone/spinal pain.

Cats

Survival with alkylating agents and prednisone—2–9 months.

MISCELLANEOUS

SEE ALSO

- Hypercalcemia • Renal Failure, Chronic

BASICS

DEFINITION

Vibrations caused by disturbed blood flow

Timing of Murmurs

- Systolic murmurs occur between S1 and S2 (systole).
- Diastolic murmurs occur between S2 and S1 (diastole).
- Continuous and to-and-fro murmurs occur throughout all or most of the cardiac cycle.
- Continuous murmurs are usually accentuated near S2 and to-and-fro murmurs are usually absent near S2.

Grading Scale for Murmurs

- Grade I—barely audible.
- Grade II—soft, but easily auscultated. Doesn't radiate far from point of maximal intensity.
- Grade III—intermediate loudness; heard easily some distance from PMI, but not to opposite side of chest; most hemodynamically important murmurs are at least grade III.
- Grade IV—loud murmur radiating widely, often including opposite side of chest.
- Grade V—very loud, audible with stethoscope barely touching the chest; palpable thrill.
- Grade VI—very loud, audible without the stethoscope touching the chest; palpable thrill.

Configuration

- Plateau murmurs have uniform loudness and are typical of regurgitant murmurs such as mitral and tricuspid insufficiency and ventricular septal defect.
- Crescendo-decrescendo murmurs get louder and then softer and are typical of ejection murmurs such as pulmonic and aortic stenosis and atrial septal defect.
- Decrescendo murmurs start loud and then get softer and are typical of diastolic murmurs such as aortic or pulmonic insufficiency and mitral or tricuspid stenosis.

Location

Dogs

- Mitral area—left fifth intercostal space at costochondral junction.
- Aortic area—left fourth intercostal space above costochondral junction.
- Pulmonic area—left second to fourth intercostal space at sternal border.
- Tricuspid area—right third to fifth intercostal space near costochondral junction.

Cats

- Mitral area—left fifth to sixth intercostal space one-fourth ventrodorsal distance from sternum.
- Aortic area—left second to third intercostal space just above the pulmonic area.
- Pulmonic area—left second to third intercostal space one-third to one-half ventrodorsal distance from sternum.

- Tricuspid area—right fourth to fifth intercostal space one-fourth ventrodorsal distance from sternum.

PATHOPHYSIOLOGY

- Disturbed blood flow associated with high flow through normal or abnormal valves or with structures vibrating in the blood flow.
- Flow disturbances associated with outflow obstruction or forward flow through stenosed valves or into a dilated great vessel.
- Flow disturbances associated with regurgitant flow through an incompetent valve, septal defect, or patent ductus arteriosus.

SYSTEMS AFFECTED

Cardiovascular

SIGNALMENT

Dog and cat

SIGNS

Relate to cause of the murmur

CAUSES

Systolic Murmurs

- Mitral and tricuspid valve endocardiosis
- Cardiomyopathy and AV valve insufficiency
- Physiologic flow murmurs
- Anemia
- Mitral and tricuspid valve dysplasia
- Systolic anterior mitral motion
- Dynamic right ventricular outflow obstruction
- Dynamic subaortic stenosis
- Atrial septal defect
- Ventricular septal defect
- Pulmonic stenosis
- Aortic stenosis
- Tetralogy of Fallot
- Mitral and tricuspid valve endocarditis
- Hyperthyroidism
- Heartworm disease

Continuous or To-and-Fro Murmurs

- Patent ductus arteriosus
- Ventricular septal defect with aortic regurgitation
- Aortic stenosis with aortic regurgitation

Diastolic Murmurs

- Mitral and tricuspid valve stenosis
- Aortic and pulmonic valve endocarditis

RISK FACTORS

Cardiac disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential Signs

- Must differentiate from other abnormal heart sounds—split sounds, ejection sounds, gallop rhythms, and clicks.
- Must differentiate from abnormal lung sounds and pleural rubs; listen to see if timing of abnormal sound is correlated with respiration or heartbeat.

Differential Causes

- Pale mucous membranes support diagnosis of anemic murmur.
- Location and radiation of murmur and timing during cardiac cycle can help determine cause; see algorithm.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia in animals with anemic murmurs
- Polycythemia in animals with right-to-left shunting congenital defects
- Leukocytosis with left-shift in animals with endocarditis

OTHER LABORATORY TESTS

N/A

IMAGING

- Thoracic radiography—useful for evaluating heart size and pulmonary vasculature in hopes of determining cause and significance of murmur.
- Echocardiography—recommended when a cardiac cause is suspected and the nature of the defect is unknown.
- Doppler studies sometimes required to confirm cause of murmur.

DIAGNOSTIC PROCEDURES

- Electrocardiography may be useful in assessing heart enlargement patterns in animals with murmurs.
- Blood cultures and serology for *Bartonella* if suspect endocarditis.

M

TREATMENT

- Outpatient unless heart failure is evident.
- Base decisions on the cause of the murmur and associated clinical signs.
- None indicated for murmur alone.

MEDICATIONS

DRUG(S)

N/A

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Low-grade systolic ejection murmurs in puppies may be physiologic; most resolve by 6 months of age. If murmur still present after 6 months, include diagnostic imaging.

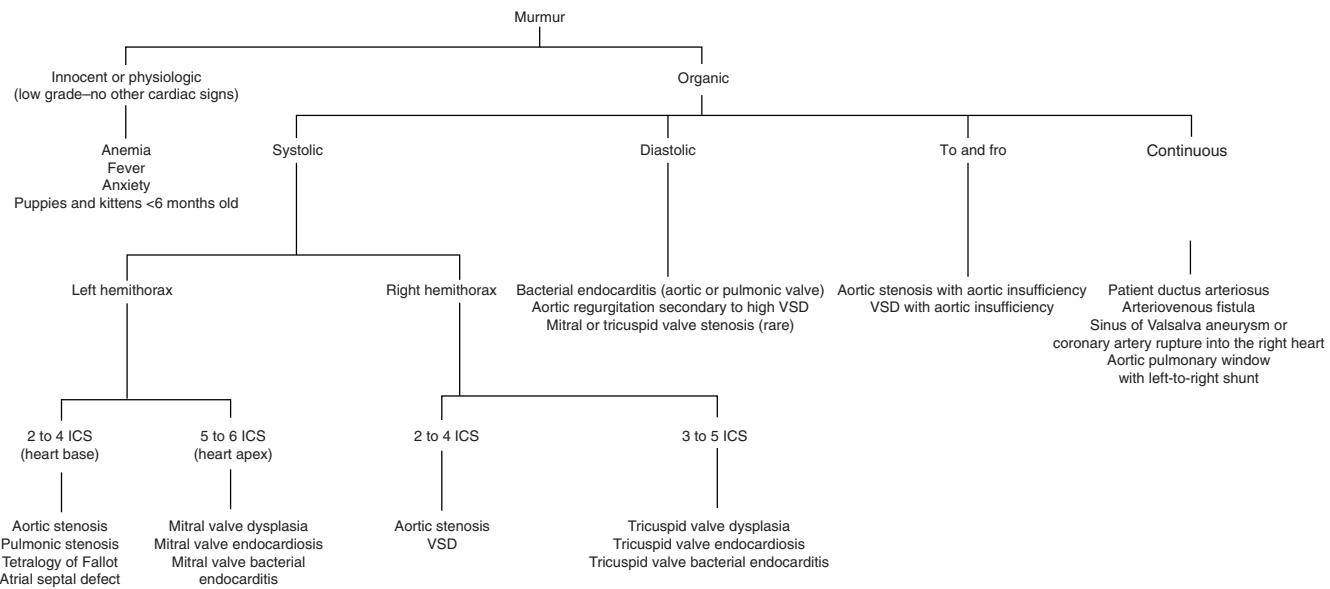

Figure 1.

POSSIBLE COMPLICATIONS

If murmur is associated with structural heart disease, may see signs of congestive heart failure (e.g., coughing, dyspnea, and ascites) or exercise intolerance.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

- Murmurs present since birth generally associated with a congenital defect or physiologic flow murmur.
 - Acquired murmurs in geriatric, small-breed dogs usually associated with degenerative valve disease.

- Acquired murmurs in large-breed dogs usually associated with dilated cardiomyopathy.
 - Acquired murmurs in geriatric cats usually associated with cardiomyopathy or hyperthyroidism.

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

Murmurs in puppies and kittens may reflect a congenital defect and thereby influence decisions on breeding that animal or repeating the mating.

MUSCLE RUPTURE (MUSCLE TEAR)

BASICS

OVERVIEW

A normal muscle may be stretched, pinched, or injured directly, resulting in fiber disruption, weakening, and immediate or delayed separation of the uninjured portions. Alternatively, the muscle structure may be compromised by systemic or iatrogenic conditions, and normal activity may cause muscle disruption. The rupture may be complete or incomplete, and it may be mid-substance or at the muscle-tendon junction. The acute stage is characterized by a typical inflammatory reaction that becomes chronic with collagen maturation, cross-linking, fibrosis, and adhesion development over time. Frequently the acute phase is overlooked, as the signs may be temporary and respond well to rest. The chronic effects are often progressive and unresponsive to support therapies.

SIGNALMENT

- Limb and masticatory muscles are the primary structures affected.
- Traumatic injury is indiscriminate, although certain activities may predispose because of exposure.
- The ruptures that are apparently unrelated to trauma seem to affect middle-aged to older working dogs, with no reported sex predilection.
- Cats are affected less frequently than dogs.

SIGNS

Acute Injury

- Immediate lameness that is characterized by the specific muscle affected.
- Localized swelling, heat, and pain.
- Generally present for a few days to a week.
- Animals may experience re-injury.

Chronic Phase (If It Develops)

- Progressive.
- Painless.
- Usually associated with scar tissue that impedes normal function of an extremity.

CAUSES & RISK FACTORS

- Trauma
- Repeated overuse
- Overextension
- Myositis
- Degenerative (unknown etiology)
- Myopathy secondary to medical conditions such as Cushing disease
- Apparent risk factor for dogs is involvement in hunting, tracking, or similar activities in the outdoors.

Gait Analysis and Physical Examination Findings

- Various disorders will result in characteristic gait abnormalities and pain elicited on specific limb manipulation—a few of which are listed below.

- Psoas muscle injury:
 - Pain on internal rotation with extension or abduction of the pelvic limb.
 - Pain on palpation of the lesser trochanter of the affected femur.
 - Short, choppy gait.
- Gracilis, semimembranosus, and semitendinosus muscle contractures:
 - These animals are typically not painful on palpation of the gracilis, semitendinosus or semimembranosus muscles.
 - Palpation of a fibrous band in the area of the affected muscle is also apparent.
 - Shortened stride with medial rotation of the paw, internal rotation of the hock, and external rotation of the calcaneus, with internal rotation of the stifle in late phase of the forward stride.
- Infraspinatus muscle contracture:
 - Significant forelimb lameness with circumduction of the affected limb.
 - Marked elbow adduction/foot abduction; upon flexion of the elbow, the distal antebrachium will deviate laterally.
 - Fibrous band will be apparent on palpation of the infraspinatus muscle.
- Quadriceps contracture:
 - Typically occurs with limb disuse/immobilization after femur fracture fixation in young dogs without appropriate physical therapy.
 - Patient will be unable to flex stifle.
- Achilles mechanism injuries:
 - Non-weight-bearing lameness with soft tissue swelling proximal to the calcaneous.
 - Hyperflexion of the tarsus.
 - Hyperflexion of the digits, if superficial digital flexor is unaffected (crab claw).
- Sartorius muscle injury/fibrosis:
 - Scant reports in the veterinary literature.
 - Non-painful, non-weight-bearing pelvic limb.
 - Palpable fibrous band in the area of the sartorius muscle.
 - Short choppy gait, characterized by an inability to extend the hip.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Neurologic dysfunction—recognized by neurologic abnormalities.
- Tendon rupture—visible or palpable disruption in the tendon.
- Origin/insertion avulsion fracture—radiographic evidence of bone fragment defect and translocation.

- Luxation/subluxation—palpable or radiographic evidence of joint instability or malalignment.

CBC/BIOCHEMISTRY/URINALYSIS

No injury-specific findings

OTHER LABORATORY TESTS

- CPK may be elevated in acute cases.
- No known specific tests available.

IMAGING

Radiographic Findings

- Soft tissue swelling may be evident in the early stages.
- Calcification of muscle can occur in the traumatized area in chronic situations.
- Avulsion fractures and calcification of the tendon of insertion or origin may be noted on radiographs.

Ultrasonographic Findings

- Local swelling and disorientation of the normal muscle fiber orientation may be seen at the site of injury in acute cases.
- Scar tissue and contracted areas of fibrous tissue can be seen in the muscle in chronic cases—noted as hyperechoic foci in the muscle belly of concern.
- Measurable differences between normal and abnormal sides may be useful in documenting the affected muscle site.

Cross-Sectional Imaging Studies

- CT findings—produces better tissue contrast than the above but still constrained to an axial plane of view.
- MRI findings—edema and hemorrhage cause a change in the signal that can be differentiated from changes due to fibrous tissue replacement of muscle. This allows localization of the problem and helps to identify the type of problem.

DIAGNOSTIC PROCEDURES

Muscle Biopsy

The presence of fibrous tissue and the loss of muscle cells may be documented. Differentiating disuse atrophy from neurologic atrophy and from injury-induced fibrosis may be impossible without corroborating evidence.

TREATMENT

- There is no documented evidence to support a single “best” way to treat acute muscle injuries, preventing fibrous contracture and adhesions. It is generally believed that immediate post-injury care should involve rest, local cold application followed within hours (24–48 hours) by heat, and passive physical therapy (movement). Severe, strict immobilization (via cast or cage) is potentially contraindicated as it may encourage muscle contracture and muscle fibrosis, leading to irreversible long-term debilitation. Light or non-weight-bearing activity is appropriate for

MUSCLE RUPTURE (MUSCLE TEAR)

(CONTINUED)

an extended period of time (4–6 weeks). Analgesics and anti-inflammatory drugs should be recommended for several days to weeks. Surgery may be performed within a few days of the injury to repair obvious, acute muscle rupture that results in a separation of the uninjured muscle segments. An essential part of muscle repair is effective tension relief for the injured muscle so that healing can occur without disruption as function returns. Internal or external orthopedic devices may be necessary to provide effective tension relief. Owners should be made aware of the possibility of scar-related problems affecting the patient's gait in the long-term.

- Once the muscle injury becomes chronic and associated with contracture or adhesions, treatment is aimed at function salvage. Surgical release of the adhesions or fibrous tissue bands is often accompanied by instantaneous symptomatic relief. The prevention of readhesion and progressive contracture is much less rewarding.
- Specific muscle injuries have widely disparate prognoses. Infraspinatus and psoas muscle contractures respond well to surgical excision of the tendon of insertion. Gracilis, semimembranosus, and semitendinosus contractures have a 100% recurrence rate after surgical resection. Quadriceps contracture has a similarly dismal failure rate after surgery.
- Muscle injuries that have healed in an elongated state have a better prognosis for surgical improvement of function than contracted muscles. The most common

elongation injury affects the muscles of the calcaneus (Achilles) group. Hock hyperflexion can be surgically reconstructed to return these animals to relatively normal function. This is usually accomplished by shortening the Achilles tendon rather than the injured muscle or musculotendinous junction.

MEDICATIONS

DRUG(S)

None are specific. Anti-inflammatory drugs may be indicated in acute situations.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Immobilization of the injured muscle in a position that allows adhesions to develop to nearby bone will often result in "tie down" contractures.

FOLLOW-UP

PATIENT MONITORING

Repetitive range-of-motion monitoring and recheck examination.

PREVENTION/AVOIDANCE

Early inflammation control and non-weight-bearing passive physical therapy accompanied by strict cage rest may be beneficial.

POSSIBLE COMPLICATIONS

Contracture of the muscle and fibrous replacement of muscle tissue.

EXPECTED COURSE AND PROGNOSIS

Specific to the muscle and the type of injury.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Joint hypermobility, angular limb deformities, flexion/extension joint abnormalities.

AGE-RELATED FACTORS

Growth plate fractures in young dogs, particularly distal femoral Salter-Harris fractures, are associated with quadriceps contracture.

ABBREVIATIONS

- CPK = creatine phosphokinase
- CT = computed tomography
- MRI = magnetic resonance imaging

MUSHROOM TOXICOSES

**BASICS****DEFINITION**

- Eight categories on basis of toxin and toxicodrome (Table 1).
- Mixed toxicodromes can occur if mixture of species consumed.

PATHOPHYSIOLOGY

See Table 2

SYSTEMS AFFECTED

See Table 3

INCIDENCE/PREVALENCE

- Cyclopeptide and gastrointestinal groups—common
- Others—occasional

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT**Species**

Dogs; others rarely

Mean Age and Range

All ages

SIGNS**General Comments**

- Psychoactive species often dried for transportation and sale; dried product remains toxic for at least 6 months.
- Psychoactive species often prepared as aqueous extracts.
- Psychoactive species often coated with chocolate to facilitate ingestion (counters the astringent taste) and smuggling; combined mushroom and chocolate toxicity may occur.
- Psychoactive species often given as holiday presents.
- In many parts of the world psychoactive species are sold openly.

Historical Findings

- Many cases involve substance abuse.

Physical Examination Findings

See Table 4

Cyclopeptide

- Three sequential disease phases—GI, latent, and hepatorenal.
- Delayed onset of GI phase and the recrudescence of hepatorenal disease following a latent period are key diagnostic features. With the exception of MMH, all other types of mushroom poisoning occur relatively rapidly and usually resolve relatively

quickly. Recrudescence characterized by hepatorenal disease does not occur in MMH poisoning.

- Gastroenteritis phase (onset > 6 hours; lasts about 24 hours)—severe vomiting, bloody diarrhea, abdominal pain, fever, dehydration, electrolyte disturbance, hypoglycemia.
- Latent phase (lasts 12–24 hours)—apparent remission.
- Hepatorenal phase (starts 3–4 days post-ingestion)—liver and kidney failure, icterus, depression, signs of hepatic encephalopathy and cerebral edema, hypoglycemia, seizures, coagulopathies, metabolic acidosis, renal insufficiency, severe ileus, cardiac conduction abnormalities, coma.
- High morbidity and mortality; death during the hepatorenal phase (3–7 days post-ingestion).

MMH (Gyrometrin)

- Gastroenteritis (onset > 6 h)—vomiting, bloody diarrhea, abdominal pain, fever, dehydration, electrolyte disturbance, hypoglycemia.
- Ataxia
- Anxiety, hyperactivity, tremor, seizure
- Typically self-limiting; resolving over several days
- In rare severe cases, hepatic failure may develop

Table 1

<i>Group</i>	<i>Key Species</i>
Cyclopeptide	<i>Amanita phalloides</i> , many <i>Amanita</i> sp., <i>Galerina</i> sp.
Monomethyl hydrazine (MMH)	<i>A. muscaria</i> (fly agaric), <i>A. pantherina</i> (panther cap), <i>Gyromitra</i> sp., <i>Lycoperdon</i> sp.
Muscarine	<i>Clitocybe</i> sp., <i>Inocybe</i> sp., <i>A. pantherina</i>
Ibotenic acid/muscimol	<i>Coprinus atramentarius</i> , <i>A. pantherina</i> , <i>A. muscaria</i>
Hallucinogens	<i>Psilocybe</i> sp., <i>Panaeolus</i> sp., <i>Gymnopilus</i> sp., <i>Stropharia</i> sp., <i>Conocybe</i> sp.
GI irritants	<i>Chlorophyllum</i> sp., many others
Acute renal failure	<i>Cortinarius</i> sp.

Table 2

<i>Group</i>	<i>Mechanism</i>
Cyclopeptide	Amatoxins inhibit RNA polymerase II blocking RNA and DNA transcription. Targets are exposed rapidly, dividing cells (intestinal crypt epithelium, hepatocytes, and renal tubular epithelia)
MMH	Phallotoxin irreversibly polymerizes actin filaments in the hepatobiliary tree, resulting in cholestasis
Muscarine	Gyromitrin hydrolyses to MMH, which causes ↓ CNS GABA
Ibotenic acid/muscimol	Post-ganglionic M ₁ and M ₂ cholinergic agonist
Hallucinogens	Ibotenic acid, a glutamate agonist, is rapidly metabolized to muscimol, a GABA-B agonist
GI irritants	Psilocybin metabolized to psilocin, a 5-HT _{1A} and 5-HT _{2A/2C} serotonin agonist
Acute renal failure (orellanine)	Irritants, allergens
	Toxins are 2,2-bipyridine and compounds resembling paraquat and diquat—redox cycling is likely mechanism

MUSHROOM TOXICOSES

(CONTINUED)

Table 3

<i>Group</i>	<i>Target</i>
Cyclopeptide	Gastrointestinal—severe gastroenteritis 6–24 h post-ingestion Hepatobiliary—delayed-onset (3–4 d) centrilobular hepatic necrosis Renal—delayed onset (3–4 d) acute renal tubular nephrosis Metabolic—hypoglycemia Hemic—coagulopathy Immune—prone to sepsis
MMH	Nervous—cerebral edema, hepatorenal encephalopathy, coma Gastrointestinal—vomiting/diarrhea 6–8 hrs post-ingestion Nervous—CNS excitation, seizure Neuromuscular—ataxia, tremor
Muscarine	Hepatobiliary—hepatitis and failure (rare) Gastrointestinal—diarrhea, emesis, excessive lacrimation Urinary—frequent urination Ophthalmic—miosis, cycloplegia Respiratory—bronchospasm, bronchoconstriction Cardiovascular—bradycardia, hypotension
Ibotenic acid/muscimol	Nervous—cycles of CNS stimulation followed by depression, visual hallucinations, confusion, agitation, aggression, pointless motor activity, seizure, coma, sympathomimetic signs Ophthalmic—mydriasis Metabolic—hyperthermia
Hallucinogens	Nervous—dysphoria, anxiety, confusion, agitation, aggression, pointless motor activity, seizure, coma, sympathomimetic signs Neuromuscular—ataxia, hyperreflexia
GI irritants	Gastrointestinal—emesis, diarrhea
Acute renal failure (orellanine)	Renal—delayed-onset (up to 20 d) tubulointerstitial nephrosis

M**Table 4**

<i>Group</i>	<i>Common DDx</i>
Cyclopeptide	GI phase— <i>infectious gastroenteritis, GI irritants and corrosives</i> Hepatorenal phase—white phosphorus, hepatotoxic mycotoxins and hepatotoxic algal toxins, hepatotoxic plants
MMH/Gyrometrin	GABA antagonists, CNS stimulants, seizure agents, isoniazid
Muscarine	Anticholinesterase pesticides, cholinergic medications and toxins
Ibotenic acid/muscimol	Other hallucinogens, stimulants, head injury, CNS infection
Hallucinogens	LSD and other hallucinogens, head injury, CNS infection
GI irritants	<i>Infectious gastroenteritis, GI irritants and corrosives</i>
Acute renal failure (orellanine)	Ethylene glycol, diquat, plants affecting the kidneys

Muscarine

- Rapid onset (15–60 minutes) • Generally resolves in 2–6 hours (max 24 hours)
- DUMBELS—diarrhea, urination, miosis, bronchospasm, bronchoconstriction, emesis, lacrimation, salivation • Rarely, liver damage

Ibotenic Acid/Muscimol

- Rapid onset (30–60 minutes) • Initial CNS stimulation, ataxia, hyperactivity, pointless running, manic excitement, seizure, visual hallucinations (“biting at imaginary flies”)

- Subsequent CNS depression—drowsiness, stupor, sleep coma • Periods of CNS excitement alternating with CNS depression
- Death is rare • GI disturbance NOT a feature

Hallucinogens

- Onset within 4 hours • Sympathomimetic signs • Dysphoria, agitation, anxiety, aggression • Hyperthermia • Rarely—convulsions, coma, death • GI disturbance NOT a feature

GI Irritants

- Onset within 2 hours • Malaise, weakness, emesis, diarrhea • Fluid and electrolyte disturbances • Usually self-limiting; resolves in 24 hours

CAUSES

See Tables 2 and 3

RISK FACTORS

- Inexperience in harvesting wild mushrooms
- Owner substance abuse
- Cultivation/trafficking of hallucinogenic species • Mushroom picking season

(CONTINUED)

MUSHROOM TOXICOSES**Table 5**

<i>Group</i>	<i>Effects</i>
Cyclopeptide	GI phase—hemococoncentration, electrolyte disturbances, GI blood loss Hepatorenal failure—enzymatic evidence of hepatocellular necrosis and cholestasis, elevated serum and urine bilirubin, elevated serum bile acids, uremia, electrolyte disturbances, initial polyuria followed by isosthenuria or anuria, hypoglycemia, coagulopathies, urinary casts, evidence of sepsis
MMH	Nonspecific; evidence of oxidative injury to erythrocytes (methemoglobinemia, ↑ free hemoglobin, ↑ sulfhemoglobin) may be present in early stages
Muscarine	Nonspecific; rarely enzymatic evidence of hepatocellular injury
Ibotenic acid/muscimol	Nonspecific
Hallucinogens	Nonspecific
GI irritants	Hemococoncentration, electrolyte disturbances
Acute renal failure (orellanine)	Initial polyuria followed by isosthenuria or anuria, electrolyte disturbance (notably hyperkalemia), uremia

Table 6

<i>Group</i>	<i>Other Tests</i>
Cyclopeptide	Expert identification of mushroom species; Meixner test for amatoxins (false negatives may occur); amanitin measurement in body fluids
MMH	Expert identification of mushroom species; blood level not well correlated with severity; detection in stomach contents, mushrooms
Muscarine	Expert identification of mushroom species; detection in body fluids, stomach contents, mushrooms
Ibotenic acid/muscimol	Expert identification of mushroom species; detection in body fluids, stomach contents, mushrooms
Hallucinogens	Expert identification of mushroom species; detection in body fluids, stomach contents, mushrooms
GI irritants	Expert identification of mushroom species
Acute renal failure	Expert identification of mushroom species; detection of orallanine in body fluids, feces, stomach contents, mushrooms

M

Table 7

<i>Group</i>	<i>Target</i>
Cyclopeptide	None proven effective Thioctic acid (1–2 mg/kg q6h) credited with xyxy↓ human mortality Silibinin (50 mg/kg/day q6h); combine with n-acetylcysteine Penicillin theoretically beneficial, but limited practical effectiveness
MMH	Pyridoxine 25 mg/kg
Muscarine	Atropine to effect (endpoint is drying of secretions)
Ibotenic acid/muscimol	N/A
Hallucinogens	N/A
GI irritants	N/A
Acute renal failure (orellanine)	N/A

MUSHROOM TOXICOSES

(CONTINUED)

Table 8

<i>Group</i>	<i>Target</i>
Cyclopeptide	IV glucose or dextrose if required Fresh frozen plasma Blood transfusion Vitamin K (Vitamin K ₁)—0.5–1.5 mg/kg IM or SC q12h up to 3 doses in 24-hour interval 1 time; oral vitamin K ₁ —1 mg/kg PO q24h if enteric bile acids and their uptake are adequate Potassium if hypokalemia of hepatic failure present Furosemide 2–4 mg/kg IV q8–12h; for oliguric or anuric renal failure in patients with normal hydration status; combine with dopamine Dopamine 0.5–3 microgram/kg for oliguric or anuric renal failure; combine with furosemide Parenteral silymarin derivatives reputedly beneficial
MMH	Diazepam 0.25–0.5 mg/kg IV or IM; for seizures
Muscarine	Atropine to effect (drying of secretions; 0.02–0.04 mg/kg half-dose IV, half-dose IM; titrate to effect)
Ibotenic acid/muscimol	Diazepam 0.25–0.5 mg/kg IV or IM; for seizures
Hallucinogens	Diazepam 0.25–0.5 mg/kg IV or IM; for seizures
GI irritants	N/A
Acute renal failure (orellanine)	Furosemide 2–4 mg/kg IV q8–12h; for oliguric or anuric renal failure in patients with normal hydration status; combine with dopamine Dopamine 0.5–3 microgram/kg for oliguric or anuric renal failure; combine with furosemide

M**DIAGNOSIS**

- DIFFERENTIAL DIAGNOSIS
 - CBC/BIOCHEMISTRY/URINALYSIS
 - OTHER LABORATORY TESTS
 - DIAGNOSTIC PROCEDURES
- See Tables 5 and 6

**TREATMENT****APPROPRIATE HEALTH CARE**

- Inpatient medical management.
- Intensive care for cyclopeptides.
- No early discharge until cyclopeptide poisoning has been disproved.

NURSING CARE

- Upper GI decontamination (preferably induction of emesis using apomorphine 0.04 mg/kg IV or into the conjunctival sac; or gastric lavage) is warranted in the case of confirmed cyclopeptide poisoning provided:

 - (1) patient presents within 2 hours of ingestion;
 - (2) emesis has not already occurred;
 - (3) contraindications (CNS excitation, preexisting cardiovascular disease) are not present. Benefits of the technique are at best unproven and at worst, useless.

- Repeat-dose activated charcoal administration (1–4 g/kg q3–6h for 24–36h; mix in water (1 g/5–10 mL water) aimed at decreasing toxin enterohepatic cycling is of potential, but unproven, benefit in cyclopeptide poisoning.
- Single-dose activated charcoal administration within 2 hours of ingestion is possible, but unproven, benefit in other types

of mushroom poisoning in the absence of contraindications.

- Fluid resuscitation (IV crystalloids) as required.

ACTIVITY

Prevent misadventure

DIET

NPO if GI distress

CLIENT EDUCATION

"There are old mushroom hunters, there are bold mushroom hunters, but there are no old and bold mushroom hunters."

**MEDICATIONS****DRUG(S) OF CHOICE**

- Antidotes: See Table 7
- Supportive: See Table 8

CONTRAINDICATIONS

- MMH poisoning—short-acting hypnotics
- Ibotenic acid/muscimol—atropine, propofol

ALTERNATIVE DRUG(S)

Methocarbamol 55–220 mg/kg IV, do not exceed 330 mg/kg/day; administer half dose quickly and then remainder to effect; for control of seizures.

**FOLLOW-UP****PATIENT MONITORING**

- Cyclopeptides—serum hepatic enzymes, serum bilirubin, serum bile acids
- Serum electrolyte status
- CNS state

- Orellanine—serum BUN and creatinine, serum electrolytes.

EXPECTED COURSE AND PROGNOSIS

- Cyclopeptides and orellanine—very poor
- Others—generally good unless organ damage present

**MISCELLANEOUS****SEE ALSO**

- Hepatic Failure, Acute
- Renal Failure, Acute
- Seizures (Convulsions, Status Epilepticus)—Cats
- Seizures (Convulsions, Status Epilepticus)—Dogs

ABBREVIATIONS

- CNS = central nervous system
- GABA = gamma-aminobutyric acid
- GI = gastrointestinal
- MMH = monomethylhydrazine

MYASTHENIA GRAVIS

BASICS

DEFINITION

A disorder of neuromuscular transmission characterized by muscular weakness and excessive fatigability.

PATOPHYSIOLOGY

Transmission failure at the neuromuscular junction—results from structural or functional abnormalities of the nicotinic AChRs or other end-plate proteins and enzymes (congenital form) and from autoantibody-mediated destruction of AChRs and postsynaptic membranes (acquired form).

SYSTEMS AFFECTED

- Neuromuscular—result of abnormalities or destruction of AChRs, choline acetyltransferase or end-plate cholinesterase.
- Respiratory—may find aspiration pneumonia secondary to megaesophagus.

GENETICS

- Congenital familial forms—Jack Russell terrier, springer spaniel, smooth fox terrier; smooth-haired miniature dachshund, Gammel Dansk Hønsehund, Labrador retriever; autosomal recessive mode of inheritance.
- Acquired—as with other autoimmune diseases, requires appropriate genetic background for disease to occur; multifactorial, involving environmental, infectious, and hormonal influences.
- Familial forms of acquired MG occur in the Newfoundland and Great Dane breeds.

INCIDENCE/PREVALENCE

- Congenital—rare
- Acquired—not uncommon in dogs; uncommon in cats

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Congenital—Jack Russell terriers; springer spaniels; smooth fox terriers; smooth-haired miniature dachshunds, Gammel Dansk Hønsehund. Labrador retriever.
- Acquired—several breeds: golden retrievers; German shepherds; Labrador retrievers; dachshunds; Scottish terriers; Akitas; and Abyssinian and Somali cats.

Mean Age and Range

- Congenital—6–8 weeks of age.
- Acquired—bimodal age of onset; dogs: 1–4 years of age and 9–13 years of age.

Predominant Sex

- Congenital—none.
- Acquired—may be a slight predilection for females in the young age group; none in the old age group.

SIGNS

General Comments

- Acquired—may have several clinical presentations ranging from focal involvement of the esophageal, pharyngeal, and extraocular muscles to acute generalized collapse.
- Should be on the differential diagnosis of any dog with acquired megaesophagus, lower motor neuron weakness, or a cranial mediastinal mass.

Historical Findings

- Regurgitation—common; important to differentiate between vomiting and regurgitation.
- Voice change.
- Exercise-related weakness.
- Acute collapse.
- Progressive weakness.
- Sleep with eyes open.

Physical Examination Findings

- Patient may look normal at rest.
- Excessive drooling, regurgitation, and repeated attempts at swallowing.
- Muscle atrophy—usually not found.
- Dyspnea—with aspiration pneumonia.
- Fatigue or cramping—with mild exercise.
- Careful neurologic examination—subtle findings: decreased or absent palpebral reflex (may be fatigable); may note a poor or absent gag reflex; spinal reflexes usually normal but fatigable (rarely absent and dog unable to support its weight).
- Ventroflexion of the neck (cats, uncommon in dogs).

CAUSES

- Congenital
- Immune-mediated
- Paraneoplastic

RISK FACTORS

- Appropriate genetic background
- Neoplasia—particularly thymoma
- Methimazole treatment (cats)—may result in reversible disease
- Vaccination can exacerbate active MG
- Intact female

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other disorders of neuromuscular transmission—tick paralysis; botulism; cholinesterase toxicity.
- Acute or chronic polyneuropathies.
- Polymyopathies—including polymyositis.
- Diagnosis depends upon a careful history, thorough physical and neurologic examinations, and specialized laboratory testing.

CBC/BIOCHEMISTRY/URINALYSIS

- Normal.
- Serum creatine kinase activity—usually normal; may be elevated if MG is associated with polymyositis and concurrent thymoma.

OTHER LABORATORY TESTS

- Serum AChR antibody titer—diagnostic for acquired form.
- Thyroid and adrenal function—may see abnormalities associated with acquired form.

IMAGING

Thoracic radiographs—megaesophagus; cranial mediastinal mass, aspiration pneumonia.

DIAGNOSTIC PROCEDURES

- Ultrasound-guided biopsy of cranial mediastinal mass—may support diagnosis of thymoma.
- Dramatic increase in muscle strength after administration of edrophonium chloride (0.1 mg/kg IV)—may see false-negative and false-positive responses.
- Decreased or absent palpebral reflex—may return after edrophonium chloride administration.
- Electrophysiologic evaluation—necessity questionable with increased availability of AChR antibody testing; many patients with acquired form are poor anesthetic risks.
- Electrocardiogram—with bradycardia; third-degree heart block has been documented in some patients with acquired disease.

PATHOLOGIC FINDINGS

Biopsy of a cranial mediastinal mass may reveal thymoma, thymic hyperplasia, or thymic atrophy.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient—until adequate dosages of anticholinesterase drugs are achieved.
- Aspiration pneumonia—may require intensive care
- Gastrostomy tube—may be required if patient is unable to eat or drink without significant regurgitation.

NURSING CARE

- Oxygen therapy, intensive antibiotic therapy, intravenous fluid therapy, and supportive care—generally required for aspiration pneumonia.
- Nutritional maintenance with a gastrostomy tube—multiple feedings of a high-caloric diet; good hygiene care.
- Elevation of food and water.

ACTIVITY

Self-limited owing to the severity of muscle weakness and extent of aspiration pneumonia.

DIET

May try different consistencies of food—gruel; hard food; soft food; evaluate what is best tolerated.

CLIENT EDUCATION

- Warn client that, although the acquired disease is treatable, most patients require months of special feeding and medication.

MYASTHENIA GRAVIS

(CONTINUED)

- Inform client that a dedicated owner is important to a favorable outcome for acquired myasthenia.
- Prognosis is poor for congenital myasthenic syndrome.

SURGICAL CONSIDERATIONS

- Cranial mediastinal mass—thymoma.
- Before attempting surgical removal, stabilize patient with anticholinesterase drugs and treat aspiration pneumonia.
- Weakness may not be clinically evident initially.
- Suspected thymoma—test all patients for acquired MG before surgery.

MEDICATIONS

DRUG(S) OF CHOICE

- Anticholinesterase drugs—prolong the action of acetylcholine at the neuromuscular junction; pyridostigmine bromide tablets or syrup (Mestinon syrup, diluted half and half in water) at 1–3 mg/kg PO q8–12h.
- Corticosteroids 0.5 mg/kg q24h; initiated if there is a poor response to pyridostigmine or if there is no response to the edrophonium chloride challenge.

M

CONTRAINDICATIONS

Avoid drugs that may reduce the safety margin of neuromuscular transmission—aminoglycoside antibiotics; antiarrhythmic agents; phenothiazines; anesthetics; narcotics; muscle relaxants; magnesium.

PRECAUTIONS

- Avoid large volumes of barium for evaluating megaesophagus.
- Large air-filled esophagus seen on survey radiographs—barium study not indicated.
- Avoid immunosuppressive dosages of prednisone—may worsen muscle weakness.
- Avoid unnecessary vaccinations.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

- Azathioprine 2 mg/kg PO through gastrostomy tube q24h. Taper to q48h when clinical remission of the disease.

- Mycophenolate 20 mg/kg PO q12h. Reduce dosage by 50% once significant improvement or resolution of clinical signs is noted.

FOLLOW-UP

PATIENT MONITORING

- Return of muscle strength should be evident.
- Thoracic radiographs—evaluated every 4–6 weeks for resolution of megaesophagus.
- AChR antibody titers—evaluated every 8–12 weeks; decrease to the normal range with immune remission.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Aspiration pneumonia
- Respiratory arrest

EXPECTED COURSE AND PROGNOSIS

- No severe aspiration pneumonia or pharyngeal weakness—good prognosis for complete recovery; resolution usually within 6–8 months.
- Thymoma present—guarded prognosis unless complete surgical removal and control of myasthenic signs are achieved.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Other autoimmune disorders—thyroiditis; skin disorders; hypoadrenocorticism, thrombocytopenia, hemolytic anemia, inflammatory bowel disease.
- Disorders of the thymus—thymoma; thymic hyperplasia.
- Other neoplasias.

AGE-RELATED FACTORS

Bimodal age of onset—1–4 years of age and 9–13 years of age.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

- Humans—weakness may improve during pregnancy but worsens after delivery; some neonates of affected mothers have a temporary myasthenia gravis-like weakness that lasts several days to weeks that is due to *in utero* transfer of autoantibodies from the mother.
- Documented in dogs after whelping.

SEE ALSO

- Chapters covering autoimmune diseases
- Megaesophagus

ABBREVIATIONS

- AChR = acetylcholine receptor
- MG = myasthenia gravis

MYCOBACTERIAL INFECTIONS

BASICS

OVERVIEW

- Mycobacteria—gram-positive, acid-fast higher bacteria (genus *Mycobacterium*); obligate or sporadic pathogens in humans and animals.
- Tuberculosis—caused by *Mycobacterium tuberculosis* (humans), *M. bovis* (cattle, wild mammals), *M. microti* and *M. microtii*-like (voles); dogs and cats exposed to infected primary hosts sporadically infected; disseminated or multi-organ disease caused by obligate parasitic organism; rare in dogs and cats.
- Leprosy—*M. lepraeumurium* (from rodents) and two unnamed leprosy organisms (*M. visibilis* [provisional]).
- Cats—two syndromes: *M. lepraeumurium* (syndrome 1) affects young cats with localized nodular disease, especially limbs, with sparse to moderate numbers of acid-fast bacilli present in lesions; unnamed species with affinity to *M. malmoense* (syndrome 2) affects older cats with generalized skin lesions and large numbers of acid-fast bacilli in lesions.
- Dogs—canine leproid granuloma syndrome caused by unnamed and uncultured *Mycobacterium* spp. identified by DNA sequencing.
- Systemic or non-cutaneous infection with non-tuberculous mycobacteria—*M. chelonae-abscessus* group, *M. avium* complex, *M. fortuitum*, *M. genavense*, *M. kansasi*, *M. massiliense*, *M. simiae*, *M. smegmatis*, *M. thermoresistable*, *M. xenopi*; sporadic infections in dogs and cats; some patients with concurrent infections or immunosuppression or the result of traumatic tissue introduction of saprophytic organism; syndromes include pleuritis, granulomas, disseminated disease, neuritis, or bronchopneumonia.
- Cutaneous/subcutaneous infections due to rapidly growing mycobacteria (mycobacterial panniculitis). • Dogs and cats—caused by saprophytic mycobacteria *M. fortuitum* group, *M. chelonae-abscessus* group, *M. smegmatis* groups, *M. phlei*, *M. terrae* complex, *M. thermoresistable*, *M. ulcerans*.

SYSTEMS AFFECTED

- Respiratory
- Skin/Exocrine
- Determined by cause

SIGNALMENT

Tuberculosis

- Cats and dogs of any age.
- Basset hound and Siamese cat reported as most susceptible; evidence unclear (possible statistical aberration).

Feline Leprosy

Free-roaming cats and kittens; kittens and young adult cats in syndrome 1; older cats (average 9 years) in syndrome 2.

Canine Leproid Granuloma

Reported cases; mostly shorthaired outdoor-housed large-breed dogs, especially boxers and German shepherd dogs.

Systemic Non-tuberculous Mycobacteriosis

A sporadic disease that can affect dogs and cats of any age

Mycobacterial Panniculitis

Adult dogs and cats

SIGNS

Tuberculosis

- Correlated with the route of exposure.
- Major sites of involvement—opharyngeal lymph nodes, cutaneous and subcutaneous tissues of the head and extremities; pulmonary system; gastrointestinal system.
- Dogs—respiratory, especially coughing.
- Cats—from contaminated milk: weight loss, chronic diarrhea, and thickened intestines; from predation: cutaneous nodules, ulcers, and draining tracts.
- Most dogs and many cats—pharyngeal and cervical lymphadenopathy; unproductive vomiting, ptalism, or tonsillar abscess; lymph nodes are visible or firm, fixed, tender; may ulcerate and drain.
- Pyrexia.
- Depression.
- Anorexia and weight loss.
- Hypertrophic osteopathy or hypercalcemia.
- Disseminated disease—body cavity effusion; visceral masses; bone or joint lesions; dermal and subcutaneous masses and ulcers; lymphadenopathy and/or abscesses; CNS signs; sudden death.

Feline Leprosy

- Syndrome 1—initially nodules on limbs; progress rapidly, may ulcerate; aggressive clinical course; recurrence after surgical excision; widespread lesions develop in several weeks.
- Syndrome 2—initially skin nodules that do not ulcerate, progressive over months to years.
- Feline multisystemic granulomatous mycobacteriosis—diffuse cutaneous thickening and multiple organ involvement.

Canine Leproid Granuloma

- Well-circumscribed painless nodules (2 mm–5 cm) in dermis or subcutis; especially dorsal fold of pinnae and head, but may be anywhere on the body; large lesions ulcerate.
- No systemic signs of illness.

Systemic Non-tuberculous Mycobacteriosis

- Pulmonary and systemic infections with AM are rare in dogs, in which case the signs are as for TB.
- With *M. avium* infection, disease most often disseminated.

Mycobacterial Panniculitis

- Cutaneous—traumatic lesion that fails to heal with therapy; spreads locally in the subcutaneous tissue (panniculitis); original lesion enlarges, forming a deep ulcer that drains hemorrhagic exudate; surrounding tissue becomes firm; satellite pinpoint ulcerations open and drain.
- Wound dehiscence at surgery sites.

CAUSES & RISK FACTORS

Tuberculosis

- Source of exposure—always an infected typical host.
- Dogs—usually from an

infected person in the household

(*M. tuberculosis*); route is ingestion of expectorated infectious material; aerosol exposure; patients often found in urban areas with immigrants.

- Cats—classically exposed by drinking unpasteurized milk of infected cattle (*M. bovis*); much less common now; may be exposed by predation on infected small mammals (*M. bovis*, undefined tuberculosis species).

Feline Leprosy

- Syndrome 1: cases have been reported from temperate coastal areas and port cities; cool climate may facilitate growth of the organism in extremities.
- Syndrome 2: cases are from rural environments; old age or immune-incompetence may be risk factors but remain undefined; exposure to rodents postulated.

Canine Leproid Granuloma

- Associated with fly bites and may fluctuate seasonally; short coats may predispose
- Disease likely to be worldwide; most cases reported from Australia, Asia and Brazil
- In the US reported in California, Hawaii, and Florida.

Systemic Non-tuberculous Mycobacteriosis

- Patients are immunosuppressed or have concurrent systemic disease
- Exposure—routes of exposure in pulmonary and systemic disease are unknown.

Mycobacterial Panniculitis

- Infections usually have antecedent trauma or surgical wound; most patients are immunocompetent.
- Trauma and accidental inoculation of the subcutaneous fat results in infection; history of bite wound possible (subcutaneous disease).
- Fat animals are more at risk than lean ones.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mycobacterial infections have different prognoses, treatments, and public health consequences but may initially have similar signs, especially cutaneous lesions.
- All manifestations: fungal and other actinomycotic infections should be considered.
- Panniculitis: nocardiosis can be clinically identical.

OTHER LABORATORY TESTS

Tuberculosis

Tuberculosis (dogs)—intradermal skin testing with PPD or BCG on inner pinna; may produce false-positive results owing to cross-reactions with non-tuberculous mycobacteria.

IMAGING

Radiography

- Thoracic, abdominal, or skeletal lesions—suggest granulomatous infectious disease

MYCOBACTERIAL INFECTIONS

(CONTINUED)

- No specific lesions for the mycobacterioses
- Pulmonary tuberculosis lesions—may become calcified or cavitated.

DIAGNOSTIC PROCEDURES

- Based on biopsy material from affected tissue. • Aspiration of purulent material from any site after disinfection of overlying skin may be used for microbiologic identification; ultrasound-guided aspiration techniques may be warranted. • Biopsy specimens—should be uncontaminated by surface bacteria; must incorporate the center of a granulomatous focus. • Smears from infected tissues—for detection with acid-fast carbolfuchsin or auramine-rhodanine fluorochromes; on routine staining, organisms are negatively stained, showing “ghosts” of bacilli within macrophages; swabs or aspirates of draining cutaneous lesions or lymph nodes, trans-tracheal wash; endoscopic brushings; rectal cytology; impressions taken at surgical biopsy; heat-fixed smears should be submitted with tissue for culture. • Culture—special media and techniques required; referral to specialized laboratories may be required for non-tuberculous organisms (*Mycobacterium Mycology Referral*, University of Texas Health Center at Tyler, Microbiology Section).
- PCR methodologies—useful for any of the mycobacterial infections using tissue specimens or fluids; for canine leproid granuloma and the two feline leprosy syndromes, primers are not commercially available, but can be used to identify the suspect organisms.

M

TREATMENT

TUBERCULOSIS

- Permission of health authorities should be obtained in cases of *Mycobacterium tuberculosis* infection and zoonotic potential should be considered. • Multiple agent chemotherapy with drugs used to treat human tuberculosis has been successful; *M. avium* complex infections are difficult to treat.

FELINE LEPROSY

- Before widespread dissemination, individual lesions may be excised with aggressive margins—possibly curative. • Surgical treatment should be preceded by systemic therapy.

CANINE LEPROID GRANULOMA

- Excision is curative; lesions often self-cure; antimicrobial therapy may assist healing.

SUBCUTANEOUS AND SYSTEMIC NON-TUBERCULOUS INFECTIONS

- Treatment should be based on organism identification and antibiotic sensitivity testing. • Multiple drug therapy is often warranted. • Aggressive surgical debulking may aid resolution; antimicrobial therapy pre- and intra-operatively is recommended.

MEDICATIONS

DRUG(S)

Tuberculosis

- Always use multi-drug oral therapy; never attempt single-drug therapy for any organism.
- Current recommendation—fluoroquinolones, clarithromycin, and rifampin for 6–9 months. • Enrofloxacin, orbifloxacin, marbofloxacin, moxifloxacin, and ciprofloxacin 5–15 mg/kg PO q24h.
- Rifampin 10–20 mg/kg PO q24h or divided q12h (maximum, 600 mg/day).
- Clarithromycin 5–10 mg/kg PO q24h.
- Isoniazid and rifampin—combinations have been used; little is known about use in cats; one report of treatment (cat) with isoniazid, rifampin, and dihydrostreptomycin for 3 months noted weight loss but successful outcome. • Isoniazid 10–20 mg/kg (up to 300 mg total) PO q24h. • Ethambutol 15 mg/kg PO q24h. • Pyrazinamide—instead of ethambutol; 15–40 mg/kg PO q24h.
- Dihydrostreptomycin 15 mg/kg IM q24h.

Feline Leprosy

- Rifampin 10–20 mg/kg q24h or divided q12h. • Clarithromycin as above.

Subcutaneous and Systemic Non-tuberculous Infections

- In vitro sensitivity testing may be used to choose chemotherapy. • Antibiotics reported to be effective against AM isolates are macrolide, trimethoprim-potentiated sulfonamide, tetracycline, aminoglycoside, and fluoroquinolone antibiotics. • Anti-TB drugs are not generally effective.
- Single-agent therapy not recommended due to poor long-term response; double-agent therapy recommended. • Fluoroquinolones, trimethoprim-potentiated sulfonamides, aminoglycosides, tetracyclines, and clarithromycin are useful for some isolates.
- Response may be predicted by which species is isolated, but long-term therapy should be based on sensitivity testing. • Treatment should be continued for 2–6 months.
- Relapses are common.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Traditional antituberculosis drugs—watch for adverse reactions; experience is limited, especially in cats.

FOLLOW-UP

PATIENT MONITORING

- Antituberculosis and antileprosy drugs—examine monthly; monitor for anorexia and weight loss. • Liver profile monthly. • Instruct owners to report cutaneous lesions immediately.

PREVENTION/AVOIDANCE

Counsel owners about the risk of reverse zoonosis when a human tuberculosis case is in a household with dogs or cats.

EXPECTED COURSE AND PROGNOSIS

Tuberculosis

- Guarded; but undefined as experience with modern drugs is limited.

Feline Leprosy

- Guarded to poor—syndrome 1.
- Fair—syndrome 2, especially if lesions are amenable to surgical excision.

Canine Leprorid Granuloma

Good

Subcutaneous and Systemic Non-tuberculous Infections

- Relapses are common; aggressive surgical approaches and multiple drug therapy may improve outlook.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Tuberculosis—affected domestic pets are potential serious zoonotic threats to owners; public health authorities should be notified of any antemortem or post-mortem diagnosis; do not attempt treatment without agreement of public health authorities.
- *M. tuberculosis*—greatest potential for zoonosis, especially with draining cutaneous lesions. • Disease transmission from dogs and cats to humans—rarely recorded.

ABBREVIATIONS

- AM = atypical mycobacteriosis • CNS = central nervous system • PCR = polymerase chain reaction • TB = tuberculosis

BASICS

DEFINITION

- Class Mollicutes (Latin, *mollis*, "soft"; *cutis*, "skin"). • Divided into hemotrophic (formerly Haemobartonella and Eperythrozoon), which are discussed elsewhere, and non-hemotrophic types, which are discussed here.
- More than 80 genera; three families: Mycoplasmas, Ureaplasmas, and Acholeplasmas.
- Smallest (0.2–0.3 μm) and simplest prokaryotic cells capable of self-replication.
- Fastidious, facultative anaerobic, gram-negative rods.
- Lack a cell wall; thus plastic, highly pleomorphic, fragile and sensitive to lysis by osmotic shock, detergents, alcohols, and specific antibody plus complement; enclosed by a trilayered cell membrane built of amphiphatic lipids (phospholipids, glycolipids, lipoglycans, sterols) and proteins; therefore resistant to lysozyme and cell wall-inhibiting antibacterials; most require sterols for growth.
- Different from wall-defective or wall-less L-form bacteria, which can revert to the normal cell wall strain.
- Reproduce by binary fission; genome replication not necessarily synchronized with cell division, resulting in budding forms and chains of beads.
- Small genome, typically 0.6–1.6 Mb.
- Low genomic G + C content (23–40 mol%).
- Small genome believed to be result of reductive evolution from a common gram-positive ancestor adapting to obligate parasitic life.
- Ubiquitous in nature as parasites, commensals, or saprophytes in animals, plants, and insects; many are pathogens of humans, animals, plants, and insects.

PATOPHYSIOLOGY

- Often part of the resident flora as commensals on mucous membranes of the upper respiratory, digestive, and genital tracts; pathogenicity and role in disease often controversial.
- Species show considerable host specificity.
- Mechanisms by which disease is caused are poorly understood.
- Some species attach to cells by specific receptors; small size and plastic nature enable them to adapt to the shape and contours of host cell surfaces.
- Intimate contact with host cells—necessary for assimilation of vital nutrients and growth factors (e.g., nucleic acid precursors), which organism cannot synthesize; along with the tendency of exogenous proteins to bind to mycoplasmal membrane may allow organism to evade the host's immune response; may incorporate host cell antigen onto mycoplasma membrane (capping) because lack of cell wall; conversely, mycoplasmal protein antigen may become incorporated onto surface of host cell, thereby involving host cell in deleterious immunologic reactions intended against the

organism.

- Products produced during growth—capsular carbohydrate, hemolysins, proteolytic enzymes, ammonia, and endonucleases; accumulation of Mycoplasma metabolites (i.e., H_2O_2 , NH_3) may contribute to cytopathic effects and tissue damage; cytotoxic glycoproteins and proteins have been isolated from the membranes of several species.
- Immune response—predominantly humoral; as with bacterial infections, IgM and IgA are first antibodies to appear, followed by IgG.
- Fibrinous exudate accompanying infections—protects organism from antibodies and antimicrobial drugs; contributes to chronicity.
- Secondary bacterial invaders—common (e.g., attachment to respiratory tract cells results in destruction of cilia, which predisposes patient to secondary bacterial infection).
- Sialidase, a virulence factor that promotes colonization, tissue invasion, and damage to host cells, varies in expression among strains of canine mycoplasma species.

SYSTEMS AFFECTED

Dogs

- Gastrointestinal—associated with colitis.
- Musculoskeletal—arthritis; from *M. spumans*.
- Renal/Urologic—urinary and genital tract infections (e.g., balanoposthitis, urethritis, prostatitis, cystitis, nephritis, vaginitis, endometritis); caused by *M. canis* and *M. spumans*.
- Reproductive—Mycoplasma and Ureaplasma; associated with infertility, early embryonic death, abortion, stillbirths or weak newborns, and neonatal mortality.
- Respiratory—pneumonia and upper respiratory infections; caused by *M. cynos*; associated with *M. canis*, *M. spumans*, *M. edwardii*, *M. feliminutum*, *M. gateae*, and *M. bovigenitalium*.

Cats

- Musculoskeletal—chronic fibrinopurulent polyarthritis and tenosynovitis; associated with *M. gateae* and unspecified mycoplasmal organisms.
- Ophthalmic—conjunctivitis; associated with *M. felis* (5–25%).
- Renal/Urologic—urinary tract infections.
- Reproductive—abortions and fetal deaths; associated with *M. gateae* and Ureaplasmas.
- Respiratory—pneumonia, associated with *M. gateae*, *M. feliminutum*, and *M. felis*; upper respiratory infections, associated with *M. felis*.
- Skin/Exocrine—chronic cutaneous abscesses.

INCIDENCE/PREVALENCE

- Frequent inhabitants of mucosal membranes; *M. gateae* and/or *M. felis* found in oral cavity or urogenital tract of 70–80% of healthy cats.
- Rate of isolation in diseased dogs much higher than in normal dogs (e.g., lung, uterus, prepuce).

GEOGRAPHIC DISTRIBUTION

Ubiquitous

SIGNALMENT

Species

Dog and cat

Mean Age and Range

All ages

SIGNS

General Comments

- Pathogenic role controversial.

Historical Findings

- Polyarthritis—chronic intermittent lameness; reluctance to move; joint pain.
- Fever.
- Malaise.
- Conjunctivitis—unilateral or bilateral.

Physical Examination Findings

- Polyarthritis—diffuse limb edema; joint swelling; pain.
- Conjunctivitis—blepharospasm; chemosis; conjunctival hyperemia; epiphora; and serous or purulent ocular discharge.
- Mild rhinitis—sneezing.

CAUSES

- *Mycoplasma* flora of dogs—*M. canis*, *M. spumans*, *M. maculosum*, *M. edwardii*, *M. cynos*, *M. molare*, *M. opalescens*, *M. feliminutum*, *M. gateae*, *M. arginini*, *M. bovigenitalium*, *M. mucosicanis*, *Acholeplasma laidlawii*, and Ureaplasmas.
- *Mycoplasma* flora of cats—*M. felis*, *M. gateae*, *M. feliminutum*, *M. arginini*, *M. pulmonis*, *M. arthritidis*, *M. gallisepticum*, *Acholeplasma laidlawii*, and Ureaplasmas.

RISK FACTORS

- Commensals—occasionally cause systemic infection associated with immunodeficiency, immunosuppression, or cancer.
- Impaired resistance of the host—may allow organism to cross the mucosal barrier and disseminate (e.g., primary ciliary dyskinesia).
- Organism may be opportunistic—one factor in a multifactorial causal complex (e.g., impaired pulmonary clearance from viral infection may allow organism to establish infection in lungs as secondary opportunistic pathogen).
- Predisposing factors—stresses (e.g., reproductive problems associated with overcrowded operations) and other factors (e.g., urinary tumors and urinary calculi).
- Rate of isolation of organism in diseased dogs much higher than in normal dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Upper respiratory infection (dogs and cats)—viruses (parainfluenza virus, canine distemper, herpesvirus, feline calcivirus, reovirus); *Chlamydia psittaci*; bacteria (*Bordetella bronchiseptica*, staphylococci, streptococci, coliforms).
- Urinary tract infection (dogs and cats)—bacteria (staphylococci, streptococci, coliforms); fungus (*Candida*); parasites.
- Infertility, early

MYCOPLASMOSIS

(CONTINUED)

embryonic death, abortion, stillbirths or weak newborns, and neonatal mortality (dogs)—bacteria (*Brucella*, *Salmonella*, *Campylobacter*, *E. coli*, *streptococcus*); viruses (canine herpesvirus, canine distemper, canine adenovirus); *Toxoplasma gondii*; endocrinopathies (progesterone deficiency, hypothyroidism). • Prostatitis (dogs)—bacteria (*E. coli*, *Brucella canis*); fungi (*Blastomyces*, *Cryptococcus*). • Arthritis (dogs and cats)—immune-mediated; bacteria (staphylococci, streptococci, coliforms, anaerobes); L-form bacteria; *Rickettsia* (*Ehrlichia*); *Borrelia burgdorferi*; fungi (*Coccidioides*, *Cryptococcus*, *Blastomyces*); protozoa (*Leishmania*); viruses (feline calicivirus). • Conjunctivitis (cats)—feline herpesvirus; feline calicivirus; feline reovirus; *Chlamydia psittaci*; bacteria.

CBC/BIOCHEMISTRY/URINALYSIS

With Polyarthritis

- Mild anemia
- Neutrophilic leukocytosis
- Hypoalbuminemia
- Hypoglobulinemia
- Proteinuria, resulting from immune-complex glomerulonephritis

OTHER LABORATORY TESTS

- Serologic tests—complement fixation, agar gel immunodiffusion, ELISA; detect organism. • Difficult to demonstrate in and from tissues. • Extremely pleomorphic—in smears (e.g., conjunctival scrapings) seen as coccobacilli, coccal forms, ring forms, spirals, and filaments. • Stains—stain poorly (gram-negative); preferred: Giemsa or other Romanowsky stain. • Fluorescent antibody test—definitive diagnosis; isolate and identify or detect the organism in tissues; can submit cotton swabs placed in Hayflick broth medium or commercially available swabs; organisms fragile; refrigerate specimens and deliver to the laboratory within 48 hours; freeze to preserve longer. • Culture urine sediment after centrifugation; fastidious, require complex growth media; form microcolonies having characteristic “fried egg” appearance. • PCR of 16S rRNA.
- PCR-DGGE—used to identify difficult-to-culture or difficult-to-differentiate mycoplasma.

IMAGING

Polyarthritis—no radiographic changes.

DIAGNOSTIC PROCEDURES

- Polyarthritis—high numbers of non-degenerative neutrophils in synovial fluid.
- Prostatic fluid—inflammatory cells with negative bacterial culture.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient

MEDICATIONS

DRUG(S) OF CHOICE

- Sensitive to antibiotics that specifically inhibit synthesis in prokaryotes.
- Tetracyclines 22 mg/kg PO q8h.
- Doxycycline 5 mg/kg PO q12h.
- Pradofloxacin 5 mg/kg PO q12h.
- Chloramphenicol 40–50 mg/kg IV, IM, SC, PO q8–12h. • No standardized procedure for in vitro antimicrobial susceptibility tests.
- Topical antibiotic—conjunctivitis.

CONTRAINDICATIONS

- Topical steroid ointments—improper use for conjunctivitis may prolong infection and predispose patient to corneal ulceration.
- Tetracyclines—avoid use in animals < 6 months of age. • Tetracycline and chloramphenicol—avoid use in pregnant animals.

PRECAUTIONS

Sulfonamides and β -lactams—Inhibit peptidoglycan synthesis; organism resistant because of lack of cell walls.

ALTERNATIVE DRUG(S)

- Gentamicin
- Kanamycin
- Spectinomycin
- Spiramycin
- Tylosin
- Erythromycin
- Nitrofurans
- Fluoroquinolones

FOLLOW-UP

PATIENT MONITORING

Treat for an extended period of time

PREVENTION/AVOIDANCE

- No vaccines are available.
- Organism readily killed by drying, sunshine, and chemical disinfection.

EXPECTED COURSE AND PROGNOSIS

Prognosis good in animals with competent immune systems and given appropriate antibiotic therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

M. pneumoniae—infects respiratory tracts in humans worldwide; causes mycoplasmal pneumonia, bronchitis, or upper respiratory infection; usually self-limited; rarely fatal.

AGE-RELATED FACTORS

Tetracyclines—avoid in animals < 6 months of age.

ZOONOTIC POTENTIAL

- Not generally considered zoonotic unless person is immunosuppressed.
- Reported development of suppurative mycoplasmal tenosynovitis in a veterinarian who was scratched by a cat being treated for colitis.
- Host specificity of mycoplasmas has been questioned by some; particularly between closely related species of mammals.

PREGNANCY/FERTILITY/BREEDING

Tetracycline and chloramphenicol—do not use in pregnant animals.

SYNONYMS

Pleuropneumonia-like organisms

ABBREVIATIONS

- ELISA = enzyme-linked immunosorbent assay
- PCR = polymerase chain reaction
- PCR-DGGE = polymerase chain reaction denaturing gradient gel electrophoresis

MYCOTOXICOSIS—AFLATOXIN

BASICS

OVERVIEW

Aflatoxins are hepatotoxic mycotoxins (mold toxins) and are the most common cause of mycotoxicosis associated with pet food. The four major forms of aflatoxin in feedstuffs are aflatoxin B1, B2, G1, and G2. Aflatoxin B1 is the most common and most toxic.

SIGNALMENT

- Rarely reported in dogs, but occurs periodically in large outbreaks associated with pet foods.
- Only reported experimentally in cats.
- Young males and pregnant females might be more susceptible.

SIGNS

Acute Onset

- Most common form in small animals
- Refusal of contaminated feeds
- Rapid onset of signs may develop up to 3 weeks post-exposure
- Vomiting and diarrhea
- Icterus
- Coagulopathy and gastrointestinal hemorrhage

Chronic

- Anorexia or feed refusal
- Vomiting
- Diarrhea
- Liver failure
- Ascites

CAUSES & RISK FACTORS

- Common in various cereal grains; peanuts, other nuts, and potatoes.
- Post-production contamination of improperly stored pet foods; foods with obvious mold spoilage; garbage ingestion.
- Mycotoxin-producing molds grow at temperatures of 24–35°C, moisture of 18–20%.
- Acute signs have been seen in dogs ingesting food containing 60 ppb aflatoxin.
- Activated to toxic epoxide by liver cytochrome P450 enzymes.
- Depletes glutathione.
- Binds with nucleic acids, proteins, and subcellular organelle.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Leptospirosis
 - Serology
- Parvovirus
 - ELISA
 - Serology
 - Viral isolation
- Anticoagulant rodenticide toxicosis
 - Anticoagulant rodenticide screen

- Other causes of subacute to chronic liver disease and associated DIC

CBC/BIOCHEMISTRY/URINALYSIS

- Decreased serum protein C, antithrombin III, and cholesterol
- Hyperbilirubinemia
- Hypoalbuminemia
- Elevated ALT
- Variable elevations in GGT, AST, and ALP

OTHER LABORATORY TESTS

Prolonged APTT and PT

DIAGNOSTIC PROCEDURES

- Liver biopsy
- Histopathology
- Assay suspect food samples for aflatoxin.
 - Contaminated food is often gone due to delayed clinical signs.

PATHOLOGIC FINDINGS

- Hepatomegaly with fatty change
- Icterus
- Ascites
- Multifocal hemorrhage, especially gastrointestinal
- Microvesicular fatty change in hepatocytes
- Centrilobular hepatocellular necrosis
- Canalicular cholestasis
- Bridging portal fibrosis, proliferation of bile ducts

TREATMENT

- Transfusion of whole blood or plasma
- Correct fluid and electrolyte imbalances
- Activated charcoal for recent, high-dose exposure
- B vitamins, vitamin K₁, vitamin E, and other antioxidants
- Gastroprotectants
- Clean, uncontaminated diet
 - High-quality protein source

MEDICATIONS

DRUG(S)

- No specific antidotal therapy.
- Limited success with hepatoprotectants.
- Parenteral N-acetylcysteine in severely affected dogs.
 - 20% solution diluted 1:4 in sterile saline slow IV at a loading dose of 140 mg/kg, follow with maintenance dose of 70 mg/kg IV q8h × 7 doses.
- S-Adenosylmethionine
 - 20 mg/kg PO daily as enteric-coated tablets given on empty stomach × 1–2 weeks.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Avoid drugs metabolized by the liver.

FOLLOW-UP

PATIENT MONITORING

- Daily serum enzymes and chemistry, including cholesterol
- PT and APTT
- Protein C

PREVENTION/AVOIDANCE

- Avoid using moldy feedstuff.
- Store food in cool, clean, dry area.
- Clean food containers and feed bowls regularly.

POSSIBLE COMPLICATIONS

Chronic liver disease possible.

EXPECTED COURSE AND PROGNOSIS

Prognosis—poor, even with treatment. Improved prognosis if treatment initiated before onset of signs.

MISCELLANEOUS

AGE-RELATED FACTORS

Young animals more susceptible to aflatoxin

PREGNANCY/FERTILITY/BREEDING

- Indirect effects on uterus
- Potentially teratogenic
- Pregnant animals may be more susceptible

ABBREVIATIONS

- ALP = alkaline phosphatase
- ALT = alanine aminotransferase
- APTT = activated partial thromboplastin time
- AST = aspartate aminotransferase
- DIC = disseminated intravascular coagulation
- ELISA = enzyme-linked immunosorbent assay
- GGT = gamma-glutamyltransferase
- PT = prothrombin time

MYCOTOXICOSIS—DEOXYNIVALENOL

BASICS

OVERVIEW

- Deoxynivalenol (DON [vomitoxin]) is a toxin that can be produced by *Fusarium* fungi in grains such as wheat, oats, barley, and corn.
- The main source of exposure for dogs and cats is through the ingestion of pet food made with DON-contaminated grain.
- Although the exact mechanism is not well defined, DON can inhibit cellular protein synthesis and activate intracellular kinases involved in signal transduction. In addition, ingestion of DON can cause feed refusal possibly related to upregulation of proinflammatory cytokines such as IL-6, and it may have a central emetic effect that results in vomiting.

SIGNALMENT

- Dogs and cats.
- No breed or sex predisposition.
- Signs may be more common in young animals.

SIGNS

- Sudden onset of anorexia and vomiting, which may result in weight loss.
- Onset of clinical signs can occur within minutes of exposure.
- Abnormal clinical signs may also resolve rapidly following removal of contaminated food.

CAUSES & RISK FACTORS

- Animals are exposed to DON when grain containing DON is mixed into their complete feed.
- There are marked species differences in toxicity: pig (most sensitive) > rodent > dog > cat > poultry > human > ruminant (least sensitive).
- Experimentally, food intake of beagles and Brittany dogs is reduced when DON concentrations in their food are $> 4.5 \pm 1.7$ mg DON/kg of food.
- Food intake in cats is reduced with DON concentrations $> 7.7 \pm 1.1$ mg/kg.
- Vomiting in dogs and cats is common when DON concentration in their food is > 8 mg.

M

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of inappetence and vomiting.
- Viral, bacterial, or parasitic infections.
- Other toxicoses (e.g., exposure to organophosphates/carbamates or ethylene glycol).
- Ingestion of poisonous plants causing irritation to the gastrointestinal tract.
- Ingestion of lilies by cats, resulting in severe kidney failure.
- Other medical conditions, such as pancreatitis, neoplasia, and inflammation of the gastrointestinal tract.

CBC/BIOCHEMISTRY/URINALYSIS

Nonspecific, but may be used to rule out other causes of inappetence and vomiting.

OTHER LABORATORY TESTS

Analysis of pet food for DON by thin-layer chromatography or high-pressure liquid chromatography.

IMAGING

May be used to rule out other causes of inappetence and vomiting.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

There are no pathognomonic gross or microscopic lesions.

TREATMENT

Removal of contaminated pet food should result in rapid cessation of vomiting and return to normal food intake.

MEDICATIONS

DRUG(S)

N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Monitor hydration and electrolytes if vomiting has been severe.
- Ensure animal returns to normal weight following removal of pet food containing DON.

PREVENTION/AVOIDANCE

Provide high-quality pet food free of DON.

EXPECTED COURSE AND PROGNOSIS

The prognosis is excellent following removal of feed containing DON.

MISCELLANEOUS

AGE-RELATED FACTORS

In other, more well-studied species (e.g., swine), young animals are more severely affected and at lower concentrations of DON in the feed than are adults.

ABBREVIATION

DON = deoxynivalenol

Suggested Reading

MYCOTOXICOSIS—TREMORGENIC TOXINS

BASICS

OVERVIEW

- Penitrem A—produced by the fungus *Penicillium crustosum* (and perhaps other *Penicillium* spp.); poisoning by this toxin has been reported in dogs ingesting moldy bread, cheese, and English walnuts.
- Roquefortine—produced by *Penicillium roquefortii* (and perhaps other *Penicillium* spp.); has been reported to cause poisoning in dogs through ingestion of moldy cheese or decaying organic material (compost).

SIGNALMENT

- Dogs and rarely cats.
- Poisoning by penitrem A and roquefortine has been reported in dogs of various ages and breeds soon after the ingestion of moldy foods or compost.

SIGNS

- Moderate to severe muscle tremors and seizures—begin minutes to hours (2–4 hours in case reports) after ingestion of moldy food or compost.
- Affected dogs may be hyperresponsive to external stimuli.
- Early signs—may include panting, hyperactivity, vomiting, ataxia, incoordination, weakness, tachycardia, and/or rigidity.
- Prolonged muscle tremors or seizures—may lead to hyperthermia, hypoglycemia, dehydration, and anorexia.
- Severe cases—may result in death.
- Liver necrosis—has been reported experimentally.

CAUSES & RISK FACTORS

- Dogs (and potentially cats) are exposed to penitrem A and roquefortine when they ingest moldy food or decomposing organic matter (compost).
- Experimentally, doses of 0.125 mg/kg penitrem A produced tremors within 30 minutes. Doses of 0.5 mg/kg of penitrem A resulted in acute onset of tremors, severe liver necrosis, and death.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Toxic causes of seizures—strychnine; insecticides (e.g., organophosphate, carbamate, organochlorine, nicotine, pyrethroid); metaldehyde; zinc phosphide; bromethalin; methylxanthines (theobromine and caffeine); amphetamines; cocaine; sago palm; xylitol.

- Non-toxic causes of seizures—
inflammation; congenital abnormal myelin formation; metabolic conditions (e.g., hepatic or uremic encephalopathy).

CBC/BIOCHEMISTRY/URINALYSIS

CBC, biochemistry, and urinalysis to assess the patient's status and to help rule out other causes of tremors and seizures.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Thin-layer chromatography or high-pressure liquid chromatography—analysis of vomitus, stomach contents, and gastric lavage washings for penitrem A or roquefortine.
- The presence of roquefortine C in vomitus or stomach contents can serve as a sensitive biomarker for penitrem A intoxication.
- Bile analysis—reported to be of value.

PATHOLOGIC FINDINGS

- There are no pathognomonic lesions associated with penitrem A or roquefortine toxicosis.
- High doses of penitrem A have been reported to cause severe liver damage experimentally.

TREATMENT

- Remove contaminated food or organic material.
- Induce vomiting (if patient is not at risk of aspirating vomitus) or institute gastric lavage followed by administration of activated charcoal.
- Thermoregulation as indicated.

MEDICATIONS

DRUG(S)

- Diazepam (0.25–1 mg/kg IV prn)—to control seizures.
- Barbiturates (phenobarbital 2–5 mg/kg IV prn)—if tremors and seizures cannot be controlled with diazepam.
- Methocarbamol to control tremors (50–220 mg/kg IV, do not exceed 330 mg/kg/day). Give 1/2 rapidly and administer rest to effect.
- Sodium bicarbonate—may be required if an acid-base imbalance exists.
- Other symptomatic and supportive therapy—as indicated.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Patients should be monitored for occurrence of tremors or seizures, hyperthermia, dehydration, acid-base imbalances, liver damage, rhabdomyolysis, and respiratory difficulties.

PREVENTION/AVOIDANCE

Prevent animals from eating moldy food items, garbage, or compost.

POSSIBLE COMPLICATIONS

- Seizures—may not be controlled with diazepam.
- Acid-base imbalances—may develop.
- Hepatic damage and rhabdomyolysis—may occur.
- Aspiration pneumonia has been reported as a sequelae to vomiting and/or gastric lavage.
- Exposure can be fatal if lethal doses are consumed and are absorbed before gastrointestinal decontamination and therapy are instituted.

EXPECTED COURSE AND PROGNOSIS

- Very good if appropriate therapy is promptly instituted, the toxin is removed from the gastrointestinal tract, and the seizures are controlled with diazepam or barbiturates.
- Recovery in most clinical cases is reported to be complete within 24–48 hours.
- In a few reported cases, signs of weakness, muscle rigidity, and incoordination were persistent and slowly resolved over 1–2 weeks.
- A few severe cases have been reported to be fatal.

M

MYELODYSPLASTIC SYNDROMES

BASICS

OVERVIEW

- Category of diseases characterized by nonregenerative anemias or cytopenias and dysplastic features in the blood or bone marrow.
- Primary myelodysplastic syndromes result from a clonal expansion of a genetically altered pluripotent stem cell resulting in a hypercellular bone marrow with maturation arrest as a consequence of apoptosis.
- Subcategorized as MDS with excessive blasts, which may progress to acute myeloid leukemia, MDS with refractory cytopenia, and MDS with erythroid predominance.
- Secondary MDS in dogs is associated with neoplasia (lymphoma, multiple myeloma), drug or toxin exposure, immune-mediated disease, infections, or ionizing radiation exposure.
- Secondary MDS in cats is typically associated with FeLV infection.

SIGNALMENT

- Dog and less commonly cat
- Primary MDS typically older dogs

SIGNS

- Lethargy
- Exercise intolerance
- Depression
- Anorexia
- Fever
- Pale mucous membranes
- Petechiation
- Heart murmur due to anemia

CAUSES & RISK FACTORS

- Viral—FeLV, FIV, parvovirus
- Neoplasia—lymphoma, multiple myeloma
- Autoimmune—immune-mediated hemolytic anemia, immune-mediated thrombocytopenia
- Drug—chemotherapeutics, estrogen, chloramphenicol, cephalosporins, phenylbutazone, trimethoprim-sulfadiazine, quinidine, thiacetarsamide, griseofulvin, albendazole
- Iron deficiency, folic acid deficiency
- Lead toxicity
- Infectious—ehrlichiosis, bacterial septicemia, and endotoxemia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Need to differentiate between primary and secondary MDS.
- Other causes of nonregenerative anemias—anemia of chronic disease, chronic renal failure, myeloproliferative diseases, lymphoproliferative diseases, myelofibrosis.

CBC/BIOCHEMISTRY/URINALYSIS

Nonregenerative anemia, cytopenias

OTHER LABORATORY TESTS

To diagnose underlying causes of secondary MDS—viral antigen/antibody titers, iron levels, tick titers, Coombs' test.

IMAGING

- As needed to rule out secondary causes of MDS.
- Abdominal radiography—evaluate for lead foreign bodies.
- Abdominal ultrasonography—evaluate for abdominal masses consistent with retained testes and Sertoli cell tumors associated with estrogen secretion.

DIAGNOSTIC PROCEDURES

Bone marrow aspirate or biopsy

TREATMENT

- Inpatient or outpatient.
- If secondary MDS—treat underlying disease (e.g., discontinue drug, treat underlying infection).
- If neutropenic—limit exposure to other sick animals.
- Blood transfusions for anemic patients.

MEDICATIONS

DRUG(S)

- For neutropenia—broad-spectrum antibiotics and filgrastim (3–5 µg/kg SC q24h in dogs and cats).

- For anemia—erythropoietin (35–50 U/kg SC 3 times a week) or darbepoetin (0.45 µg/kg once a week).
- Chemotherapy for primary MDS has been reported—hydroxyurea, cytosine arabinoside, prednisone, cyclosporine A, vincristine.
- Interferon α (cats with FeLV).

FOLLOW-UP

- Serial monitoring of CBC for resolution of cytopenias.
- Prognosis dependent on primary versus secondary.
- Increasing blast percentage, multiple cytopenias, marked cellular atypia are poor prognostic factors for patients with primary MDS.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- Do not use chemotherapy in pregnant or nursing animals.
- It is not recommended to breed animals with cancer.

SEE ALSO

- Feline Immunodeficiency Virus Infection
- Feline Leukemia Virus Infection
- Myeloproliferative Disorders

ABBREVIATIONS

- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus
- MDS = myelodysplastic syndromes

Consulting Editor Timothy M. Fan

MYELOMALACIA, SPINAL CORD (ASCENDING, DESCENDING)

BASICS

OVERVIEW

- Acute, progressive, ischemic, or hemorrhagic necrosis of the spinal cord after acute spinal cord injury (SCI).
- First appears at the site of injury; then progresses both cranially and caudally.
- Death is caused by respiratory paralysis once the intercostal and phrenic nerves become affected.
- Prevalence is about 10% in dogs with acute paraplegia and loss of pain perception following acute intervertebral disc herniation (IVDH).

SIGNALMENT

- Any age or breed.
- Because of the close association between acute (type I) IVDH and myelomalacia, chondrodystrophic breeds (such as dachshunds Cocker Spaniel, French bulldog) most commonly affected because of their predisposition to the former.

SIGNS

- **Not clinically recognizable in acute phase of SCI.**
- Acute onset of paraplegia with loss of pain sensation following spinal injury—initial clinical sign.
- Thoracolumbar injury—pelvic limbs paralysis (absent motor function) with normal to exaggerated spinal reflexes in the pelvic limbs; some dogs might present with absent spinal reflexes.
- Pain perception—usually absent caudal to the lesion.
- Spinal cord malacia—progresses to involve the lumbosacral spinal segments within 12–72 hours causing pelvic limb areflexia and atonia, absent deep pain perception in pelvic limbs and tail, dilated anus, decreased abdominal tone and flaccid, easily expressed urinary bladder; thoracic and cervical spinal cord segments may be involved within 24 hours to 10 days after the initial insult causing loss of the cutaneous trunci reflex, progression to tetraplegia, bilateral Horner syndrome, hypoventilation and death.
- Subarachnoid hemorrhage secondary to necrosis of the microvasculature in the spinal cord—may cause hyperthermia and extreme diffuse meningeal pain.

CAUSES & RISK FACTORS

- Acute intervertebral disc herniation (type I disc)
- Acute vertebral or spinal cord trauma
- Fibrocartilaginous embolisms

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cannot be differentiated from spinal shock following acute SCI (acute paralysis with

initial areflexia that improves after a few hours to days post injury).

- Diagnosis based on hind limb upper motor neuron paralysis with absent nociception that progresses to a lower motor neuron paralysis and a rostrally advancing line of analgesia and cutaneous trunci reflex.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal, initially.
- Road accident—nonspecific abnormalities related to other organ injury.
- After condition has developed, degenerative left-shift caused by massive spinal cord necrosis may occur.

OTHER LABORATORY TESTS

Serum glial fibrillary acidic protein (GFAP)—elevated; experimental test not widely available and requiring spectrophotometry.

IMAGING

- Spinal survey radiography—evidence of calcified, herniated disc, narrowed intervertebral disc space; vertebral fracture or luxation.
- Myelography—cord compression; edema; contrast medium infiltration into the spinal parenchyma.
- MRI—parenchymal T1 hypointensity, T2 hyperintensity (suggestive if length of the hyperintense region is more than 6 times the length of L2 vertebrae on T2W sagittal view), extensive spinal cord swelling; associated with other evidence of spinal injury.

DIAGNOSTIC PROCEDURES

Cerebellomedullary cistern CSF—unspecific results related to stage of development of clinical ascending/descending myelomalacia; neutrophilic pleocytosis, hemorrhagic xanthochromia (yellow discoloration) and high protein concentration can be present.

PATHOLOGIC FINDINGS

Extensive necrosis with ischemic changes, neutrophils and macrophages infiltration, multifocal hemorrhages with necrotic blood vessels, swollen axons and neuronal degeneration.

TREATMENT

- None to reverse spinal cord damage and stop disease progression.
- Rapid spinal cord decompression—indicated for IVDH but myelomalacia cannot be reliably diagnosed in the acute phase of SCI; delaying surgical treatment on a dog with complete sensorimotor loss can significantly alter its chances of recovery; owners should be informed of the risk of development of myelomalacia postoperatively despite rapid decompression.
- Strong suspicion of

myelomalacia—poor outcome, consider euthanasia.

MEDICATIONS

DRUG(S)

- Therapy is controversial.
- Pain medications; gabapentin (10 mg/kg q8h), opioids (fentanyl, hydromorphone) to relieve pain associated with SCI.

CONTRAINdications/POSSIBLE INTERACTIONS

- Gabapentin may cause sedation.
- Common opioids side effects include sedation, nausea, constipation, dysphoria.

FOLLOW-UP

- In rare cases, condition progresses only caudally; paralysis is permanent, but respiratory compromise does not occur.
- Reported after decompressive hemilaminectomy or laminectomy, suggesting that surgery does not prevent its occurrence.

MISCELLANEOUS

SEE ALSO

Intervertebral Disc Disease, Thoracolumbar

ABBREVIATIONS

- CSF = cerebrospinal fluid
- IVDH = intervertebral disc disease
- MRI = magnetic resonance imaging
- SCI = spinal cord injury

MYELOPATHY—PARESIS/PARALYSIS—CATS

BASICS

DEFINITION

- Myelopathy—any disease affecting the spinal cord; can cause paralysis (complete loss of voluntary movements) or paresis (weakness) that may affect all four limbs (tetraparesis/plegia), the pelvic limbs (para-only, the ipsilateral front and pelvic limbs (hemi-), or one limb (mono-). • Paresis/paralysis can also be caused by neuromuscular disorders.

PATHOPHYSIOLOGY

- Myelopathy—can affect gray or white matter of the spinal cord or, most often, both.
- Lesions of the ascending white matter tracts—affect sensory modalities such as touch, pressure, proprioception, pain, and temperature sensation below the level of the lesion.
- Lesions of the descending white matter tracts—affect the motor pathways producing signs of upper motor neuron disorder. The upper motor neurons cell bodies are located in the brain; they control voluntary activity and have inhibitory function on the lower motor neurons. Signs of upper motor neuron disease include paresis/paralysis, normal to increased muscle tone (hypertonia), and normal to exaggerated spinal reflexes (hyperreflexia) below the level of the lesion.
- Lesions in the gray matter of the spinal cord—affect sensory and motor functions of the region innervated by the nerves whose cell bodies are located in the gray matter. The motor nerves in the gray matter of the spinal cord are also called lower motor neurons. Signs of lower motor neuron disease include paresis/paralysis, decreased or absent muscle tone (hypo- or atonia), atrophy of the muscles innervated by that segment, and, reduced or absent spinal reflexes (hypo- or areflexia).

SYSTEMS AFFECTED

Nervous

GENETICS

- Lysosomal storage diseases—gangliosidosis GM1/GM2, sphingomyelinosis (Niemann-Pick disease), mucopolysaccharidosis VI (MPS VI), and glycogenosis type IV cause paresis or paralysis in cats; autosomal recessive pattern of inheritance.
- Neuroaxonal dystrophy and spinal muscular atrophy—degenerative diseases of the spinal cord reported as autosomal recessive conditions.
- Syringohydromyelia/myelodysplasia may be associated with sacrocaudal (sacrococcygeal) dysgenesis—autosomal dominant condition in Manx cats.

SIGNALMENT

Breed Predilections

- Gangliosidosis GM1/GM2—Siamese, Burmese, Korat cats, and DSH. • Glycogen

storage disease type IV—Norwegian forest cats. • Spinal muscular atrophy—Maine Coon. • Syringohydromyelia/myelodysplasia—Manx and Manx crosses with sacrocaudal dysgenesis.

- Sphingomyelinosis (Niemann-Pick disease)—Siamese, Balinese, and DSH.
- Mucopolysaccharidosis type VI—Siamese and DSH. • Mucopolysaccharidosis type VII—DSH. • Idiopathic complex polysaccharide storage disease—Abyssinians.
- Neuroaxonal dystrophy—Siamese and DSH.

SIGNS

- Signs vary with location and severity of lesion.
- Cervical lesion—all limbs or ipsilateral limbs affected with proprioceptive ataxia and tetraparesis/plegia, hemiparesis/plegia; normal to increased reflexes and tone; ± neck pain; ± ipsi-/bilateral Horner's syndrome; ± urinary incontinence with bladder difficult to express; increased urethral sphincter tone and tense bladder.
- Cervicothoracic lesion—all limbs or ipsilateral limbs affected with proprioceptive ataxia and tetraparesis/plegia, hemiparesis/plegia; hypo-/areflexia, hypo-/ataxia and muscle atrophy in front limbs with normal to increased reflexes and tone in pelvic limbs; ± neck pain; ± ipsi-/bilateral Horner's syndrome; ipsi-/bilateral decreased/absent cutaneous trunci reflex; ± urinary incontinence with bladder difficult to express; increased urethral sphincter tone and tense bladder.
- Thoracolumbar lesion—normal front limbs; both hind limbs or ipsilateral hind limb affected with proprioceptive ataxia and paraparesis/plegia; normal to increased reflexes and tone; ± thoracolumbar pain; ± decreased/absent cutaneous trunci reflex below the lesion; ± decreased/absent sensation below lesion; ± Schiff-Sherrington posture; ± urinary incontinence with bladder difficult to express, increased urethral sphincter tone and tense bladder.
- Lumbosacral lesion—normal front limbs; hind limbs or ipsilateral hind limb affected with proprioceptive ataxia and paraparesis/plegia or monoparesis/plegia; hypo-/areflexia; hypo-/ataxia; muscle atrophy; ± regional pain; ± urinary and fecal incontinence, large and flaccid bladder easy to express, decreased urethral sphincter tone; ± decreased or absent tail and anal tone; ± decreased or absent sensation below lesion.

CAUSES

- Degenerative and/or inherited—neuroaxonal or neuronal dystrophy, spinal muscular atrophy, storage diseases (gangliosidosis GM1/GM2, sphingomyelinosis, glycogenosis type IV, idiopathic complex polysaccharide storage disease, and mucopolysaccharidosis type VI) and spinal dural ossification.
- Anomalous—syringohydromyelia, myelodysplasia, meningocele or meningomyelocele, and

tethered spinal cord often associated with sacrocaudal dysgenesis, spinal arachnoid cyst, spinal intradural epithelial cyst, spinal dermoid cyst/sinus. • Metabolic—hypervitaminosis A, nutritional secondary hyperparathyroidism, cobalamin deficiency-associated myelopathy.

- Neoplastic—lymphoma, vertebral column neoplasia (osteosarcoma, fibrosarcoma, plasma cell tumor, and chondrosarcoma), meningiomas, sarcomas, histiocytic tumors, glial tumors (astrocytoma, oligodendrogioma, gliomatosis cerebri), primitive neuroectodermal tumors, peripheral nerve sheath tumors, and metastatic tumors.

• Inflammatory or infectious—FIP, Borna virus (Europe), bacterial meningomyelitis, fungal meningomyelitis (*Cryptococcus neoformans*, *Coccidioides immitis*, *Histoplasma capsulatum*), *Toxoplasma gondii* meningomyelitis, eosinophilic meningomyelitis, idiopathic poliomyelitis, and FeLV-associated myelopathy.

- Traumatic—vertebral fractures/luxations and penetrating wounds (bite wounds, BB pellets, microchips); intervertebral disc disease.
- Vascular—ischemia or infarct of unknown etiology, fibro-cartilaginous embolisms, ischemic myelopathy secondary to hyaline arteriopathy, intraosseous vascular malformations, and myelopathy secondary to aortocaval fistula.

RISK FACTORS

- Outdoor cats—at risk for traumatic and infectious myelitis.
- FeLV-positive cats—at risk for lymphoma and FeLV-associated myelopathy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiate from other disease processes that can cause paresis/paralysis—ischemic neuromyopathy caused by arterial thromboembolism, and peripheral neuromuscular diseases such as diabetic neuropathy, polyradiculoneuritis, hypokalemic myopathy, muscular dystrophy, polymyositis, and myasthenia gravis.

CBC/BIOCHEMISTRY/URINALYSIS

- Often normal. • Various nonspecific abnormalities can be found associated with infectious myelitis and lymphoma.
- Lysosomal storage diseases—abnormal accumulation of products of cell metabolism can be seen within the cytoplasm of peripheral leukocytes.

OTHER LABORATORY TESTS

- Serology—FeLV/FIV, *Cryptococcus neoformans*, *Coccidioides immitis*, *Histoplasma capsulatum*, and *Toxoplasma gondii*. • Latex agglutination test—*Cryptococcus neoformans* (serum or cerebrospinal fluid).
- α-Acid

(CONTINUED)

glycoprotein (AGP) can be used as a discriminating marker for FIP when coupled with other high-risk factors. • Urine metabolic screening for lysosomal storage diseases. • Genetic test for glycogen storage disease type IV in Norwegian forest cats, mucopolysaccharidoses type VI and VII, GM2 in Burmese and related breeds, GM1 and GM2 in Korat cats, spinal muscular atrophy in Maine Coon.

IMAGING

- Spinal radiography—may reveal congenital or acquired (MPS VI) vertebral malformations, discospondylitis, vertebral fractures and luxations, bony tumors, and radiographic signs suggestive of intervertebral disc disease.
- Myelography—may reveal extradural compression consistent with intervertebral disc disease or tumor, or intradural-extramedullary tumors.
- CT—more sensitive than radiography for diagnosis of discospondylitis, vertebral fractures, and bony tumors; may reveal syringomyelia and intramedullary tumors.
- MRI—more sensitive than CT for diagnosis of intramedullary tumors, inflammatory/infectious and vascular diseases, and anomalies, such as syringomyelia, myelodysplasia, meningocele or meningomyelocele, tethered spinal cord, spinal arachnoid cyst, spinal intradural epithelial cyst, and spinal dermoid cyst/sinus.

DIAGNOSTIC PROCEDURES

Cerebrospinal Fluid

- To confirm an inflammatory process affecting meninges and/or spinal cord.
- Elevated total nucleated cell count and proteins suggest an inflammatory process affecting meninges and/or spinal cord; should be examined for fungal and bacterial organisms.
- Other laboratory tests performed on CSF—latex agglutination test for *Cryptococcus neoformans*; ELISA for *Cryptococcus neoformans* and *Histoplasma capsulatum*; PCR for feline coronavirus and *Toxoplasma gondii*; bacterial and fungal culture.

Electrodiagnostics

Electromyography, nerve conduction velocity, repetitive stimulations—help differentiating paresis/paralysis caused by a myelopathy from peripheral neuromuscular disorders.

TREATMENT

APPROPRIATE HEALTH CARE

- Emergency evaluation and possible surgery—when a traumatic cause of paresis/paralysis is suspected.
- Inpatient medical management—for severe neurologic deficits such as paralysis and urinary incontinence.

NURSING CARE

- Non-ambulatory cats should be confined to a soft padded crate or enclosed area, kept dry and clean, and turned every 6 hours if they are not able to assume a sternal position.
- If there is urinary incontinence, the bladder should be expressed every 6–8 hours.
- Prevent/treat decubital ulcers and urine scalding.
- Treat constipation.
- Physical therapy is useful to prevent muscle atrophy and contractures and to keep the joints flexible, especially for postoperative rehabilitation in vertebral trauma or intervertebral disc disease.

ACTIVITY

Restricted—especially when a traumatic cause of paresis/paralysis is suspected, but also to prevent trauma secondary to paresis/paralysis.

CLIENT EDUCATION

If the cat is treated as an outpatient, discuss all aspects of nursing care and possible complications with the client.

SURGICAL CONSIDERATIONS

Surgical management—for vertebral fractures and luxations, intervertebral disc disease, and some neoplasms.

MEDICATIONS

DRUG(S) OF CHOICE

- Not recommended until a diagnosis has been established.
- Spinal trauma—methylprednisolone sodium succinate administered within 8 hours from injury, 30 mg/kg as slow IV bolus followed by 15 mg/kg IV, 2 and 6 hours later, followed by CRI at 2.5 mg/kg/h for 42 hours.

CONTRAINdicATIONS

Corticosteroids—contraindicated when an infectious disease is suspected; may also alter CSF, MRI, or CT results, precluding reaching a diagnosis.

FOLLOW-UP

PATIENT MONITORING

Repeat neurologic examination—frequency determined by the severity and progression of the neurologic status.

POSSIBLE COMPLICATIONS

- Urinary infection
- Urine scalding
- Constipation or fecal incontinence
- Muscle atrophy and contractures
- Decubital ulcers

MISCELLANEOUS

SEE ALSO

Schiff-Sherrington Phenomenon

AGE-RELATED FACTORS

- Cats < 2 years—myelopathies often caused by anomalous or inherited, inflammatory, or infectious, metabolic, and traumatic diseases.
- FIP is the most important cause of myelopathy in this age group.
- Cats 2–8 years—LSA, FIP, and trauma important causes of myelopathy.
- Cats > 8 years—vascular and neoplastic diseases more common, especially LSA and vertebral tumors.

ZOONOTIC POTENTIAL

Toxoplasma gondii infections represent a zoonotic potential.

ABBREVIATIONS

- CSF = cerebrospinal fluid
- CT = computed tomography
- ELISA = enzyme-linked immunosorbent assay
- FeLV = feline leukemia virus
- FIP = feline infectious peritonitis
- FIV = feline immunodeficiency virus
- LSA = lymphoma
- MPS = mucopolysaccharidosis
- MRI = magnetic resonance imaging

M

MYELOPROLIFERATIVE DISORDERS

BASICS

OVERVIEW

- Unregulated neoplastic proliferation of nonlymphoid cells originating in the bone marrow (granulocytic, monocytic, erythrocytic, and megakaryocytic cells) resulting in accumulations of differentiated cells.
- Includes polycythemia vera, chronic myelogenous leukemia, essential thrombocythemia, and possibly primary myelofibrosis.
- Believed to represent a spectrum of disorders in which the stem cell involved is a hematopoietic precursor capable of differentiating into all blood cell types except lymphocytes.

SIGNALMENT

- Cat and dog—more common in cat
- May be more common in large-breed dogs than small-breed dogs

SIGNS

- Pale mucous membranes
- Petechiation
- Lethargy
- Inappetance
- Weight loss
- Hepatosplenomegaly
- Peripheral lymphadenomegaly—occasionally
- Neurologic signs—disorientation, ataxia, seizure

CAUSES & RISK FACTORS

- Cats—most commonly associated with FeLV infection; when recovering from panleukopenia or hemobartonellosis, may be a relatively higher risk of developing a mutant cell line induced by FeLV.
- Dogs—has been experimentally induced with chronic low-dose radiation exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute lymphocytic leukemia—usually differentiated by special staining techniques (immunohistochemistry or immunocytochemistry for lymphoid markers) or PARR.
- Leukemoid response secondary to inflammation.

- Other causes of eosinophilia—parasitism; allergic disease; eosinophilic gastroenteritis; mast cell neoplasia; differentiate from eosinophilic leukemia.

- Relative and secondary absolute polycythemia.
- Reactive thrombocytosis—secondary to inflammation, hemolytic or iron deficiency anemia, splenectomy, rebound from immune-mediated thrombocytopenia, and drug-induced (e.g., vincristine).

CBC/BIOCHEMISTRY/URINALYSIS

- Severe, nonregenerative anemia
- Severe elevated hematocrit in cases of primary polycythemia vera
- Circulating nucleated red blood cells
- Megaloblastic erythrocytes
- Leukocytosis or leukopenia
- Thrombocytopenia with abnormal platelet morphology
- Thrombocytosis in cases of essential thrombocythemia
- Circulation of immature myeloid cells

OTHER LABORATORY TESTS

- Examination of bone marrow aspirate or core biopsy—reveals hypercellular bone marrow with abnormal morphology in all cell lines; neoplastic proliferation or absence of one cell line.
- Immunohistochemical or other special stains—may be necessary to determine cell lineage.

IMAGING

Abdominal radiography and ultrasonography—hepatomegaly and splenomegaly common.

DIAGNOSTIC PROCEDURES

Examination of bone marrow aspirates or core biopsy

TREATMENT

- Outpatient or inpatient.
- Supportive care—blood transfusions and fluid administration to correct dehydration.
- Therapeutic phlebotomies.
- Radiophosphorus (^{32}P) has been effective in cases of polycythemia vera and essential thrombocythemia but there are limited facilities that can offer this therapy.
- Seek consultation from a veterinary oncologist regarding treatment.

MEDICATIONS

DRUG(S)

- Little information available in the literature regarding treatment.
- Cytosine arabinoside—may be used; $100 \text{ mg/m}^2 \text{ SC}$ divided q12h 4 days per week, or as a constant rate infusion over 6–8 hours at a dose of 400 mg/m^2 .
- Hydroxyurea $30\text{--}45 \text{ mg/kg q24h}$ for 7–10 days; then $30\text{--}45 \text{ mg/kg q48h}$ or 15 mg/kg q24h ; essentially, titrate dosage to patient response.
- Antibiotics—may be indicated to combat secondary infection.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Chemotherapy can be toxic; seek advice before treatment if unfamiliar with cytotoxic drugs.

FOLLOW-UP

- Complete blood count and examination of bone marrow aspirate—determine response to treatment and progression of disease.
- Prognosis—guarded.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- Chemotherapy drugs are contraindicated in pregnant animals.
- It is not recommended to breed animals with neoplasia.

ABBREVIATIONS

- FeLV = feline leukemia virus
- PARR = polymerase chain reaction for antigen receptor rearrangement

Suggested Reading

MYOCARDIAL INFARCTION

BASICS

OVERVIEW

- Rapid development of myocardial necrosis resulting from sustained, complete reduction of blood flow to a portion of the myocardium, caused by thrombus formation.
- Uncommon as a naturally occurring disease in dogs. • Microscopic intramural myocardial infarctions and focal areas of myocardial fibrosis are common in dogs with acquired cardiovascular disease. • Consistent ECG characteristics of spontaneous myocardial infarction are not well characterized in dogs and cats.

SIGNALMENT

Rare in dog and cat

SIGNS

Historical Findings

- Lethargy • Anorexia • Weakness • Dyspnea
- Collapse • Vomiting • Obesity • Unexpected death

Physical Examination Findings

- Lameness • Tachycardia • Heart murmur
- Cardiac rhythm disturbances • Low-grade fever

CAUSES & RISK FACTORS

- Atherosclerosis and coronary artery disease
- Nephrotic syndrome • Vasculitis
- Hypothyroidism • Bacterial endocarditis
- Neoplasia • Septicemia • Intramural coronary arteriosclerosis in old dogs
- Subvalvular aortic stenosis

Cats

- Cardiomyopathy • Thromboembolism

DIAGNOSIS

Generally presumptive, based on acute onset of signs in a patient with predisposing factors

and consistent ECG changes (ST segment changes).

DIFFERENTIAL DIAGNOSIS

Other Causes of ST Segment Changes

- Normal variation • Myocardial ischemia/hypoxia • Hyperkalemia or hypokalemia
- Digitalis toxicity • Trauma to the heart
- Pericarditis • Artifact—wandering baseline

Other Causes of Weakness and Collapse

- Trauma • Neurologic disease • Thromboembolism • Pericardial effusion • Arrhythmia

CBC/BIOCHEMISTRY/URINALYSIS

- Mild leukocytosis • High liver enzymes
- Hyperlipidemia—if animal is hypothyroid
- High amylase • High creatine kinase and cardiac isoenzymes

OTHER LABORATORY TESTS

Low T_4 and T_3

IMAGING

- Echocardiography—2-D and M-mode echocardiography useful in evaluating wall motion abnormalities and overall left ventricular function.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

- Sudden deviation of the ST segment • Tall peaked T waves—first few hours • Sudden development of Q waves or a change in direction of the T wave • Axis shift of the frontal plane • Low-voltage QRS complexes
- Sudden development of bundle branch block or heart block • Sudden onset of ventricular arrhythmias because of myocardial ischemia • Sloppy “R” wave descent may be associated with intramural myocardial infarction

TREATMENT

- Treat the underlying disorder; likewise the symptomatic therapy (e.g., congestive heart failure). • Must identify and immediately treat life-threatening arrhythmias.

Figure 1.

Transmural infarction of the left ventricle in a dog with arteriosclerosis and hypothyroidism. The first three rapid successive complexes represent ventricular tachycardia. The sinus rhythm that follows illustrates small complexes, marked elevation of the S-T segment, and first-degree AV block (prolonged P-R interval). (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

MEDICATIONS

DRUG(S)

- Thrombolytic agents, IV—(e.g., streptokinase); cost prohibitive and lack of experience with myocardial infarction in veterinary medicine with dosage and use.
- Lidocaine for ventricular arrhythmias.
- Beta-blockers—use cautiously with dilated cardiomyopathy because of possible development of low-output CHF. • Antithrombotic agents (e.g., dalteparin; low molecular weight heparin, heparin and aspirin).

FOLLOW-UP

- Determined by clinical status and diagnosis of underlying disorder. • Monitor anticoagulated patient; CBC and bleeding profiles, including fibrinogen.

MISCELLANEOUS

ABBREVIATIONS

- CHF = congestive heart failure • ECG = electrocardiogram • T_3 = triiodothyronine
- T_4 = thyroxine

Consulting Editors Larry P. Tilley and Francis W.K. Smith, Jr.

MYOCARDIAL TUMORS

BASICS

OVERVIEW

- Primary and metastatic myocardial tumors are rare tumors in dogs and cats.
- Incidence 0.19% in dogs and 0.03% in cats.
- Reported primary tumors include hemangiosarcoma, ectopic thyroid carcinoma, lymphoma, rhabdomyoma, rhabdomyosarcoma, thymoma, mesothelioma, chondrosarcoma, osteosarcoma, fibrosarcoma, myxoma, myxosarcoma, lipoma, peripheral nerve sheath tumor, granular cell tumor.

SIGNALMENT

- Dog and cat—but less common in cat.
- In dog—any age but more common between 7 and 15 years.
- Possible increased incidence in neutered animals.
- Increased incidence in saluki, French bulldog, Irish water spaniel, flat-coated retriever, golden retriever, boxer, Afghan hound, English setter, Scottish terrier, Boston terrier, bulldog, German shepherd dog.

SIGNS

- Sudden collapse
- Abdominal distention
- Exercise intolerance
- Dyspnea
- Anorexia
- Vomiting
- Diarrhea
- Acute death

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Idiopathic pericardial effusion
- Pericarditis
- Cardiomyopathy
- Heart failure
- Valvular disease
- Heart base tumors

CBC/BIOCHEMISTRY/URINALYSIS

Anemia in some patients

OTHER LABORATORY TESTS

Serum/plasma cardiac troponin I levels are increased in patients with cardiac hemangiosarcoma and might have utility for the detection of other myocardial neoplasms.

IMAGING

- Thoracic radiography—may reveal a globoid heart suggestive of pericardial effusion, masses in the area of the atria, or metastatic lesions in the lungs.
- Echocardiography—helpful in finding primary masses—positive predictive value of 92%, negative predictive values 64%.

DIAGNOSTIC PROCEDURES

- Pericardiocentesis and fluid evaluation—helpful in diagnosis of lymphoma.
- Cytology of pericardial effusion limited in usefulness in differentiating neoplastic from non-neoplastic effusions.
- ECG—may be normal or display a variety of arrhythmias, may see electrical alternans and small complexes with pericardial effusion.
- Surgical biopsy of mass—if possible.

TREATMENT

- Surgical removal of mass—if possible
- Pericardectomy—may offer relief of pericardial effusion
- Address concern for sudden death with owner

MEDICATIONS

DRUG(S)

- Management of arrhythmias—lidocaine (dogs) 2–4 mg/kg IV (to a maximum 8 mg/kg over 10-minute period), CRI—25–75 µg/kg/minute IV, mexiletine (dogs) 5–8 mg/kg PO q8–12h, sotalol 1–2 mg/kg PO q12h.
- Chemotherapy dependent on tumor type (see Lymphoma and Hemangiosarcoma chapters).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Chemotherapy can cause gastrointestinal, bone marrow, cardiac, and other

toxicities—seek advice if unfamiliar with cytotoxic drugs.

FOLLOW-UP

- Serial echocardiograms—to monitor tumor response to chemotherapy.
- Thoracic radiography and abdominal ultrasonography—to monitor for metastatic disease progression.
- ECG—to monitor response to anti-arrhythmogenic medications.
- Blood tests—especially CBC to monitor for bone marrow suppression secondary to chemotherapy.
- Prognosis—guarded to poor.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- It is not recommended to breed animals with cancer.
- Chemotherapy is teratogenic—do not give to pregnant animals.

SEE ALSO

- Chemodectoma
- Hemangiosarcoma, Heart
- Lymphoma—Cats
- Lymphoma—Dogs

MYOCARDITIS

BASICS

DEFINITION

- Inflammation of the heart muscle, often caused by infectious agents affecting the myocytes, interstitium, vascular elements, or pericardium.
- Viral, bacterial, rickettsial, fungal, and protozoal diseases are all associated with myocardial inflammation (i.e., myocarditis).
- Pharmacologic agents (e.g., doxorubicin) can also be causative.

PATHOPHYSIOLOGY

- Mechanisms—toxin production, direct invasion of myocardial tissue, and immune-mediated myocardial damage; vasculitis associated with systemic disease; allergic reactions and direct myocyte damage caused by pharmacologic agents. Protozoa (e.g., *Trypanosoma cruzi*) lead to granulomatous myocarditis; viral myocarditis is associated with cell-mediated immunologic reactions.
- Myocardial involvement may be focal or diffuse. Clinical manifestations depend on the extent of the lesions. Diffuse, severe involvement may lead to global myocardial damage and CHF; discrete lesions involving the conduction system may cause profound arrhythmias.

SYSTEMS AFFECTED

- Systemic organ involvement depends on the causative agent
- Cardiovascular—myocardial failure or arrhythmias
- Respiratory—if pulmonary edema develops

INCIDENCE/PREVALENCE

- Viral myocarditis (e.g., parvovirus, distemper virus, and herpesvirus)—rare; very young puppies in their first months of life may be profoundly affected; in a second form (parvoviral), dilated cardiomyopathy develops in dogs 5–6 months of age that were infected during their first weeks of life.
- Protozoal myocarditis associated with *T. cruzi* (i.e., Chagas disease) reported in dogs < 2 years old from the southeastern United States. Males are more commonly affected than females.
- Toxoplasma gondii* occasionally causes myocarditis. Immunosuppressed animals (e.g., cats with feline leukemia virus) are at high risk.
- Hepatozoon canis* reported in dogs living in the Texas Gulf region.
- Fungal myocarditis—primarily seen in association with systemic fungal infection; myocardial involvement varies with regional prevalence and prevalence of the systemic manifestation.
- Bacterial myocarditis—can be caused by generalized sepsis and bacteremia.
- Doxorubicin cardiotoxicity—reported in dogs receiving cumulative doses = 150–240 mg/m².
- Spirochetal myocarditis associated with *Borrelia burgdorferi*—documented in 10% of humans with Lyme disease; incidence and prevalence in dogs not well documented.

GEOGRAPHIC DISTRIBUTION

Suspect myocarditis associated with infectious agents wherever these diseases are endemic (see above).

SIGNALMENT

Species

Dog and cat

Mean Age and Range

Viral myocarditis—seen primarily in animals < 1 year of age

SIGNS

General Comments

- Related to the degree and location of myocardial involvement.
- Range from those of arrhythmias to those of CHF.
- Onset of cardiac dysfunction in association with systemic illness or the use of specific pharmacologic agents is often the hallmark of myocarditis.

Historical Findings

- Coughing, exercise intolerance, dyspnea—associated with CHF.
- Syncope and weakness—associated with arrhythmias.
- Concurrent systemic manifestations—often seen with infective myocarditis.
- Use of antineoplastic or other pharmacologic agents—associated with the onset of cardiac dysfunction.

Physical Examination Findings

- Gallop rhythm or murmur may be found—depends on the nature of the myocardial damage.
- Arrhythmias—may be auscultated.
- Fever—common in patients with active infection associated with myocarditis.

CAUSES

- Virus (e.g., parvovirus, distemper virus, herpesvirus, West Nile virus).
- Protozoa (e.g., *Trypanosoma cruzi*, *Toxoplasma gondii*, *Neospora caninum*, *Hepatozoon Canis*, *Babesia* spp., and *Leishmania* spp.).
- Bacteria (e.g., *Bartonella vinsonii* subsp. *Berkhoffii*).
- Fungus (e.g., *Cryptococcus neoformans*, *Coccidioides immitis*, *Blastomycetes dermatitidis*, and *Aspergillus terreus*).
- Algae (e.g., *Prototricha* spp.).
- Doxorubicin.

RISK FACTORS

- Exposure to infectious agents
- Use of myocardiotoxic compounds
- Immunosuppression
- Debilitating diseases

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Always consider preexisting heart disease, including congenital defects, cardiomyopathy, and acquired valvular disease.
- History of a heart murmur or the presence of arrhythmias before onset of systemic illness helps differentiate from other diseases.
- Extracardiac organ involvement and identification of infectious agents may aid in the diagnosis.

CBC/BIOCHEMISTRY/URINALYSIS

Abnormalities—vary, depending on organ involvement.

OTHER LABORATORY TESTS

- Serologic tests to help identify an infectious agent.
- Cytologic examination of pericardial, pleural, and peritoneal effusions to identify the infectious organism.
- Blood culture to diagnose bacteremia.
- Troponin—levels may be high.

IMAGING

Thoracic Radiographic Findings

- Cardiac silhouette may appear large or normal depending on the extent of involvement.
- Pulmonary edema, congestion, or pleural effusion in patients with CHF.
- Globoid heart in some animals with pericardial effusion.
- Pulmonary granuloma may be found in animals with granulomatous myocardial infection.

Echocardiographic Findings

- Reflect the extent of myocardial damage; may be normal if lesions are small or primarily affect the conduction system.
- Pericardial effusion in some patients; pericardium may appear thickened and hyperechoic, depending on the extent of pericardial involvement.
- Myocardium may appear mottled with patchy areas of hyperechogenicity caused by myocardial inflammation, fibrosis, or granulomas.
- Regional dyskinesis caused by focal involvement may be appreciated on 2-D echocardiography.

Angiography

- Because of the quality and non-invasive nature of echocardiography, cardiac catheterization is rarely indicated for the diagnosis.
- May use angiography to detect specific chamber involvement or pericardial effusion, if echocardiography is not available.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

- Heart enlargement patterns in some patients—depending on the extent of chamber involvement.
- Arrhythmias—include both atrial and ventricular tachyarrhythmias.
- Differentiate right and left bundle branch blocks and hemiblocks from ventricular enlargement patterns.
- Atrioventricular nodal conduction disturbances in some patients.

Endomyocardial Biopsy

- Useful for detection of infectious agents (e.g., protozoa, fungal elements) or inflammatory cell infiltrates.

Pericardiocentesis

- Alleviates pericardial effusion.
- Submit fluid for cytologic examination and possible bacterial culture.

Holter Monitor Study

- To detect arrhythmias, frequency, and severity.
- To monitor antiarrhythmic therapy.

M

MYOCARDITIS

(CONTINUED)

PATHOLOGIC FINDINGS

- Dilated cardiac chambers with patchy areas of hyperemia, necrosis, or fibrosis.
- Granulomas seen grossly in some patients.
- Microscopic examination of the myocardium or pericardium may reveal inflammatory cells (e.g., lymphocytes, plasma cells, and macrophages), patchy fibrosis, or the infectious agents themselves.
- Myofiber dropout—seen in patients with doxorubicin toxicity.

TREATMENT

APPROPRIATE HEALTH CARE

- Hospitalize patients with CHF for initial medical management.
- Hospitalize patients with severe ventricular arrhythmias for initial antiarrhythmic therapy.
- Hospitalize patients with severe systemic manifestations for aggressive medical therapy.

ACTIVITY

Restricted

DIET

Sodium restriction if CHF

CLIENT EDUCATION

- Cardiac manifestations may persist even with resolution of systemic illness.
- Certain arrhythmias (i.e., ventricular tachyarrhythmias) may predispose to sudden death.
- Antemortem diagnosis may be difficult.
- Some infectious agents may pose a public health risk.

SURGICAL CONSIDERATIONS

Complete atrioventricular block may require pacemaker implantation.

MEDICATIONS

DRUG(S) OF CHOICE

- If a specific etiologic agent is identified, direct treatment against it.
- Tailor antiarrhythmic therapy to the predominant arrhythmia.
- Treat CHF with furosemide (1–2 mg/kg PO q6–12h), enalapril (0.25–0.5 mg/kg PO q12–24h), and digoxin (0.22 mg/m² PO q12h) or pimobendan (0.25 mg/kg PO q12h).

CONTRAINDICATIONS

Public health considerations may preclude treatment of some infectious diseases (i.e., *T. cruzi*).

PRECAUTIONS

- All antiarrhythmic drugs have proarrhythmic properties and should be monitored closely.
- Systemic organ involvement (e.g., renal involvement) may necessitate modifying drug dosages or use of various cardiac drugs; monitor systemic function carefully.

FOLLOW-UP

PATIENT MONITORING

- Antiarrhythmic therapy—frequent auscultation and ECG
- Serologic titers when appropriate
- Auscultation and follow-up radiographs—treatment of CHF
- Hemograms and serum biochemical analysis—systemic effects

PREVENTION/AVOIDANCE

- Avoid breeding animals with a poor vaccination history.
- Avoid endemic areas if possible.
- Monitor ECG and echocardiogram when using doxorubicin.

EXPECTED COURSE AND PROGNOSIS

- Depend on the extent and severity of myocardial involvement.
- Many systemic fungal and protozoal diseases do not respond well to medical management.
- Patients with extensive myocardial inflammation, degeneration, and signs of CHF—very poor prognosis.
- Patients with isolated, controllable arrhythmias—good prognosis if the underlying cause can be treated successfully.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Often accompanies systemic illness

AGE-RELATED FACTORS

Viral myocarditis—most often seen in animals < 1 year old

ZOONOTIC POTENTIAL

- Varies with infectious agent involved
- May be high with protozoal and mycotic infections

PREGNANCY/FERTILITY/BREEDING

Some viral diseases (e.g., canine herpesvirus and parvovirus) have been passed to the fetus during pregnancy.

Acknowledgment The author and editors acknowledge the prior contribution of Michael B. Lesser.

BASICS

OVERVIEW

- Involuntary, rhythmic or irregular muscle jerks. Can involve only a few adjacent muscles (focal), many or most muscles of the body (generalized), or many muscles in different jerks (multifocal) synchronously or asynchronously. • The myoclonic movements are spontaneous or activated by sensory stimulation (reflex myoclonus). • May persist during sleep. • CNS dysfunction involving segmental lower motor neurons and interneurons of the spinal cord or the brainstem. • Canine distemper virus infection—most frequent cause of myoclonus in dogs; thought to be secondary to some pacemaker activity in neurons damaged by the virus. May be caused by other encephalitides and degenerative processes affecting motor neurons.

SIGNALMENT

Acquired

- Dog and rarely cat. • No breed, sex, or age predispositions.

Congenital

- Familial reflex myoclonus—Labrador retriever and Dalmatian; develops in the first 3 weeks of life. • Spongy degeneration of either gray and/or white matter—dogs: myoclonus of the paravertebral muscles in neonate silky terrier; Samoyed at 2 weeks; Saluki at 3 months; Labrador retriever at 4–6 months. Cats—Egyptian mau at 7 weeks. Rare syndromes.

SIGNS

Historical Findings

- Canine distemper—after a bout of gastrointestinal signs, cough, and/or ocular or nasal purulent discharge; persists at rest and even during sleep or light anesthesia; consistent frequency in a given patient; distemper diagnosis may precede the myoclonus by months to years; occurs more frequently in chronic phase of distemper.
- Familial reflex myoclonus—observed when the patient starts walking; intermittent muscle contractions induced by auditory or tactile stimulus and by exercise; involves all limbs, neck, and head (e.g., the facial and masticatory muscles); patient unable to rise without assistance. • With spongy degeneration—variety of signs observed such as tremor, spasticity, opisthotonus, and myoclonus. • Chlorambucil-induced myoclonus reported in a cat with lymphoma.

Physical Examination Findings

- The patient may be otherwise healthy.
- Masticatory and appendicular muscles—most frequent affected muscles in distemper virus-induced myoclonus; may be paresis of the affected limb. • May see other signs

suggesting distemper (e.g., hard pads, ocular and nasal purulent discharge, and chorioretinitis). • Neurologic deficits suggest multifocal lesions in some patients.

CAUSES & RISK FACTORS

Congenital

- Familial in Labrador retrievers. • Spongy degeneration of unknown cause but likely inherited. • Treatment with chlorambucil in cats.

Acquired

- Canine distemper virus—the only CNS disease repeatedly associated with myoclonus in dogs; unvaccinated dogs at risk.
- Encephalitis of any cause—dogs and cats.
- Degenerative disease—especially spongy degeneration. • Described in a dog with lead poisoning. • Total intravenous anesthesia with propofol. • Intrathecal administration of morphine.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The quickness of the jerks and the absence of voluntary influence help differentiating myoclonus from other movement disorders.
- Congenital myoclonus—in neonates or during the first months of life in otherwise healthy dogs. Excitement, voluntary activity, and tactile/auditory stimuli often increase the myoclonus. • Canine distemper virus—unvaccinated dog; observed before, during, or after the acute CNS disease; more frequently observed later when the animal is otherwise healthy. Myoclonus involves one limb, more than one limb, the facial or the masticatory muscles. • Lafora disease (progressive myoclonic epilepsy)—neurodegenerative disease that can cause myoclonic jerks. Differentiated on presence of other seizure types (generalized tonic-clonic seizures) and altered mentation. • Myoclonic epilepsy—jerks usually generalized, proximal more than distal, and flexor more than extensor; exacerbated by sensory stimulus (light, noise) and voluntary movements. Other types of seizures may be present concomitantly.

CBC/BIOCHEMISTRY/URINALYSIS

- Congenital or post canine distemper virus infection—normal. • Other acquired forms—may suggest a specific cause if the patient has infectious encephalomyelitis; otherwise, normal.

IMAGING

MRI—may help determine diagnosis in acute acquired disease.

DIAGNOSTIC PROCEDURES

Acute onset—CSF analysis, serologic testing, imaging to determine the cause if other physical or neurologic signs present. Electroencephalography and

electromyography—may help differentiate myoclonic epilepsy and peripheral nervous system disease from myoclonus.

TREATMENT

- Active encephalomyelitis—inpatient; establish a diagnosis and initiate treatment.
- Exercise—as tolerated. • Diet—ensure proper nutrition with active CNS disease; modify, if necessary, with vomiting or diarrhea. • Familial reflex myoclonus—clinical signs in Labrador retriever and Dalmatian are severe and usually not compatible with quality of life.

MEDICATIONS

DRUG(S)

- With chronic, inactive canine distemper—treatment often unnecessary; alleviation may be obtained with procainamide (125–250 mg/dog PO q6–12h).
- Gabapentin reported beneficial in tremor syndrome (10–20 mg/kg q8h). • Clorazepate (0.6–2 mg/kg PO q8h)—familial reflex myoclonus; may see improvement. • Active encephalomyelitis—treat accordingly.

FOLLOW-UP

- Monitor CNS disease. • Myoclonus usually persists indefinitely; spontaneous remission may occur. • Active distemper virus infection—poor-to-grave prognosis.
- Chronic distemper—myoclonus persists but patient otherwise healthy.

MISCELLANEOUS

ABBREVIATIONS

- CNS = central nervous system • CSF = cerebrospinal fluid • MRI = magnetic resonance imaging

MYOPATHY, FOCAL INFLAMMATORY

BASICS

DEFINITION

- Masticatory—focal inflammatory myopathy affecting the muscles of mastication (temporalis, masseter, and pterygoid muscles) and sparing the limb muscles.
- Extraocular—selectively affects the extraocular muscles, sparing limb and masticatory muscles.

PATOPHYSIOLOGY

- Masticatory—suspected immune-mediated cause owing to auto-antibodies against type 2M fibers and a positive clinical response to immunosuppressive doses of corticosteroids.
- Extraocular—suspected immune-mediated cause owing to positive clinical response to corticosteroids.

SYSTEMS AFFECTED

Neuromuscular—muscles of mastication; extraocular muscles

GENETICS

- Unknown.
- As with auto-immune diseases in general, the appropriate genetic background must exist.
- Masticatory—Cavalier King Charles spaniels have a familial form and may be affected at less than 6 months of age.
- Extraocular—golden retrievers may have a genetic predisposition.

INCIDENCE/PREVALENCE

- Unknown
- Masticatory—relatively common

GEOGRAPHIC DISTRIBUTION

Probably worldwide

SIGNALMENT

Species

- Dog (common)
- Cat (rare)

Breed Predilections

- Various.
- Masticatory—rottweiler, Doberman, Samoyed, and Cavalier King Charles spaniel develop severe forms.
- Extraocular—golden retriever.

Mean Age and Range

No obvious age predisposition

Predominant Sex

None obvious

SIGNS

General Comments

Masticatory—usually related to abnormalities of jaw movement, jaw pain, and masticatory muscle atrophy; not a “tabletop” diagnosis; usually requires laboratory testing to confirm diagnosis.

Historical Findings

- Masticatory—acute or chronic pain when opening the jaw; inability to pick up a ball or

get food into the mouth; acutely swollen muscles; progressive muscle atrophy.

- Extraocular—bilateral exophthalmos.

Physical Examination Findings

- Masticatory—marked jaw pain with manipulation and/or trismus; acute muscle swelling with exophthalmos; muscle atrophy with enophthalmos; inability to open the jaw under anesthesia.
- Extraocular—bilateral exophthalmos; impaired vision.

CAUSES

Immune-mediated

RISK FACTORS

- Appropriate genetic background.
- Possible previous bacterial or viral infection.
- Vaccination may exacerbate active disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Retro-orbital abscess—probe behind last upper molar.
- Temporomandibular joint disease—radiographically abnormal joint.
- Polymyositis—high serum creatine kinase activity; generalized EMG abnormalities; diagnostic muscle biopsies.
- Neurogenic atrophy of temporalis muscles—determined by EMG and muscle biopsy.
- Atrophy of masticatory muscles from corticosteroids—history of corticosteroid use; characteristic changes on muscle biopsy.
- Atrophy of masticatory muscles from endocrine disorders—test for thyroid and adrenal disorders.

CBC/BIOCHEMISTRY/URINALYSIS

Serum creatine kinase activity—normal or mildly elevated

OTHER LABORATORY TESTS

- Muscle biopsy—diagnostic test of choice for masticatory muscle disease.
- Immunohistochemical assay—demonstrate auto-antibodies against masticatory muscle type 2M fibers in frozen muscle biopsy sections; negative in polymyositis and extraocular disease.
- ELISA—demonstrate auto-antibodies against masticatory muscle type 2M fiber proteins.

IMAGING

- Radiography of the temporomandibular joints.
- Orbital sonogram—for extraorbital disease; demonstrate swollen extraocular muscles.
- MRI—for demonstration of inflammation/myonecrosis in muscles.

DIAGNOSTIC PROCEDURES

EMG—differentiate between extraocular disease and polymyositis; abnormal masticatory muscles in masticatory myositis

only; generalized abnormalities including masticatory muscles in polymyositis.

PATHOLOGIC FINDINGS

Masticatory

- Swelling or atrophy of the masticatory muscles.
- Biopsy specimen—may see myofiber necrosis, phagocytosis, mononuclear cell infiltration with a multifocal and perivascular distribution; may see myofiber atrophy and fibrosis with chronic condition; eosinophils rare.

Extraocular

Mononuclear cell infiltration—restricted to extraocular muscles

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient

NURSING CARE

Gastrostomy tube—may be required with severe restrictions in jaw mobility; requires good hygiene and supportive care.

ACTIVITY

N/A

DIET

Masticatory—may require liquid food or gruel until jaw mobility is regained; may need a gastric feeding tube to facilitate fluid and caloric intake.

CLIENT EDUCATION

- Warn client that long-term corticosteroid therapy may be required.
- Inform client that residual muscle atrophy and restricted jaw movement may occur with chronic masticatory muscle disease.

SURGICAL CONSIDERATIONS

Not indicated

MEDICATIONS

DRUG(S) OF CHOICE

Corticosteroids—immunosuppressive dosages, tapered as jaw mobility, swelling, and serum creatine kinase activity return to normal; maintained at lowest alternate-day dosage that prevents restricted jaw mobility; treated for a minimum of 6 months.

CONTRAINdicATIONS

N/A

PRECAUTIONS

- Corticosteroids—watch for infection and undesirable side effects.
- Clinical signs may recur if treatment is stopped too soon.

POSSIBLE INTERACTIONS

N/A

(CONTINUED)

MYOPATHY, FOCAL INFLAMMATORY**ALTERNATIVE DRUG(S)**

Intolerable side effects of corticosteroids—
institute a lower dose of corticosteroids and
combine with another drug (e.g.,
azathioprine).

**FOLLOW-UP****PATIENT MONITORING**

- Masticatory—return of jaw mobility and decreased serum creatine kinase activity.
- Extraocular—decreased swelling of extraocular muscles.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Corticosteroids—undesirable side effects.
- Recurrence of clinical signs—treatment stopped too early.
- Poor clinical response—inadequate dosages of corticosteroids.
- Restrictive strabismus (extraocular myositis).
- Note position of tongue—venous congestion and tongue protrusion may occur under anesthesia.

EXPECTED COURSE AND PROGNOSIS

- Masticatory—jaw mobility should return to normal unless the condition is chronic and severe fibrosis develops; good prognosis if treated early with adequate dosages of corticosteroids.
- Extraocular—good response to corticosteroids; good prognosis unless chronic with restrictive strabismus.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Other concurrent auto-immune disorders

AGE-RELATED FACTORS

M

MYOPATHY, GENERALIZED INFLAMMATORY

BASICS

DEFINITION

- Polymyositis—a condition in which skeletal muscles are damaged by a non-suppurative inflammatory process dominated by lymphocytic infiltration. Terminology restricted to the immune-mediated form.
- Dermatomyositis—polymyositis is associated with characteristic skin lesions.

PATOPHYSIOLOGY

- Inflammation of skeletal muscles—results in muscle weakness, stiffness, myalgia, and atrophy.
- Muscle inflammation—may be a result of immune-mediated, infectious, or paraneoplastic disorders; may be a sequela to certain drug therapies.

SYSTEMS AFFECTED

- Gastrointestinal—particularly the pharyngeal and esophageal muscles, because they are composed predominantly of skeletal muscle in dogs.
- Neuromuscular—generalized muscle involvement including masticatory and limb muscles.
- Skin/Exocrine—particularly if related to a generalized immune-mediated connective tissue disorder. Skin lesions predominate over neuromuscular signs in canine dermatomyositis.

GENETICS

- Unknown.
- As for autoimmune diseases in general, the appropriate genetic background must exist.
- Familial form of autoimmune polymyositis in Newfoundland and Vizsla.
- Dermatomyositis—reported to have an autosomal dominant inheritance pattern in rough-coated collie and Shetland sheepdog.

INCIDENCE/PREVALENCE

- Unknown.
- Generalized inflammatory myopathies—not common but recognition may be increasing.

GEOGRAPHIC DISTRIBUTION

Probably worldwide

SIGNALMENT

Species

Dog and rarely cat

Breed Predilections

- Polymyositis—various breeds of dogs and cats may be affected; breed-associated in Newfoundland, boxer, and Vizsla.
- Dermatomyositis—reported in rough-coated collie, Shetland sheepdog, and Australian cattle dog.

Mean Age and Range

- Polymyositis—none obvious
- Dermatomyositis—3–5 months of age

Predominant Sex

None obvious

SIGNS

General Comments

- Polymyositis—usually associated with a stiff-stilted gait, variable myalgia, and/or muscle weakness. May see regurgitation and megaesophagus.
- Elevated serum creatine kinase activity—supports but does not make the diagnosis of myositis. Do not rule out polymyositis if creatine kinase activity normal.
- Muscle biopsy—needed to confirm the diagnosis.

Historical Findings

- Stiff-stilted gait—acute or chronic
- Muscle swelling and/or atrophy
- Variable muscle pain
- Generalized muscle weakness and exercise intolerance
- Regurgitation of food or difficulty swallowing

Physical Examination Findings

- Variable pain upon palpation of muscle groups
- Generalized muscle atrophy, including the muscles of mastication
- Gait abnormalities, including a stiff-stilted gait
- Neurologic examination—not abnormal; may be a decreased gag reflex if the pharyngeal muscles are affected
- Dermatomyositis (dogs)—typical skin lesions

CAUSES

- Immune-mediated
- Infectious—*Toxoplasma gondii*; *Neospora canis*; *Sarcocystis spp*; tick-related diseases, bacterial infection uncommon
- Drug-induced
- Paraneoplastic or pre-neoplastic syndrome

RISK FACTORS

- Appropriate genetic background
- Possibly previous bacterial or viral infection
- Neoplasia, possibly occult
- Exposure to ticks

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Polyarthritis—differentiated by physical examination and evaluation of joint fluid.
- Noninflammatory muscle disorders—differentiated by muscle biopsy.
- Polyneuropathy—differentiated by neurologic examination, electrophysiology, and muscle and peripheral nerve biopsies.
- Chronic intervertebral disc disease—differentiated by neurologic examination and serum creatine kinase activity.
- Myasthenia gravis—differentiated by positive AChR antibody titer.

CBC/BIOCHEMISTRY/URINALYSIS

Serum creatine kinase activity—variably elevated

OTHER LABORATORY TESTS

- Serum antinuclear antibody titer—may be positive in connective tissue disorders.
- May see concurrent hypothyroidism.
- Cardiac troponin I—may have concurrent myocarditis.

IMAGING

- Regurgitation—evaluate thoracic radiography for esophageal dilatation, neoplasia.
- Cardiac silhouette—evaluate myocardial size and shape.
- Pharyngeal weakness—perform a dynamic study for the evaluation of the swallowing process.

DIAGNOSTIC PROCEDURES

- Muscle biopsy—single most important test for diagnosing polymyositis; sample multiple muscles, because condition may be missed if distribution is patchy.
- Echocardiograph—evaluate myocardial function.
- Electrodiagnostic evaluation (EMG, measurement of nerve conduction velocity)—performed to determine the distribution of muscle involvement and the muscles to be biopsied; should help differentiate myopathic from neuropathic causes of muscle weakness.

PATHOLOGIC FINDINGS

- Muscle swelling or atrophy.
- Biopsy specimens—usually contain mononuclear cell infiltrates.
- Rare neutrophils or eosinophils—may be noted.
- Regenerating myofibers—may be observed.
- Intramyofiber parasite cyst—rare.
- Chronic condition—may see extensive myofiber atrophy and fibrosis.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient

NURSING CARE

Supportive care—may be required to prevent skin wounds and decubital ulcers in non-ambulatory severely affected patients.

ACTIVITY

Should increase, along with muscle strength, as muscle inflammation decreases.

DIET

- Megaeosophagus—may require feeding from an elevation; try foods of different consistencies.
- Severe regurgitation—may need to place a gastric feeding tube to maintain hydration and nutrition.

CLIENT EDUCATION

- Warn client that long-term immunosuppressive therapy may be required for an immune-mediated condition.

(CONTINUED)

- Inform client that residual muscle atrophy and contractures may occur with chronic disease and extensive fibrosis.
- Suggest genetic counseling for familial disorders.

SURGICAL CONSIDERATIONS

Only for concurrent neoplasia

MEDICATIONS

DRUG(S) OF CHOICE

- Corticosteroids—immunosuppressive dosages usually result in clinical improvement of immune-mediated condition; decrease to the lowest alternate-day dosage that maintains normal creatine kinase activity and improved muscle strength and mobility; may require long-term therapy.
- Identified infectious agent—initiate specific therapy.
- Identified myocardial failure—initiate specific therapy.

CONTRAINdications

N/A

PRECAUTIONS

Corticosteroids—observe for infection and undesirable side effects; remember that chronic therapy may lead to muscle atrophy (steroid myopathy).

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Intolerable side effects of corticosteroids— institute a lower dose of corticosteroids combined with another drug (e.g., azathioprine, cyclosporine).

MYOPATHY, GENERALIZED INFLAMMATORY

FOLLOW-UP

PATIENT MONITORING

- Serum creatine kinase activity—periodic evaluation; if elevated, should decrease into the normal range.
- Corticosteroids—side effects.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Corticosteroids—undesirable side effects.
- Recurrence of clinical signs—treatment stopped too early.
- Poor clinical response—inadequate dosages of corticosteroids. May need additional or alternative immunosuppressant.

EXPECTED COURSE AND PROGNOSIS

- Immune-mediated condition—good to fair prognosis.
- Paraneoplastic disorder associated with occult neoplasia—guarded prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Other concurrent autoimmune disorders
- Neoplasia

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Unknown

SEE ALSO

Myopathy, Noninflammatory—Endocrine

ABBREVIATIONS

- AChR = acetylcholine receptor
- EMG = electromyogram

MYOPATHY, NONINFLAMMATORY—ENDOCRINE

BASICS

DEFINITION

Myopathies associated with various endocrinopathies (including hypothyroidism, hyperthyroidism, hypoadrenocorticism, hyperadrenocorticism) and associated with exogenous corticosteroid use (steroid myopathy).

PATHOPHYSIOLOGY

With Adrenal Dysfunction

- Glucocorticoid excess—impaired muscle protein metabolism; may accelerate degradation of myofibrillar and soluble protein in skeletal muscle; impairment of carbohydrate metabolism owing to induction of an insulin-resistant state; may note elevated ACTH levels.
- Adrenal insufficiency—circulatory insufficiency; fluid and electrolyte imbalance; impaired carbohydrate metabolism.

With Thyroid Disease

- Hyperthyroidism—increased mitochondrial respiration; accelerated protein degradation and lipid oxidation; glycogen depletion; impaired glucose uptake.
- Hypothyroidism—impaired muscle energy metabolism by reduced glycogen breakdown, gluconeogenesis, and oxidative and glycolytic capacity; impaired insulin-stimulated carbohydrate metabolism.

SYSTEMS AFFECTED

- Neuromuscular—impaired energy metabolism.
- Cardiovascular—impaired energy metabolism; circulatory disorders.

GENETICS

N/A

INCIDENCE/PREVALENCE

- Exact incidence unknown.
- Myopathies related to exogenous corticosteroids—common.
- Myopathies associated with Cushing syndrome and hypothyroidism—not uncommon.

GEOGRAPHIC DISTRIBUTION

Probably worldwide

SIGNALMENT

Species

- Dog—steroid myopathy; weakness associated with hyperadrenocorticism and hypoadrenocorticism; hypothyroidism.
- Cat—weakness associated with hyperthyroidism.

Breed Predilections

Affects several breeds

Mean Age and Range

- Steroid myopathy—dogs of any age
- Other disorders—see specific disease

Predominant Sex

None found

SIGNS

General Comments

Corticosteroid use in dogs—muscles very susceptible; muscle atrophy (particularly the masticatory muscles) is not uncommon with prolonged corticosteroid use.

Historical Findings

- Muscle weakness, atrophy, and stiffness
- Regurgitation
- Dysphagia
- Dysphonia

Physical Examination Findings

- Muscle weakness, stiffness, cramping, and myalgia
- Muscle hypertrophy or atrophy
- May not note other clinical signs of an endocrine disorder

CAUSES

- Endocrine dysfunction
- Auto-immune
- Neoplastic

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inflammatory myopathies—distinguished by muscle biopsy.
- Noninflammatory myopathies—distinguished by muscle biopsy.

CBC/BIOCHEMISTRY/URINALYSIS

- Baseline testing—abnormalities consistent with endocrine disorder.
- Serum creatine kinase activity—usually normal, but may be mildly elevated if necrotic muscle fibers.

OTHER LABORATORY TESTS

Thyroid and adrenal function tests—should be diagnostic

IMAGING

- Dynamic studies—evaluate pharyngeal and esophageal function; with regurgitation and dysphagia.
- Cardiac evaluation—for cats with hyperthyroidism.

DIAGNOSTIC PROCEDURES

- Muscle biopsy—fiber typing in fresh frozen muscle biopsy sections important; paraffin sections will not be diagnostic.
- Electromyography.

PATHOLOGIC FINDINGS

- Hyperadrenocorticism and steroid myopathies—selective atrophy of type 2 muscle fibers; may see lobulated or ragged-red fibers with associated myotonia.
- Hypoadrenocorticism—muscle biopsies normal.

- Hyperthyroidism (cats)—muscle biopsies normal.

- Hypothyroidism—atrophy of type 2 fibers; may see an increase in type 1 fibers; may see PAS-positive deposits and nemaline rod bodies.

TREATMENT

APPROPRIATE HEALTH CARE

Depends on specific endocrine disorder

NURSING CARE

Physical therapy—with musculoskeletal manifestations

ACTIVITY

- Clinical corticosteroid myopathy (humans)—inactivity worsens condition; increased muscle activity may partially prevent atrophy.
- Physical therapy—may help prevent and treat muscle weakness and wasting in dogs receiving glucocorticoids.

DIET

- Regurgitation and megaesophagus—feed from an elevation.
- Dysphagia and esophageal dilation—give food with the best-tolerated consistency.
- Gastric feeding tube—if oral feeding is not tolerated.

CLIENT EDUCATION

Depends on specific endocrine disorder

SURGICAL CONSIDERATIONS

Removal of neoplasia

MEDICATIONS

DRUG(S) OF CHOICE

- Depends on specific endocrine disorder.
- Corticosteroid myopathy—decrease corticosteroid dosage to the lowest possible level; use a non-fluorinated corticosteroid and alternate-day dosing.
- Intramyofiber lipid storage with steroid myopathy—L-carnitine (50 mg/kg PO q12h) may improve muscle strength.

CONTRAINdications

N/A

PRECAUTIONS

Depend on specific endocrine disorder

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Fluorinated corticosteroids, triamcinolone, betamethasone, and dexamethasone—most likely to produce muscle weakness; use an equivalent dose of another corticosteroid.

(CONTINUED)

MYOPATHY, NONINFLAMMATORY—ENDOCRINE**FOLLOW-UP****PATIENT MONITORING**

- Depends on specific endocrine disorder.
- Steroid myopathy—should note return of muscle strength and mass with decreased steroid use.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Depend on specific endocrine disorders

EXPECTED COURSE AND PROGNOSIS

- Myotonia associated with hyperadrenocorticism—poor prognosis for resolution.
- Steroid myopathy—good prognosis for return of muscle strength and mass; recovery may take weeks.
- Hypothyroid myopathy—improvement in muscle pain and stiffness common.

- Hyperthyroidism (cats)—good prognosis for return of muscle strength following reversion to euthyroid state.
- Hypoadrenocorticism—good prognosis for return of muscle strength.
- Dysphagia and regurgitation—may resolve with adequate treatment.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- May note multiple endocrinopathies
- Hypothyroidism (dogs)—concurrent myasthenia gravis

AGE-RELATED FACTORS

M

MYOPATHY, NONINFLAMMATORY—HEREDITARY LABRADOR RETRIEVER

BASICS

OVERVIEW

- An inherited myopathy of Labrador retrievers.
- Recognized worldwide.
- Autosomal recessive mode of inheritance.
- More recently named centronuclear myopathy (CNM).
- Pathophysiologic mechanism(s) are still unclear; however, the causative genetic mutation has been identified (*PTPLA* gene mutation).
- Loss of tendon reflexes and histologic examination of muscle—may be more typical of a neurogenic than a myopathic cause.
- No immunohistochemical abnormalities to suggest a disorder of muscle protein.
- No morphologic changes in the CNS or peripheral nerves identified.

SIGNALMENT

- Occurs in black and yellow Labrador retrievers.
- Age of onset—variable (6 weeks–7 months); most commonly recognized at 3–4 months.
- Affects males and females.
- A similar inherited CNM has been identified in young male and female Great Danes.

M

SIGNS

- Severity ranges from stilted gait and exercise intolerance to severe muscle weakness, bunny-hopping pelvic limb gait, ventroflexion of the head and neck, arched back, and abnormal joint posture (cow-hocked stance, hyperextended carpi).
- Worsens with exercise, excitement, and cold weather.
- Patient may collapse with forced exercise.
- Some improvement with rest.
- Generalized muscle atrophy—mild to severe.
- Atrophy of proximal limb and masticatory muscles often most prominent.
- Tendon reflexes—normal, hypoactive, or absent.
- Occasionally, patients become recumbent or develop megaesophagus.

CAUSES & RISK FACTORS

Autosomal recessive mode of inheritance

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- With little muscle atrophy—exercise intolerance may mimic signs of myasthenia gravis, cardiac or orthopedic disease.
- Exercise-induced collapse syndrome also recognized in this breed; however, not associated with muscle atrophy and collapse seen only after strenuous exercise.

- With marked muscle atrophy—consider other myopathies (infectious, immune-mediated, metabolic, congenital) and generalized lower motor neuron disorders.
- Infectious myopathy due to congenital neospora caninum infection has a higher incidence in Labrador retrievers.
- Congenital muscular dystrophy in a male due to dystrophin deficiency and in a female due to sarcolemmal collagen deficiency myopathy have also been reported in Labrador retrievers.
- An X linked myotubular myopathy (XLMTM), which is an unrelated centronuclear myopathy, due to a mutation in *MTM1* gene, has also been identified in young male Labrador retrievers. Affected dogs show progressive weakness and muscle atrophy in the first 2 months of life resulting in euthanasia before 6 months of age.

CBC/BIOCHEMISTRY/URINALYSIS

Creatine kinase—normal or mildly or moderately elevated

OTHER LABORATORY TESTS

A DNA test is available for the causative genetic mutation.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- EMG—spontaneous activity, including complex repetitive discharges, especially in proximal limb and masticatory muscles; may reveal no abnormalities with mild disease.
- Muscle histology—reveals variation in fiber size, angular atrophy of both type 1 and 2 myofibers, grouped atrophy, increase in central nuclei, muscle degeneration and regeneration, and fibrosis; may note deficiency in type 2 myofibers or predominance of type 1 myofibers.
- DNA test for causative genetic mutation.

TREATMENT

- None specific.
- Avoid cold, because it exacerbates clinical signs.
- Discourage breeding of affected animals and parents and littermates of affected dogs.
- Do not repeat dam-sire matings that result in affected offspring.

MEDICATIONS

DRUG(S)

Supplementation with L-carnitine (50 mg/kg PO q12h) may be of benefit in improving muscle strength.

CONTRAINdications/POSSible INTERACTIONS

None known

FOLLOW-UP

- Clinical signs generally stabilize at approximately 1 year of age.
- Mild disease—may be an acceptable pet; may show some improvement in exercise tolerance.
- Aspiration pneumonia—a risk in dogs with megaesophagus.

MYOPATHY, NONINFLAMMATORY—HEREDITARY MUSCULAR DYSTROPHY

BASICS

OVERVIEW

- Muscular dystrophy is an inherited, progressive and degenerative, generalized myopathy. Most muscular dystrophies are due to mutations in genes that code for muscle membrane associated proteins in the dystrophin-glycoprotein (DAG) complex
- Most common form in dogs occurs as a result of a deficiency of the protein dystrophin.
- Muscular dystrophy due to dystrophin deficiency has an X-linked mode of inheritance and affected animals are predominantly male.
- Dystrophin deficiency—identified first in golden retrievers. Subsequently cases have been reported in Irish terriers, Samoyeds, rottweilers, Belgian shepherds, Pembroke Welsh corgis, Brittany spaniels, German shorthaired pointers, rat terriers, miniature schnauzers, Labrador retrievers, Alaskan malamutes, wirehaired fox terriers, Japanese spitz, Cavalier King Charles spaniels. Sporadic cases in other breeds are likely.
- The dystrophin gene is large and new mutations are likely to occur.
- Hypertrophic muscular dystrophy associated with dystrophin deficiency also occurs in domestic shorthair cats.
- Deficiency of other muscle-associated proteins, e.g., alpha2 laminin (merosin) and sarcoglycan, has been identified more recently in dogs and cats and is not necessarily X-linked (females affected).
- A muscular dystrophy associated with loss of alpha-dystroglycan with an autosomal recessive mode of inheritance occurs in young Devon Rex and Sphynx cats.
- Unclassified muscular dystrophies have also been reported in other dogs (males and females).

SIGNALMENT

- Seen primarily in neonate and young dogs (< 1 year).
- Described in cats.
- Muscular dystrophy due to dystrophin deficiency primarily affects males.
- Several dog breeds known to be affected. Best described in golden retrievers.
- Females—usually carriers of dystrophin gene defect, but dystrophin-deficient females may exhibit muscle weakness, tremors, limb deformities, and exercise intolerance.
- Muscular dystrophy due to other muscle protein or unclassified defects may be seen in young male or female dogs and cats of any breed.

SIGNS

Dogs

- Golden retrievers—exercise intolerance; stilted gait; bunny-hopping pelvic limb gait; plantigrade stance; partial trismus; muscle atrophy (especially the trunci and temporalis

muscles); hypertrophy of some muscles (especially the tongue); kyphosis; lordosis; drooling; dysphagia; aspiration pneumonia (due to pharyngeal and/or esophageal involvement).

- Other breeds—similar; include vomiting and megaesophagus.
- Abnormalities vary in severity, onset, and progression; may be seen as early as 6 weeks; tend to stabilize by 6 months.
- Stunting and ineffective suckling—may be evident in younger pups.
- Cardiac failure—may occur owing to cardiomyopathy.
- Severe muscle contractures may develop.
- Spinal reflexes—normal initially; may become hypoactive.

Cats

- Dystrophin deficient—muscle hypertrophy; stiff gait; cervical rigidity; exercise intolerance; vomiting; may see calcified nodules on the tongue.
- Usually young animals but not apparent in one cat until 21 months of age.
- Other hereditary myopathies in cats may cause muscle atrophy; weakness; ventroflexion of the head and neck; dorsal protrusion of the scapulae with triceps brachii and dorsal cervical muscles most severely affected.

CAUSES & RISK FACTORS

- Dystrophin deficiency—inherited defect of the X chromosome.
- Other muscular dystrophies may not be X-linked.
- Devon Rex myopathy—autosomal recessive.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other inherited myopathies including centronuclear myopathies, X-linked myotubular myopathy, infectious (especially protozoal), immune-mediated, or metabolic myopathies; distinguished by muscle histology and demonstration of dystrophin deficiency or other muscle membrane protein associated deficiency.

CBC/BIOCHEMISTRY/URINALYSIS

- Dystrophin deficiency—normal except for marked elevation in serum creatine kinase (may be > 10,000 U/L; further increased after exercise). AST also likely to be elevated.
- Other muscular dystrophy—CK may be normal.

OTHER LABORATORY TESTS

- Muscle biopsy—dystrophin deficiency demonstrated by immunohistochemical evaluation of fresh frozen muscle; diagnostic.
- Immunohistochemistry and immunoblotting analysis of muscle biopsy specimens can also assess abnormalities of other muscle proteins including dystrophin associated proteins, laminin, sarcoglycan.

- DNA tests available for specific genetic abnormalities in some breeds.
- Serologic testing—may be warranted to rule out infectious and immune-mediated causes.

DIAGNOSTIC PROCEDURES

Electromyography—shows complex repetitive discharges.

PATHOLOGIC FINDINGS

Histologic examination of muscle—muscle fiber necrosis and regeneration; myofiber mineralization (may be dramatic); myofiber hypertrophy (may be variation in myofiber size); fibrosis.

TREATMENT

None proven effective

MEDICATIONS

DRUG(S)

Glucocorticosteroids—may provide some improvement; reason unknown. However, myofiber calcification increases, which may be deleterious.

FOLLOW-UP

PATIENT MONITORING

Monitor periodically for aspiration pneumonia or cardiomyopathy.

PREVENTION/AVOIDANCE

- Discourage breeding of affected animals.
- Do not repeat dam-sire matings that result in affected offspring.

EXPECTED COURSE AND PROGNOSIS

- Overall prognosis—guarded to poor as no effective palliative treatment.
- Golden retrievers—signs tend to stabilize at 6 months.
- Other dog breeds and cats—progression variable.

MISCELLANEOUS

ABBREVIATION

AST = aspartate aminotransferase

MYOPATHY, NONINFLAMMATORY—HEREDITARY MYOTONIA

BASICS

OVERVIEW

- Characterized by persistent contraction or delayed relaxation of muscle fibers on initiation of movement or when stimulated to contract. • May affect all skeletal muscles.
- Myotonia may be congenital or acquired.
- A genetic basis has been determined in some breeds • Acquired myotonia may be associated with non-inflammatory or inflammatory myopathy. • Neuromyotonia and myokymia, characterized by continuous muscle fiber activity, are believed to be due to hyperexcitability of terminal nerve branches (neuromyotonia) or hyperexcitability of the motor nerve axon at any level (myokymia) rather than a primary muscle disorder.
- Neuromyotonia is characterized by muscle stiffness and delayed relaxation. • Myokymia describes rhythmic undulating muscle movements that produce a rippling movement of the skin. • The cause of neuromyotonia and myokymia (CMFA) in all reported cases remains unclear. • CMFA and spinocerebellar ataxia may occur concurrently in Jack Russell Terriers (and related breeds) and both are associated with a genetic mutation causing neuronal ion channel dysfunction.

M

SIGNALMENT

- Congenital myotonia—chow chows, miniature schnauzers and Australian cattledogs; rarely seen in other dog breeds.
- Clinical signs seen when affected puppies begin to walk. • Acquired myotonia—all breeds of any age potentially susceptible.
- Myotonia reported in young domestic cats.
- Neuromyotonia and myokymia (CMFA)—described in predominantly young JRTs worldwide, rarely in other breeds and a cat.

SIGNS

- Difficulty rising. • Stiffness after rest or initiation of activity. • May note dyspnea, voice change, dysphagia, and/or regurgitation, especially after eating. • May improve with exercise. • May be exacerbated by cold.
- Muscle stiffness and myokymia observed in young JRTs may result in life threatening hyperthermia. In this breed clinical signs are episodic but dogs may have continuous ataxia.

Physical Examination Findings

- Hypertrophy of proximal limb muscles, neck muscles, and tongue. • Tongue may protrude from the mouth. • Abduction of thoracic limbs. • Stiff, stilted, pelvic limb gait.
- Patient may fall and remain rigid in lateral recumbency for short periods. May become cyanotic. • Affected miniature schnauzers may have craniofacial abnormalities such as mandibular shortening.

CAUSES & RISK FACTORS

- Chow chows—suspected autosomal recessive mode of inheritance. • Miniature schnauzers, Australian cattledogs—autosomal recessive mode of inheritance (*CLCN1* gene).
- Jack Russell terrier group CMFA and spinocerebellar ataxia—autosomal recessive mode of inheritance (*KCNJ10* gene).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other myopathies—distinguished by signalment and clinical, electromyographic, and histologic findings. • Hypertonicity disorders or other movement disorders—recognized breed association.

CBC/BIOCHEMISTRY/URINALYSIS

Creatine kinase—may be normal or slightly elevated.

OTHER LABORATORY TESTS

DNA testing for known genetic mutations

DIAGNOSTIC PROCEDURES

- Percussion of muscles and tongue—causes sustained dimpling. • Electromyography—myotonia characterized by multifocal or generalized high-frequency discharges that wax and wane in amplitude and frequency (dive bomber—sounding potentials) and are increased after muscle percussion. Myokymic discharges—rhythmic high-frequency bursts of single motor unit potentials are characteristic findings in myokymia.

PATHOLOGIC FINDINGS

- Muscle histology—congenital myotonia : normal or mild changes. • Degenerative and/or inflammatory changes on muscle histology may be seen in cases of acquired myotonia. • No abnormalities found on muscle biopsy in JRTs with neuromyotonia and myokymia (CMFA).

TREATMENT

- None specific. • Discourage activities that result in hyperventilation. • Avoid strenuous exercise and excitement. • Avoid cold.
- Anesthesia (induction and recovery)—possible risk of respiratory obstruction owing to adduction of vocal cords or regurgitation.

MEDICATIONS

DRUG(S)

- Membrane-stabilizing drugs—procainamide, quinidine, phenytoin, and

mexiletine; may decrease severity of clinical signs.

- Procainamide reported to be most effective in chow chows. Treatment may decrease stiffness, stridor, and regurgitation, but gait remains abnormal.
- Extended release procainamide 40–50 mg/kg q8–12h or mexiletine 8.3 mg/kg q8h reported to be effective in miniature schnauzers.
- Procainamide 10 mg/kg q8h or mexiletine 4 mg/kg q12h or sustained-release phenytoin at an increasing dose 50–100 mg/kg for 6 weeks then on serum concentration monitoring 2–8 mg/L reported to reduce frequency of episodes of CMFA in approximately half of affected JRTs, but response is generally temporary.
- Anaesthesia and cooling to treat hyperthermia may be required to treat episodes of CMFA in JRTs.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Myotonia in humans is worsened with treatment with dantrolene, beta-adrenergic blocking agents, diuretics, and neuromuscular blocking agents. Bromide-containing agents such as potassium bromide may be contraindicated.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Chow chows, miniature schnauzers, Australian cattledogs—inherited condition; advise owner regarding breeding. • DNA testing for carrier dogs prior to breeding.
- Discourage breeding of affected animals.
- Do not repeat dam-sire matings that resulted in affected offspring.

POSSIBLE COMPLICATIONS

- Respiratory obstruction and/or aspiration of regurgitated food—may be life-threatening; advise owners of the clinical symptoms and treatment. • Hyperthermia associated with CMFA in JRTs is life-threatening.

EXPECTED COURSE AND PROGNOSIS

Prognosis guarded

ABBREVIATIONS

- CMFA = continuous muscle fiber activity
- JRT = Jack Russell terrier

MYOPATHY, NONINFLAMMATORY—HEREDITARY SCOTTY CRAMP

BASICS

OVERVIEW

- Inherited disorder in Scottish terriers characterized by episodic muscle hypertonicity or cramping.
- Not associated with any morphologic changes in muscle, peripheral nerve, or the CNS.
- Is better characterized as a hypertonicity disorder than a myopathy.
- Thought to be the result of a disorder in serotonin metabolism within the CNS.
- Similar condition (reflex myoclonus) reported in young Dalmatians and Labrador retrievers—may be result of low numbers of neurotransmitter glycine receptors in the CNS.
- Episodic muscle hypertonicity syndromes also occur in Cavalier King Charles spaniels (episodic falling syndrome), Norwich terriers, Bichon frises, border terriers (Spike's disease or canine epileptoid cramping syndrome), Wheaten terriers, springer spaniels, and sporadically in other breeds.

SIGNALMENT

- Young Scottish terriers, typically < 1 year of age. Clinical signs may be seen in puppies as early as 6–8 weeks of age.
- No known sex predilection.

SIGNS

- Normal at rest and on initial exercise.
- Further exercise or excitement—abduction of the thoracic limbs; arching (kyphosis) of the thoracolumbar vertebral column; stiffening or overflexion of the pelvic limbs (goose-stepping gait).
- Patient may fall, with tail and pelvic limbs flexed tightly against the body.
- Respiration—may cease for a short time.
- Facial muscles—may be contracted.
- No loss of consciousness.
- Severity varies.
- Episodes—may last up to 30 minutes.

CAUSES & RISK FACTORS

Inherited condition with probable autosomal recessive mode of transmission

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Seizure disorder—distinguished on basis of family history, typical clinical signs with no

loss of consciousness, and induction of signs with serotonin antagonists.

- Cerebellar cortical degeneration described in Scottish terriers—clinical signs are not episodic and neurologic abnormalities are slowly progressive.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

DNA test available for episodic falling syndrome in Cavalier King Charles spaniels. Genetic abnormality associated with other hypertonicity disorders not yet determined.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Clinical signs may be induced by giving the serotonin antagonist methysergide (0.3 mg/kg PO). Cramping is evident in 2 hours and may last for 8 hours.

TREATMENT

Behavioral modification and/or environmental changes—eliminate triggering situations (excitement, stress); may be adequate in controlling episodes.

MEDICATIONS

DRUG(S)

- Acepromazine maleate (0.1–0.75 mg/kg IM or PO), diazepam (0.5–1.5 mg/kg PO q8h), or vitamin E (> 125 U/kg q24h)—may reduce the incidence and severity of Scottie cramp.
- Fluoxetine, a selective serotonin reuptake inhibitor, resulted in a marked reduction in the clinical signs in one Scottish terrier at a dose of 1.2 mg/kg q12h initially followed by 0.8 mg/kg q12h. Clinical improvement has been maintained for > 1 year.
- Clonazepam 0.5 mg/kg q8h may result in improvement in Cavalier King Charles spaniels with hypertonicity syndrome (episodic falling syndrome).

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Serotonin antagonists—increase severity of clinical signs.
- Aspirin, indomethacin, phenylbutazone, Banamine (flunixin meglumine), and penicillin—may exacerbate clinical signs.

FOLLOW-UP

PATIENT MONITORING

Nonprogressive

PREVENTION/AVOIDANCE

- Discourage breeding of affected and related animals.
- Do not repeat dam-sire matings that result in affected offspring.

EXPECTED COURSE AND PROGNOSIS

- Mild to moderate—fair to good long-term prognosis; usually manageable disability by owners; nonprogressive.
- Severe—guarded prognosis.

MYOPATHY, NONINFLAMMATORY—METABOLIC

BASICS

DEFINITION

- Myopathy associated with disorders of glycogen metabolism, lipid metabolism, or oxidative phosphorylation and mitochondrial metabolism.
- Currently poorly characterized in veterinary medicine.

PATOPHYSIOLOGY

- Usually associated with inherited or acquired enzyme defects involving major metabolic pathways.
- May result in storage of the abnormal metabolic byproduct or morphologic abnormalities of mitochondria.

SYSTEMS AFFECTED

- Cardiovascular—dependent on oxidative metabolism for energy.
- Hemic/Lymphatic/Immune—RBCs depend on glycolytic metabolism.
- Nervous—dependent on glycolytic and oxidative metabolism for energy.
- Neuromuscular—dependent on oxidative metabolism for energy.
- Storage products in other organs—liver, spleen.

M

GENETICS

Undetermined

INCIDENCE/PREVALENCE

Rare, except lipid-storage myopathies

GEOGRAPHIC DISTRIBUTION

Unknown; probably worldwide

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Muscle phosphofructokinase deficiency—English springer spaniel, American cocker spaniel, whippet.
- Acid maltase deficiency—Lapland dog.
- Branching enzyme deficiency—Norwegian forest cat.
- Debranching enzyme deficiency—German shepherd, Akita, curly-coated retrievers.
- Pyruvate dehydrogenase phosphatase 1 deficiency—Clumber spaniel, Sussex spaniel.
- Mitochondrial myopathy—Old English sheepdog, Yorkshire terrier, possibly Jack Russell terrier.

Mean Age and Range

- Inherited metabolic defects—2–3 months
- Acquired metabolic defects—adults

Predominant Sex

None found

SIGNS

General Comments

Very few of these conditions have been adequately described.

Historical Findings

- Muscular weakness
- Exercise intolerance
- Cramping
- Collapse
- Regurgitation and/or dysphagia
- Esophageal and/or pharyngeal abnormalities
- Dark urine; myoglobinuria, hemoglobinuria
- Encephalopathy.
- Vomiting

Physical Examination Findings

- Exercise-related weakness, stiffness, and/or cramping
- Abnormal neurologic examination—disorientation; stupor; coma
- Abdominal distention—storage product accumulation in liver
- May appear normal, with fluctuating clinical signs

CAUSES

- Inborn error of metabolism
- Acquired metabolic defect
- Viral infections
- Drug-induced
- Environmental factors

RISK FACTORS

- Inherited disorders
- Appropriate genetic background
- Others unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inflammatory myopathies—differentiated by muscle biopsy.
- Other non-inflammatory myopathies—differentiated by muscle biopsy.
- Other metabolic encephalopathies—differentiated by laboratory evaluation.

CBC/BIOCHEMISTRY/URINALYSIS

- Plasma lactate and pyruvate levels—elevated resting or post-exercise with disorders of fatty acid oxidation or oxidative phosphorylation; no elevation with glycolytic disorders.
- Serum creatine kinase activity—may be elevated with exercise and normal at rest; may be persistently elevated.
- Hypoglycemia—may occur with some glycolytic and oxidative disorders.
- Hyperammonemia—may occur with urea cycle defects.

OTHER LABORATORY TESTS

- Quantitation of plasma amino acids—abnormal accumulations.
- Quantitation of urine organic acids—demonstrate abnormal organic acid production.
- Quantitation of plasma, urine, and muscle carnitine—may be low with primary or secondary disorders of carnitine; low with primary organic acidurias.
- Specific enzyme assays—depend on suspected metabolic defect.

- Fibroblast cultures—study metabolic defect.
- DNA-based tests to identify affected dogs and carriers when available.

IMAGING

MRI—evaluate the CNS; reveals abnormalities in humans.

DIAGNOSTIC PROCEDURES

- Light microscopy—fresh frozen muscle sections; demonstrates storage products (glycogen, lipid) or abnormal mitochondria.
- Electron microscopy of muscle reveals abnormal mitochondria, paracrystalline inclusions, and glycogen or lipid accumulation.
- Cardiovascular system evaluation—may have concurrent cardiomyopathy.
- Other organ biopsies—with organomegaly.

PATHOLOGIC FINDINGS

- Triglyceride droplets in muscle—lipid storage myopathy
- Ragged-red fibers in muscle—mitochondrial myopathy
- Glycogen deposition in muscle—glycogen storage disorder

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient—may require intensive care for severe encephalopathy, seizures, lactic acidemia, hypoglycemia, or hyperammonemia.
- Outpatient—clinical signs related only to neuromuscular system.

NURSING CARE

Depends on type and severity of disorder

ACTIVITY

Exercise restriction—with muscle weakness, stiffness, or exercise-induced collapse.

DIET

- Avoid prolonged periods of fasting.
- Restrictions—depend on underlying defect.
- Vitamin and co-factor therapy—determined by underlying defect.

CLIENT EDUCATION

- Warn client that most inherited metabolic defects cannot be cured, although some can be treated.
- Advise against breeding affected individuals.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

- Depend on the abnormality and clinical signs.
- Lipid storage myopathies—L-carnitine (50 mg/kg PO q12h); riboflavin (50–100 mg

(CONTINUED)

PO q24h); coenzyme Q10 (1 mg/kg PO q24h).

- Mitochondrial myopathies—may benefit from therapy similar to that listed for lipid storage myopathies.

CONTRAINDICATIONS

None known

PRECAUTIONS

Avoid fasting and strenuous exercise if they precipitate clinical signs.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Lipid storage myopathies—return of muscle strength; elimination of muscle pain.
- Elevated serum creatine kinase—should return to normal.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Severe neurologic impairment

EXPECTED COURSE AND PROGNOSIS

- Untreatable disorder—poor prognosis.
- Lipid storage myopathies—good prognosis if no underlying organic academia.

MYOPATHY, NONINFLAMMATORY—METABOLIC

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Iatrogenic and naturally occurring Cushing syndrome
- Lipid storage myopathies—found in some dogs
- Hemolytic anemia—due to underlying metabolic defect

AGE-RELATED FACTORS

- Inborn errors—usually found in young dogs
- Acquired defects—found in adult dogs

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Unknown

SYNONYMS

- Acid maltase deficiency—glycogenosis type II
- Cori disease—glycogenosis type III
- Glycogen storage disorders
- Lipid storage myopathies
- Mitochondrial myopathies
- Phosphofructokinase deficiency—glycogenosis type VII

ABBREVIATIONS

- CNS = central nervous system
- MRI = magnetic resonance imaging
- RBC = red blood cell

MYXEDEMA AND MYXEDEMA COMA

BASICS

OVERVIEW

• Myxedema coma is a rare, life-threatening, manifestation of severe hypothyroidism and is considered an endocrine emergency. • The development of myxedema coma requires a precipitating event that overwhelms normal homeostatic mechanisms. No single event has been identified in animals. • The greatest challenge with myxedema coma is recognizing the syndrome. Once it is recognized, immediate and intensive supportive care is necessary. Successful treatment has been reported; however, mortality rates can be high.

SIGNALMENT

- Dogs, the majority of which have been Doberman pinschers • Age range: 5–7 years
- No sex predilection • Myxedema coma is not reported in cats

SIGNS

Historical Findings

• The common findings in patients with myxedema coma are changes in mental status, altered thermoregulation, and non-pitting skin edema. • Mentation changes, due to brain edema, can range from altered alertness to coma. Mental depression is the most common assessment of mental status. Coma is not consistently reported. • Other signs consistent with hypothyroidism may be reported. • Patients may have been previously diagnosed with hypothyroidism.

Physical Examination Findings

• Hypothermia without shivering is a consistent finding with myxedema coma. Thyroxine amplifies catecholamine function, helping to stimulate muscular activity associated with shivering. Reduced T_4 level blunts the ability to shiver. • Cold extremities due to peripheral vasoconstriction and central shunting of blood secondary to hypothermia. • Non-pitting edema of the skin is due to cutaneous deposition of glycosaminoglycans in the interstitial space. • Decreases in lung and heart sounds may be noted due to pleural effusion (present in up to 50% of cases).

CAUSES & RISK FACTORS

• Myxedema coma results from chronic untreated severe primary hypothyroidism. • Both forms of primary hypothyroidism (lymphocytic thyroiditis and idiopathic thyroid atrophy) have reportedly been associated with the development of myxedema coma. • A secondary precipitating event is usually associated with the onset of a myxedema crisis. Precipitating events can include, but are not limited to, infections, respiratory disease, heart failure, and hypovolemia. • Sporadic reports exist suggesting that exposure to cold temperatures may act as a precipitating event, though this has not been consistently reported.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Weakness may be associated with cardiovascular disease, neurologic disease, and other endocrinopathies. • Dilated cardiomyopathy if patient is a Doberman pinscher. • Hypothermia may be associated with shock and other cardiovascular and endocrine diseases. Hypothermia associated with factors other than myxedema coma will usually be accompanied by shivering.

CBC/BIOCHEMISTRY/URINALYSIS

- Mild nonregenerative anemia is most commonly noted • Hypercholesterolemia
- Hypertriglyceridemia • Hypoglycemia
- Hyponatremia • Hypoxemia • Hypercarbia
- Urinalysis is normal

OTHER LABORATORY TESTS

- Thyroid function tests indicate severe hypothyroidism with low total T_4 , low free T_4 , and elevated TSH levels. • Buccal mucosal bleeding time is prolonged (hypothermia reduces platelet function).
- Fluid analysis of pleural effusion—modified transudate.

IMAGING

Thoracic radiographs—pleural effusion in up to 50% of cases. Pulmonary edema localized in the perihilar region is rarely noted.

PATHOLOGIC FINDINGS

Skin biopsies may demonstrate dermal thickening, myxedema, and vacuolation of arrector pili muscles.

TREATMENT

- Myxedema coma is a medical emergency.
- Once a presumptive diagnosis of myxedema coma is made, immediate inpatient treatment is necessary. • Due to the critical and life-threatening nature of myxedema coma, treatment must be initiated before thyroid function test results confirm a clinical suspicion of myxedema. • Immediate provision of a patent airway and resuscitation of hypotension are necessary. • Mechanical ventilation may be necessary. • IV fluid therapy is administered to support blood pressure and to address decreased sodium levels. Patients with myxedema coma have a decreased ability to clear free water.
- Administer intravenous fluids: 0.9% sodium chloride (20 mL/kg—initial bolus). Reassess and continue intravenous fluids (2.5–7 mL/kg/h). Rate selected based on blood pressure, heart rhythm, heart rate, and respiratory rate. • The hallmark of therapy is intravenous administration of synthetic thyroid hormone. • Rapid rewarming must be avoided as this may cause peripheral

vasodilatation, hypotension, and potential cardiovascular collapse. Correction of hypothermia should be passive and occur over a number of hours.

MEDICATIONS

DRUG(S)

- Definitive immediate treatment: levothyroxine, 5 $\mu\text{g}/\text{kg}$ (0.005 mg/kg) IV q12h. • A more conservative replacement dose should be used when there is concern about cardiac function, especially the heart's ability to deal with a sudden and rapid increase in metabolic rate. Decrease levothyroxine dose by 50–75% in these cases.
- Once the patient's condition has stabilized and the patient is able to swallow, oral levothyroxine therapy should be initiated at 0.02 mg/kg PO q12h.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Lower IV levothyroxine dose should be considered in patients with cardiac disease.
- Rapid rewarming must be avoided.

FOLLOW-UP

- Prognosis is grave. • If patient survives initial treatment, treatment and monitoring as recommended for hypothyroidism must be initiated. • Evaluation for potential underlying precipitating event.

MISCELLANEOUS

NAIL (CLAW) AND NAILBED (CLAWFOLD) DISORDERS

BASICS

DEFINITION

- Ungual fold—crescent-shaped tissue that surrounds the proximal nail • Coronary band and dorsal ridge—produces most of the nail
- Paronychia—inflammation of soft tissue around the nail • Onychomycosis—fungal infection of the nail • Onychorrhexis—brittle nails that tend to split or break
- Onychomadesis—sloughing of the nail
- Nail dystrophy—deformity caused by abnormal growth; often a sequela of a disorder
- Onychomalacia—softening of the nails

PATOPHYSIOLOGY

Nails and unguial folds—subject to trauma, infection, vascular insufficiency, immune-mediated disease, neoplasia, defects in keratinization, and congenital abnormalities.

SIGNALMENT

- Dog and cat • Mean age range—SLO 3–8 years • No predominant sex reported
- Dachshunds—onychorrhexis • German shepherd dogs, rottweilers, possibly giant schnauzers and Doberman pinschers—SLO
- Siberian huskies, dachshunds, Rhodesian ridgebacks, rottweilers, cocker spaniels—idiopathic onychodystrophy • German shepherd dogs, whippets, English springer spaniels—idiopathic onychomadesis

SIGNS

- Licking at the feet and/or unguial folds
- Lameness • Pain • Swelling, erythema, and exudate of unguial fold • Deformity or sloughing of nail • Discoloration of the nail
- Hemorrhage from the nail or at loss of a nail
- Previous description of being “tender-footed”

CAUSES

Paronychia

- Infection—bacteria, dermatophyte, yeast (*Candida*, *Malassezia*), leishmaniasis
- Demodicosis • Immune-mediated—pemphigus, bullous pemphigoid, SLE, drug eruption, SLO • Neoplasia—subungual squamous cell carcinoma, melanoma, eccrine carcinoma, osteosarcoma, subungual keratoacanthoma, inverted squamous papilloma • Arteriovenous fistula

Onychomycosis

- Dogs—*Trichophyton mentagrophytes*—usually generalized • Cats—*Microsporum canis*

Onychorrhexis

- Idiopathic—especially in dachshunds; multiple nails • Trauma • Infection—dermatophytosis, leishmaniasis

Onychomadesis

- Trauma • Infection • Immune-mediated—pemphigus, bullous pemphigoid, SLE, drug eruption, SLO • Vascular insufficiency—vasculitis, cold agglutinin disease
- Neoplasia—see above • Idiopathic

Nail Dystrophy

- Acromegaly • Feline hyperthyroidism
- Zinc-responsive dermatosis • Congenital malformations

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Trauma or neoplasia often affects a single nail. • Involvement of multiple nails suggests a systemic disease. • Immune-mediated diseases (except SLO) usually have other skin lesions in addition to nail or unguial fold lesions.

CBC/BIOCHEMISTRY/URINALYSIS

May show evidence of SLE, diabetes mellitus, hyperthyroidism, or other systemic illness.

OTHER LABORATORY TESTS

- FeLV • Serum thyroxine • ANA titer

IMAGING

Radiographs—osteomyelitis of third phalanx, neoplastic change

OTHER DIAGNOSTIC PROCEDURES

- Biopsy—often involves a third phalanx amputation; inclusion of the coronary band required for diagnosis of most diseases
- Cytology of exudate from the nail and/or fold • Skin scraping • Bacterial and fungal culture

TREATMENT

PARONYCHIA

- Surgical removal of nail plate (shell)
- Antimicrobial soaks • Identify underlying condition and treat specifically.

ONYCHOMYCOSIS

- Antifungal soaks—chlorhexidine, povidone iodine, lime sulfur • Surgical removal of nail plate—may improve response to systemic medication • Amputation of third phalanx

ONYCHORRHEXIS

- Repair with fingernail glue (type used to attach false nails in humans). • Remove splintered pieces and maintain with rotary sander (Dremel). • Treat underlying cause. • Amputate third phalanx, last resort.

ONYCHOMADESIS

- Antimicrobial soaks • Treat underlying cause

NEOPLASIA

- Determined by biologic behavior of specific tumor • Surgical excision • Amputation of digit or leg • Chemotherapy and/or radiation therapy

NAIL DYSTROPHY

Treat underlying cause

MEDICATIONS

DRUG(S) OF CHOICE

- Bacterial paronychia—systemic antibiotics based on culture and sensitivity. • Yeast paronychia—*Candida* or *Malassezia* paronychia—ketoconazole (5–10 mg/kg PO q12–24h); topical nystatin or miconazole. • Onychomycosis—griseofulvin (50–150 mg/kg PO/day) or ketoconazole (5–10 mg/kg PO q12h) for 6–12 months until negative cultures; itraconazole (10 mg/kg PO q24h) for 3 weeks and then pulse therapy until resolved.

- Onychomadesis—determined by cause; immunomodulation therapy for immune-mediated diseases; medications include cyclosporine, doxycycline with niacinamide, pentoxifylline, vitamin E, essential fatty acid supplementations, and chemotherapeutic agents (e.g., azathioprine, chlorambucil).

CONTRAINdications

Griseofulvin—do not use in pregnant animals.

PRECAUTIONS

- Griseofulvin—may cause bone marrow suppression, anorexia, vomiting, and diarrhea; absorption enhanced if given with a high-fat meal. • Ketoconazole—may cause anorexia, gastric irritation, hepatic toxicity, and lightening of the hair coat.

N

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Bacterial or yeast paronychia and onychomycosis—treatment may be prolonged and response may be influenced by underlying factors. • Onychorrhexis—may require amputation of the third phalanx for resolution. • Onychomadesis—prognosis determined by underlying cause; immune-mediated diseases and vascular problems carry a more guarded prognosis than do trauma or infectious causes. • Neoplasia—excised by amputation of the digit; malignant tumors metastasize by the time of diagnosis.

MISCELLANEOUS

ABBREVIATIONS

- ANA = antinuclear antibody • FeLV = feline leukemia virus • SLE = systemic lupus erythematosus • SLO = symmetrical lupoid onychodystrophy

NARCOLEPSY AND CATAPLEXY

BASICS

OVERVIEW

Narcolepsy/cataplexy refer to the same disorder, cataplexy being the clinical sign easiest to recognize in domestic animals.

Narcolepsy

- Sleep disorders.
- Syndrome characterized by excessive sleepiness, cataplexy, sleep paralysis, and hypnagogic hallucinations (humans). Sudden episodes of paradoxical sleep without a preceding period of slow-wave sleep.

Cataplexy

- Sudden, episodic, and spontaneous collapse secondary to complete atonia of skeletal muscles (flaccid paralysis) caused by inhibition of spinal cord lower motor neurons.
- Patient stays alert and will follow with its eyes.
- Most common clinical sign of narcolepsy in small animals.

SIGNALMENT

- Dog and rarely cat.
- Proven hereditary—Labrador retriever, dachshund, and Doberman pinscher.
- Autosomal recessive gene mutation—*canarc-1* gene found on chromosome 12, which codes for a hypocretin (orexin) receptor. Mutations of *OxR2* (type II orexin receptor gene). Increased microglial expression of MHC II in Doberman pinscher.
- Assumed genetic basis for miniature poodle—mode of inheritance unknown.
- For inherited disease, clinical signs appear between 2 and 4 months of age with escalation of signs around 1 year of age. Possible disappearance of clinical signs later in life.

- Acquired form may develop in older animals (possible depletion of hypocretin production by hypothalamus) and can occur in any dog breed or mixed breed, at any age.
- Clinical signs in acquired form will usually remain for life.

SIGNS

- Physical and neurologic examinations—normal except during an episode.
- Onset—peracute.
- Excessive daytime sleepiness and fragmented sleep patterns reported in domestic animals, but cataplexy is usually the clinical sign recognized by owners.
- Cataplexy episodes—acute onset of flaccid paralysis without loss of consciousness lasting a few seconds to minutes (up to 20 minutes) with sudden return to normal; multiple episodes in 1 day.
- Narcolepsy—eye movements, muscular twitching, and whining (as in REM sleep) frequently observed during episodes.

- Patients are usually aroused by loud noises, petting, or other external stimuli.

CAUSES & RISK FACTORS

- Hereditary in some breeds.
- Possible immune system involvement in acquired disease.
- Neurotransmitter abnormalities—serotonin, dopamine, norepinephrine, neuropeptide hypocretin (orexin).
- Rarely reported with pontomedullary (brainstem) lesions.
- Excitement, emotions, feeding, and general anesthesia may induce narcoleptic episodes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Syncope.
- Seizure activity—urinary or fecal incontinence, excessive salivation and muscle rigidity are not characteristic of narcolepsy in which atonia predominates. Recovery after a narcoleptic event is immediate.
- Non-convulsive seizure (drop attack).
- Neuromuscular disorders—onset of clinical signs usually not as sudden and recovery not immediate as in narcolepsy.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

- DNA test for specific breeds (Labrador retriever, dachshund, and Doberman pinscher).
- CSF—normal. Low levels of orexin A in CSF.
- Standardized food-elicited cataplexy test; play-elicited cataplexy.

IMAGING

Brain MRI—normal

DIAGNOSTIC PROCEDURES

- Observe an episode—if a consistent activity (feeding, excitement, etc.) elicits attacks, attempt to simulate the activity.
- Food-elicited cataplexy test—place 10 pieces of food in a row 12–24 inches apart; record the time required for the patient to eat all the pieces and the number, type, and duration of any attacks that occur; normal dogs eat all food in < 45 seconds and have no attacks; affected dogs take > 2 minutes to eat the food and can have 2–20 attacks.
- Play-elicited cataplexy: 2 dogs are left in a room and allowed to interact together and with toys.
- Physostigmine (cholinesterase inhibitor) challenge to induce cataplexy in an affected dog—administer 0.025–0.1 mg/kg IV; repeat the food-elicited test 5–15 minutes after the injection; increase dosage if necessary (0.05 mg/kg; 0.075 mg/kg; 0.10 mg/kg); effects of each dose last 15–45 minutes.

TREATMENT

- Primary goal—reduce the severity and frequency of cataplectic episodes.
- Inform client that cataplexy is not a fatal disease, choking on food and airway obstruction do not occur, and the pet is not suffering.
- Inform client that activities such as hunting, swimming, and unleashed exercise put the patient at risk.
- If episodes are infrequent and quality of life is preserved, treatment should be postponed and environment adapted to avoid specific stimulations.

MEDICATIONS

DRUG(S)

- Imipramine 0.5 mg/kg PO q8h
- Methylphenidate 0.25 mg/kg PO q12–24h
- Selegiline 2 mg/kg q24h
- Yohimbine 50–100 µg/kg SC or PO q8–12h
- Combination also possible—imipramine and methylphenidate

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Many patients develop drug tolerance; change of drug may become necessary.
- Increased heart and respiratory rates, anorexia, tremors, exercise-induced hyperthermia.

FOLLOW-UP

- Avoiding inciting activities may reduce episodes so that medication is not needed.
- Patients with the inherited form may improve with age.
- Prognosis varies even with treatment; some patients remain symptomatic.

MISCELLANEOUS

ABBREVIATIONS

- CSF = cerebrospinal fluid
- MRI = magnetic resonance imaging

NASAL AND NASOPHARYNGEAL POLYPS

BASICS

OVERVIEW

- Non-neoplastic, inflammatory growths arising from epithelium, usually originate from a stalk.
- Nasal—uncommon; originate from the mucosa of the nasal turbinates and are inflammatory in dogs and cats.
- Nasopharyngeal—relatively common; originate from the base of the epithelial lining of the tympanic bulla or eustachian tube; when polyps extend into the nasopharynx referred to as nasopharyngeal polyps; when extending into the ear, known as middle ear polyps, aural or auricular polyps, or benign, inflammatory polyps.

SIGNALMENT

- Nasal polyps—middle-aged to older dogs and cats.
- Nasopharyngeal polyps—typically kittens and young adult cats, but can be seen in older cats (months—15 years), rarely seen in dogs.

SIGNS

Nasal Polyps

- Chronic mucopurulent nasal discharge
- Noisy breathing—stertor
- Nasal congestion and/or discharge
- Sneezing or epistaxis
- Decreased nasal airflow, generally unilateral
- Generally non-responsive to antibiotics

Nasopharyngeal or Aural Polyps

- Inspiratory stridor
- Gagging
- Cyanosis
- Voice change
- Dysphagia
- Chronic, non-responsive otitis
- Head tilt
- Nystagmus
- Ataxia
- Horner's syndrome

CAUSES & RISK FACTORS

Unknown—suspect congenital or response to chronic inflammatory processes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Feline upper respiratory disease complex
- Nasopharyngeal stenosis
- Chronic otitis externa or media
- Nasal or nasopharyngeal foreign body
- Laryngeal paralysis
- Nasal neoplasia—lymphoma, nasal adenocarcinoma

- Laryngeal neoplasia—squamous cell carcinoma, lymphoma, adenocarcinoma
- Aural neoplasia—ceruminous adenocarcinoma

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

FeLV/FIV—general retroviral screening

IMAGING

- Skull radiographs—soft tissue density within nasal cavity, nasopharynx, tympanic bulla, external ear canal; 25% false negative rate.
- Computerized tomography and MRI—better sensitivity for nasal, nasopharyngeal, and aural masses.

DIAGNOSTIC PROCEDURES

- Digital palpation of soft palate, visual examination of the nasopharynx and larynx under general anesthesia utilizing spay hook, dental mirror, and laryngoscope.
- Flexible fiber-optic caudal rhinoscopy to examine the dorsal nasopharynx, choanae, and caudal nasal cavity.
- Rigid rostral rhinoscopy to examine the nasal cavity.
- Deep otoscopic examination.
- Fine-needle aspirate and/or biopsy.
- Cytology and histopathology.

TREATMENT

- Excisional biopsy for nasal polyps.
- Traction removal of nasopharyngeal polyps via oral cavity.
- Ventral bulla osteotomy for nasopharyngeal polyps to release stalk and remove epithelial lining.
- Surgery—treatment of choice: excision via the oral cavity for nasopharyngeal polyps, or rhinotomy for nasal polyps; complete excision of root and base of polyp is mandatory to prevent recurrence.
- Concurrent bulla osteotomy—may prevent recurrence of nasopharyngeal polyps. Recommended if bullous involvement is obvious.

MEDICATIONS

DRUG(S)

- Appropriate antimicrobial medications if secondary nasal or otic infection present.
- Consider anti-inflammatory course of corticosteroids following traction removal of nasopharyngeal polyps; decreased recurrence rate reported.

FOLLOW-UP

- Incomplete removal of polyp and stalk may result in recurrence.
- Horner's syndrome can occur following removal by traction or ventral bulla osteotomy, usually transient but can be permanent.
- Facial paresis or paralysis or vestibular syndrome may develop after bulla osteotomy but is generally transient.
- Prognosis excellent with complete removal.

MISCELLANEOUS

ABBREVIATIONS

- FeLV = feline leukemia
- FIV = feline immunodeficiency virus
- MRI = magnetic resonance imaging

Consulting Editor Lynelle R. Johnson

N

NASAL DERMATOSES—CANINE

BASICS

DEFINITION

Pathologic condition of the nasal skin involving either the haired portion (bridge of the nose/dorsal muzzle) or non-haired portion (nasal planum).

PATHOPHYSIOLOGY

Dependent on cause

SYSTEMS AFFECTED

Skin/Exocrine

SIGNALMENT

- Dogs < 1 year of age—dermatophytosis, zinc-responsive dermatosis, dermatomyositis, demodicosis, eosinophilic nasal furunculosis (often insect trigger; also seen in adult patients).
- Zinc-responsive dermatosis—Siberian husky, Alaskan malamute.
- Dermatomyositis—collie, Shetland sheepdog.
- Uveodermatologic syndrome—Akita, Samoyed, Siberian husky.
- Systemic lupus erythematosus and discoid lupus erythematosus—collie, Shetland sheepdog, German shepherd dog.
- DLE may occur more often in females.
- Epitheliotropic lymphoma—old dogs.
- Nasal arteritis—St Bernard.
- Nasal solar dermatosis—lightly pigmented breeds.
- Nasal parakeratosis—Labrador retriever.
- Senile idiopathic nasal hyperkeratosis—older cocker spaniel.
- Seasonal nasal hypopigmentation—Labrador retriever, golden retriever, Siberian husky, Bernese mountain dog.
- Idiopathic leukoderma/leukotrichia (vitiligo)—Doberman pinscher, rottweiler, dachshund.
- Reactive histiocytosis (“clown nose”)—Bernese mountain dog, golden retriever.

SIGNS

- Depigmentation
- Hyperpigmentation
- Erythema
- Erosion/ulceration
- Hemorrhage
- Vesicles/pustules
- Crusts
- Scarring
- Alopecia
- Nodules/plaques

CAUSES

- Nasal pyoderma/furunculosis
- Demodicosis
- Dermatophytosis
- Other fungal infections—cryptoccosis, sporotrichosis, aspergillosis
- DLE and SLE
- Eosinophilic nasal furunculosis

- Mosquito-bite dermatitis
- Pemphigus foliaceus
- Pemphigus erythematosus
- Pemphigus vulgaris
- Arteritis
- Nasal solar dermatitis
- Dermatomyositis
- Zinc-responsive dermatosis
- Uveodermatologic syndrome
- Superficial necrolytic dermatitis
- Vitiligo
- Idiopathic nasal depigmentation
- Contact hypersensitivity—plastic dish dermatitis, topical drug hypersensitivity (neomycin)
- Neoplasia—squamous cell carcinoma, basal cell carcinoma, epitheliotropic lymphoma, fibrosarcoma, cutaneous histiocytosis
- Trauma
- Idiopathic sterile granuloma
- Idiopathic nasal hyperkeratosis
- Distemper virus dermatitis
- Insect trigger

RISK FACTORS

- Adult cats—may be inapparent carriers of dermatophytes.
- Rooting behavior—pyoderma, dermatophytosis.
- Sun exposure—nasal solar dermatitis, DLE, SLE, PE.
- Poorly pigmented nose—nasal solar dermatitis, squamous cell carcinoma.
- Large, rapidly growing breeds—zinc-responsive dermatosis.
- Immunosuppression—demodicosis, pyoderma, dermatophytosis.
- Insect exposure—mosquito-bite dermatitis and possibly eosinophilic nasal furunculosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Nasal Solar Dermatitis

- Lesions—confined to nose; precipitated by heavy sunlight exposure.
- Begins in poorly pigmented skin at junction of nasal planum and dorsal muzzle.
- Lightly pigmented eyelid margins may also be affected.
- Negative direct immunofluorescence.

DLE

- Primarily affects nasal area.
- May affect mucocutaneous margins of the lips and eyelids.
- Exacerbated by sunlight.
- Dermatitis often preceded by depigmentation.
- Positive DIF at basement membrane zone.
- Biopsy—interface dermatitis with pigmentary incontinence.

SLE

- Multisystemic disease.

- Skin lesions—often involve nose, face, mucocutaneous junctions; multifocal or generalized.
- ANA positive.
- Positive DIF at basement membrane zone.

Pemphigus Foliaceus

- Lesions—usually start on face and ears; commonly involve footpads; eventually generalize.
- Progressive development, often first noted at junction of nasal planum and dorsal muzzle.
- Biopsy—subcorneal pustules with acantholysis.
- Positive DIF in intercellular spaces of epidermis.

Pemphigus Erythematosus

- Lesions—primarily confined to face and ears; typically more severe than lesions of DLE.
- Dermatitis often preceded by depigmentation.
- Biopsy—intradermal pustules with acantholysis and pigmentary incontinence.
- Positive DIF at basement membrane zone and intercellular spaces.

Demodicosis

- Often starts on face or forelimbs; affects only haired skin of the dorsal muzzle.
- Juvenile-onset frequently facial at first.
- May generalize.
- Diagnosis by skin scrapings.

Plastic (or Rubber) Dish Dermatitis

- Depigmentation and erythema of anterior nasal planum and anterior lips.
- No ulceration or crusting.
- History of exposure.
- Similar to contact dermatitis.
- Uncommon; overly suspected—lesions more often due to trauma from roughened bowl edges. Similar symptoms seen with trauma from Kong and other rubber toys.

Dermatomyositis

- Breeds at increased risk.
- Young age of onset.
- Nasal, facial, and extremity lesions—characterized by erosion, alopecia, scarring, and hyperpigmentation.
- Lesions especially noted at points of trauma or pressure.
- Polymyositis and megaesophagus may be seen.
- Biopsy—interface dermatitis with follicular atrophy.
- Negative DIF.

Uveodermatologic Syndrome

- Breeds at increased risk.
- Dermatitis often preceded by ocular symptoms.
- Uveitis and cutaneous macular depigmentation without inflammation—nose, lips, and eyelids.
- Striking leukotrichia and leukoderma.
- Biopsy of early lesions—interface dermatitis, pigmentary incontinence.

(CONTINUED)

NASAL DERMATOSES—CANINE**Zinc-Responsive Dermatoses**

- Breeds at increased risk.
- Typical signalment or diet (i.e., high-fiber or calcium supplementation).
- Crusted lesions—face, mucocutaneous junctions, pressure points, footpads.
- Biopsy—parakeratotic hyperkeratosis.

Other

- Nasal pyoderma/furunculosis—acute onset of folliculitis on haired portion of nose.
- Dermatophytosis—haired portion of the nose; diagnose by culture or biopsy.
- Eosinophilic nasal furunculosis—haired portion of dorsal muzzle; diagnose by biopsy.
- Vitiligo—cutaneous macular depigmentation without inflammation on nose, lips, eyelids, footpads, and nails; leukotrichia with leukoderma may be seen; diagnose by biopsy.
- Nasal hypopigmentation—normal black coloration of nasal planum fades to light brown or whitish color; may be seasonal or wax and wane; considered cosmetic not pathologic.
- Idiopathic nasal hyperkeratosis—dry, horny growths of keratin localized to nasal planum; may or may not be associated with digital hyperkeratosis.
- Other diseases—differentiate by history or biopsy (i.e., neoplastic cell infiltrate).

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- SLE—may see hemolytic anemia, thrombocytopenia, evidence of glomerulonephritis (high BUN, proteinuria), joint disease, or other symptoms based on body system(s) affected.

DIAGNOSTIC PROCEDURES

- Skin scrapings—*Demodex*.
- Cytology—fungal organisms, bacteria, eosinophils, or acantholytic keratinocytes (pemphigus).
- Dermatophyte test medium—dermatophytosis.
- Culture on Sabouraud agar—other fungal infections.
- Bacterial culture and sensitivity or cytologic evaluation—pyoderma.
- Joint tap—evidence of polyarthritis in SLE.
- ANA—positive in cases of SLE.
- Ocular examination—uveitis in uveodermatologic syndrome.
- ECG—evidence of myocarditis in SLE.
- EMG—evidence of polymyositis in SLE and dermatomyositis.
- DIF—deposition of immunoglobulin at the basement membrane zone in DLE, SLE, and PE, and intercellular spaces of epidermis in PF, PE, and PV.
- Neoplasia—cytology or biopsy.
- Skin biopsy.

PATHOLOGIC FINDINGS

- Folliculitis/furunculosis (\pm mites, bacteria, fungal elements)—demodicosis, dermatophytosis, nasal pyoderma/furunculosis.

- Eosinophilic predominance—mosquito-bite dermatitis, eosinophilic nasal furunculosis.
- Follicular atrophy and perifollicular fibrosis—dermatomyositis.
- Interface dermatitis—DLE, SLE, dermatomyositis, uveodermatologic syndrome.
- Intraepidermal pustules with acantholysis—PF and PE.
- Suprabasilar acantholysis—PV.
- Parakeratotic hyperkeratosis—zinc-responsive dermatosis.
- Hypomelanosis—vitiligo, uveodermatologic syndrome.
- Granulomatous/pyogranulomatous dermatitis—pyoderma, fungal, foreign body, idiopathic sterile granuloma.
- Neoplastic cell infiltrate—cutaneous histiocytosis, other neoplasia.

**TREATMENT**

- Outpatient, except SLE with multi-organ dysfunction or tumors requiring surgical excision or radiation therapy.
- Reduce exposure to sunlight—DLE, SLE, PE, nasal solar dermatitis, squamous cell carcinoma.
- Discourage rooting behavior—pyoderma, dermatophytosis.
- Protection from insects.
- Warm soaks—aid removal of exudate and crusts.
- Replace plastic or rubber dish and avoid contact with topical drug or other agent causing hypersensitivity reaction.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Fungal infections—systemic antifungals: griseofulvin, ketoconazole, itraconazole; topical enilconazole for aspergillosis; surgical excision of early discrete lesions.
- Nasal solar dermatitis—topical corticosteroids; antibiotics for secondary infection; sunscreens.
- Idiopathic sterile granuloma—surgical excision when feasible; immunosuppressive therapy with glucocorticoids \pm azathioprine, cyclosporine, tetracycline and niacinamide.
- DLE and PE—topical corticosteroids or tacrolimus; tetracycline and niacinamide; oral therapy (as for PF) if temporarily needed in severe cases.
- PF, PV, SLE—immunosuppressive therapy with prednisolone \pm azathioprine (dogs), chlorambucil, chrysotherapy.
- Vitiligo/nasal depigmentation—no treatment.
- Neoplasia—surgical excision; chemotherapy; radiation therapy.

- Idiopathic nasal hyperkeratosis—topical antibiotic-corticosteroid cream, topical keratolytic and humectant topical tacrolimus (Protopic).
- Other diseases—see specific cause.

CONTRAINDICATIONS

Avoid chrysotherapy in patients with renal disease.

PRECAUTIONS

- Griseofulvin—can cause anorexia, vomiting, diarrhea, and bone marrow suppression; feed with high-fat diet.
- Ketoconazole—may cause anorexia, gastric irritation, hepatotoxicity, and lightening of hair coat.

**FOLLOW-UP****PATIENT MONITORING**

Varies with specific disease and treatment prescribed.

POSSIBLE COMPLICATIONS

Scarring with deep infections or overly vigorous cleaning.

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

Dermatophytosis

PREGNANCY/FERTILITY/BREEDING

Griseofulvin is teratogenic

SYNONYMS

- Superficial necrolytic dermatitis = superficial necrolytic migratory erythema and hepatocutaneous syndrome
- Uveodermatologic = Vogt-Koyanagi-Harada-like syndrome

ABBREVIATIONS

- ANA = antinuclear antibody
- DIF = direct immunofluorescence
- DLE = discoid lupus erythematosus
- ECG = electrocardiogram
- EMG = electromyography
- PE = pemphigus erythematosus
- PF = pemphigus foliaceus
- PV = pemphigus vulgaris
- SLE = systemic lupus erythematosus

NASAL DISCHARGE

BASICS

DEFINITION

Can be serous, mucoid, mucopurulent, purulent, blood tinged, or frank blood (epistaxis); may contain food debris.

PATHOPHYSIOLOGY

- Secretions—produced by mucous cells of the epithelium and submucosal glands; increased production from glandular hypertrophy and hyperplasia owing to irritation of the nasal mucosa by infectious, mechanical, chemical, or inflammatory stimuli.
- Xeromycteria—“dry nose”; facial nerve damage secondary to middle ear disease can decrease serous secretions from the lateral nasal glands leading to compensatory mucoid secretion; usually unilateral with unilateral nasal planum hyperkeratosis, ± keratoconjunctivitis sicca.

SYSTEMS AFFECTED

- Respiratory—mucosa of the upper tract, including the nasal cavities, sinuses, and nasopharynx; lower tract disease can also result in secretions from the upper airways.
- Gastrointestinal—signs may be observed with swallowing disorders or esophageal or gastrointestinal diseases when secretions are forced into the nasopharynx.
- Hemic/Lymphatic/Immune—blood-tinged discharge or epistaxis owing to platelet or hemostatic defects.
- Ophthalmic—may have KCS ipsilaterally if there is nerve damage due to middle ear disease.

SIGNALMENT

- Dog and cat.
- Young animals—cleft palate; nasal polyp, ciliary dyskinesia; immunoglobulin deficiency.
- Older animals—nasal tumors; primary dental disease (tooth root abscess).
- Hunting dogs—foreign body.
- Dolichocephalic dogs—aspergillosis, nasal neoplasia.

SIGNS

Historical Findings

- Sneezing—often found concurrently.
- Reverse sneezing—can be found concurrently, if nasopharyngeal involvement or passage of nasal secretions through the choanae towards the nasopharynx.
- Important to know both the initial and current character of the discharge as well as whether it originally started unilaterally or bilaterally.
- Stertor—owners frequently report noisy breathing, especially when animal is sleeping.
- Response to previous antibiotic therapy common due to secondary bacterial infection.

Physical Examination Findings

- Secretions or dried discharge on the hair of the muzzle or forelimbs.
- May note reduction in nasal air flow, particularly with nasal neoplasia or fungal infection in the cat.
- Concurrent dental, nasopharyngeal, or lower airway disease.
- Bony involvement—with a tumor or fourth premolar abscess; may be detected as facial or hard palate swelling or as pain secondary to fungal or bacterial osteomyelitis or neoplasia.
- Mucosal depigmentation of the nasal alar cartilage—observed with canine nasal aspergillosis.
- Mandibular lymphadenomegaly—neoplasia, fungal infection, dental disease.
- Polyp—may be visible on otoscopic exam, or pushing the soft palate down on oral exam.
- Chorioretinitis—may be seen with canine distemper or cryptococcosis.
- Deviation of the globe (abscess, sinoorbital aspergillosis in cats, tumors).

CAUSES

- Unilateral—often associated with non-systemic processes; foreign body; dental-related disease; fungal infections; nasal tumor; facial nerve damage leading to xeromycteria.
- Bilateral—infectious agents (e.g., feline viral rhinotracheitis or calicivirus, canine herpesvirus, canine distemper, secondary bacterial infection); IgA deficiency; airborne irritant; allergy; ciliary dyskinesia; lymphoplasmacytic or hyperplastic rhinitis, nasopharyngeal stenosis or atresia.
- Unilateral progressing to bilateral—*Aspergillus*; nasal tumor.
- Either unilateral or bilateral—epistaxis; foreign body; extranasal disease; nasal parasites, inflammatory rhinitis.
- Extranasal diseases—chronic pneumonia, chronic vomiting, nasopharyngeal diseases.

RISK FACTORS

- Dental disease
- Foreign bodies
- Infectious—poorly vaccinated animal; kennel situations, exposure to other animals
- Nasal aspergillosis
- Thrombocyte disorder—thrombocytopenia or thrombocytopathy: primary immune or secondary to infectious (i.e., rickettsial) disease or neoplasia
- Coagulation defect due to rodenticide intoxication
- Nasal mites—kennel-raised dogs
- Immunosuppression, chronic corticosteroid use, FeLV or FIV infection
- Chronic, low-grade pneumonia
- Chronic vomiting
- Chronic otitis (facial nerve damage)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Important to differentiate nasal discharge, secretions, or crusting from diseases that occur at mucocutaneous junctions, such as pemphigus, vasculitis, or leishmaniasis.

Differential Diagnosis Causes

- Serous—mild irritation; viral and parasitic (e.g., nasal mites) disorders.
- Mucoid—allergy; nonspecific airborne irritants; early neoplasia.
- Purulent (or mucopurulent)—secondary bacterial or fungal infection, neoplasia.
- Serosanguinous to epistaxis—nasal tumor and aspergillosis; secondary to violent or paroxysmal sneezing episodes; coagulopathy, platelet disorder, and systemic hypertension.

CBC/BIOCHEMISTRY/URINALYSIS

Results not specific for any particular cause but can detect concurrent problems; part of a thorough evaluation before general anesthesia for diagnostic procedures.

OTHER LABORATORY TESTS

- Serologic tests—help to diagnose fungal or rickettsial disease.
- Coagulation studies—determine platelet numbers and function, coagulation panel.
- Immunoglobulin quantification—investigates IgA deficiency.

IMAGING

Skull Imaging

- Anesthetize and carefully position patient.
- Perform before rhinoscopy and periodontal probing, which can cause nasal bleeding and alter radiographic density.
- Radiography (rarely performed when CT is available):
 - Lateral view—detect any periosteal reaction; note gross changes in the maxillary teeth, nasal cavity, and frontal sinuses; evaluate air column outlining the nasopharynx for filling defects.
 - Open-mouth ventrodorsal and intraoral views (using sheet film)—excellent for evaluating nasal cavities and turbinates.
 - Rostro-caudal view—evaluate each frontal sinus (periosteal reaction and filling).
- CT and MRI—CT superior to radiography in making diagnosis; CT and MRI help detect the extent of bony changes or CNS involvement associated with nasal tumors, fungal rhinitis, or chronic otitis.

Thoracic Radiography

Can reveal alveolar infiltrates in patient with chronic pneumonia; situs inversus or bronchiectasis in some dogs with primary ciliary dyskinesia.

(CONTINUED)

DIAGNOSTIC PROCEDURES

- Blood pressure, platelets, and coagulation profile for epistaxis.
- Rhinoscopy—indicated with chronic or recurrent nasal discharge; acute epistaxis; evaluate both anterior and posterior; may be contraindicated with bleeding disorders.
- Nasal cytologic examination—nonspecific inflammation most commonly found.
- Fungal culture—difficult to interpret; need visualized sampling of a plaque lesion; false-negatives common.
- Bacterial culture could be useful when resistant organisms are suspected, but requires deep nasal sampling under anesthesia.
- Biopsy of the nasal cavity—indicated with chronic nasal discharge or visualized abnormalities; multiple samples required to ensure adequate representation; may perform electron microscopy for suspected ciliary dyskinesia.
- Bronchoscopy—indicated if there has been a history of coughing with nasal discharge.
- Periodontal probing of all upper teeth—perform after rhinoscopy; the normal gingival sulcus: dogs, \leq 4 mm; cats, \leq 1 mm.
- Schirmer tear test, otoscopic exam or CT—to evaluate for possible facial nerve damage from chronic otitis.
- Tracheal scintigraphy and electron transmission microscopy—to confirm primary ciliary dyskinesia.

**TREATMENT**

- Outpatient—adequate hydration, nutrition, warmth, and hygiene (keeping nares clean)—important with chronic sneezing and nasal discharge. Prioritize local therapy (nasal drops, nasal nebulization).
- Inpatient—any surgical treatment, topical therapy for aspergillosis.

**MEDICATIONS****DRUG(S)**

- Secondary bacterial infection—antibiotics; choose a good gram-positive spectrum of activity (e.g., amoxicillin, clavamox, clindamycin, azithromycin, cephalosporins).
- Attempt to dry up serous nasal secretions—decongestants (ephedrine: dogs, 10–50 mg total PO q8–12h, to a maximum of 4 mg/kg; cats, 2–4 mg/kg q8–12h); topical vasoconstrictors (neosynephrine at 0.25–0.5% q8–24h or oxymetazoline at 0.25% q24h) but for a limited period of

time—less than 1 week—these drugs do not treat a specific cause and could induce damage to the nasal mucosa.

- Dental-associated rhinitis—antibiotics; dental surgery as indicated.
- Foreign body—removal, antibiotics.
- Nasal parasites—ivermectin (300 μ g/kg PO or SC weekly for 3 weeks) or milbemycin (in collie and similar breeds at 1 mg/kg PO weekly for 3 weeks) to treat *Pneumonyssoides*; fenbendazole (50 mg/kg PO q24h for 10 days) to treat *Eucoleus* (nasal nematode).
- Nonspecific inflammation—prednisolone (1–2 mg/kg PO q12–24h) or piroxicam (0.3 mg/kg PO q24–48h).
- Canine nasal aspergillosis—topical treatment with enilconazole or clotrimazole.
- Feline cryptococcosis or sporothricosis—itraconazole (5–10 mg/kg PO q24h) or fluconazole (50 mg/cat q12h).
- Feline aspergillosis—topical therapy, itraconazole.
- Neoplasia—radiotherapy and chemotherapy.
- Xeromycteria—oral administration of ophthalmic pilocarpine in an attempt to stimulate nasal secretions.

CONTRAINdications

- Ephedrine—in cardiac patients
- Ivermectin—in collies and similar breeds

PRECAUTIONS

- Itraconazole—anorexia, nausea, vomiting, and high liver enzymes
- Rebound phenomenon—reported with overuse of topical nasal vasoconstrictors

**FOLLOW-UP****PATIENT MONITORING**

- Nasal discharge and sneezing—note changes in frequency, volume, and character.
- Repeat rhinoscopy—indicated to ensure adequate response to treatment of fungal rhinitis.
- Recheck thoracic radiographs or bronchoscopy—monitor response to treatment for chronic pneumonia.

POSSIBLE COMPLICATIONS

- Loss of appetite—especially in cats.
- Extension of primary disease (e.g., fungal infection, tumor) into the mouth, eye, or brain.
- Respiratory distress—with nasal obstruction.
- Involvement of the cribriform plate in dogs with aspergillosis—CNS damage during topical drug therapy is a risk.

NASAL DISCHARGE**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Sinusitis
- Dental disease
- Secondary causes—coagulopathy, pneumonia, cricopharyngeal disease, megaesophagus

AGE-RELATED FACTORS

Middle-aged to old patients—often associated with dental or neoplastic conditions.

PREGNANCY/FERTILITY/BREEDING

The safety of most recommended drugs has not been established in pregnant animals.

SEE ALSO

- Aspergillosis, Nasal
- Cryptococcosis
- Epistaxis
- Nasal and Nasopharyngeal Polyps
- Nasal tumor chapters
- Nasopharyngeal Stenosis
- Primary Ciliary Dyskinesia
- Rhinitis and Sinusitis

ABBREVIATIONS

- CNS = central nervous system
- CT = computed tomography
- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus
- KCS = keratoconjunctivitis sicca
- MRI = magnetic resonance imaging

N

NASOPHARYNGEAL STENOSIS

BASICS

OVERVIEW

- Formation of a thin but tough membrane at the choanae or anywhere above the soft palate, resulting in the occlusion of the caudal nasopharyngeal openings or narrowing of the orifice from a 1+ cm oval opening to a 1- to 2-mm opening or less.
- Inflammation secondary to chronic rhinitis, or from chronic regurgitation or vomiting of material into the nasopharynx should be considered as possible causes.
- Congenital narrowing or dysgenesis of the region is also suspected; thickened palatopharyngeal muscles have been reported as a cause of nasopharyngeal stenosis in the dachshund.

SIGNALMENT

- Cats of any breed or sex.
- Less commonly seen in dogs.
- Age—any age as long as ample time has passed since exposure to the inciting cause; congenital cases may present early or late in life.

SIGNS

- Evidence of upper respiratory obstruction
- Whistling or snoring sounds during respiration
- Open-mouth breathing
- Minimal nasal discharge in many cases
- Duration of signs for at least several months
- Aggravation of signs during eating or drinking
- Failure to respond to antibiotics or corticosteroids
- Absence of nasal airflow from one or both nares

CAUSES & RISK FACTORS

- Chronic upper respiratory disease.
- Foreign body or irritant contacting the affected area (perianesthetic regurgitation, reflux of gastric contents secondary to esophageal or gastric disease).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Nasopharyngeal polyps—seen during oral examination or by radiography or endoscopy.
- Chronic rhinitis or sinusitis—moderate to severe nasal discharge and sneezing; obvious radiographic changes commonly seen.
- Foreign body—unilateral mucopurulent nasal discharge; radiographic abnormalities.
- Intranasal neoplasia—unilateral obstruction; nasal discharge often bloody; radiographic changes.
- Mycotic rhinitis—moderate-to-severe nasal discharge, often hemorrhagic; radiographic changes.
- Laryngeal disease—no improvement with open-mouth breathing; lack of snorting and nasal discharge; abnormalities on oral examination.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

IMAGING

- Near-normal radiographic findings.
- Nasopharyngeal stenosis sometimes can be visualized on computed tomography. Sagittal reconstruction of the images can be required.

DIAGNOSTIC PROCEDURES

- Inability to pass a 3.5 French catheter through the ventral nasal meatus into the pharynx in a cat.
- Visualization of the stenosis by use of a retroflexed pediatric bronchoscope into the nasopharynx or use of an illuminated dental mirror.

TREATMENT

- Balloon dilatation—non-invasive; fluoroscopy simplifies procedure; repeat episodes can be required (more in the dog than cat).

- Stent placement may be needed for cases with recurrent stenosis.

MEDICATIONS

DRUG(S)

Antibiotics and steroids sometimes used post balloon dilation.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

Have owners evaluate nasal airflow at home and warn that recurrence is possible.

MISCELLANEOUS

Author Lynelle R. Johnson

Consulting Editor Lynelle R. Johnson

N

BASICS

DEFINITION

Discomfort along the vertebral column

PATHOPHYSIOLOGY

Caused by multiple neurologic or non-neurologic diseases (e.g., polyarthritis). Secondary to stimulation of nociceptors located in meninges, nerve roots, spinal nerves, vertebrae and associated structures (e.g., periosteum, joint capsules), and epaxial musculature. An intracranial disease can develop referred neck pain when intracranial pressure is elevated.

SYSTEMS AFFECTED

- Nervous • Musculoskeletal
- Neuromuscular

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Intervertebral disc herniation—dogs; extrusion chondrodystrophic breeds, protrusion large breeds. Less common in cats.
- Cervical spondylomyopathy—Doberman, Great Dane, Bernese mountain dog, Rottweiler, Dalmatian. • Atlantoaxial instability—small and miniature canine breeds (e.g., Yorkshire terrier, Chihuahua).
- Steroid-responsive meningitis-arteritis—Bernese mountain dog, Boxer, Beagle.
- Caudal occipital malformation syndrome and syringomyelia—Cavalier King Charles spaniel. • Immune-mediated polymyositis—Newfoundland, Boxer.

Mean Age and Range

- IVDD extrusion—unusual < 2 years, peak 3–8 years. • IVDD protrusion—> 5 years.
- CSM—middle-aged to older Dobermanns (mean: 6 years), young Great Danes (< 3 years). • AA instability—young to middle-aged. • SRMA—< 2 years (8–18 months). • Lumbosacral syndrome—middle-aged large dogs; German shepherd.

SIGNS

Historical Findings

Primary complaint—relates to perceived discomfort; e.g., vocalization, decreased activity, reluctance to get up or lie down, reluctance to go up or down stairs, inability to drink or eat from bowls on the floor (neck), neck muscle spasms. Neck pain may be intermittent.

Physical Examination Findings

- Abnormal neck carriage, reluctance to move the head, stiff neck posture. • Arched back (kyphosis). • Pain on spinal palpation and/or neck manipulation. • Abdominal rigidity (referred from back pain). • Increased epaxial muscle tone. • Intermittent neck muscle spasms. • Reluctance to walk, stilted gait,

limb stiffness, guarded short stride.

- Non-weight-bearing lameness (nerve root signature). • Autonomic signs (e.g., tachycardia, pupillary dilation). • Neurologic deficits possible (e.g., paresis, ataxia).
- Pyrexia (SRMA, infectious diseases).

CAUSES

Degenerative

- IVDD—most common cause of spinal pain in dogs • CSM. • Spinal synovial cysts
- Vertebral facet hypertrophy • Calcification circumscripta

Anomalous/Developmental

- AA instability • COMS and syringomyelia
- Vertebral malformations: e.g., hemivertebra (usually asymptomatic)
- Osteochondromatosis • Dermoid sinus

Neoplastic

- Spinal (primary or secondary), nerve root-peripheral nerve (e.g., peripheral nerve sheath tumor), muscle. • Intracranial tumors with secondary increased ICP (referred neck pain).

Nutritional

Feline hypervitaminosis A

Inflammatory

- Discospondylitis, vertebral osteomyelitis, vertebral physisis. • Infectious meningitis-meningomyelitis—viral (e.g., FIP), bacterial, rickettsial, fungal, protozoal, parasitic, algae.
- Non-infectious meningitis-meningomyelitis—SRMA, MUO/GME.
- Spinal epidural empyema. • Paraspinal abscess. • Polyarthritis—immune-mediated, infectious. • Polymyositis—immune-mediated polymyositis, infectious, exertional rhabdomyolysis.

Idiopathic

Subarachnoid diverticulum (rarely painful)

Traumatic

- Spinal fracture, luxation • Traumatic disc herniation

Vascular

Spinal hemorrhage

RISK FACTORS

- Breed—chondrodystrophic (IVDD), miniature dog (AA instability) • Trauma
- Previous surgical procedure (discospondylitis, subluxation) • Malignant neoplasm • Bite wound, foreign body, UTI, endocarditis • Coagulopathy • Liver diet (hypervitaminosis A) • FeLV infection (spinal lymphoma)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Orthopedic disease • Abdominal pain (back) • Behavioral or abnormal mentation (delirium) • Increased ICP (referred neck pain) • Non-painful myelopathy—e.g., degenerative myelopathy, fibrocartilaginous

NECK AND BACK PAIN

embolic myelopathy • Paroxysmal disorders

- Feline hyperesthesia syndrome

CBC/BIOCHEMISTRY/URINALYSIS

- CBC usually normal. May see neutrophilia (SRMA, dyskostyndylitis), thrombocytopenia (rickettsial disease, malignant neoplasm). • Elevated CK, AST—myositis, recumbence, trauma, anorexia (cat).
- Hyperproteinemia—neoplastic, infectious.
- UTI—focus for discospondylitis, with urinary retention. • Myoglobinuria—myositis.

OTHER LABORATORY TESTS

- Serologic titers, PCR (blood, CSF) for infectious diseases • Blood/urine cultures—discospondylitis • IgA and acute phase proteins levels (blood, CSF) in SRMA
- Serum protein electrophoresis
- Coagulation panel

IMAGING

Survey Spinal Radiography

- Not able to identify spinal cord compression. • IVDD—may detect narrowed intervertebral space, calcified disc. • Detects discospondylitis (normal first 2–3 weeks).
- Spinal neoplasms—osteolysis, bony proliferation, wider vertebral canal. • Detects fractures, luxations, AA instability, facet hypertrophy, malformations, calcification circumscripta, osteochondromatosis.

Thoracic Radiography and Ultrasonography

Detect neoplasms (primary or metastatic), disseminated infections, endocarditis, trauma-related lesions.

Myelography

Detects and delineates spinal cord lesions as extradural, intradural-extramedullary and intramedullary. Low sensitivity in detecting parenchymal lesions.

CT

- More sensitive than radiographs for discospondylitis, vertebral fractures, bone tumors. Clearly defines bony lesions but less soft tissue contrast than MRI. Can be useful to diagnose IVDD extrusion if calcified material. • CT-myelogram—more sensitive to assess spinal cord compressive lesions.

MRI

More sensitive than CT for soft tissue. Most rewarding imaging technique for identifying location and extent of spinal cord parenchymal lesion, nerve roots, nerves, and muscle.

DIAGNOSTIC PROCEDURES

CSF

- Useful in meningitis/meningomyelitis, but normal or nonspecific in many other situations. Rarely, neoplastic cells can be detected (spinal lymphoma). • Consider measuring IgA levels, acute phase proteins, serologic titers, PCRs, culture.

NECK AND BACK PAIN

(CONTINUED)

Arthrocentesis and Synovial Fluid Analysis

Polyarthritis

Electrodiagnostics

EMG, nerve conduction studies—detect and localize neuromuscular disease (e.g., polymyositis).

Fluoroscopy or CT-Guided Percutaneous FNA

Discospondylitis, neoplasms

Biopsy

Bone (e.g., neoplasia, osteomyelitis), muscle (e.g., polymyositis).

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient—when severe clinical signs; emergency intensive care due to severe pain or neurologic deficit.
- Outpatient—when medical treatment is pursued (restricted exercise can be done).
- Emergency surgery—if traumatic spinal instability or severe neurologic deficit (non-ambulatory paraparesis, tetraplegia) due to an acute spinal cord compression.

NURSING CARE

- Non-ambulatory patients—soft bedding, alternate recumbence site.
- Vertebral instability—extreme care on manipulation to avoid exacerbating injury.

ACTIVITY

Restrict exercise at least 3–4 weeks in medically treated patients.

DIET

Change diet in case of hypervitaminosis A

CLIENT EDUCATION

- Monitor pain, response to treatment and possible gait abnormalities. Relapses common in many diseases.
- Most common cause of spinal pain in dogs is IVDD. Inform that restricted activity and cage confinement for 3–4 weeks are necessary when medical treatment is pursued; recurrence frequent. If pain persists or neurologic status deteriorates, surgical treatment is recommended, even as an emergency procedure.

SURGICAL CONSIDERATIONS

Vary according to disease. Generally, deep pain perception is considered the most important prognostic indicator for functional recovery in neurologic disease. AA instability correction is associated with high perioperative morbidity and mortality.

MEDICATIONS

DRUG(S) OF CHOICE

- Opioids—tramadol (1–5 mg/kg q6–12h PO, dog), morphine (0.1–1.0 mg/kg q4h,

dog), hydromorphone (0.05–0.2 mg/kg q4h, dog), fentanyl (transdermal patch).

- Glucocorticoids—prednisone 0.5–1 mg/kg q24h (dog) in decreasing dosage. Use of glucocorticoids in acute spinal cord trauma is controversial. Medical management of acute IVDD should focus on cage confinement. Higher doses required in immune-mediated disease (2–4 mg/kg q24h). • NSAIDs—potentially more effective in acute cervical IVDD, Meloxicam (0.1 mg/kg q24h, dog), carprofen (2.2 mg/kg q12h, dog).
- Gabapentin 10–15 mg/kg q8h PO, dog; chronic neuropathic pain (syringomyelia, nerve root disease).
- According to disease—antimicrobials (e.g., discospondylitis), immunosuppressive drugs, chemotherapy (neoplasms).

CONTRAINDICATIONS

- Glucocorticoids, immunosuppressive agents—*infections*.
- Opioids—diarrhea caused by a toxic ingestion, gastrointestinal obstruction.

PRECAUTIONS

- Concurrent administration of NSAIDs and glucocorticoids is strongly contraindicated.
- Glucocorticoids, NSAIDs—may cause gastrointestinal ulceration/hemorrhage.
- Glucocorticoids—may cause UTI.
- Vertebral instability or IVDD—strict cage rest mandatory while on anti-inflammatory and analgesic drugs; increased activity can exacerbate the problem.
- Opioids—caution if respiratory dysfunction, increased ICP, CNS depression, bradycardia, arrhythmias.
- Gabapentin—caution if renal insufficiency.

POSSIBLE INTERACTIONS

- Opioids—increased CNS and respiratory depression when combined with other CNS depressants.
- Gabapentin—oral antacids may decrease oral bioavailability 20%.

ALTERNATIVE DRUG(S)

- NMDA antagonists (e.g., ketamine)—analgesics
- Pregabalin—chronic neuropathic pain
- Furosemide, omeprazol—COMS/syringomyelia
- Azathioprine, cyclosporine, cytosine arabinoside—immune-mediated diseases

FOLLOW-UP

PATIENT MONITORING

- Primarily based on clinical signs and response to treatment. Initially, monitor at least once a week. If acute severe pain and/or neurologic deficit present, inpatient or daily monitoring recommended. Make adjustments or consider surgery when medical treatment is not effective.
- CSF analysis (e.g., SRMA), spinal radiographs (e.g., discospondylitis), acute phase proteins levels, bloodwork/thoracic radiographs/ultrasound (e.g., neoplasms, infectious diseases).

PREVENTION/AVOIDANCE

Avoid excessive activity, jumping, going upstairs/downstairs, and excess weight. Avoid collars.

POSSIBLE COMPLICATIONS

- Recurrences or deterioration. Surgical treatment can be recommended on an emergency basis according to disease.
- Chronic unresponsive pain.
- Permanent neurologic dysfunction.
- Spread to other locations, pathologic vertebral fracture/luxation (discospondylitis, neoplasms).
- Degenerative joint disease (polyarthritis).

EXPECTED COURSE AND PROGNOSIS

- Varies with disease, severity of clinical signs, and neurologic deficit.
- IVDD extrusion—success with medical treatment in dogs with only pain or mild deficits is about 50% at the most.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Immune-mediated non-erosive polyarthritis and SRMA.
- Discospondylitis and UTI.
- FeLV and feline spinal lymphoma.
- Polymyositis and lymphoma.
- Polymyopathies/myositis—megAESOPHAGUS/dysphagia and aspiration pneumonia.

NECROTIZING ENCEPHALITIS

BASICS

DEFINITION

Necrotizing encephalitis historically restricted to a few breeds such as the pug, Yorkshire terrier, and Maltese dog is described nowadays also in other breeds such as the Chihuahua, the Shih Tzu, and others. It includes necrotizing meningoencephalitis (NME) and necrotizing leukoencephalitis (NLE), since an overlap of clinical signs and histopathologic findings occurs.

SYSTEMS AFFECTED

Nervous

GENETICS

A genetic basis probable; in pug dogs familial inheritance pattern; multifactorial disorder suspected

INCIDENCE/PREVALENCE

Not determined but disease occurring regularly

GEOGRAPHIC DISTRIBUTION

Occurs worldwide, mostly seen in toy breeds

SIGNALMENT

Breed Predilections

Maltese, Pugs, Yorkshire terriers, French bulldogs, Chihuahuas, Shih Tzus, Pekingese, and other toy breeds.

Mean Age and Range

Mostly young adult dogs (range 4 months–10 years)

Predominant Sex

No sex predilection

SIGNS

Progressive signs related to a forebrain lesion (abnormal behavior, seizures, circling, blindness), brainstem lesions with central vestibular signs, or a multifocal lesion.

CAUSES & RISK FACTORS

- Genetic risk factors.
- An infectious agent might be suspected.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other CNS inflammatory/infectious diseases—differentiated on serology, CSF, and MRI results.
- Neoplasia—differentiated on MRI findings.

CBC/BIOCHEMISTRY/URINALYSIS

Results are usually normal

OTHER LABORATORY TESTS

Genetic test for predisposition in pug dogs.

IMAGING

CT/MRI—results help support the clinical diagnosis considering breed, age, clinical signs, and course of the disease. Lesions may be asymmetric, multifocal prosencephalic with varying contrast enhancement, and can include multiple cystic areas of necrosis.

DIAGNOSTIC PROCEDURES

- CSF—pleocytosis with predominantly mononuclear cells; mild to marked protein elevation.
- Brain biopsy—to confirm diagnosis.

PATHOLOGIC FINDINGS

- Necrosis and non-suppurative inflammation of the cerebral gray and white matter; multifocal lesions; active lesions consist of a large malacic gliotic center surrounded by a wall of severe mononuclear inflammation.
- Old lesions consist of rarefied or cystic areas surrounded by intense astroglial sclerosis.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient or outpatient based on the neurologic status
- Symptomatic treatment recommended

NURSING CARE

N/A

CLIENT EDUCATION

- Disease cannot be treated specifically; there may be an improvement with anti-inflammatory or immunosuppressive drugs.
- Seizures may be the only sign at onset of the disease in pug dogs—diagnostic workup of pug dogs presented with seizures is recommended.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

- Symptomatic treatment.
- To control seizures, phenobarbital (2–6 mg/kg PO q12h).
- Corticosteroids can reduce the inflammatory response and improve clinical signs (e.g., prednisolone or prednisone 1–2 mg/kg PO q24h for the first 1–2 weeks; then the dosage can be tapered slowly); other immunosuppressive drugs are used successfully.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Cytosine arabinoside, procarbazine, azathioprine, cyclosporine, leflunomide, lomustine, mycophenolate mofetil.

FOLLOW-UP

PATIENT MONITORING

- Regular clinical and neurologic examinations to monitor response to symptomatic treatment.
- Monitoring of phenobarbital serum levels.

PREVENTION/AVOIDANCE

N/A

EXPECTED COURSE AND PROGNOSIS

- The course of the disease is chronic for months or even years; in every confirmed case, the neurologic signs have been progressive.
- Prognosis is guarded.

MISCELLANEOUS

ASSOCIATED CONDITIONS

In one pug dog, myocardial necrosis was seen in addition to the encephalitic lesions.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Three pugs described in Japan had a history of pregnancy before onset of clinical signs.

N

ABBREVIATIONS

- CNS = central nervous system
- CSF = cerebrospinal fluid
- CT = computed tomography
- MRI = magnetic resonance imaging

NEONATAL MORTALITY (FADING SYNDROME)

BASICS

DEFINITION

- Death occurring between birth and 2–3 weeks of age.
- Fading syndrome describes a clinical presentation rather than a specific etiology.

PATHOPHYSIOLOGY

- Four major factors lead to vulnerability of neonates: poorly developed thermoregulatory mechanisms; increased risk of dehydration (immature kidney function); increased risk of hypoglycemia (small reserve of glycogen); and immunologic immaturity (95% antibodies from colostrum).
- Highly susceptible to environmental, infectious, nutritional, and metabolic factors.

SYSTEMS AFFECTED

- Cardiovascular
- Endocrine
- Metabolic
- Hepatobiliary
- Gastrointestinal
- Nervous
- Renal/Urologic
- Respiratory
- Ocular/Hemic/Lymphatic/immune
- Skin/exocrine

SIGNALMENT

- Dogs and cats.
- Pedigree puppies and kittens—more prone to congenital (and hereditary) defects, higher overall incidence of stillbirth and neonatal mortality.

SIGNS

General Comments

- Preweaning losses—typically 10–30%; about 65% occur during the first week; greater losses in a cattery or kennel should be considered abnormal.
- A thorough history should be taken to identify potential underlying causes. Particular attention should be given to signalment, breeding history, vaccination and worming history, exposure to toxins, problems during parturition, size of the litter and mothering abilities.

Historical Findings

- Low birth weight, loss of weight, and/or failure to gain weight.
- Decreased activity and appetite.
- Weakness.
- Poor suckling response.
- Constantly vocal or restless early, quiet and inactive later.
- Tendency to remain separate from the dam and the rest of the litter.
- Low Apgar scores at birth. (Apgar scores can be used to assess neonatal viability and short-term survival prognosis.)

Physical Examination Findings

- Nonspecific.
- Dark red or bluish ventral abdominal skin indicative of sepsis or cyanosis.
- Red to purple toes, swollen red and/or purulent umbilical stump may indicate sepsis.
- Gross anatomic defects—open fontanelles, cleft palate, imperforate anus, pectus excavatum, or asymmetry of limbs may be noticed. Hair coat abnormalities over the dorsum may indicate spina bifida.
- Weakness, hypothermia (newborn temperature is 34.7–37.2°C [94.5–99°F],

rising to 36.1–37.8°C [99–100°F] during the first week of life), hypoglycemia, and dehydration are common and interrelated.

- Respiratory distress, diarrhea, or hemoglobinuria may be seen.

CAUSES

- Four most common causes: infection, poor maternal management, low birthweight, congenital abnormalities.

Non-infectious

- Dam-related—dystocia or prolonged labor; cannibalism; lactation failure; trauma; inattention or overattention; inadequate nutrition, including taurine deficiency in kittens. Signalment—breed, age (older), size of litter (larger litters) associated with mortality rate.
- Environmental—any factor that discourages nursing and allows hypothermia, including temperature extremes, humidity extremes, inadequate sanitation, overcrowding, and stress.
- Nutritional—inadequate or ineffective nursing; hypoglycemia; hypothermia-induced digestive malfunction.
- Neonatal isoerythrolysis—queen with blood type B; kitten with blood type A.

Birth Defects

- Gross anatomic defects—more frequent in kittens (about 10% of non-surviving neonates) than in puppies. Failure of midline craniofacial closure causing herniation.
- Alimentary—cleft palate; segmental intestinal agenesis or atresia, imperforate anus, congenital megaesophagus, portosystemic shunt, mucopolysaccharide storage disease.
- Cardiac defects—valvular dysplasia; ventricular septal defect; atrioventricular fistula, tetralogy of Fallot, patent ductus arteriosus, congenital rhythm disorders.
- Respiratory defects—thoracic wall abnormalities; pectus excavatum; primary ciliary dyskinesia; surfactant deficiency.
- Renal defects—agenesis, dysplasia, fanconi syndrome, polycystic kidney disease, ureteral abnormalities.
- Endocrine—diabetes mellitus, hypothyroidism, hyposomatotropism, central diabetes insipidus.
- Central nervous system—cerebellar hypoplasia and abiotrophy, hydrocephalus, spinal dysraphism, neuronopathies and lysosomal storage disease.
- Hematologic—coagulopathies, von Willebrand disease, pyruvate kinase deficiency, hemolytic anemia, phosphofructokinase deficiency.
- Immune system—thymus dysfunction and atrophy.
- Miscellaneous—skin defects, ocular defects.

Infectious

- Viral: Kittens—feline calicivirus; FeLV; FIV; feline herpesvirus type 1, feline panleukopenia virus. Puppies—canine adenovirus type 1; canine distemper virus; canine herpesvirus; canine parvovirus type 1 (minute virus) and type 2; canine influenza virus, canine coronavirus.
- Bacterial—acquired mainly

across the placenta or via the umbilicus but can also occur through the gastrointestinal tract, respiratory tract, urinary tract, and skin wounds. *E. coli*, β -hemolytic *Streptococcus*, coagulase-positive *Staphylococcus*, *Salmonella* spp., *Campylobacter* spp., *Bordetella bronchiseptica*, *Pasteurella multocida*, *Brucella canis*, *Leptospirosis*.

- Parasitic (helminths)—*Toxocara* spp., *Ancylostoma* spp.; (protozoal)—*Toxoplasma*, *Neospora*, *Cryptosporidium*, or *Giardia*, (Coccidia) *Isospora*.

RISK FACTORS

- Subnormal birth weight or failure to grow normally—kittens: minimum daily gain of 7–10 g; puppies: should double in weight by 10–12 days; both: 5–10% gain per day generally acceptable.
- Dystocia or prolonged labor.
- Inbreeding—higher incidence of homozygous recessive genotype.
- Sire with blood type A and queen with blood type B.
- Increased litter size, older dam, certain breeds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Excessive losses often due to a combination of environmental, immunologic, nutritional, infectious, and metabolic factors; detection and correction of problems in each area is necessary to prevent ongoing losses.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Hydration status and age influence results.
- Mild normocytic, normochromic anemia (normal PCV at 1 week 33–52%, at 2 weeks 29–34%).
- White cell counts variable; may note thrombocytopenia and mild to moderate neutrophilia (with left shift) if septic.

Biochemistry

- Hypoglycemia.
- Hypercholesterolemia, hypertriglyceridemia.
- Low alkaline phosphatase and phosphorus (depressed growth).
- Low gamma-glutamyl transferase—indicator of failure to receive colostrum.
- Other changes depend on organ system involved.

Urinalysis

- Hemoglobinuria—with neonatal isoerythrolysis.
- Bacteria—with infection.
- Urine specific gravity > 1.017 suggests inadequate hydration.

OTHER LABORATORY TESTS

- FeLV antigen test.
- FIV antibody test.
- Serology—*Brucella canis*; canine herpesvirus; canine influenza virus; *Toxoplasma*; *Neospora*; *Leptospirosis*.

IMAGING

- Abdominal ultrasound examination may be useful.
- Thoracic and abdominal radiographs can be helpful (e.g., aspiration pneumonia); however, can be difficult to obtain diagnostic

(CONTINUED)

NEONATAL MORTALITY (FADING SYNDROME)

films. May help to radiograph age-matched individual at the same time.

DIAGNOSTIC PROCEDURES

- Histopathologic—examination of multiple tissues collected at necropsy.
- Metabolic screening of urine sample—rule out inborn errors of metabolism.
- Virus isolation.
- Bacterial culture.
- Blood typing in pedigree cats (dam and kitten).
- Fecal examination—parasites.

PATHOLOGIC FINDINGS

- Post-mortem—extremely important; examine as soon after death as possible to minimize autolysis; give special notice to the following items.
 - Stomach—devoid of contents: lack of nursing; consider dam-related causes (e.g., inappropriate behavior or lactation) or neonatal problems (e.g., weakness, trauma, or physiologic abnormality); filled with milk: suggests sudden death (e.g., trauma, peracute illness) or gastrointestinal dysfunction (body temperature $<35^{\circ}\text{C}$ [95°F]).
 - Thymus subnormal size—not pathognomonic for thymic dysfunction; atrophy can be a result of multiple causes (e.g., viral infection, stress, toxins, nutrition, and defective immune system).
 - Petechiation—common; accompanied by hemorrhage in other organ systems suggests coagulopathy or septicemia.
 - Urine in the urinary bladder—implies a degree of renal dysfunction or inadequate care by the dam.
 - Lungs—should appear the same as an adult's; homogeneous dark red color typical of a stillborn animal that has not taken a breath; hemorrhage, edema, congestion, and mottled color abnormal but nonspecific.
- Note malformations.
- Multiple tissue samples—submit to a diagnostic laboratory; virus isolation, bacterial culture and sensitivity, and histopathology; check with laboratory for proper submission.

**TREATMENT**

- Correct any underlying deficiencies in husbandry or breeding selection.
- Warmth—slowly warm neonate to $36\text{--}37.2^{\circ}\text{C}$ ($97\text{--}99^{\circ}\text{ F}$) over several hours (one degree celsius per hour), if necessary; provide ambient temperature of $29\text{--}35^{\circ}\text{C}$ ($85\text{--}95^{\circ}\text{F}$) and relative humidity of 55%–65%.
- Oxygen—supplement at

30%–40%, if necessary. (Difficult to detect hypoxia as puppies and kittens do not always hyperventilate; clinical signs can include increased respiratory effort, bradycardia, hypotension, and a distended abdomen due to aerophagia.)

- Fluid therapy—intravenous via a jugular or cephalic vein or intraosseous in femur or humerus. Fluid requirements: 80–100 mL/kg/day. Care as volume overload can occur.
- Dextrose supplementation 0.5–1.0 g/kg as part of 5–10% solution (D5W or 5% dextrose in Ringer's solution).
- Do not attempt to feed if body temperature $<35^{\circ}\text{C}$ (95°F) and no sucking reflex; once warmed, encourage nursing.
- Neonatal isoerythrolysis—disallow nursing for first 24 hours after birth.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Antibiotics—commonly used are penicillins (penicillin G, ampicillin, amoxicillin, amoxicillin with clavulanic acid) and first-generation cephalosporins; reduce adult dose by one-half and use same dosage interval.
- Supplement—milk replacer formula.
- Vitamin K₁—0.01–0.1 mg SC or IM once.

CONTRAINdicATIONS

Aminoglycosides, tetracyclines, fluoroquinolones, trimethoprim/sulfonamide, and chloramphenicol—avoid during the neonatal period.

PRECAUTIONS

Drug absorption, distribution, metabolism, and excretion for dogs and cats differ significantly during the first 5 weeks of life from those of adults.

POSSIBLE INTERACTIONSN/ALTERNATIVE DRUGS

N/A

**FOLLOW-UP****PATIENT MONITORING**

- Hydration status—monitor regularly (mucous membranes, urine specific gravity).
 - Body weight—monitor daily or every other day in growing neonates.
 - Dam—monitor mothering abilities and milk production.
- Provide supplemental nutrition to neonates if required.

POSSIBLE COMPLICATIONS

N/A

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

Some infectious agents have zoonotic potential (e.g., *Toxoplasma*, *Leptospira*).

PREGNANCY/FERTILITY/BREEDING

Do not breed individuals with congenital defects.

SYNONYMS

- Fading puppy or kitten syndrome
- Wasting syndrome

ABBREVIATIONS

- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus

NEONICOTINOID TOXICOSIS

BASICS

OVERVIEW

- Neonicotinoids are a class of neuro-active insecticides chemically similar to nicotine.
- Act on insects at three different post-synaptic nicotinic receptors found in CNS.
- Wide safety margin in mammals due to high selectivity for specific subtypes of nicotinic receptors in insects.
- Compounds include imidacloprid and nitenpyram, commonly used veterinary products, as well as acetamiprid, clothianidin, dinotefuran, nithiazine, sulfoxaflor, and thiamethoxam.
- Widespread use in veterinary medicine for flea control (tablets, e.g. Capstar®, collars, topical spot on products, etc.).
- Used in termite and grub control, and crop production against sucking and chewing pests in a variety of formulations.

SIGNALMENT

- Primarily dogs: chewing up ant bait containers, collars, boxes of tablets, bags, liquid products.
- Rarely reported in cats.

SIGNS

- Imidacloprid has shown no adverse effects when used at 5X the maximum dosage in dogs and cats.
- Alopecia and erythema has been reported following dermal application.
- Oral toxicity is possible if the dose or concentration is excessively high.
- Most common complaint following ingestion is hypersalivation.
- Most common adverse effects observed with dosing of neonicotinoids were decreased activity, tremors, mydriasis or miosis and incoordinated gait; hypothermia was observed at higher doses.

CAUSES & RISK FACTORS

- Dogs chewing on containers.
- Wide availability and frequent access to products.

DIAGNOSIS

History of exposure and clinical signs.

TREATMENT

- Dermal exposure—bathe with liquid dishwashing detergent.
- Oral exposure—dilution with cool water, emesis, gastric lavage, activated charcoal, depending on amount ingested and clinical signs.
- Baseline CBC, chemistry profile, and urinalysis to rule out any pre-existing organ dysfunction, which could increase the risk for toxicosis.
- Antihistamines for signs of dermal hypersensitivity.
- Methocarbamol for tremors.
- IV fluids with a balanced crystalloid.

MEDICATIONS

- Dog emesis: apomorphine 0.03 mg/kg IV,
- Cat emesis: xylazine 0.44 mg/kg IM Avoid hydrogen peroxide due to risk for hemorrhagic gastroenteritis.
- Activated charcoal (0.5–1 g/kg PO) and an osmotic cathartic (sodium sulfate, 125 mg/kg PO) × 1 dose.
- Methocarbamol: 50–220 mg/kg IV. Max daily dose 330 mg/kg/day (cats and dogs). Give 1/2 dose rapidly, wait until animal relaxes, and give remainder of dose to effect.

FOLLOW-UP

Patients usually recover with symptomatic and supportive care; no long term organ damage is expected.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

- Puppies /young dogs are less discriminate and more likely to chew up product containers.
- Young and geriatric animals may have lower detoxification capabilities.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Studies confirmed that imidacloprid is not mutagenic, non-embryotoxic, and non-teratogenic.

ABBREVIATION

CNS = central nervous system

INTERNET RESOURCES

NEOSPOROSIS

BASICS

OVERVIEW

- *Neospora caninum*—recently recognized coccidian protozoan previously confused with *Toxoplasma gondii*; tachyzoites and tissue cysts resemble *T. gondii* under light microscopy.
- Dogs (and coyotes)—definitive host: excrete oocysts in feces, are infective to other dogs and cattle by contaminating feed. Neosporosis is a major cause of abortion in cattle (intermediate host).
- Disease caused by necrosis associated with tissue damage from cyst rupture and tachyzoite invasion.
- Transmission—transplacental, resulting in congenital infection. Ingestion of sporulated oocysts passed in feces of dog, or tissue cysts in tissues from intermediate hosts.

SIGNALMENT

- Dogs—natural infections (mainly puppies); hunting dogs overrepresented.
- Cats—experimentally infected, although antibodies found in domestic and wild cats.

SIGNS

- Similar to those of toxoplasmosis, except neurologic and muscular abnormalities predominate and are often more severe.
- Young dogs (< 6 months)—ascending lower motor neuron rigid paralysis to tetraparesis more common; distinguished from other forms of paralysis by gradual muscle atrophy; stiffness of pelvic limbs more affected than thoracic limbs; progresses to rigid contracture of limbs.
- Cervical weakness and dysphagia, trismus, glossal paralysis—gradually develop, respiratory muscle paralysis eventually leading to death.
- Ataxia secondary to atrophy of the cerebellum.
- Old dogs—usually CNS involvement (seizures, tremors, behavior changes, blindness), polymyositis (lower motor neuron flaccid paralysis), myocarditis, and dermatitis; as in toxoplasmosis, virtually any organ may be affected; head tremor; postural deficits from cerebellar disease; Horner's syndrome.
- Generalized ulcerative and pyogranulomatous dermatitis seen in dogs on immunosuppressive treatment for SLE and lymphoma.

CAUSES & RISK FACTORS

N. caninum: feeding of raw meat to dogs may be a risk factor and should be avoided.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Young dogs—other causes of peripheral multifocal neurologic signs, mainly including

infectious diseases (toxoplasmosis, distemper); progressive polyradiculomyositis; other causes of diffuse lower motor neuron muscular diseases rare.

- Old dogs with CNS disease—other infectious diseases (fungal, rabies, pseudorabies); toxicity (lead, organophosphorus, carbamate, chlorinated hydrocarbon, strychnine); nonsuppurative encephalitis; meningitis; granulomatous meningoencephalitis; metabolic disease (hypoglycemia, hepatic encephalopathy).

CBC/BIOCHEMISTRY/URINALYSIS

- Depending on the organ system involved.
- Muscle involvement—creatinine phosphokinase and AST activities may be high.

OTHER LABORATORY TESTS

- Serologic testing (IFA, ELISA, and immunoprecipitation)—CSF or serum.
- Antibodies do not cross-react with *T. gondii*, but do with *N. hughesi*, a neospora affecting horses.
- Organism detection—oocysts in feces need to be distinguished from *Hammondia* spp.
- Tachyzoites in aspirates, smears, or tissue sections need to be differentiated from those of *Toxoplasma* (immunohistochemistry).
- PCR—used successfully as a diagnostic tool and distinguishes between other parasites.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

CSF—slight increase in protein and nucleated cell number; cells mainly mononuclear; neutrophils may be seen, but some cases have high numbers of eosinophils.

PATHOLOGIC FINDINGS

- Non-suppurative encephalomylitis.
- Severe non-suppurative inflammation of cerebra leptomeninges and cortex.
- Myositis.
- Myofibrosis.
- Polyradiculoneuritis.
- Pneumonia, cerebella atrophy, multifocal necrotizing myocarditis, and nodular dermatitis—described.
- Ulcerative and pyogranulomatous dermatitis.
- *N. caninum* seems to induce more inflammation than does *T. gondii*.
- Histology—differentiation by location in host cell cytoplasm (not within a parasitophorous vacuole as *T. gondii*).
- Tissue cysts—those of *N. caninum* have thicker walls; differentiated from *T. gondii* by immunohistochemical staining.
- Electron microscopy—rhoptries of *N. caninum* tachyzoites electron dense; those of *T. gondii* honeycomb.

TREATMENT

- Once muscle contracture or ascending paralysis has occurred, the prognosis for clinical improvement is poor. Prognosis is grave in young puppies.
- Progression of clinical disease might be arrested by treatment.

MEDICATIONS

DRUG(S)

- See Toxoplasmosis.
- Clindamycin 25–50 mg/kg PO or IM/day, divided into 2 doses; continue for at least 2 weeks after clinical signs cleared.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Treat for an extended period of time.
- Serologically test dam or other in-contact dogs and cattle.

MISCELLANEOUS

ZOONOTIC POTENTIAL

None identified (unlike *T. gondii*)

NEPHROLITHIASIS

BASICS

DEFINITION

- Nephroliths—urooliths located in the renal pelvis or collecting diverticula of the kidney(s).
- Nephroliths or nephrolith fragments may pass into the ureters (ureteroliths).
- Nephroliths that are not infected, not causing obstruction or clinical signs, and not progressively enlarging are termed *inactive*.

PATHOPHYSIOLOGY

Nephroliths can obstruct the renal pelvis or ureter, predispose to pyelonephritis, and result in compressive injury of the renal parenchyma leading to renal failure; see chapters on the different urolith types for pathophysiology of urolithiasis; in cats, nephroliths composed of blood clots that may be mineralized with calcium phosphate or calcium oxalate can form secondarily to chronic renal hematuria.

SYSTEMS AFFECTED

- Renal/urologic—affects the urinary tract, with potential for obstruction, recurrent urinary tract infections, or renal failure.
- Obstruction of the renal pelvis or ureter in an animal with pyelonephritis may result in septicemia and thus affect any body system.

GENETICS

Refer to chapters describing genetics related to different types of uroliths.

INCIDENCE/PREVALENCE

Nephroliths retrieved from dogs and cats compose 1–1.5% of uroliths submitted to the Minnesota Urolith Center for analysis. The true incidence of nephroliths is likely much higher. Many animals with nephroliths are asymptomatic, or are not treated by methods that encompass retrieval of uroliths that can be quantitatively analyzed.

Mineral compositions of canine nephroliths submitted for analysis, in descending frequency—calcium oxalate (38%), struvite (27%), compound (13%), purines (e.g., ammonium urate, sodium urate, uric acid; 12%), mixed (4%), calcium phosphate (3%), cystine (1.5%), and silica (0.6%). Mineral compositions of nephroliths in cats submitted for analysis, in descending frequency—calcium oxalate (76%), struvite (7%), non-crystalline matrix (including dried blood clots) (6%), compound (5.5%), calcium phosphate (2.5%), and purines (< 1%).

SIGNALMENT

Species

Dog and cat

Breed Predilections

Dogs

- Calcium oxalate nephroliths—Shih Tzu, Yorkshire terrier, mixed, miniature schnauzer, and maltese.

- Struvite nephroliths—miniature schnauzer, mixed, Shih Tzu, pug, and miniature poodle.
- Purine nephroliths—English bulldog, Dalmatian, Yorkshire terrier, and Shih Tzu.
- Cystine—mixed, Yorkshire terrier, English bulldog, and French bulldog.

Cats

- Domestic shorthair (42%), European shorthair (7%), American shorthair (4%), domestic longhair (3.5%), Persian (5%), Siamese and Scottish fold both (2.5%), unknown (includes mixed) breed (19%).

Mean Age and Range

- Dogs—mean age of affected animals, 10 years (range, 2 months–21.5 years).
- Cats—mean age of affected animals, 7.7 years (range, 5 months–19.5 years).

Predominant Sex

- Dogs—overall, nephroliths slightly more common in females (59%) than males (39%) (2% unspecified gender); struvite nephroliths, females (82.5%) > males (15.3%); however, calcium oxalate, cystine, and urate nephroliths males > females.
- Cat—overall, nephroliths slightly more common in females (50%) than males (48%) (2% unspecified gender); for calcium oxalate females (55.5%), males (42%); however, non-crystalline matrix (includes dried blood), urate, and struvite nephroliths males > females.

SIGNS

General Comments

Many patients are asymptomatic, and the nephroliths are diagnosed during evaluation of other problems.

Historical Findings

- None or hematuria, vomiting, and recurrent urinary tract infection; dysuria and pollakiuria in animals with urinary tract infection or concomitant urocystoliths.
- Signs attributable to uremia in animals with bilateral obstruction or renal failure.
- Signs referable to lower urinary tract urolithiasis if uroliths are present in the upper and lower urinary tract.
- Renal colic with acute abdominal/lumbar pain and vomiting is uncommon.

Physical Examination Findings

Abdominal or lumbar pain upon palpation or no significant findings.

CAUSES

- For an extensive listing of causes, see chapters on each urolith type. Oversaturation of the urine with calculogenic minerals is a risk factor for urolithiasis.
- Calcium oxalate urolithiasis—hypercalciuria, hypercalcemia, hypocitraturia, hyperoxaluria, primary hyperparathyroidism, excess dietary calcium.
- Calcium phosphate urolithiasis—chronic renal bleeding (cats), hypercalcemia,

hyperparathyroidism, excess dietary calcium and phosphorus, renal tubular acidosis.

- Cystine urolithiasis—cystinuria.

Infection-induced struvite urolithiasis—urinary tract infection with urease-producing microbes. High-protein diets that produce a large quantity of urea that is excreted in urine are also an integral part of the etiopathogenesis of infection-induced struvite uroliths.

- Urate urolithiasis—genetic urate transporter defect in conversion of uric acid to allantoin (Dalmatians, bulldogs, and others), portosystemic shunt.

Xanthine urolithiasis—allopurinol administration and high dietary purine in dogs predisposed to urate urolithiasis. Allopurinol administration in the treatment of leishmaniasis. Apparently an inborn error of purine metabolism in cats.

RISK FACTORS

- Alkaline urine—struvite and calcium phosphate uroliths.
- Acid urine—calcium oxalate, cystine, urate, and xanthine uroliths.
- Urine retention and formation of highly concentrated urine.
- Lower urinary tract infection—ascending infection and pyelonephritis.
- Conditions that predispose to urinary tract infection (e.g., perineal urethrostomy, ectopic ureters, vesicoureteral reflux, and exogenous steroid administration or hyperadrenocorticism [calcium oxalate uroliths]).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Consider nephroliths in any patient with renal failure, recurrent urinary tract infection, acute vomiting (acute pancreatitis, acute gastroenteritis, intestinal or gastric obstruction, etc.), or abdominal or lumbar pain (e.g., intervertebral disc protrusion, peritonitis).
- Nephroliths are usually confirmed by radiographs or ultrasonography; differentiate mineralization of the renal pelvis or collecting diverticula from true nephrolithiasis.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC results—usually normal unless the patient has pyelonephritis; patients with pyelonephritis may have leukocytosis and immature neutrophilia.
- Serum biochemistry analysis—usually normal unless bilateral obstruction, pyelonephritis, or compressive renal injury leads to renal failure (azotemia with an inappropriate urine specific gravity, hyperphosphatemia); hypercalcemia may

(CONTINUED)

contribute to formation of calcium oxalate or calcium phosphate nephroliths.

- Urinalysis—may reveal hematuria and crystalluria; crystal type may indicate mineral composition; pyuria, proteinuria, and bacteriuria may also be seen in animals with urinary tract infection.

OTHER LABORATORY TESTS

- Submit all retrieved nephroliths or nephrolith fragments for quantitative analysis. Although definitive identification of nephrolith type requires quantitative analysis, mineral composition can frequently be predicted on the basis of signalment, radiographic appearance, and urinalysis findings.
- Results of bacterial culture of urine may confirm urinary tract infection in animals with concurrent pyelonephritis.

IMAGING

- Can detect radiopaque nephroliths (e.g., calcium phosphate, calcium oxalate, struvite) by survey radiography; cystine and silica are slightly radiopaque.
- Purines (ammonium urate, sodium urate, uric acid, xanthine etc.) are usually radiolucent unless they contain a mixture of radiodense biogenic minerals.
- Use ultrasonography or excretory urography to confirm, size and number of nephroliths or ureteroliths regardless of radiographic density.

DIAGNOSTIC PROCEDURES

After ESWL, nephrolith fragments can be retrieved for quantitative analysis by voiding, cystoscopy, catheter-assisted retrieval, or voiding urohydropropulsion.

TREATMENT

APPROPRIATE HEALTH CARE

Manage patients with inactive nephroliths as outpatients. When appropriate, medical dissolution protocols can be administered to outpatients. Removal of nephroliths by surgery or ESWL requires hospitalization.

DIET

Medical dissolution of nephroliths requires a diet appropriate for the specific nephrolith type. See "Medications."

CLIENT EDUCATION

- Inactive nephroliths—may not require removal but should be monitored periodically by urinalysis, urine culture, and radiography. Nephroliths can potentially cause obstruction at any time, which can result in hydronephrosis without clinical signs. Conservative management and monitoring carries a slight risk of undetected and potentially irreversible renal damage, which must be weighed against the potential renal damage from nephrotomy.

- Nephroliths (especially metabolic uroliths) tend to recur after removal; monitor the patient every 3–6 months.

SURGICAL CONSIDERATIONS

- Indications for removal of nephroliths—obstruction, recurrent infection, symptomatic nephroliths, progressive nephrolith enlargement, and a non-functional contralateral kidney.
- Treatment options for nephroliths—medical dissolution, surgery, and ESWL. Calcium oxalate is the most common mineral detected in nephroliths retrieved from dogs and cats, and not yet amenable to medical dissolution. Ureteroliths or nephroliths causing complete obstruction are also not amenable to medical dissolution.
- Surgical options—nephrotomy or pyelolithotomy. Because the nephroliths are surrounded by renal tissue, nephrotomy is required in most dogs and cats. Nephrolith removal by percutaneous nephrolithotomy has been reported in dogs.
- ESWL—safe and effective method of treating canine nephroliths and ureteroliths; nephrolith fragments pass down the ureter into the bladder and are voided with urine.
- ESWL—not as effective for treatment of nephroliths and ureteroliths in cats compared with dogs.

MEDICATIONS

DRUG(S) OF CHOICE

- Antibiotics selected on the basis of urine culture and sensitivity testing as needed; perioperative antibiotics are recommended when infected nephroliths are treated by ESWL or surgical removal.
- Medical dissolution protocols are limited to struvite, purine, and cystine uroliths.
- When feasible, consumption of water in high moisture (canned) foods should be incorporated into treatment protocol. Try to increase excretion of urine with a specific gravity < 1.020 (dogs), or < 1.025 (cats).
- Medical dissolution protocols for struvite nephroliths include a calculolytic food (Hill's Prescription Diet s/d) and appropriate antibiotic therapy (i.e., if patient has a urinary tract infection) for the duration of treatment.
- Medical dissolution of canine purine nephroliths can be attempted by a protein and purine restricted, alkalinizing food (Hill's Prescription Diet Canine u/d), allopurinol (15 mg/kg PO q12h), and supplemental potassium citrate as needed to maintain urine pH ~7.0.
- Medical dissolution of canine cystine nephrolithiasis can be attempted using a protein-restricted, alkalinizing diet (Hill's Prescription Diet Canine u/d), 2-MPG or tiopronin (Thiola, 15 mg/kg PO q12h), and

supplemental potassium citrate as needed to maintain urine pH ~7.5.

CONTRAINDICATIONS

- Do not use allopurinol without dietary purine restriction because this combination may cause xanthine nephrolithiasis in dogs predisposed to urate urolithiasis.
- Do not give acidifying diets to azotemic patients unless blood pH and total CO₂ are monitored for development of metabolic acidosis.

FOLLOW-UP

PATIENT MONITORING

Abdominal radiographs (ultrasonography for radiolucent uroliths), urinalysis, and urine culture every 3–6 months to detect nephrolith recurrence. Dogs treated with ESWL—check every 2–4 weeks by radiographs and ultrasonography until nephrolith fragments have passed through the excretory system.

PREVENTION/AVOIDANCE

Eliminate factors predisposing to individual urolith type, augment urine volume, and correct factors contributing to urine retention.

POSSIBLE COMPLICATIONS

Hydronephrosis, renal failure, recurrent urinary tract infection, and pyelonephritis.

EXPECTED COURSE AND PROGNOSIS

- Highly variable; depends on nephrolith type, location, and size, secondary complications (e.g., obstruction, infection, renal failure), and owner compliance with treatment and prevention protocol.
- Inactive nephroliths may remain inactive for years, resulting in an excellent prognosis.
- Excellent results have been reported using ESWL to treat dogs with nephroliths—return to normal health and an excellent prognosis.
- The prognosis for patients with renal failure caused by nephrolithiasis depends on the severity and rate of progression of renal failure.
- Nephroliths causing outflow obstruction or associated with non-functioning kidneys cannot be dissolved medically.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Hyperadrenocorticism and chronic glucocorticoid administration are associated with calcium oxalate uroliths, and urinary tract infection resulting in struvite urolithiasis.

PREGNANCY/FERTILITY/BREEDING

- Contraindication to ESWL
- Acetohydroxamic acid, a urease inhibitor, is teratogenic

NEPHROTIC SYNDROME

BASICS

DEFINITION

Concurrent proteinuria, hypoalbuminemia, hypercholesterolemia, and third-space fluid accumulation (i.e., ascites, subcutaneous edema, etc.).

PATOPHYSIOLOGY

- Glomerular disease may result in marked urinary protein loss. Greater than 3.5 g albumin loss per day in humans often results in nephrotic syndrome. Magnitude of hypoalbuminemia and proteinuria required for development of nephrotic syndrome in dogs and cats is unknown; although affected patients usually have very low serum albumin concentrations, not all dogs with very low serum albumin concentrations will develop nephrotic syndrome.
- Reduced plasma oncotic pressure may result in hyperaldosteronism, which induces sodium and water retention, leading to edema and ascites.
- Alternatively, non-aldosterone mediated sodium retention, or a hypothetical “vascular permeability factor,” have been suggested as mechanisms whereby glomerular protein loss may increase, along with fluid loss from the systemic vasculature.
- Hypercholesterolemia is a consequence of decreased catabolism and increased hepatic synthesis of lipoproteins.
- Other glomerular disease complications frequently diagnosed in dogs with nephrotic syndrome include hypertension, hypercoagulability, muscle wasting, and weight loss.
- Thromboembolism is a consequence of a generalized pro-coagulative state, due in part to increased platelet number and sensitivity, urinary loss of antithrombin, and increased concentrations of some clotting factors.

SYSTEMS AFFECTED

- Renal/Urologic—persistent proteinuria initially without active urine sediment. With progressive disease and nephron loss, azotemia, chronic kidney disease and uremia may occur.
- Cardiovascular—dependent edema, ascites, hypercholesterolemia/hyperlipidemia, hypertension, hypercoagulability, and thromboembolic disease.

GENETICS

Familial glomerular diseases have been reported in several breeds (see Glomerulonephritis and Amyloidosis chapters), but are less likely to result in nephrotic syndrome than non-familial protein-losing nephropathies.

INCIDENCE/PREVALENCE

- Nephrotic syndrome is an uncommon complication of glomerular disease, with a median of 0.5 new cases per year diagnosed at 8 veterinary teaching hospitals in 1 study.

- Nephrotic syndrome has not been associated with histologic subtype of glomerular disease.

SIGNALMENT

Species

Dog and cat

Breed Predilections

No breed appears to be at increased risk of the nephrotic syndrome complication with glomerular disease.

Mean Age and Range

Dogs with nephrotic syndrome are typically younger than those with non-nephrotic glomerular disease (mean, 6.2 years vs. 8.4 years at time of initial diagnosis).

Predominant Sex

None recognized

SIGNS

Historical Findings

- Pitting subcutaneous edema and/or ascites are the most common presenting complaints.
- Clinical signs associated with an underlying infectious, inflammatory, or neoplastic disease may be the primary reason for seeking veterinary care. Subtle edema or ascites may then be detected by physical examination or with diagnostic imaging.
- Rarely, dogs may develop acute dyspnea, severe panting, weakness, or collapse due to pleural or pericardial effusion, pulmonary edema, or pulmonary thromboembolism.

Physical Examination Findings

- Dependent pitting, subcutaneous edema, or ascites.
- Complications of hypertension: retinal hemorrhage or detachment, papilledema, arrhythmias and/or murmurs secondary to left ventricular hypertrophy.
- Dyspnea and/or cyanosis in dogs with pleural effusion or pulmonary thromboembolism.

CAUSES

- Glomerular disease may be a consequence of chronic inflammatory conditions (e.g., infection, neoplasia, or immune-mediated diseases).
- Nephrotic syndrome is unlikely to be solely a consequence of severe proteinuria; additional unidentified factors appear to be necessary.

RISK FACTORS

See “Causes”

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Proteinuria

- Often due to inflammatory post-glomerular urinary tract disease (e.g., bacterial cystitis/pyelonephritis, urolithiasis, tubular renal failure, or lower urinary tract neoplasia). Inflammation of the urinary tract is usually (but not always) associated with active urine

sediment.

- Hyperglobulinemia may be associated with proteinuria, and may be more likely discovered when urinalysis includes the sulfosalicylic acid turbidimetric test (Bumini test).
- Protein-losing nephropathies typically result in inactive urine sediment (although hyaline casts may be present); renal biopsy is the only accurate way to distinguish the various types of glomerular disease.

Hypoalbuminemia

Decreased albumin production (severe liver disease) and gastrointestinal albumin loss (protein-losing enteropathies) must be distinguished from hypoalbuminemia secondary to glomerular disease.

CBC/BIOCHEMISTRY/URINALYSIS

- Persistent, significant proteinuria with inactive urine sediment.
- Hypoalbuminemia and hypercholesterolemia are by definition essential components of the nephrotic syndrome.
- Renal failure may occur with advanced disease. Azotemia may precede loss of urine concentrating ability.

OTHER LABORATORY TESTS

Urine Protein:Creatinine Ratio

- Confirms and quantifies the severity of proteinuria.
- Magnitude of proteinuria can be used to assess response to therapy or progression of disease.

Protein Electrophoresis

Urine and serum protein electrophoresis may identify pre-glomerular proteinuria in patients with monoclonal gammopathies or urinary immunoglobulin light chains (Bence-Jones proteins).

IMAGING

- Radiography—loss of abdominal detail due to ascites is the most common abnormality. Pleural effusion (uncommon), pulmonary edema, or pericardial effusion (very uncommon) may be present.
- Abdominal ultrasonography—usually confirms large volume of peritoneal and retroperitoneal fluid. Mild renomegaly may be observed with glomerular diseases.

DIAGNOSTIC PROCEDURES

Renal biopsy is indicated if significant and persistent proteinuria with inactive urine sediment exists. Microscopic evaluation of renal tissue will establish subtype of glomerular disease and help in formulating a prognosis. Consider renal biopsy only after less-invasive tests (CBC, serum biochemistry profile, urinalysis, quantitation of proteinuria) are completed and blood clotting ability has been assessed.

TREATMENT

APPROPRIATE HEALTH CARE

- Most dogs and cats can be treated as outpatients.
- Severely azotemic or

N

NEPHROTIC SYNDROME

(CONTINUED)

hypertensive patients, or patients with thromboembolic disease, may require hospitalization.

NURSING CARE

- Abdominocentesis—reserve for patients with respiratory distress or abdominal discomfort caused by ascites. Excessive fluid removal will promote further fluid accumulation and contribute to electrolyte abnormalities.
- Plasma transfusion is not indicated for routine treatment of hypoalbuminemia. Very large volumes of plasma are required to significantly increase serum albumin concentration, and transfused proteins have relatively short half-lives.
- Intravenous human albumin can be used in patients with life-threatening complications due to fluid accumulation (e.g., pulmonary edema; pleural effusion).
- Use of low-sodium, "maintenance"-type fluids (e.g., 0.45% NaCl) for all crystalloid needs may minimize extravascular fluid accumulation in hospitalized animals.
- Intravenous synthetic colloids frequently exacerbate fluid extravasation in patients with nephrotic syndrome. There is a faster return to baseline oncotic pressure in nephrotic patients than in healthy animals after colloidal fluid administration, likely due to increased urinary loss and accumulation within interstitial tissues. These fluids should therefore be limited to patients with immediate, life-threatening needs for oncotic pressure support.

ACTIVITY

Activity restriction may decrease likelihood of thromboembolic disease; conversely, increased activity in humans with nephrotic syndrome promotes fluid mobilization and lymphatic uptake.

DIET

- Sodium-reduced, high-quality, low-quantity protein diets are currently recommended. Prescription "renal diets" meet these criteria.
- Normal or high dietary protein may contribute to renal disease progression by exacerbating glomerular hyperfiltration, proteinuria, and glomerulosclerosis.

CLIENT EDUCATION

- If the underlying cause cannot be identified and corrected, glomerular disease usually progresses to azotemic chronic kidney disease.
- Renal biopsy is required to differentiate between the various subtypes of glomerular disease and to optimize treatment protocols.
- Once azotemia and uremia develop, prognosis is poor due to rapid progression of renal failure.
- Nephrotic syndrome is associated with shortened survival time. In one study, median survival time of 61 dogs

with nephrotic syndrome was 12.5 days (range, 0–2,783 days), as compared to 104.5 day (range, 0–3,124 days) median survival time of 99 dogs with non-nephrotic glomerular disease.

MEDICATIONS

DRUG(S)

See Glomerulonephritis chapter for general treatment recommendations.

Edema and Ascites

- Dietary sodium reduction.
- Reserve abdominocentesis and diuretics for patients with respiratory distress or abdominal discomfort. Overzealous diuretic use may result in dehydration and acute renal decompensation.
- Patients who require maintenance diuretic therapy for severe, persistent extravascular fluid accumulation should be treated with an aldosterone antagonist (spironolactone 1–2 mg/kg PO q12h), and supplemented with low doses of loop diuretics (i.e., furosemide 0.5–2 mg/kg PO q8–12h) as needed.
- Plasma or albumin transfusions provide only temporary benefit, and are not recommended when the risk of therapy outweighs any potential benefit.

Proteinuria

- Angiotensin converting enzyme (ACE) inhibitors (e.g., enalapril 0.5 mg/kg PO q12h) decrease severity of proteinuria (see Glomerulonephritis chapter). Because proteinuria is toxic to renal tubules, ACE-inhibitor therapy should be initiated at the time of diagnosis, unless severe azotemia is present.
- Aspirin (0.5 mg/kg PO q12h) decreases thromboembolism risk and should be initiated when serum albumin decreases below 2.0–2.5 g/dL.

PRECAUTIONS

- Dose adjustment of highly protein-bound drugs (e.g., aspirin) may be needed.
- Use ACE inhibitors with caution in patients with serum creatinine > 5.0 mg/dL.
- Diuretics should be used with extreme caution in patients with nephrotic syndrome because of the risk of causing or worsening azotemia.

POSSIBLE INTERACTIONS

See "Precautions"

FOLLOW-UP

PATIENT MONITORING

Urinary protein:creatinine ratio; serum urea nitrogen, creatinine, albumin, and electrolyte

concentrations; blood pressure; and body weight. Ideally, recheck examinations should be scheduled 1, 3, 6, 9, and 12 months after initiation of treatment.

POSSIBLE COMPLICATIONS

- See Glomerulonephritis chapter for discussion of glomerular disease complications unassociated with nephrotic syndrome.
- Complications more likely to develop in nephrotic (vs. non-nephrotic) dogs and cats with glomerular disease include:
- Arterial or venous thrombosis (e.g., pulmonary thromboembolism)
- Electrolyte disturbances, particularly with repeated abdominocenteses or high doses of diuretics
- Faster progression to azotemia and uremia, and decreased median survival time.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Amyloidosis
- Glomerulonephritis
- Glomerulopathy
- Hypercoagulability
- Hypertension

PREGNANCY/FERTILITY/BREEDING

Likely high risk in those patients with severe hypoalbuminemia and/or hypertension.

NEPHROTOXICITY, DRUG-INDUCED

BASICS

DEFINITION

Renal injury caused by a pharmacologic agent used to diagnose or treat a medical disorder.

PATHOPHYSIOLOGY

- Drugs can cause nephrotoxicosis by interfering with renal blood flow, glomerular function, tubular function, or interstitial inflammation.
- Many drugs are nephrotoxic because they are excreted primarily by the kidneys.
- Most nephrotoxic drugs cause proximal renal tubular necrosis.
- If renal injury is severe, acute kidney failure develops.

SYSTEMS AFFECTED

- Renal/Urologic.
- Gastrointestinal—inappetence, vomiting, diarrhea, or melena due to gastrointestinal irritation or uremic ulceration.
- Endocrine/Metabolic—metabolic acidosis due to decreased elimination of acid by kidneys and inability to reclaim bicarbonate filtered into tubules by glomeruli.
- Hemic/Lymphatic/Immune—anemia due to blood loss or decreased red blood cell survival in patients with uremia; increased susceptibility to infections because of immune dysfunction in patients with uremia.
- Nervous—depression, lethargy associated with effect of uremic toxins on the central nervous system.
- Neuromuscular—weakness due to systemic effects of uremia.
- Respiratory—tachypnea or respiratory distress due to uremic pneumonitis or compensatory response for metabolic acidosis.

SIGNALMENT

Species

Dog and cat

Breed Predilections

N/A

Mean Age and Range

Any age; older patients are more susceptible

Predominant Sex

N/A

SIGNS

Historical Findings

- Polyuria and polydipsia; sometimes oliguria
- Inappetence
- Depression
- Vomiting
- Diarrhea

Physical Examination Findings

- Dehydration
- Oral ulcers
- Uremic halitosis

CAUSES

Antimicrobial Drugs

- Aminoglycosides—all drugs in this class are potentially nephrotoxic, including neomycin, gentamicin, amikacin, kanamycin, and streptomycin. Due to frequent use in the past, nephrotoxicosis associated with aminoglycoside treatment was most often associated with gentamicin.
- Tetracyclines—outdated products can cause acquired Fanconi-like syndrome characterized by glucosuria, proteinuria, and renal tubular acidosis; IV administration to dogs at high dosages ($> 30 \text{ mg/kg}$) can cause acute kidney injury.
- Administration of sulfa drugs (e.g., trimethoprim-sulfadiazine) has been associated with acute kidney injury in dogs, but no causal relationship has been proven.

Antifungal Drugs

Amphotericin B

Antineoplastic Drugs

- Cisplatin—clinically important cause of nephrotoxicosis in dogs.
- Doxorubicin—possible cause of nephrotoxicosis in cats but not well documented.

NSAIDs

- Aspirin, ibuprofen, naproxen, carprofen, piroxicam, meloxicam, flunixin meglumine, and others may cause nephrotoxicosis.
- Most likely to cause renal injury in patients with preexisting kidney disease or patients with concomitant dehydration or other causes of hypovolemia.

ACE Inhibitors

- Enalapril, benazepril, and others.
- Most likely to cause acute kidney injury in patients with hyponatremia, dehydration, or congestive heart failure.

Radiographic Contrast Agents

- Intravenous administration of ionic radiographic contrast agents can cause acute kidney injury, especially in patients with dehydration, hypovolemia, or hypotension associated with inhalational anesthesia.

RISK FACTORS

- Dehydration.
- Advanced age, probably because older patients have preexisting kidney disease.
- Kidney disease, inactive or active.
- Renal hypoperfusion; potential causes include any disorder associated with hypovolemia (e.g., vomiting, hemorrhage, hypoadrenocorticism), low cardiac output (e.g., congestive heart failure, pericardial disease, cardiac arrhythmias, inhalational anesthesia), or renal vasoconstriction (e.g., NSAID administration).
- Electrolyte and acid-base abnormalities including hypokalemia, hyponatremia,

hypocalcemia, hypomagnesemia, and metabolic acidosis.

- Concurrent drug therapy—administration of furosemide increases nephrotoxicosis of aminoglycosides; treatment with cytotoxic drugs (e.g., cyclophosphamide) may increase nephrotoxic potential of drugs.

- Fever.
- Sepsis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Must differentiate from other causes of acute kidney injury (e.g., ethylene glycol toxicosis, raisin/grape ingestion [dogs], lily toxicosis [cats], renal ischemia, leptospirosis).
- Most patients have a history of recent treatment (i.e., within the previous 2 weeks) with a potentially nephrotoxic drug; acute kidney injury may occur several days after discontinuation of an aminoglycoside.
- Accidental ingestion of large doses of medications may occur, especially with palatable chewable formulations (prescribed for this patient or other animals).
- Determine all drugs that have been administered to the patient, including over-the-counter preparations (e.g., aspirin, ibuprofen, and naproxen) and medications prescribed for human use (e.g., NSAID or ACE inhibitor).

CBC/BIOCHEMISTRY/URINALYSIS

- Hemogram—usually normal unless concomitant problems exist (e.g., gastrointestinal hemorrhage associated with administration of NSAIDs).
- Biochemistry—normal in early stages of drug-induced nephrotoxicosis or reveals signs consistent with acute kidney injury including azotemia, hyperphosphatemia, and metabolic acidosis.
- Urinalysis—may reveal low urinary specific gravity (often < 1.025), proteinuria, glucosuria, or cylindruria. Casts may be one of the earliest indicators of acute kidney injury.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Renal biopsy may be indicated to determine cause of acute kidney injury and potential for reversibility, especially in patients that do not favorably respond to treatment as expected. The magnitude of renal morphologic changes may appear mild compared to the magnitude of azotemia.

PATHOLOGIC FINDINGS

Most nephrotoxic drugs cause proximal renal tubular necrosis.

N

NEPHROTOXICITY, DRUG-INDUCED

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

- Manage patients with acute kidney injury as inpatients.
- Manage patients without azotemia that can eat, and drink enough to maintain hydration, as outpatients.

NURSING CARE

- Administer balanced polyionic fluid (e.g., lactated Ringer's solution).
- Correct hydration deficits rapidly (i.e., over 6–8 hours) to minimize further renal injury. Calculate volume of fluid to administer as follows: volume (mL) = body weight (kg) ×% dehydration × 1,000 mL.
- In addition to correcting hydration deficits, administer maintenance requirements (~66 mL/kg/day) unless the patient is oliguric or anuric, and replace any ongoing losses caused by vomiting and diarrhea. As a minimum, assume that patients with acute kidney failure are losing 3–5% of their body weight because of ongoing losses.

ACTIVITY

Reduce

DIET

- Outpatients can be fed their regular food.
- Avoid oral feeding until vomiting is controlled, but initiate nutritional support as early as possible with acute kidney injury.
- If oral feeding is not possible initially, consider total or partial parenteral nutrition.
- The appropriate nutritional composition for patients with severe acute kidney injury has not been determined.
- Patients that recover from drug-induced nephrotoxicosis may develop chronic kidney disease, which should be managed by feeding a therapeutic renal diet indefinitely.

CLIENT EDUCATION

- Provide unlimited access to clean, fresh water at all times.
- If any signs of illness such as inappetence, vomiting, or diarrhea develop, return the patient immediately for veterinary care to minimize worsening of renal function.

SURGICAL CONSIDERATIONS

- Avoid elective surgery until kidney disease is resolved.
- If surgery is necessary, administer fluids (5–20 mL/kg/h) during anesthesia to maintain adequate mean arterial blood pressure (> 60 mmHg) and renal perfusion. Monitor urine output and adjust rate of fluid

administration to maintain urine production of 1–2 mL/kg/h.

MEDICATIONS

DRUG(S) OF CHOICE

None

CONTRAINDICATIONS

Do not use furosemide to promote diuresis in patients with aminoglycoside nephrotoxicosis.

PRECAUTIONS

- Avoid drugs that may worsen renal injury in patients with nephrotoxicosis, including NSAIDs, vasodilators, and ACE inhibitors.
- Use less toxic drugs when possible (e.g., carboplatin instead of cisplatin, other effective antimicrobials instead of aminoglycosides).

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Weigh hospitalized patients several times daily to detect changes in fluid balance and adjust fluid therapy accordingly.
- Perform biochemical analysis, including electrolytes, every 1–2 days to evaluate severity of azotemia and to detect electrolyte and acid/base abnormalities.
- Patients receiving aminoglycosides—perform urinalysis every 1–2 days to detect early signs of nephrotoxicosis such as glucosuria, increased proteinuria, and cylindruria; discontinue aminoglycoside if any of these signs are observed.
- Measure urine output to determine if patient is polyuric or oliguric; adjust fluid therapy on the basis of these findings and determine need for additional treatment to stimulate urine production. Do not overhydrate patient with parenteral fluids.

PREVENTION/AVOIDANCE

- Avoid or correct risk factors that predispose to development of drug-induced nephrotoxicosis.
- Initiate saline diuresis to all dogs receiving cisplatin.
- Avoid using nephrotoxic drugs unless they are necessary (e.g., use aminoglycosides only if patient has overwhelming sepsis and culture results indicate aminoglycosides are the only effective antimicrobial).
- Monitor serum aminoglycoside concentration and perform frequent

urinalyses while administering an aminoglycoside.

- Do not administer furosemide with an aminoglycoside as this combination is likely to enhance nephrotoxicity of the aminoglycoside.

POSSIBLE COMPLICATIONS

- Acute kidney injury
- Chronic kidney disease

EXPECTED COURSE AND PROGNOSIS

- Patients without azotemia may develop acute kidney injury after several days of exposure, especially to aminoglycosides.
- Renal injury caused by nephrotoxic drugs may lead to development of chronic kidney disease months to years after recovery from drug-induced renal injury.

NERVE SHEATH TUMORS

BASICS

OVERVIEW

- Tumors of the peripheral nerves, spinal nerves, or nerve roots.
- Malignant peripheral nerve sheath tumor is the recommended denomination for these tumors, instead of schwannoma, neurilemmoma, or neurofibroma, since determination of the cell of origin is often impossible.
- Most tumors (80%) occur in the thoracic limb of dogs.
- Approximately 50% of the tumors are located in the plexus or peripheral nerve region and 50% in the nerve root region.

SIGNALMENT

- Dogs—no breed or gender predisposition.
- Mean age in dogs—7.9 years; uncommon in dogs younger than 3 years.
- Rare in cats.

SIGNS

- Chronic progressive thoracic limb lameness.
- Muscle atrophy (neurogenic atrophy) often present, more severe than that observed with orthopedic disorders.
- Decreased muscle tone and decreased flexor reflex can be observed.
- Axillary palpation detects a mass in less than 30% of cases.
- Axillary pain upon palpation occasionally.
- Horner's syndrome can be seen in tumors involving the T1–T3 nerve roots.
- Ataxia, paresis, and asymmetric proprioceptive deficits can be seen if the tumor compresses the spinal cord.
- Cutaneous trunci reflex may be poor to absent on the affected side.
- In lumbosacral tumors, rectal palpation can be useful for mass detection.
- Self-mutilation is occasionally observed.

CAUSES & RISK FACTORS

Mutation of the *neu* oncogene was identified in some cases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Orthopedic conditions causing thoracic or pelvic limb lameness. Differentiate by orthopedic examination, radiographs, or scintigraphy, and response to rest and anti-inflammatory drugs. The severity of muscle atrophy also useful.
- Lateralized nerve root compression by intervertebral disc disease, lumbosacral disease, or spinal neoplasia. Intervertebral disc disease and lumbosacral disease are usually associated with spinal pain. Advanced imaging (CT or MRI) is required to distinguish these diseases.
- Secondary nerve neoplasia—lymphoma, histiocytic sarcoma, chondrosarcoma. Fine-needle or core biopsy needed to differentiate these conditions.

OTHER LABORATORY TESTS

- CSF analysis—nonspecific findings.
- Cytology—ultrasound-guided fine-needle biopsy can provide diagnostic sample. Cytologic features of MPNST are characteristics of a soft tissue sarcoma.

IMAGING

- Survey radiographs—well-positioned survey radiographs may allow visualization of an enlarged intervertebral foramen; most often unrewarding.
- US—can identify a mass in cases where axillary palpation is unrewarding. Patient sedation allows better positioning and US-guided fine-needle aspiration biopsy. Tumor echogenicity is variable.
- Myelography—if the neoplasm has invaded the vertebral canal, an intradural-extradural pattern can be seen. Due to the location of neoplasms, myelography is diagnostic in approximately 50% of dogs.
- CT and MRI—to visualize proximal or distal limb tumors. Hyperintensity on T2 weighted images is the most common MRI pattern. MPNSTs usually show contrast enhancement on both CT and MRI. Due to the high soft tissue characterization, MRI is the diagnostic modality of choice.

DIAGNOSTIC PROCEDURES

- EMG—to differentiate neurogenic from disuse muscle atrophy. Fibrillation potentials and positive sharp waves are suggestive of neurogenic muscle atrophy. EMG changes found in 96% of dogs with confirmed or suspected nerve sheath tumors. Epaxial muscle EMG changes predictive of vertebral canal invasion in cases of proximal tumors.
- Nerve conduction velocity—conduction velocities may be prolonged with amplitude reduced.
- F-wave, H-wave, cord dorsum potentials—evaluate the root portion of the nerve and can be useful to differentiate a lesion affecting predominantly the sensory or motor root.

TREATMENT

- Surgical resection following the principles of oncologic surgery is the recommended treatment.
- Amputation is usually required to minimize the chance of local recurrence.
- Hemilaminectomy or dorsal laminectomy may be required to allow resection of the nerve root region.
- Oral corticosteroids may allow clinical improvement by reduction of peritumoral edema.
- Radiation therapy—can be used for nonresectable tumors or in cases where surgery is contraindicated. It can also be used postoperatively to decrease the chance of local recurrence.

MEDICATIONS

DRUG(S)

- Chemotherapy—metronomic therapy (cyclophosphamide 10 mg/m² and piroxicam 0.3 mg/kg) can be used for incompletely resected nerve sheath tumors in dogs.
- Dexamethasone 0.1–0.25 mg/kg q24h or prednisone 0.5–1 mg/kg q12–24h can be used to provide short-term improvement.
- Gabapentin 5–20 mg/kg q8–12h can be used for analgesia in cases of neuropathic pain.
- Pregabalin 2–4 mg/kg q12h can be used in cases refractory to gabapentin.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Corticosteroids should not be used in conjunction with nonsteroidal anti-inflammatory drugs.

FOLLOW-UP

- Nerve sheath tumors are locally invasive and rarely metastasize.
- Postoperative local recurrence is common (up to 72% of cases).

MISCELLANEOUS

ABBREVIATIONS

- CSF = cerebrospinal fluid
- CT = computed tomography
- EMG = electromyography
- MPNST = malignant peripheral nerve sheath tumor
- MRI = magnetic resonance imaging
- US = ultrasonography

NEUROAXONAL DYSTROPHY

BASICS

OVERVIEW

- Inherited degenerative diseases of neurons in diverse regions of the CNS, particularly the cerebellum and associated pathways.
- Primary neuroaxonal dystrophy disorders are sometimes classified as abiotrophies.
- Inheritance—autosomal recessive in breeds where heritability is proven. • The main pathologic feature of NAD, axonal spheroids, also occurs in normal aging, as well as secondary to a number of other diseases, such as acquired or inherited metabolic diseases, and toxicities.

SIGNALMENT

- Dog and cat. • Breeds predisposed—domestic and Siamese cats, rottweilers, collies, Papillons, Chihuahuas, German shepherd dogs, Jack Russell terriers, and boxers. • Age at onset—breed-specific, ranging from under 2 months of age in cats, Chihuahuas, and Papillons, to 1–2 years in rottweilers.

SIGNS

- Cerebellar ataxia—progressive dysmetria and hypermetria of the limbs (rarely hypometria) with patellar hyperreflexia.
- Strength and proprioception normal in most cases. Rottweilers may have extensive involvement of the dorsal columns of the cervical spinal cord and may exhibit proprioceptive deficits.
- Loss of menace responses despite normal vision and facial nerves.
- Progressive signs of brainstem involvement may be a feature, especially in papillons, including loss of swallowing reflex and tongue movement; tetraplegia may develop in the final stages.
- Mild intention tremor or head and neck dysmetria in some patients.
- Primarily cerebellar signs in rottweilers, collies, Chihuahuas, and domestic cats; predominantly spinal cord lesions in German shepherd dogs and boxers; tremor and cerebellar ataxia present in all affected animals.

CAUSES & RISK FACTORS

- Unknown
- Usually classified as neuronal abiotrophy
- Autosomal recessive inheritance proven in some breeds
- Breed predisposition

DIAGNOSIS

- Suspicion is based on clinical signs in a predisposed breed, usually in juvenile animals.
- Definitive diagnosis requires histopathologic examination of CNS tissue, usually post-mortem.

DIFFERENTIAL DIAGNOSIS

- Other congenital cerebellar anomalies, abiotrophies, and degenerative disorders. Reported occasionally in cats, and in a number of breeds of dog including border collie, Brittany, Coton de Tulear, Gordon setter, Jack Russell (Parson Russell) terrier, Labrador retriever, Old English sheepdog, and many others.
- Other structural anomalies of the caudal brainstem, including caudal occipital malformation syndrome and Dandy-Walker syndrome. Differentiated by imaging studies, particularly MRI. Certain breeds are predisposed, e.g., caudal occipital malformation syndrome in the Cavalier King Charles spaniel.
- Cerebellar hypoplasia caused by *in utero* infection of kittens with feline panleukopenia virus—apparent by 3–6 weeks of age; non-progressive.
- Distemper encephalitis—differentiated on the basis of systemic signs preceding or accompanying the neurologic deficits and on results of CSF analysis (normal with neuroaxonal dystrophy).
- Other infectious encephalitides—fungal, rickettsial, and protozoal; differentiated on the basis of multisystemic signs in some patients, serologic testing, and CSF analysis.
- Non-infectious inflammatory encephalitides, particularly granulomatous meningoencephalomyelitis. Breed-specific encephalitides (pug, Maltese terrier, Yorkshire terrier) usually cause forebrain signs (seizures), but cerebellar involvement may occur. Differentiated by the presence of inflammatory changes in CSF and, in some cases, by contrast-enhancing lesions in the brain apparent with MRI.
- Neoplasia affecting the cerebellum—primary, metastatic, or locally invasive. Occurs in older dogs and cats, usually over 5 years of age. Differentiated on the basis of imaging studies (particularly MRI), CSF analysis in some cases, and systemic involvement in the case of metastatic neoplasia.
- Cervical spinal cord disease—proprioceptive deficits and tetraparesis.
- Diagnosis of neuroaxonal dystrophy is by exclusion; it may not be possible to reach an antemortem diagnosis.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

N/A

IMAGING

Atrophy of the cerebellum may be appreciable on MRI in certain patients (e.g., papillons).

DIAGNOSTIC PROCEDURES

All antemortem routine tests are normal.

PATHOLOGIC FINDINGS

- Axonal spheroids—present throughout the CNS gray or white matter, depending on the

breed affected. Spheroids contain abnormal accumulations of intracellular proteins, particularly several associated with axonal transport and synaptic function.

TREATMENT

- None available that alters the course of the disease.
- Activity—restrict activity to areas where a fall can be avoided (avoid stairs, swimming pools, etc.).

MEDICATIONS

DRUG(S)

N/A

FOLLOW-UP

- Rottweilers—worsen over 1–5 years; develop clonic patellar and crossed extensor reflexes.
- Not fatal, but severely incapacitating.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- CNS = central nervous system
- CSF = cerebrospinal fluid
- MRI = magnetic resonance imaging
- NAD = neuroaxonal dystrophy

NEUTROPENIA

BASICS

DEFINITION

- Neutrophil count < 3,000 neutrophils/ μL in dogs and < 2,500 neutrophils/ μL in cats.
- Can develop alone or as a component of pancytopenia. • Often accompanied by a left shift and toxic changes (e.g., cytoplasmic basophilia, foamy cytoplasmic vacuolation, Döhle bodies, and/or toxic granulation).
- Certain breeds, such as greyhounds or Belgian Tervurens, can normally have a neutrophil count below the reference interval for other dogs.

PATHOPHYSIOLOGY

Results from one of four mechanisms—(1) decreased production or release of neutrophils from the bone marrow, (2) a shift of neutrophils from the circulating pool within the large vessels to the marginating pool, adhered to the endothelium of capillaries, (3) increased migration into the tissues from the blood due to severe inflammation/tissue consumption, and (4) immune-mediated destruction.

SYSTEMS AFFECTED

- Predisposes the patient to systemic infection by a variety of pathogens. • Many body systems can be affected in any combination, depending on the site(s) of infection.

GENETICS

- Canine cyclic hematopoiesis is autosomal recessive, involving the adaptor protein complex 3 (AP3) β -subunit, which redirects neutrophil elastase trafficking from membranes to granules. • A genetic trait with delayed penetrance seems likely to explain the age-related neutropenia in Belgian Tervurens.
- Selective cobalamin malabsorption is autosomal recessive, resulting in neutropenia due to failure to express the receptor for intrinsic factor-cobalamin complex. A *CUBN* frameshift mutation is likely causative for Imerslund-Gräsbeck Syndrome (selective cobalamin malabsorption) in border collies.
- An autosomal recessive neutropenia, known as trapped neutrophil syndrome (TNS), has been seen in Australian and New Zealand border collies with a deficiency of segmented neutrophils in the blood and hyperplasia of myeloid cells in the bone marrow due to an alternately spliced transcript of *VPS13B*, similar to Cohen syndrome in humans.

SIGNALMENT

- Nothing specific for generalized infection.
- Schnauzers, beagles, Australian shepherds, Shar-Peis, and border collies with inherited cobalamin malabsorption. • Gray collies and possibly border collies with canine cyclic hematopoiesis. • Belgian Tervuren dogs.
- Related border collies in Australia and New Zealand with chronic neutropenia. • G-CSF

deficiency has been reported in a rottweiler with chronic idiopathic neutropenia.

SIGNS

- Septic animals usually present with nonspecific signs of illness such as lethargy, weakness, and inappetence. They are often febrile, but normothermia does not rule out infection. Other signs can include tachycardia, injected mucous membranes, prolonged capillary refill time, and weak pulses, some of which are related to septicemia and endotoxic shock. • Gray collies with cyclic hematopoiesis exhibit severe neutropenia every 12–14 days. Episodes of fever, diarrhea, gingivitis, respiratory infection, lymphadenitis, and arthritis occur in association with the neutropenia. These dogs seldom live past 1 year of age.
- No clinical signs in Belgian Tervurens.
- Related border collies in Australia and New Zealand with chronic neutropenia had recurrent bacterial infections manifesting as osteomyelitis and gastroenteritis. A dog with heat stroke demonstrated inappropriate rubricytosis with a high normal PCV, moderate mature neutropenia and lymphopenia, and petechiation despite only mild thrombocytopenia. Numerous leukocytes showed evidence of apoptosis; many neutrophils had botryoid nuclei.

CAUSES

Deficient Neutrophil Production, Stem Cell Death, or Inhibition

- Infectious agents—dogs and cats, parvoviruses, bacteria-induced myelonecrosis, and systemic mycosis; cats, FeLV and FIV; dogs, monocytic and granulocytic ehrlichiosis, Babesia infections. • Drugs, chemicals, and toxins—dogs and cats, chemotherapy agents and cephalosporins; cats, T-2 mycotoxin ingestion, chloramphenicol and benzene-ring compounds, methimazole, and griseofulvin; dogs, estrogen, phenylbutazone, trimethoprim-sulfadiazine, phenobarbital.
- Lack of trophic factors—hereditary malabsorption of cobalamin/vitamin B₁₂.
- Ionizing radiation.

Reduced Hematopoietic Space Secondary to Myelophthisis

- Myelonecrosis • Myelofibrosis
- Disseminated neoplasia, leukemia, and myelodysplastic syndrome • Disseminated granulomatous disease (histoplasmosis and cryptococcosis)

Cyclic Stem Cell Proliferation

- Inherited cyclic hematopoiesis
- Cyclophosphamide treatment • Idiopathic disease • Immune-mediated suppression of granulopoiesis • Poorly documented in dogs and cats

Neutrophil Migration

A shift in neutrophils from the circulating neutrophil pool to the marginating neutrophil pool occurs in patients with endotoxemia. Thought to be the mechanism behind

neutropenia in septicemic animals due to *Bartonella* spp. and other bacteria. During the acute phase, neutropenia suggests intense tissue recruitment in response to endothelial damage caused by *Rangelia vitalii* infection. Anaphylaxis is another, although uncommon, cause.

Reduced Survival

- Severe bacterial infection (most common cause)—sepsis, pneumonia, peritonitis, and pyothorax. • Immune-mediated destruction (uncommon). • Drug-induced destruction.
- Hypersplenism (sequestration).
- Neutropenia likely due to oncotic and apoptotic death of mature neutrophils in heat stroke.

RISK FACTORS

- Inherited disease—cyclic hematopoiesis in Gray collies and possibly border collies.
- Inherited cobalamin malabsorption in giant schnauzers, beagles, Australian shepherds, and border collies. • Drug and chemical exposure—estrogen overdose in dogs (pancytopenia) and chloramphenicol and benzene-ring compounds in cats. • Exposure to various infectious agents—dogs and cats, overwhelming bacterial infection; dogs, acute infection with *Ehrlichia canis*, parvovirus, *Babesia canis rossi* (travel history to/from South Africa), *Rangelia vitalii* (travel history to/from Brazil), and *Anaplasma phagocytophilum* (more likely lymphopenic and eosinopenic than neutropenic); cats, panleukopenia, FIV, and FeLV infection.
- Middle-aged and old animals are less effective at repopulating the bone marrow after a severe toxic insult.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Most neutropenias are due to non-bacterial infectious diseases such as FeLV, FIV, systemic mycoses, and parvoviruses. • Bacterial infection with marked inflammation and/or endotoxemia. • Direct cytotoxic effects of drugs or other toxins on myeloid stem cells and circulating cells. • Primary bone marrow disease. • Immune-mediated destruction.
- Breed of dog may promote suspicion of inherited disease.

CBC/BIOCHEMISTRY/URINALYSIS

- Diagnosis is verified by CBC and leukocyte differential counts. • Multiple CBCs necessary to confirm true neutropenia and/or exclude a diagnosis of cyclic hematopoiesis.
- Urinalysis with bacterial culture and sensitivity to evaluate for urinary tract infection.

Factors That May Erroneously Alter Laboratory Results

- Failure to properly mix the blood specimen before sampling for CBC (laboratory error).

NEUTROPENIA

(CONTINUED)

- Obtaining blood specimen from an IV catheter used for fluid administration (diluted specimen).
- Partial clotting of the blood specimen with neutrophil entrapment or aggregation (poor anticoagulation).
- Leukocytosis/leukocyte agglutination can happen in the tube after sample is collected due to the coating of WBCs with antibody. This will falsely decrease the WBC count as the clumped WBCs are not counted by automated hematology analyzers.

OTHER LABORATORY TESTS

- Serologic test—exclude ehrlichiosis, anaplasmosis, and parvovirus in dogs and panleukopenia, FeLV, and FIV infections in cats.
- Demonstration of anti-neutrophil antibodies by flow cytometry and observation of leukoagglutination—essential for diagnosing immune-mediated neutropenia.
- Consider microbiologic culture of blood or putative sites(s) of bacterial infection or empiric antibiotic administration if occult infection is suspected.

IMAGING

Survey radiography and ultrasonography may help locate occult sites of infection not apparent during physical examination.

DIAGNOSTIC PROCEDURES/PATHOLOGIC FINDINGS

- Examination of a bone marrow aspirate and core biopsy—to evaluate neutrophil production and exclude myelophthisis, myelonecrosis, and myelofibrosis. Animals rebounding from peripheral neutropenia can potentially be misdiagnosed with acute leukemia due to high percentage of myeloblasts in marrows that have extreme left-shifting.
- Cytologic examination of preparations—to document excess tissue demand for neutrophils, verify sequestration of neutrophils in body cavities or between tissue planes, confirm bacterial infection, and identify sites of insensible or occult loss of neutrophils from mucous membranes or skin lesions.
- Culture of infection site or blood culture in febrile animals.
- Provocative exposure to parenteral cobalamin/vitamin B₁₂ should reverse anemia, neutropenia, and neutrophil hypersegmentation in affected breeds.

TREATMENT

APPROPRIATE HEALTH CARE

- Primary concern is the presence or development of infection.
- In the absence of pyrexia, broad-spectrum oral antibiotics that spare normal anaerobic GI flora should be given prophylactically on an outpatient basis

(especially if the count is < 1,000 neutrophils/ μ L). • Pyrexia—indicates current infection; treated more aggressively; inpatient treatment recommended for administration of parenteral crystalloid fluids and antibiotics that target both anaerobic and aerobic bacteria until the infection is contained.

MEDICATIONS

DRUG(S)

- Non-febrile (dogs and cats)—trimethoprim-sulfadiazine (15 mg/kg PO q12h) or cephalaxin (30 mg/kg PO q12h) or enrofloxacin (5–20 mg/kg PO q24h; note potential for retinal toxicity in cats at doses > 5 mg/kg).
- Febrile (dogs and cats)—ampicillin (22 mg/kg IV q6–8h) or ampicillin + sulbactam (15 mg/kg IV q8h) or cefazolin (20–30 mg/kg IV q6–8h) and enrofloxacin (5–10 mg/kg IV q24h; note potential for retinal toxicity in cats).
- If clinically warranted, additional anaerobic coverage is provided by metronidazole (15 mg/kg IV q12h) and/or a later generation cephalosporin.
- rhG-CSF (dogs and cats) 5–10 mg/kg/day SC for 3–6 doses may be effective to stimulate neutrophilic production short term; however, it is a foreign protein and eventually elicits the production of a neutralizing antibody in 14–21 days, which may then cross-react with endogenous G-CSF.
- Neutrophilia subsides within 5 days after G-CSF is discontinued.
- Immune-mediated neutropenia—prednisolone (1–4 mg/kg PO q12h).

PRECAUTIONS

Maintain hydration when administering sulfa drugs to prevent renal crystallization.

FOLLOW-UP

PATIENT MONITORING

- Neutropenia is most likely to occur 7–10 days after the administration of most chemotherapeutic drugs but may develop as late as 2–3 weeks following lomustine and carboplatin administration.
- Periodic CBCs; improvement denoted by a rising leukocyte or neutrophil count, resolution of left shift, and disappearance of toxic changes. Seen after appropriate antimicrobial therapy if bacterial sepsis was the initiating cause of the neutropenia.
- Rebound neutrophilic leukocytosis expected during recovery from neutropenia.
- With the accelerated neutrophil production seen with rhG-CSF therapy, toxicity and left-shifting are expected and cannot be interpreted as sepsis.

POSSIBLE COMPLICATIONS

Secondary infections

MISCELLANEOUS

ASSOCIATED CONDITIONS

Secondary infection, sepsis

AGE-RELATED FACTORS

Repopulation of bone marrow with hematopoietic cells is more difficult in middle-aged and old animals because of age-related reduction in stem cell numbers.

PREGNANCY/FERTILITY/BREEDING

Pregnant Animals

- Drugs listed should be used only if the benefits supersede the inherent risks.
- Sulfa drugs cross the placenta and can cause jaundice, hemolytic anemia, and kernicterus.
- Trimethoprim crosses the placenta; no harm accompanies drug administration in early pregnancy; however, this drug should not be used near term because of folic acid inhibition.
- Adequately controlled safety studies of rhG-CSF have not been performed in dogs and cats (including pregnant animals); high-dose administration (80 μ g/kg/day) of rhG-CSF in pregnant rabbits was associated with fetal resorption, abortion, and increased genitourinary tract hemorrhage.

NOCARDIOSIS

BASICS

OVERVIEW

- An uncommon infection of dogs and cats.
- Organism—soil saprophyte; enters body through contamination of wounds or by respiratory inhalation.
- A compromised immune system enhances the likelihood of infection.

SYSTEMS AFFECTED

- Lymphatic • Musculoskeletal • Nervous
- Respiratory • Skin/Exocrine

SIGNALMENT

Dogs and cats of any breed

SIGNS

- Depends on the site of infection.
- Pleural—pyothorax, resulting in dyspnea, emaciation, and fever.
- Cutaneous—chronic, non-healing wounds; often accompanied by fistulous tracts; if extended, may result in lymphadenopathy, draining lymph nodes, and osteomyelitis.
- Disseminated—most common in young dogs; usually begins in the respiratory tract; lethargy, fever, and weight loss; cyclic fever may be characteristic; CNS may be affected; pleural and/or abdominal effusion may occur.
- May cause pneumonia or pyothorax in cats.

CAUSES & RISK FACTORS

- *Nocardia asteroides* (dogs and cats)
- *N. brasiliensis* (cats only) • *N. nova* (common in Australia; now in United States)
- *Proactinomyces* spp. (rare)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Cutaneous

- Actinomycosis • Atypical mycobacteriosis
- Leprosy • Sporotrichosis • Bite wound abscesses • Draining tracts resulting from foreign bodies

Pleural

- Bacterial pyothorax • Thoracic neoplasia
- Chronic diaphragmatic hernia

Disseminated

- Plague • Systemic fungal infections • Feline infectious peritonitis

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilic leukocytosis.
- Nonregenerative anemia—with long-standing infections (anemia of chronic disease).
- Chemistries—usually normal; hypergammaglobulinemia may be seen with long-standing infections.

OTHER LABORATORY TESTS

N/A

IMAGING

Radiographs—may reveal pleural or peritoneal effusion, pleuropneumonia, or osteomyelitis.

DIAGNOSTIC PROCEDURES

- Cytology—thoracentesis or abdominocentesis for samples; stain these or other exudates with Romanowsky, gram, and modified acid-fast stains for rapid diagnosis; may reveal gram-positive branching filamentous rods and cocci; cannot be distinguished from *Actinomyces* spp.
- Culture—diagnostic; aerobic culturing on Sabouraud medium.

PATHOLOGIC FINDINGS

- *N. asteroides*—more suppurative pyogranulomatous reaction than with *Actinomyces* spp.
- *N. brasiliensis*—granulomatous reaction with extensive fibrosis.
- Although the organism is usually present, it cannot be distinguished histopathologically from *Actinomyces* spp.

TREATMENT

- Pleural or peritoneal effusions and disseminated form—inpatient until clinically stable and effusion removed; fluid therapy for rehydration and maintenance often needed.
- Long-term antibiotic therapy and draining fistulous tracts—outpatient.
- Diet—encourage consumption by offering foods with appealing tastes and smells; forced enteral feeding for anorectic inpatients essential; orogastric tube feeding preferred.
- Surgery—when feasible, surgical drainage should accompany medical therapy; important to place a thoracostomy tube for pleural effusion; attempt surgical drainage and debridement of draining tracts and lymph nodes; take care to identify foreign bodies.

MEDICATIONS

DRUG(S)

- Cultured organism—antibiotic sensitivity testing.
- No culture or results pending—good first-choice drugs: sulfonamides (e.g., sulfadiazine at 100 mg/kg IV, PO as a loading dose followed by 50 mg/kg IV, PO q12h) and sulfonamide-trimethoprim combinations (15–30 mg/kg PO q12h).
- Aminoglycosides—gentamicin (3 mg/kg IV, IM, SC q8h); amikacin (6.5 mg/kg IV, IM, SC q8h).
- Tetracyclines—doxycycline (10 mg/kg PO q24h); tetracycline hydrochloride

(15–20 mg/kg PO q8h); minocycline (5–12.5 mg/kg PO q12h).

- Erythromycin 10–20 mg/kg PO q8h; or combined with ampicillin (20–40 mg/kg PO q8h) or amoxicillin (6–20 mg/kg PO q8–12h).
- Amoxicillin or ampicillin plus an aminoglycoside—synergistic combination; consider in any serious infection when culturing is not possible or is pending.
- Average treatment period is 6 weeks; however, medical treatment should extend several weeks past apparent remission of the disease.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Tetracyclines (cats)—may cause fever up to 41.5°C (107°F); discontinue and replace if fever increases during therapy.
- Long-term sulfonamide-trimethoprim may cause anorexia and irreversible bone marrow suppression in cats. Prevent by supplementing with folate administration (1 mg PO q24h).

FOLLOW-UP

Monitor carefully for fever, weight loss, seizures, dyspnea, and lameness the first year after apparently successful therapy because of the potential for bone and CNS involvement.

Consulting Editor Stephen C. Barr

NONSTEROIDAL ANTI-INFLAMMATORY DRUG TOXICOSIS

BASICS

DEFINITION

- Toxicosis secondary to the acute or chronic ingestion of an NSAID.
- NSAIDs—classified as carboxylic acids (aspirin, indomethacin, sulindac, ibuprofen, naproxen, carprofen, meclofenamic acid, etodolac, and flunixin meglumine) or enolic acids (phenylbutazone, dipyrone, meloxicam, tepoxalin, and piroxicam); selective COX-2 inhibitors (deracoxib, firocoxib, mavacoxib (Europe), and robenacoxib).
- Newer selective COX-2 inhibitors and NSAIDs with preferential activity against COX-2 may have fewer adverse reactions than older COX-1 inhibitors.

PATHOPHYSIOLOGY

- Action—analgesic, antipyretic, and anti-inflammatory due to the inhibition of cyclooxygenase; decreases production of prostaglandins that act as mediators of inflammation.
- Well absorbed orally.
- Clearance—varies greatly among species; eliminated slowly in dogs and cats.
- Metabolized in the liver to active or inactive metabolites.
- Excreted in the kidney via glomerular filtration and tubular secretion, and/or biliary excretion.

SYSTEMS AFFECTED

- Gastrointestinal—erosions and ulcers.
- Hemic/Lymphatic/Immune—may note bleeding disorders secondary to decreased platelet aggregation.
- Hepatobiliary—idiosyncratic hepatocellular damage.
- Renal/Urologic—acute renal failure; acute interstitial nephritis.

GENETICS

- Species differences in absorption, excretion, and metabolism of different agents are dramatic; avoid extrapolation of data from other species or dosages.
- Off-label use of NSAIDs can result in significant, potentially life-threatening adverse effects in all species, especially in cats.
- Over-the-counter NSAIDs (especially ibuprofen and naproxen) are common causes of NSAID toxicosis in dogs and cats.

Naproxen has an extremely long half-life in domestic animals and exposures carry a high risk of significant adverse effects.

INCIDENCE/PREVALENCE

Among the ten most common toxicoses reported to both the American Society for the Prevention of Cruelty to Animals Animal Poison Control Center and the Pet Poison Helpline.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

- Dogs and cats
- No breed or gender predilections

SIGNS

General Comments

- Gastrointestinal irritation—usually develops within a few hours.
- Renal involvement or gastrointestinal ulceration—may be delayed several days.

Historical Findings

- Evidence of accidental consumption of owner's medication.
- Lethargy.
- Anorexia.
- Vomiting—with or without blood.
- Diarrhea.
- Icterus.
- Melena.
- Collapse and sudden death—may occur secondary to a perforated gastric ulcer.
- Polyuria, polydipsia, and oliguria.
- Ataxia, seizures, coma—may occur with large ingestions.

Physical Examination Findings

- Depression
- Pale mucous membranes
- Painful abdomen
- Dehydration
- Fever
- Tachycardia
- Icterus

CAUSES

Accidental exposure or inappropriate administration

RISK FACTORS

- Animals predisposed to renal disease—old age; preexisting renal, hepatic, or cardiovascular disease; hypotension; other concurrent illness and/or medications.
- Neonates may be more sensitive.
- Previous history of gastrointestinal ulcer or bleeding.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other conditions (medical or intoxications) that cause gastrointestinal and renal effects; diagnosis based on history of exposure and compatible clinical signs.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia—regenerative or nonregenerative, depending on duration of bleeding.
- Leukocytosis—associated with perforated gastric ulcer and accompanying peritonitis.
- BUN and creatinine—may be elevated secondary to prerenal azotemia or primary renal insult.
- Liver enzymes—occasionally elevated.
- Monitor urine output for evidence of oliguria; monitor for glucosuria, proteinuria, and casts.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Endoscopy—verify gastrointestinal ulceration.

PATHOLOGIC FINDINGS

- Gastrointestinal irritation, ulceration, or hemorrhage with possible gastric perforation and peritonitis.
- Renal tubular or papillary necrosis or interstitial nephritis.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—mild clinical signs (with low ingested dose); managed at home with appropriate medication and dietary and symptomatic measures.
- Inpatient—high ingested dose; potential for renal toxicosis; relatively serious clinical signs (frequent vomiting, bloody vomitus, melena, anemia, or evidence of renal involvement); aggressive treatment to avoid life-threatening complications.

Recent Ingestion

- Ingestion within a few hours and no vomiting—induce emesis (apomorphine or hydrogen peroxide) unless patient has seizures or marked CNS depression.
- After emesis—activated charcoal (1–2 g/kg PO) and a cathartic (magnesium or sodium sulfate at 0.25 tsp/5 kg or 70% sorbitol at 3 mL/kg) if no diarrhea.
- Repeat activated charcoal (one-half the original dose) for NSAIDs that undergo enterohepatic recirculation.

NURSING CARE

- Fluid therapy—restore hydration when moderate to severe vomiting; administration of at least twice maintenance rates with known or potential renal involvement (see Renal Failure, Acute).
- If severely anemic, a blood transfusion may be indicated.

ACTIVITY

N/A

DIET

- Vomiting—NPO
- Vomiting resolved—begin with a bland, low-protein diet

CLIENT EDUCATION

- Stress the importance of contacting a veterinarian, ASPCA APCC, or PPH whenever an animal is exposed to a non-prescribed NSAID.
- Inform client that dogs and particularly cats have a low tolerance to NSAIDs.

(CONTINUED)

NONSTEROIDAL ANTI-INFLAMMATORY DRUG TOXICOSIS

- With a prescribed NSAID, instruct client to look for adverse or idiosyncratic effects and to stop the drug and contact the clinic if they occur.

SURGICAL CONSIDERATIONS

Surgical intervention may be required for a perforated gastric ulcer.

**MEDICATIONS****DRUG(S) OF CHOICE*****H₂-Receptor Antagonists***

- For gastrointestinal upset or ulceration.
- Primarily effective for treating ulcers from acute overdose or from chronic administration after the drug withdrawn.
- Ranitidine or famotidine may be best choices as cimetidine may inhibit microsomal enzymes that metabolize some NSAIDs.
- Ranitidine—dogs, 2 mg/kg PO, IV q8h; cats, 2.5 mg/kg IV q12h or 3.5 mg/kg PO q12h.
- Famotidine—dogs, 0.5–1.0 mg/kg PO, SC, IV, or IM q12–24h; cats, 0.5 mg/kg PO, SC, IV, or IM q12–24h.

Other

- Sucralfate—dogs, 0.5–1 g PO q8–12h; cats, 0.25 g PO q8h; binds to proteins in the ulcer base; stimulates mucus and bicarbonate secretion.
- Misoprostol 1–3 µg/kg PO q8h; PGE₂ analog; prevents gastrointestinal bleeding and ulceration; promotes healing during chronic use in humans and dogs treated with aspirin.
- Omeprazole—0.5–1 mg/kg PO q24h; potent inhibitor of gastric acid secretion; blocks the final step of hydrochloric acid production.
- Dopamine—may be indicated for acute renal failure.
- Standard anticonvulsant therapy—diazepam, pentobarbital, phenobarbital, if needed.
- A test dose of naloxone may be useful in comatose patients.
- Duration of treatment—depends on the half-life of the particular agent ingested.

CONTRAINDICATIONS

Avoid concomitant use of corticosteroids or multiple NSAIDs together; contraindicated in pregnancy (abortifacient effect).

PRECAUTIONS

Patients using other nephroactive or nephrotoxic drugs (e.g., aminoglycosides and ACE inhibitors)—at higher risk for developing NSAID nephropathy.

POSSIBLE INTERACTIONS

NSAIDs—highly protein-bound; may be affected by concurrent use of other highly protein-bound drugs.

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

- Urine output—monitor carefully for oliguria; examine for casts, protein, and glucose.
- Stool and vomitus—check for gastrointestinal bleeding (may not develop for several days).
- BUN and creatinine—daily for several days (full extent of renal damage may not be immediately evident).

PREVENTION/AVOIDANCE

- Store medications out of the reach of pets.
- Discourage owners from medicating pet without supervision of a veterinarian.
- Pretest high-risk patients with appropriate laboratory tests before beginning therapy.

POSSIBLE COMPLICATIONS

- Perforation of a gastric ulcer and peritonitis
- Irreversible acute and chronic renal failure

EXPECTED COURSE AND PROGNOSIS

- Gastric upset or ulceration—usually complete recovery with appropriate treatment.
- Renal effects—generally reversible with early and aggressive treatment.
- Acute hepatopathies—generally resolve with symptomatic treatment after discontinuation of the drug.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

- Exposure during pregnancy—risk for fetal cardiopulmonary and renal effects.
- May prolong pregnancy, especially if administered during the third trimester and before the onset of labor.

NOTOEDRIC MANGE

BASICS

OVERVIEW

- A non-seasonal, intensely pruritic, highly contagious parasitic skin disease of cats caused by *Notoedres cati*.
- The mite is closely related to *Sarcoptes scabiei* var. *canis*.
- Mites burrow through the superficial skin between follicles causing intense pruritus.
- Can cause transient pruritus in humans.

SIGNALMENT

- Domestic cats of all ages and both sexes.
- Fairly host-specific, but can also produce symptoms in dogs, cheetahs, raccoons, rabbits, coatis, palm civets, bobcats, ocelots, foxes, and humans.
- All in-contact cats usually develop clinical signs.
- Epizootic in localized areas.
- Endemic in large feral cat populations.
- Transmission by direct contact: the mite is very short-lived when off the host.

SIGNS

- Non-seasonal intense pruritus.
- Following exposure, initial pruritus may be mild, but progresses to severe.
- Change from mild pruritus to onset of severe pruritus (incubation period) of 3–6 weeks may indicate eventual seroconversion and the development of hypersensitivity (IgG as well as humoral response).
- Rare individuals do not seroconvert, and therefore may not develop severe pruritus.
- Papules and crusts develop on pinnae and spread to eyelids, face, and neck (also known as “head mange”).
- Progresses to the legs, feet (due to sleeping position) and perineum.
- Severe self-trauma leads to secondary lesions.
- Skin becomes thickened, lichenified, and covered with gray-yellow crust.
- Large patches of lesions and alopecia develop over the entire body if untreated.
- Unlike canine scabies, large numbers of mites are present on the skin.
- Peripheral lymphadenopathy often develops.
- Causes significant debilitation in severe cases.

CAUSES & RISK FACTORS

Close contact with other cats

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Atopy
- Cutaneous adverse reaction to food
- Bacterial folliculitis

- Dermatophytosis
- Demodicosis
- *Malassezia* dermatitis
- *Cheyletiellosis*
- Trombiculosis (chiggers)
- Otodectic dermatitis
- Pemphigus foliaceus
- Pemphigus erythematosus
- Systemic lupus erythematosus

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Superficial skin scraping—relatively easy to find mites.
- Mite smaller than *S. scabiei*, with dorsal anus, typical dorsal concentric “finger print” striae, and only two pairs of forelegs protruding from the body line.
- Serum testing (ELISA) for mite antibody not available.

TREATMENT

- When scabicidal dips are used, the entire cat must be treated.
- Treatment failures occur if product is not applied to the face and ears.
- All in-contact cats should be treated.
- Response is usually quick if all in-contact animals are treated.
- Thorough cleaning of the cat's environment may be helpful if severely contaminated.
- Systemic antibiotics—may be needed to resolve secondary bacterial folliculitis.

MEDICATIONS

DRUG(S) OF CHOICE

- Lime sulfur rinses 2%–3%; apply to entire body weekly for six to eight applications; clipping might be necessary to permit adequate contact with the skin.
- Ivermectin—effective; 0.2–0.3 mg/kg SC every 2 weeks for two to three treatments.
- Amitraz rinse (125–250 ppm) weekly for a minimum of three treatments.
- Doramectin 0.2–0.3 mg/kg SC once.
- Selamectin—off-label; applied every 2 weeks for three applications.
- Imidacloprid/moxidectin spot-on applied once or twice as directed on the label.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Amitraz rinse may cause sedation.
- Lime sulfur has unpleasant odor and is staining.

FOLLOW-UP

PREVENTION/AVOIDANCE

Reinfestation may occur if contact with infested animals continues; the source of infestation must be determined (if possible) as well as all in-contact cats must be treated.

POSSIBLE COMPLICATIONS

- Topical scabicidal treatments are more prone to failure because of incomplete application of the treatment solution.
- Persistent infection if not all in-contact animals are treated.

EXPECTED COURSE AND PROGNOSIS

- Response to therapy is rapid providing all in-contact animals are treated; symptoms should significantly reduce within 2 weeks of treatment.
- There is no immunity from repeat infestation; clinical signs following a reinfestation are likely to be more rapid due to previous exposure and sensitization.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Humans in close contact with an affected cat may develop a pruritic, papular rash (often on arms, chest, or abdomen).
- Human lesions are usually transient and resolve spontaneously following treatment of affected animals.

ABBREVIATION

ELISA = enzyme-linked immunosorbent assay

Suggested Reading

Consulting Editor Alexander H. Werner

NYSTAGMUS

BASICS

DEFINITION

- Involuntary, rhythmic oscillation of the eyeballs.
- Jerk nystagmus—most common; slow eye movements in one direction with a rapid recovery phase in the opposite direction.
- Pendular nystagmus—seen less frequently; characterized by small oscillations of the eyes with no fast or slow component.

PATHOPHYSIOLOGY

- Neural projections traverse in the brainstem from the vestibular nuclei to CN III, IV, and VI nuclei, which innervate the extraocular muscles. This system provides coordinated conjugate eye movements in association with changes in head position.
- Physiologic nystagmus (ocular-vestibular reflex)—normal finding, induced by rotating the head from side to side; characterized by a jerk nystagmus with a slow drifting of the eye in the opposite direction of the head rotation followed by a fast compensatory phase in the same direction as the head movement. Decreased to absent physiologic nystagmus is indicative of vestibular disease.
- Pathologic nystagmus—a sign of vestibular dysfunction; characterized by a jerk nystagmus that develops independent of head movement. The nystagmus is described according to the axis of movement of the globe (horizontal, rotary or vertical), and the direction of the fast phase of movement.
- Spontaneous nystagmus—pathologic nystagmus that occurs when the head is in a normal position and not moving; frequently resolves after several days.
- Positional nystagmus—pathologic nystagmus, elicited only when the head is placed in unusual position; can often be seen in more chronic conditions.
- Jerk nystagmus must be differentiated from pendular nystagmus, which is most often observed as an incidental finding in Siamese, Birman, and Himalayan cats.
- Pendular nystagmus—congenital abnormality in which a larger-than-usual portion of the optic nerve fibers crosses in the chiasm; can also be seen with cerebellar disease and with visual deficits.

SYSTEMS AFFECTED

Nervous

GENETICS

N/A

INCIDENCE/PREVALENCE

Nystagmus, as a sign of vestibular disease, is a relatively common clinical presentation in dogs and cats.

SIGNALMENT

Species

Dog and cat

Breed Predilections

None

Mean Age and Range

Varies, depending on underlying cause; neoplastic and vascular conditions and canine geriatric vestibular disease more common in older animals.

Predominant Sex

None

CAUSES

Peripheral Vestibular Disease

- Metabolic—hypothyroidism.
- Neoplastic—nerve sheath tumor or tumor involving surrounding bone or soft tissues.
- Inflammatory—otitis media-interna; nasopharyngeal polyps (cats).
- Idiopathic—canine geriatric vestibular disease; feline idiopathic vestibular disease.
- Toxic—e.g., aminoglycosides, topical iodophors, topical chlorhexidine.
- Trauma.

Central Vestibular Disease

- Degenerative—storage disorders; neuronal degeneration; demyelinating disease.
- Neoplastic—primary or metastatic tumors.
- Nutritional—thiamin deficiency.
- Inflammatory/infectious—viral (canine distemper, feline infectious peritonitis); bacterial; protozoal (toxoplasmosis, neosporosis); fungal (cryptococcosis, blastomycosis, histoplasmosis, coccidioidomycosis, aspergillosis); rickettsial (ehrlichiosis, Rocky Mountain spotted fever); inflammatory, non-infectious (granulomatous meningoencephalomyelitis, necrotizing encephalitis).
- Toxic—lead; hexachlorophene; metronidazole.
- Trauma.
- Vascular—hemorrhage; infarction.

RISK FACTORS

Systemic administration of certain antibiotics (metronidazole, aminoglycoside), otic administration of iodophors and chlorhexidine solutions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Peripheral Vestibular Disease

- Nystagmus—either rotary or horizontal in character, with the fast phase directed away from the side of the lesion; does not change direction.
- Other signs of vestibular disease—head tilt, ataxia, circling, falling or rolling, and vestibular strabismus often present and occur ipsilateral to the lesion.
- Ipsilateral facial nerve deficits and/or Horner's syndrome—can be seen due to the close association of CN VII and sympathetic

nerve to CN VIII as they course through the petrous temporal bone.

Central Vestibular Disease

- Nystagmus—horizontal, rotary, or vertical; can change direction with different head positions.
- Other signs of vestibular disease—head tilt, ataxia, circling, falling or rolling, and vestibular strabismus often present.
- Involvement of other brainstem structures—alterations in level of consciousness, paresis, postural reaction deficits, and other CN deficits (V and VII most common); deficits are typically ipsilateral to the lesion.
- Paradoxical vestibular disease—with certain lesions of the cerebellum; in these cases, postural reaction deficits occur ipsilateral to the lesion whereas the head tilt and other vestibular signs are contralateral to the lesion.

CBC/BIOCHEMISTRY/URINALYSIS

Results usually normal

OTHER LABORATORY TESTS

- Thyroid profile—if hypothyroidism is suspected.
- Bacterial culture of sample obtained via myringotomy—if otitis media-interna is likely.
- Serologic testing—for potential infectious agents.

IMAGING

- Imaging of the tympanic bullae to assess for otitis media-interna—survey radiographs of limited value; CT and MR are more sensitive.
- Brain imaging (CT or MR)—indicated in animals with central vestibular disease to evaluate for structural brain abnormalities. MR is superior to CT for imaging the brain.

DIAGNOSTIC PROCEDURES

Cerebrospinal fluid—if central disease, to evaluate for inflammation.

PATHOLOGIC FINDINGS

Variable, depending of the underlying cause

TREATMENT

APPROPRIATE HEALTH CARE

- The cause of the disease and the severity of signs determine whether the animal is best treated on an inpatient or an outpatient basis.
- In general, animals with central disease require more intensive care than those with peripheral disease.

NURSING CARE

- Fluid therapy is indicated in the acute stages of disease for animals that experience anorexia and vomiting.
- Animals with severe vestibular dysfunction should be confined to a well-padded area in the acute stage of the disease to minimize self-trauma secondary to disorientation.

N

NYSTAGMUS

(CONTINUED)

ACTIVITY

- Animals should be housed on non-slippery surfaces; stairs should be avoided.
- Exercise should be supervised, with assistance provided until signs of imbalance resolve.

DIET

N/A

CLIENT EDUCATION

- Many animals show improvement over the first several days; the nervous system is able to compensate for vestibular disturbances that remain static or are slowly progressive regardless of cause.
- Compensation involves visual and somatosensory (tactile) cues and is dependent on feedback from vestibular pathways; return to normal activity should be encouraged to enhance compensatory mechanisms.

SURGICAL CONSIDERATIONS

Signs of vestibular dysfunction can transiently worsen after an anesthetic episode; most likely reflects a loss of compensation.

MEDICATIONS

DRUG(S) OF CHOICE

- Meclizine (dogs, 4 mg/kg PO q24h) or maropitant (dogs, 1 mg/kg SC or 2 mg/kg PO q24h; cats, 1 mg/kg SC q24h)—used to treat motion sickness; can alleviate nausea and vomiting associated with acute disease.
- Diazepam (dogs, 0.5 mg/kg PO q8h)—recommended in cases of metronidazole toxicity; can help decrease acute vestibular signs from other causes by decreasing the resting activity of vestibular neurons and alleviating the imbalance in vestibular input to the brain.
- Specific medical therapy is directed at the underlying cause, if one can be identified.

N

CONTRAINDICATIONS

- Avoid potential ototoxic drugs, such as aminoglycosides. Toxicity is more likely in animals with renal impairment.
- Avoid instilling topical medications into the ear of an animal with suspected otitis media-interna, especially if the tympanic membrane cannot be visualized or is not intact. Such agents can exacerbate vestibular signs and cause deafness.

PRECAUTIONS

- Avoid the use of metronidazole at daily doses greater than 60 mg/kg, as this has been associated with vestibular dysfunction in dogs.
- Vestibular dysfunction can develop after administration of metronidazole at lower dosages but is less likely.

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

Repeat neurologic examination—perform 2 weeks after initial diagnosis to monitor for improvement or progression of disease.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Dehydration and electrolyte imbalance associated with anorexia and vomiting.
- Rare extension of otitis media-interna into the adjacent brainstem.

EXPECTED COURSE AND PROGNOSIS

- Prognosis varies, depending on the cause of the vestibular disturbance.
- In general, animals with peripheral vestibular disease have a better prognosis than those with central involvement.

- Residual deficits can remain after resolution of the underlying disease process due to irreversible damage to the neural structures.
- Recurrence is possible with some of the conditions (otitis media/interna, canine geriatric vestibular disease, feline idiopathic vestibular disease).

Consulting Editor Joane M. Parent

BASICS

DEFINITION

An excess of body fat frequently resulting in adverse health effects. Even a moderate excess in body fat can increase morbidity and reduce lifespan.

PATHOPHYSIOLOGY

Accumulation of adipose tissue due to an imbalance between energy intake and energy expenditure. Contributing factors are lifestyle related, including neutering, limited activity, and abundant access to food. Secondary complications from obesity may be due to increased inflammatory mediators and oxidative stress, along with insulin resistance induced in obese subjects.

SYSTEMS AFFECTED

- Endocrine
- Musculoskeletal
- Adipose tissue from obese subjects is infiltrated with macrophages. Both adipocytes and associated macrophages secrete inflammatory and endocrine mediators such as tumor necrosis factor-alpha, resistin, interleukins, and other mediators. These mediators contribute to insulin resistance or arthritic changes common in obese individuals. Secondary problems more common in obese dogs and cats include diabetes mellitus, orthopedic problems, dermatologic conditions, urinary tract disease, and liver, cardiac, and renal dysfunction.

SIGNALMENT

- Dog and cat.
- All ages, with the greatest prevalence (nearly 50%) in middle-aged dogs and cats.
- Most common in neutered, indoor pets.

SIGNS

Historical Findings

- Weight gain
- Exercise intolerance may be reported

Physical Examination Findings

Excess body fat and body condition score (see "Diagnostic Procedures")

CAUSES & RISK FACTORS

- Obesity is caused by an imbalance between energy intake and energy expenditure, with intake exceeding expenditure.
- Neutering, decreased opportunities for activity, and age can reduce energy expenditure.
- Overfeeding of high-calorie foods, frequently alternating foods, and provision of excess treats contribute to excess energy intake.
- Hypothyroidism, insulinoma, or hyperadrenocorticism are infrequent causes of obesity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Abdominal distention from pregnancy, ascites, or neoplasia

DIAGNOSTIC PROCEDURES

- Diagnosis of obesity is by body condition scoring and body weight.
- Body condition scoring provides a semiquantitative assessment of composition. It involves visual assessment and palpation, especially over the ribs, lumbar area, and tailhead, and comparison with a standard. Using a nine-point system, each unit above ideal reflects an excess of body weight of about 10–15%. Animals with a BCS ≥ 7 are obese.
- Body weight.

TREATMENT

- Weight loss, induced by reducing calorie intake below calorie expenditure.
- Successful weight loss also requires long-term maintenance of the reduced weight.
- Both of these goals depend on changes in the way the owner feeds and interacts with the pet.

CLIENT EDUCATION

• Obesity management relies on client compliance and changes in feeding and behavioral interactions. Client-focused steps to a successful weight management program include:

- Recognition of the problem—many owners do not recognize their own pet as overweight. Use a BCS system to illustrate how the diagnosis is being made. Show the owner how to assess and monitor the BCS of his or her own pet.
- Importance of the problem—clients that perceive obesity strictly as an aesthetic problem may not be sufficiently motivated to manage it. Educate clients about the increased risk for diseases (e.g., osteoarthritis, diabetes mellitus, feline lower urinary tract diseases, etc.) or shortened lifespan to identify this as a condition that requires appropriate management.
- Client input regarding the weight loss program—determine what clients are willing and able to do. Will they feed a therapeutic diet? Do they provide table foods? Can they feed measured amounts and/or multiple meals? Can they increase the pet's exercise? In multiple-pet households, will clients feed pets separately?
- Compliance with a weight loss program—clients should receive written instructions regarding specific amounts to provide using

the agreed-upon food. Be sure the client understands that "cups" of food refers to an 8-oz. measuring cup. For cats and small dogs, a smaller measure or use of a kitchen or gram scale to measure food allowances can aid accuracy. Treats should be offered as part of the program (see below) since most clients will continue to provide these.

- Ongoing communication—frequent follow-up during the weight loss program aids client compliance.

DIET

- Certain macronutrients can facilitate healthier or easier weight loss:
 - Protein—increased dietary protein facilitates loss of body fat while minimizing loss of lean body mass, which is the metabolically active tissue. Preserving LBM should help with long-term weight control by maintaining a higher resting energy requirement. Protein also stimulates metabolism, increases energy expenditure, and contributes to satiety.
 - Fiber—dietary fiber provides little dietary energy so helps reduce total calories in the diet. Fiber also stimulates intestinal metabolism and contributes to satiety.
 - Decreased fat—fat is energy dense, so low-fat diets are lower in energy.
- Increased moisture—use of high-moisture canned foods can reduce energy density (as fed) so allows the owner to feed a greater volume. Use of high-moisture diets can facilitate short-term weight loss in cats.
- Other dietary factors that may aid in weight management:
 - Carnitine—produced endogenously from lysine and methionine, this compound is necessary for fat oxidation. Supplementation may be beneficial when dietary protein intake is limited.
 - Isoflavones—metabolically active phytonutrients that stimulate energy metabolism: may reduce weight rebound and support maintenance of lean body mass.

Main Meal

- Calories should be restricted without excessive restriction of essential nutrients. A low-calorie therapeutic diet with an increased nutrient:calorie ratio is recommended for weight loss.
- The amount fed should target a 1–2% loss in body weight/week. Faster weight loss may increase loss of lean body mass and stimulate weight rebound once weight loss is achieved.
- Initial feeding is based on 60–75% of calculated MER using target body weight. Target body weight can be estimated using the current weight and BCS; or an intermediate target, e.g., 20% below current weight, can be selected.

OBESITY

(CONTINUED)

- Average MER = 55 kcal/kg for cats; 110 kcal/kg^{0.75} for dogs.
- Adjust feeding amounts monthly to compensate for decreases in MER due to calorie restriction and weight loss, as well as individual differences in MER.
- High-moisture diets can be used to reduce calories/serving. This approach appears to be more effective for cats versus dogs, as cats tend to control their intake based on volume.
- If the client is not willing to use a therapeutic diet, severe calorie restriction should be avoided. A food diary can be used to record current intake over 3–7 days. Subsequently, the pet should be fed 10–20% less than it previously received.

Treats

- Treats are often part of the owner-pet bond.
- Complete avoidance of treats is a hurdle to compliance with weight loss programs.
- Instead, offer a “treat allowance” of 10% of the daily calories and provide a list of low-calorie treats suitable for dogs or cats.

ACTIVITY

- Calorie restriction results in compensatory decreases in basal energy expenditure. Increased activity helps compensate for this and provides alternate opportunities for owner-pet interactions. Provide several suggestions suitable for each client and patient. For example:
 - Leash walking for dogs and trained cats—at least 15 minutes twice daily.
 - Activities such as “fetch,” interactive toys for cats, or playing with a laser light.
 - Food balls—built to hold treats or kibbles and randomly release them while the dog or cat plays. The food inside must be part of the daily calorie allowance.

MEDICATIONS

DRUG(S) OF CHOICE

No approved medications for management of obesity are currently available in the United States.

FOLLOW-UP

- Frequent client communication is important during the weight management program.
- 1 week—telephone call from clinic to address any minor questions and to reinforce the importance of the program.
- Monthly—patient should be weighed in clinic on a monthly basis. If needed, adjustments in food allowance guidelines should be made at this time.
- Upon achieving target weight—once the patient has achieved an ideal BCS, guidelines should be provided for weight maintenance.
- Energy needs will be lower than before weight loss, although this may increase somewhat with time.
- Clients should continue to measure food, monitor BCS or body weight, and adjust food allowance as needed to maintain the loss.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Osteoarthritis
- Diabetes mellitus or insulin resistance
- Dermatoses
- Feline hepatic lipidosis
- Feline lower urinary tract diseases
- Decreased lifespan

AGE-RELATED FACTORS

- MER decreases with age in dogs, which increases the risk for obesity.
- In cats, MER decreases with age until about 10–12 years of age, then increases.
- The highest prevalence of obesity occurs between 5 and 10 years of age in both dogs and cats.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

- Obesity may interfere with a female's ability to become pregnant or deliver healthy offspring.
- Calorie restriction during pregnancy or lactation is discouraged, as nutrient restriction can have long-term adverse effects on offspring.

SYNONYM

Overweight

ABBREVIATIONS

- BCS = body condition score
- LBM = lean body mass
- MER = maintenance energy requirements

available online

BASICS

OVERVIEW

- Odontoma—oral mass that arises from odontogenic epithelial and mesenchymal origin.
 - Ameloblastic fibro-odontoma (AFO) (formerly ameloblastic odontoma)—radiolucent, mass with osteolysis and varying amounts of intralesional mineralization.
 - Complex odontoma—radiodense mass with fully differentiated dental components (more organized than AFO), but unorganized at the cellular level with no tooth-like structures.
 - Compound odontoma—mass with fully differentiated dental components resulting in the presence of denticles (tooth-like structures, see clinical features below).
- Hamartoma—proliferation of normal cellular components with an abnormal organization—not a true neoplasm (applicable to complex and compound odontoma types).
 - A definition to help delineate the three types of odontoma, not a type in itself.

SIGNALMENT

Typically found in young animals.

SIGNS

- Oral swelling or mass
- Delayed deciduous tooth exfoliation or delayed or abnormal tooth eruption at site
- AFO
 - Most lesions are radiolucent with single or multiple (multilocular) expansile lesions of irregular configurations of dental components.
 - Some lesions are associated with impacted teeth.
 - Neoplastic mechanism, may recur (WHO—benign neoplasm).
- Complex
 - Disorganized tissues within a thin, fibrous capsule.
 - Radiographically, often a radial structure of hard tissue particles inside a radiolucent zone, embedded in the maxilla or mandible.
 - Erupted teeth in that area may allow for communication between the odontoma and oral cavity, with a potential for bacterial contamination and infection.
- Compound
 - The presence of denticles is pathognomonic.
 - Small, rudimentary teeth with crown formed, but the roots are often misshapen (dilacerated).
 - Denticles often associated with radiolucency.
 - May be embedded or have some extent of eruption.

CAUSES AND RISK FACTORS

AFO

- Mixed odontogenic tumor with differentiation of odontoblasts, ameloblasts and cementoblasts embedded in cellular mesenchymal tissue.
- Reciprocal inductive interaction of epithelial and mesenchymal tissues.
- WHO classification as a benign neoplasm with possible reoccurrence.

Complex Odontoma

Inductive processes resulting in dental components but not fully organized.

Compound Odontoma

Differentiation of dental components into varying levels of organization—denticles.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infection
- Foreign body
- Dentigerous cyst
- Other oral masses
 - Ameloblastic fibroma—similar to AFO but would contain no hard tissue.
 - CEOT—Calcifying epithelial odontogenic tumor. Osteolysis but not mineralization or dental (mesenchymal) aspect. Slow, not inductive, non-invasive.
 - APOT—Amyloid producing odontogenic tumor. Similar to CEOT, but amyloid producing. Shares biologic features with ameloblastoma.
 - Peripheral odontoma (4 human cases diagnosed). Develops in gingiva or alveolar mucosa with no attachment to bone. Associated with impacted or retained teeth. Similar to erupted odontoma.

CBC/BIOCHEMISTRY/URINALYSIS

Typically not affected

IMAGING

- Intraoral radiography
- Advanced imaging typically not warranted

DIAGNOSTIC PROCEDURES

- Histopathology
- Complete oral examination

TREATMENT

SURGICAL CONSIDERATIONS

Procedures

- Appropriate antimicrobial and pain management therapy when indicated.
- Appropriate patient monitoring and support during anesthetic procedures.
- AFO
 - More aggressive excision may be necessary due to neoplastic classification.

- Monitor for local recurrence.

- Complex and compound odontoma
 - Enucleation and intracapsular excision with aggressive debridement of cyst. More aggressive surgical excision can decrease the chance of recurrence.
 - No chemotherapeutic regimens recommended.
 - Rarely radiotherapy may be beneficial by treating microscopically recurring disease.

MEDICATIONS

None indicated

FOLLOW-UP

PATIENT MONITORING

Typical postoperative—pain management, nutrition

POSSIBLE COMPLICATIONS

Recurrence, local infection, fragile jaw structure

EXPECTED COURSE AND PROGNOSIS

- AFO—fair to guarded prognosis, as there is a chance of recurrence.
- Complex and compound odontoma—short- and long-term prognosis good with adequate therapy.

MISCELLANEOUS

ABBREVIATIONS

- AFO = ameloblastic fibro-odontoma
- APOT = amyloid-producing odontogenic tumor
- CEOT = calcifying epithelial odontogenic tumor
- WHO = World Health Organization

OLIGURIA AND ANURIA

BASICS

DEFINITION

- Oliguria—production of an abnormally small amount of urine (variably described as urine production rate < 0.27 , < 0.5 , or $< 1.0\text{--}2.0 \text{ mL/kg/h}$). In euvolemic or hypervolemic patients with good perfusion, urine production $< 1.0 \text{ mL/kg/h}$ = absolute oliguria. Hydrated dogs and cats receiving fluids should produce at least 1.0 mL/kg/h .
- Anuria—limited/no urine formation (urine production rate $< 0.08 \text{ mL/kg/h}$).

PATOPHYSIOLOGY

- Physiologic (prerenal) oliguria: kidneys limit water loss during episodes of reduced renal perfusion to preserve fluid and electrolyte balance. High plasma osmolality or low circulating fluid volume stimulate ADH synthesis and release. ADH acts on the kidneys to induce formation of small quantities of concentrated urine.
- Pathologic (renal) oliguria: severe renal parenchymal impairment. Factors include: high resistance in afferent glomerular vessels, low glomerular permeability, back leak of filtrate from damaged renal tubules, renal intratubular obstruction, extensive loss of nephrons resulting in marked reduction of glomerular filtrate produced.
- Anuria: may be renal or post-renal origin. Severe renal disease occasionally causes anuria. True anuria is more indicative of urinary obstruction. Mechanisms are the same as for pathologic oliguria (e.g., UTO or excretory pathway rupture).

SYSTEMS AFFECTED

- Renal—inability to adequately eliminate wastes and water; hyperkalemia.
- Urologic—obstruction-induced distension of the collecting system. Increased risk of urinary tract infection due to failure to empty the bladder.

SIGNALMENT

- Dog and cat.
- Young adult cats: higher incidence of anuria associated with UTO.
- Risk of acute kidney injury increases with age.

SIGNS

- Reduction in quantity of urine voided.
- Enlarged urinary bladder, straining to void, increased frequency of attempted voiding with urethral obstruction.
- Systemic signs of uremia if oliguria/anuria persists.

CAUSES

- Physiologic oliguria—renal hypoperfusion (caused by low blood volume or hypotension) or hypertonicity (usually caused by hypernatremia).
- Pathologic oliguria—acute oliguric kidney injury (renal failure), advanced CKD.
- Anuria—complete UTO, urinary excretory pathway rupture, or severe primary kidney disease.

RISK FACTORS

- Physiologic oliguria—causes include: dehydration, decreased cardiac output, hypotension, ECF volume contraction.
- Pathologic oliguria and anuria: caused by primary kidney disease, preexisting kidney disease, nephrotoxin exposure, dehydration, low cardiac output, hypotension, ECF volume contraction, electrolyte imbalance, acidosis, advanced age, fever, sepsis, liver disease, multiple organ failure, trauma, diabetes mellitus, hypoalbuminemia, hyperviscosity syndrome.
- Anuria—caused by urolithiasis, urinary tract neoplasia, idiopathic feline lower urinary tract disease, functional micturition disorder, trauma, gross hematuria.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Physiologic oliguria: poor tissue perfusion (e.g., dehydration; prolonged capillary refill time; pale mucous membranes; weak, rapid, irregular pulse; cool extremities); history of recent fluid loss (vomiting, diarrhea, polyuria, hemorrhage); signs of uremia are typically absent. Oliguria resolves rapidly when renal hypoperfusion is corrected.
 - Suspect pathologic oliguria and renal anuria with detection of any of the risk factors; (risk factors are additive). Patients with pathologic oliguria caused by CKD have a history of progressive kidney disease (including long-standing polyuria, polydipsia, poor appetite, weight loss). Patients with CKD are at risk of developing acute kidney injury. Signs of uremia are commonly observed; fluid therapy and other measures to restore adequate renal perfusion often fail to increase urine flow.
 - Suspect anuria due to UTO or rupture of the excretory pathway with repeated straining to void but inability to produce urine. Patients may have a history of pollakiuria, dysuria, stranguria, hematuria, urolithiasis, trauma, instrumentation of the urinary tract. Physical exam UTO patient may reveal: enlarged urinary bladder, painful posterior abdomen, masses or uroliths in the urethra or bladder. Physical exam of patients with rupture of the urinary tract may reveal ascites, fluid infiltration in tissues, painful caudal abdomen, masses or uroliths in the bladder or urethra, or evidence of trauma (e.g., pelvic fracture).
 - UTO caused by functional urinary obstruction: suspect in patients with urinary bladder enlargement, increased resistance to manual bladder expression, and neurologic signs affecting the hind limbs and/or tail. Signs of uremia may develop. Restoring urinary flow/correcting rents in the excretory pathway rapidly restores adequate urine flow.
- CBC/BIOCHEMISTRY/URINALYSIS**
- Serum urea nitrogen/creatinine concentrations: elevated unless onset of

oliguria or anuria is very recent.

- Hyperkalemia: common with pathologic oliguria and anuria, less common/less severe in animals with physiologic oliguria (except with hypoadrenocorticism).
- Physiologic oliguria: characterized by high USG (> 1.030 , cats > 1.035). Oliguria associated with lower USG suggests renal parenchymal disease or UTO. Patients with urine-concentrating defects due to other diseases or drugs are the exception to this rule.
- Renal parenchymal anuria is typically characterized by USG < 1.030 (dogs) or < 1.035 (cats). USG varies in patients with post-renal anuria. Adequate urine-concentrating ability often lost after UTO.

IMAGING

- Abdominal radiographs and ultrasound are useful to rule out UTO/excretory pathway rupture.
- Excretory urography, retrograde urethrocytography, pyelography, or vaginourethrocytography may provide definitive proof of UTO/excretory pathway rupture.
- Distension of the excretory pathway or detection of uroliths in the ureters, bladder neck, urethra suggest UTO.
- Detection of fluid within the peritoneum supports a diagnosis of excretory pathway rupture. Contrast media leakage confirms a rupture.

DIAGNOSTIC PROCEDURES

- Electrocardiography: to identify significant hyperkalemia (see Hyperkalemia).
- Urethrocytostomy: may provide evidence for UTO/ urinary tract rupture.
- Urinary catheterization: may provide information about the integrity of the lower urinary tract. Not recommended as a diagnostic procedure because it may be misleading and may cause additional trauma, iatrogenic UTI.

TREATMENT

- Oliguria and anuria are emergencies. Untreated, may lead to death within hours to days. Death results from uremia, hyperkalemia, acidosis, sepsis.
- Persistent hypovolemia may lead to ischemic renal injury.
- Correct renal hypoperfusion rapidly by intravenous administration of normal saline or lactated Ringer's solution.
- Therapy for primary renal oliguria/anuria is limited to symptomatic, supportive care while awaiting spontaneous renal function recovery. Elimination of causative factors may slow or stop further renal injury (e.g., terminating aminoglycoside therapy, correcting hypercalcemia, or restoring adequate renal perfusion); however, once pathologic oliguria/anuria has developed, few kidney diseases will be amenable to specific treatment (exception = leptospirosis).
- Correct post-renal causes for anuria by non-surgical/surgical methods including retrograde

(CONTINUED)

OLIGURIA AND ANURIA

urohydropropulsion of uroliths/urethral plugs; placement of transurethral catheters to restore low-pressure urinary flow; removal of uroliths, polyps, neoplastic tissue; or surgical repair of rents, strictures, malposition of kidneys, ureters, bladder, urethra.

**MEDICATIONS****DRUG(S)**

- Diuretics: indicated after establishing euvoolemia in patients with renal oliguria. Diuretic-induced increased urine production facilitates fluid and electrolyte therapy and implies less severe kidney injury.
- Administration of diuretics before restoring adequate renal perfusion is counterproductive and may promote renal injury.
- Avoid diuretic-induced dehydration.
- Furosemide (2–4 mg/kg IV): often used first in patients with renal oliguria. Urinary flow should increase within 1 hour if not, repeat at the same or double dosage. If diuresis ensues, administer CRI of furosemide to sustain diuresis (0.25–1 mg/kg/h or 2–4 mg/kg IV q8h). Bolus injection followed by CRI may be most effective.
- Mannitol (0.25–1 g/kg IV) can be given as a 10% or 20% solution over 15–20 minutes. Urinary flow should increase within 1 hour. Do not repeat if diuresis does not ensue; may cause excessive volume expansion. If diuresis ensues, mannitol may be continued as CRI (1–2 mg/kg/h) or intermittent IV doses (0.25–0.5 g/kg every 4–6 hours) to sustain diuresis. Avoid mannitol when overhydration, pulmonary edema, congestive heart failure present.
- Dogs, dopamine (0.5–3 µg/kg/min) may increase urine flow by increasing renal blood flow, glomerular filtration, renal sodium excretion. Higher doses may cause renal vasoconstriction, tachycardia, and cardiac arrhythmias and are contraindicated in AKI. Dopamine is generally administered concurrent with furosemide. Diuresis should ensue within 1–2 hours. If diuresis ensues, dopamine should be continued until fluid and electrolyte balance can be maintained without further drug therapy. If urine flow does not increase within 2 hours, discontinue dopamine. Dopamine has not been established to be an effective treatment for

oliguria in dogs. Dopamine is not appropriate for oliguric cats.

- Fenoldopam (0.1–0.6 µg/kg/min), a selective dopamine A1 receptor antagonist, promotes a delayed (4- to 6-hour) diuresis in normal cats; however, its effectiveness in oliguric cats has not been established.

CONTRAINDICATIONS

Nephrotoxic drugs

PRECAUTIONS

- Administer fluids carefully to patients that are persistently oliguric or anuric to avoid overhydration. Do not continue to administer fluids to oliguric/anuric patients after their fluid volume deficit has been restored absent a plan to prevent development of overhydration. In patients with unresponsive renal oliguria; peritoneal dialysis/hemodialysis may be required to correct iatrogenic fluid-induced volume overexpansion.
- Failure to correct fluid deficits before initiating diuretic administration may cause further renal hypoperfusion and ischemic renal injury.
- Use drugs requiring renal excretion with caution.
- Avoid electrolyte solutions containing more than 4 mEq of potassium per liter in most animals. However, some hypokalemic patients may require cautious administration of higher doses of potassium.
- Dopamine can cause cardiac arrhythmias, particularly in animals with hyperkalemia. ECG monitoring is recommended when high dosages are used and in animals with hyperkalemia.

POSSIBLE INTERACTIONS

Furosemide may promote the nephrotoxicity associated with aminoglycoside antibiotics.

**FOLLOW-UP****PATIENT MONITORING**

- Urinary flow rate—determine early during the course of case management. When unclear, consider transurethral catheterization to accurately determine urine production. Place catheters using aseptic technique. Intermittent catheterization is less likely to cause UTI than indwelling catheter. Short catheter indwelling time lowers the risk of UTI. Properly placed/managed indwelling

catheters are usually safe for at least 48 hours. Use a closed, sterile drainage system.

- Creatinine, serum urea nitrogen, and potassium concentrations should be reevaluated after 12–24 hours; patients with severe hyperkalemia may need more frequent monitoring.
- ECG should be performed at appropriate intervals to assess cardiac effects of drugs and hyperkalemia and to monitor response to therapy.

PREVENTION/AVOIDANCE

- Avoid nephrotoxic drugs and substances.
- Avoid dehydration and volume contraction.

POSSIBLE COMPLICATIONS

- Hyperkalemia and associated cardiotoxicity
- Uremia leading to death
- Dehydration
- Overhydration
- Bacterial UTI and sepsis

EXPECTED COURSE AND PROGNOSIS

- Oliguria and anuria are poor prognostic signs in acute or CKD; unless urine outflow can be corrected, survival is not expected.
- Anuria associated with UTO is often reversible if urethral patency is restored.

**MISCELLANEOUS****SEE ALSO**

- Azotemia and Uremia
- Hyperkalemia
- Nephrotoxicity, Drug-Induced
- Renal Failure, Acute
- Renal Failure, Chronic
- Urinary Tract Obstruction

ABBREVIATIONS

- ADH = antidiuretic hormone
- AKI = acute kidney injury
- CKD = chronic kidney disease

OLLULANUS INFECTION

BASICS

OVERVIEW

A trichostrongyloid nematode—adult worms are found in the stomach wall of cats, causing chronic gastritis resulting in anorexia, vomiting, and weight loss. Females are oviparous and larvae may mature to adults without leaving the stomach. It is thought that the main mode of transmission is through vomitus to other cats.

SIGNALMENT

- Colony cats—predisposed, probably because they have close access to other cats' vomitus.
- Stray cats living in urban areas heavily populated with cats—high incidence of infection.
- Captive cheetahs, lions, tigers, cougars—susceptible to infection.

SIGNS

- Chronic vomiting, anorexia, weight loss
- Death from chronic gastritis

CAUSES & RISK FACTORS

- *Ollulanus tricuspis*—adults (only up to 1 mm in length) coil into the gastric mucosa, causing superficial erosions.
- Over time, gastric erosions can become severe with marked inflammation, accumulation of lymphoid aggregates, and fibrous changes in the mucosa and submucosa.
- Eggs—hatch within the female worms and larvae develop to infective L3 larvae within the stomach.
- L3 larvae—vomited; infective to other cats.
- Adult male and female worms passed in the vomitus—can also infect other cats.
- Distributed throughout North America, Australia, New Zealand, Europe, Argentina, Chile.
- Germany—up to 40% of free-roaming cats may be infected.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of vomiting including:
 - Dietary
 - Toxins—lead, ethylene glycol

- Metabolic—diabetes mellitus, renal disease, liver disease, acidosis, heat stroke, hypoadrenocorticism, hyperthyroidism
- Gastric abnormalities—inflammatory bowel disease, neoplasia, obstruction, atrophic gastritis, ulcers, dilatation/volvulus, parasitic such as *Physaloptera*
- Gastroesophageal junction disorders—hiatal hernia
- Small intestinal disorders—inflammatory bowel disease, neoplasia, fungal, viral, obstruction, paralytic ileus
- Large intestinal disorders—colitis, obstipation, inflammatory bowel disease
- Abdominal disorders—pancreatitis, gastrinoma, peritonitis, steatitis, pyometra, diaphragmatic hernia, neoplasia
- Neurologic disorders—psychogenic, motion sickness, vestibular lesions, head trauma, brain neoplasia
- Miscellaneous—heartworm disease and heart disease.

CBC/BIOCHEMISTRY/URINALYSIS

Reflects diarrhea/vomiting—dehydration

OTHER LABORATORY TESTS

- Larvae (or eggs)—seldom found in feces as they are digested within the GIT.
- Vomitus—examine with Baermann method for L3 larvae.
- Vomiting can be induced in the cat using xylazine (0.5 mg/kg IV, or 1 mg/kg IM)—successful in about 70% of cases.

IMAGING

Abdominal ultrasound—may show gastric thickening; rarely see parasites.

DIAGNOSTIC PROCEDURES

- View worms through an endoscope—difficult due to size of worms.
- Gastric lavage—using saline collection followed by centrifugation to precipitate L3 larvae, or use Baermann technique.
- Histopathology—gastric biopsy occasionally shows parasites.

TREATMENT

Few treatments have been reported.

MEDICATIONS

DRUG(S)

- Tetramisole—give as a 2.5% formulation at 5 mg/kg PO once; effective but not available in the United States.
- Fenbendazole, oxfendazole, and pyrantel pamoate are recommended but there is little data available regarding treatment success.

CONTRAINdications/POSSIBLE INTERACTIONS

Tetramisole—at this dose should not cause any side effects in cats.

FOLLOW-UP

Warn owner to watch for further vomiting—treat with another round of tetramisole if it occurs.

MISCELLANEOUS

Ollulanus infection has been identified in a cat with concurrent gastric adenocarcinoma.

ABBREVIATION

- GIT = gastrointestinal tract

OPHTHALMIA NEONATORUM

BASICS

OVERVIEW

- Infection of the conjunctiva and/or cornea before or just after the separation of the eyelids in the neonate.
- Occurs in puppies and kittens.
- Associated with *Staphylococcus* spp. or *Streptococcus* spp. in dogs and cats, and with herpesvirus in cats.
- Potentially vision threatening.
- Source of infection—believed to be from an intrauterine infection, a vaginal infection of the dam at the time of birth, or from a non-hygienic environment.

SIGNALMENT

- Affects all breeds of cats and dogs.
- Neonates before the time that the eyelids open (10–14 days postpartum).

SIGNS

- Upper and lower eyelid margins are fused (physiologic ankyloblepharon) and the lids bulge outward because of the accumulation of debris and discharge within the conjunctival sac.
- May note a mucous to mucopurulent discharge extruding through a patent opening at the medial canthus.
- Cornea and conjunctiva may be ulcerated.
- May note adhesions (symplepharon) of the conjunctiva to the cornea or to other areas of the conjunctiva (including that of the nictitans).
- Perforation of the cornea with iris prolapse and collapse of the globe is occasionally seen.

CAUSES & RISK FACTORS

- Intrauterine or vaginal infections in the dam near the time of birth.
- Unclean environment for the neonates.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Neonates with entropion in which the eyelids have already separated—mucous to mucopurulent discharge may be present; view of the cornea may be obscured; may have appearance of ankyloblepharon; differentiated by age (patients older than 10–14 days) and ability to separate the eyelids.

CBC/BIOCHEMISTRY/URINALYSIS

Normal unless there is a concurrent systemic infection.

OTHER LABORATORY TESTS

- Cultures of neonate's ocular discharge and/or dam's vaginal discharge—may help diagnose bacterial infection and guide antibacterial therapy.
- Cytology of the affected tissues—may help diagnose bacterial infection and guide antibacterial therapy.
- Immunofluorescent antibody or polymerase chain reaction tests (cats)—feline herpesvirus.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Full physical examination of the dam and neonate.
- Fluorescein staining—corneal or conjunctival ulceration.

TREATMENT

- Separation of the eyelids—cornerstone of treatment; can be accomplished by manual traction beginning at the medial canthus or introduction of a closed hemostat, small blunt scissor blade or the blunt, butt end of a scalpel blade into the patent opening or groove of the future lid fissure at the medial canthus and gently separating (not cutting) the eyelids.
- Lavage of conjunctival sac and cornea with warm saline or a 1:50 diluted povidone-iodine aqueous solution to remove the discharge.
- Warm compresses may aid in separating the eyelids and preventing readherence.
- Systemic support as needed.

MEDICATIONS

DRUG(S)

- Broad-spectrum, topical antibiotics—e.g., neomycin/bacitracin/polymyxin B; applied 4 times daily for at least 1 week; antibiotic chosen on basis of bacterial culture and sensitivity, if available.
- Antiviral therapy in the case of herpesvirus infection in cats.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Tetracycline—do not use in neonates because of the risk of affecting bone or teeth; topical ofloxacin or ciprofloxacin is drug of choice for *Chlamydophila*.
- Topical corticosteroids—contraindicated.

FOLLOW-UP

PATIENT MONITORING

- Warm compresses—may be necessary for a few days to keep the eyelids from readhering.
- Topical antibiotics—continued for a minimum of 7 days.
- Observe littermates that are not initially affected.
- Treat vaginal infections in the dam with appropriate medications.

PREVENTION/AVOIDANCE

- Keep the external environment and the dam's nipples clean.
- Treat vaginal infection in the dam before delivery, if possible.

POSSIBLE COMPLICATIONS

- Severe keratitis with scarring and symblepharon.
- Rupture of the cornea with secondary phthisis; blindness may be irreversible.

EXPECTED COURSE AND PROGNOSIS

Favorable with correct and timely diagnosis and treatment and if no major complications occur.

MISCELLANEOUS

Suggested Reading

Stades FC, van der Woerdt A. Diseases and surgery of the canine eyelid. In: Gelatt KN, Gilger BC, Kern TJ, eds. Veterinary Ophthalmology, 5th ed. Ames, IA: Wiley-Blackwell, 2013, pp. 832–893.

OPTIC NEURITIS AND PAPILLEDEMA

BASICS

DEFINITION

- Optic neuritis—Inflammation of one or both optic nerves, resulting in reduction of visual function.
- Papilledema is edema of the optic nerve head that does not obviously affect the function of the optic nerve.

PATHOPHYSIOLOGY

- Optic neuritis may be a primary disease or secondary to CNS disease because the optic nerve communicates with the subarachnoid space.
- Papilledema occurs when CSF pressure is elevated.
- Papilledema may occur separately from optic neuritis.
- Optic neuritis may also feature papilledema.

SYSTEMS AFFECTED

- Nervous
- Ophthalmic

GENETICS

No genetic basis

INCIDENCE/PREVALENCE

Occasional cause of blindness in dogs; rare in cats

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species
Dog and cat

Breed Predilections
None

Mean Age and Range
Middle-aged

Predominant Sex
None

SIGNS

Historical Findings

- Optic neuritis—acute blindness, may report other neurologic signs such as ataxia, seizures or behavior changes.
- Papilledema—no clinically detectable visual abnormalities but may report other neurologic signs.

Physical Examination Findings

- Optic neuritis—may be unilateral or bilateral; absent menace, absent dazzle, mydriatic and nonresponsive pupil, may have anisocoria if unilaterally affected, usually normal anterior segment, hyperemia, congestion, and hemorrhages of the optic nerve head, retina surrounding optic nerve may be detached, may have chorioretinitis concurrently.

- Papilledema—usually bilateral, menace present, dazzle present, normal pupillary light reflexes, normal anterior segment, swelling and elevation of optic nerve head, loss of physiologic cup in center of optic nerve head, retina usually normal.

CAUSES

Optic neuritis

- Idiopathic (dogs)
- Systemic mycoses
- Canine distemper (dogs)
- FIP (cats)
- Neoplasm—primary or metastatic
- Toxoplasmosis
- *Neosporum caninum*
- Granulomatous meningoencephalomyelitis
- Ehrlichiosis
- Orbital cellulitis
- Hepatozoonosis
- Toxicity—lead
- Tick-borne encephalitis virus

Papilledema

- CNS neoplasia (primary or metastatic)
- Hepatic encephalopathy
- Hydrocephalus
- Distemper (dogs)
- FIP (cats)
- Systemic mycoses
- Toxoplasmosis
- Granulomatous meningoencephalitis
- Trauma

RISK FACTORS

None

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Papilledema is differentiated from optic neuritis by presence of normal pupillary light reflexes and no obvious visual deficits.
- Cortical blindness—normal pupillary light reflex; normal fundus examination; possibly other neurologic deficits; normal electroretinogram.
- SARDS (dogs)—normal to absent pupillary light reflex; normal fundus (early in course); flat electroretinogram.

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities

OTHER LABORATORY TESTS

Specific viral, protozoal, or fungal serologic tests on serum

IMAGING

Neuroimaging—MRI and/or CT

DIAGNOSTIC PROCEDURES

- CSF analysis.
- Electroretinogram—investigate retinal function; normal in optic neuritis and papilledema, flat in SARDS.
- Measure intracranial pressure.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—most cases will need to be hospitalized for workup and medical therapy depending on primary disease process.

NURSING CARE

Depending on degree of neurologic impairment, special attention to patient cleanliness, passive range of motion.

ACTIVITY

Activity may need to be restricted if visual deficits are present and depending on degree of neurologic impairment.

DIET

May need to be altered depending on degree of neurologic impairment.

CLIENT EDUCATION

Optic neuritis—important to emphasize that vision may not return, particularly in idiopathic cases, and treatment may be life-long (immunosuppressive therapy).

SURGICAL CONSIDERATIONS

Surgery infrequently indicated with the exceptions of resectable CNS disease.

MEDICATIONS

DRUG(S) OF CHOICE

Optic neuritis

- Depends on primary disease process when identifiable, always treat any infectious process identified.
- Idiopathic—prednisone 2 mg/kg q12h for 14 days; then 1 mg/kg q12h for 14 days; then gradual reduction to maintenance dosage.

Papilledema

- Mannitol 1 g/kg IV over 20 minutes; repeated as necessary.
- Hypertonic saline 3 mL/kg IV over 10 minutes.
- Corticosteroids—prednisone (0.5 mg/kg PO q12h) or dexamethasone SP 0.25 mg/kg IV q8–12h); not indicated for head trauma.

CONTRAINDICATIONS

Immunosuppressive drugs may be contraindicated in patients where disease etiology is unknown.

PRECAUTIONS

Ensure patients receiving mannitol can urinate; immunosuppressive agents should be used cautiously in infectious processes.

POSSIBLE INTERACTIONS

None

(CONTINUED)

**FOLLOW-UP****PATIENT MONITORING**

Serial ophthalmic examinations should be performed, including fundic exam; careful attention to visual deficits; visual deficits resolving indicate improvement in disease, but patient may also adapt to vision loss, making client's reports of vision unreliable.

PREVENTION/AVOIDANCE

None

POSSIBLE COMPLICATIONS

- Optic neuritis—vision loss may be permanent.
- Papilledema—increased CSF pressure may be associated with brain herniation.

EXPECTED COURSE AND PROGNOSIS

- Optic neuritis—guarded to poor prognosis for return of vision, but idiopathic cases have good prognosis for life.
- Papilledema—guarded to poor prognosis for life.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Optic neuritis—chorioretinitis, CNS disease
- Papilledema—CNS disease

AGE-RELATED FACTORS

None

ZOONOTIC POTENTIAL

Zoonotic infectious CNS disease is rare.

PREGNANCY/FERTILITY/BREEDING

Infectious diseases such as canine distemper may be associated with fetal disease and congenital abnormalities.

SEE ALSO**ABBREVIATIONS**

- CNS = central nervous system
- CSF = cerebrospinal fluid

- CT = computed tomography
- FIP = feline infectious peritonitis
- MRI = magnetic resonance imaging
- SARDS = sudden acquired retinal degeneration syndrome

Suggested Reading

ORAL CAVITY TUMORS, UNDIFFERENTIATED MALIGNANT TUMORS

BASICS

OVERVIEW

- Uncommon, highly aggressive, rapidly growing tumor typically located in the caudal maxilla and orbit of young dogs.
- Most are highly bone-invasive and are non-encapsulated with a smooth to slightly nodular surface (mistaken as benign); may become ulcerated.
- Biopsy—reveals undifferentiated malignancy of undetermined histogenesis.
- Highly metastatic.
- Cervical lymphadenopathy common.

SIGNALMENT

- Dog
- Primarily a disease of large breeds
- All dogs < 2 years old; range, 6–22 months
- No sex predilection

SIGNS

Historical Findings

- Excessive salivation
- Halitosis
- Dysphagia, dysorexia
- Bloody oral discharge
- Weight loss

Physical Examination Findings

- Oral mass
- Loose teeth
- Facial deformity, exophthalmia
- Cervical lymphadenopathy—occasionally
- Pain upon palpating or opening the mouth

CAUSES & RISK FACTORS

None identified

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other aggressive oral malignancy including melanoma and squamous cell carcinoma
- Acanthomatous ameloblastoma
- Abscess

CBC/BIOCHEMISTRY/URINALYSIS

May be normal

OTHER LABORATORY TESTS

- Cytologic evaluation of primary tumor and draining lymph node—may provide tentative diagnosis.
- Histopathology consistent with an undifferentiated tumor without characteristic morphologic features of mesenchymal or epithelial origin.
- Immunocytochemistry (various markers) required to rule out other tumors, including rhabdomyosarcoma (aggressive tumor also seen in young dogs).

IMAGING

- Skull radiography—detect bone invasion deep to the mass.
- Thoracic radiography—detect lung metastasis.
- Advanced sectional imaging (CT or MRI)—define local and regional extent of disease, and facilitate therapeutic planning.

DIAGNOSTIC PROCEDURES

- Carefully palpate regional lymph nodes (mandibular, retropharyngeal).
- Large, deep tissue biopsy required to differentiate from other oral malignancies.

TREATMENT

DIET

Soft foods—may be recommended to prevent tumor ulceration or after radical oral excision.

SURGICAL CONSIDERATIONS

Radical surgical excision—often ineffective because of extensive local disease or regional metastasis at diagnosis; if attempted, must have margins of at least 2 cm into normal bone and soft tissues and ideally be planned with the help of contrast enhanced advanced sectional imaging.

RADIATION

- Efficacy unreported.
- Undifferentiated tumors often poorly responsive to megavoltage radiation therapy.
- Considered for palliation (hypofractionated protocol).

MEDICATIONS

DRUG(S)

- Chemotherapy—efficacy unreported; undifferentiated tumors often poorly responsive to systemic chemotherapy.
- Pain management with multimodal analgesic therapy is mandatory (NSAID, opioid, adjuvant analgesic drugs, aminobisphosphonate if osteolytic).

CONTRAINdications/POSSIBLE INTERACTIONS

Chemotherapy can be toxic; seek advice of a medical oncologist before initiating treatment if you are unfamiliar with cytotoxic drugs.

FOLLOW-UP

Most dogs have detectable metastatic dissemination at diagnosis; usually euthanized within 30 days of diagnosis because tumor growth is progressive and uncontrolled, resulting in decreased quality of life and condition.

MISCELLANEOUS

ABBREVIATIONS

- CT = computed tomography
- MRI = magnetic resonance imaging
- NSAID = nonsteroidal anti-inflammatory drug

Consulting Editor Timothy M. Fan

BASICS

DEFINITION

- Oral cavity growth that may be benign or malignant.
- Fourth most common area of malignancy in dogs and cats.
- The majority of oral malignancies are locally aggressive and slow to metastasize.

PATHOPHYSIOLOGY

Cat

- Squamous cell carcinoma—age range, 3–21 years (mean, 12.5); sites include gingival, sublingual and tonsillar; common presenting signs include excessive drooling and/or bleeding from the mouth; frequently invades bone, loosening teeth; morbidity and mortality result from local disease rather than distant metastasis. There is speculation that a viral association maybe possible.
- Fibrosarcomas—age range, 1–21 years (mean, 10.3); no particular predilection site; all associated with local tissue destruction; muscle and bone invasion are occasionally seen.

Dog

- Epulis is a general term referring to a gingival mass of any type (see Epulis).
 - Previous categorization of fibromatous epulis (FE) has been subdivided into FFH—focal fibromatous hyperplasia (no odontogenic epithelium) and POF—peripheral odontogenic fibroma (with odontogenic epithelium and varying degrees of ossification).
 - Previous categorization of acanthomatous epulis now termed CAA—canine acanthomatous ameloblastomas—locally aggressive.
- Malignant melanoma (see Melanocytic Tumors, Oral)—the most common oral malignant tumor in the dog; cocker spaniels, German shepherds, chow chows, and dogs with heavily pigmented mucous membranes are predisposed; masses can be amelanotic, males more frequently affected than females. Occurs in many places in the oral cavity (the most common site in order of occurrence is gingival, buccal mucosa, lip, tongue, and palate); locally invasive and metastasize to lungs and regional lymph nodes; common presenting complaints are oral bleeding, ptalism, or halitosis; tumor size on presentation is important to patient survival; in the dog, melanomas < 2 cm carry a better survival rate (median 511 days) than those > 2 cm (median 164 days); tumors located rostrally have better prognosis than those located distally.

- Squamous cell carcinoma (see Squamous Cell Carcinoma, Gingiva; Squamous Cell Carcinoma, Tongue; Squamous Cell Carcinoma, Tonsil)—the next most common oral malignancy; originates from the gingival epithelium; red, ulcerated, and may have cauliflower projections; large-breed dogs are predisposed; prognosis depends on location in the oral cavity; those located rostrally carry a better prognosis than those at the base of the tongue or occurring in the tonsils; lesions on the lips and buccal mucosa have a low metastatic rate; gingival lesions infiltrate readily to the underlying bone; lesions on the tongue (due to movement) and tonsils tend to metastasize and are the most aggressive.
- Papillary squamous cell carcinoma—a rapidly growing tumor typically in young dogs (< 1 year), but has been identified in mature dogs; in the papillary gingiva; locally aggressive but does not metastasize; treatment of choice is excision. There is speculation that papillary squamous cell carcinoma is associated with papilloma virus.
- Fibrosarcoma (see Fibrosarcoma, Bone; Fibrosarcoma, Gingiva; Fibrosarcoma, Nasal and Paranasal Sinus)—the third most common oral malignancy in dogs (and the second most common in cats); fibrosarcomas have a predilection for the maxilla of large, male, older dogs; the gingiva is commonly affected, especially around the maxillary fourth premolar, followed by the hard palate and oral mucosa; slowly invasive but rarely metastasize.
- Osteosarcoma—primarily occurs in middle-aged medium- to large-breed dogs. Local bone invasion results in significant facial swelling and is locally aggressive with a low rate of metastasis.
- Odontoma (see Odontoma)
 - Complex odontoma—rare benign tumor composed of disorganized dental components not forming toothlike structures. They are locally destructive with no metastasis and are enclosed in a cystic capsule.
 - Compound odontoma—similar to complex odontomas with the exception that it is composed of organized dental components forming toothlike structures.
- Plasmacytoma—plasma cell origin; occurring primarily in older dogs; aggressive and can metastasize.
- Other tumor types include undifferentiated carcinoma, lymphoma, fibroma, melanocytoma, papilloma, mast cell tumor, giant cell tumor, neurofibroma, myxofibrosarcoma, and rhabdomyosarcoma.

SYSTEMS AFFECTED

Gastrointestinal—oral cavity

GENETICS

N/A

INCIDENCE/PREVALENCE

- Not uncommon. Varies with type of mass. See “Pathophysiology.”
- The oral cavity is the fourth most common site for tumor localization in dogs and cats.

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dogs and cats

Breed Predilections

Golden retrievers, German shorthaired pointers, Weimaraners, Saint Bernards, and cocker spaniels are more prone to oral tumors; dachshunds and beagles less prone to oral tumors; boxer, gingival hyperplasia.

Mean Age and Range

- Older animals are affected most often.
- Complex odontoma, compound odontoma, papilloma, and papillary squamous cell carcinoma usually occur in dogs less than 2 years of age.

Predominant Sex

- Males are more commonly affected with oral melanomas and fibrosarcomas than females.
- Females are more commonly affected with osteosarcomas than males.

SIGNS

Historical Findings

- Weight loss
- Anorexia
- Can eat only soft food
- Reluctance or pain to chew
- Chews only on one side

Physical Examination Findings

- Often no signs
- Halitosis
- Tooth displacement
- Malocclusion
- Oral hemorrhage
- Dysphasia
- Abnormal salivation
- Inability to open or close the mouth
- Abnormal facial symmetry
- Facial swelling
- Head shyness
- Tooth mobility
- Tooth loss

CAUSES

- Unknown
- Papilloma—papilloma virus

RISK FACTORS

- Tonsillar squamous cell carcinoma occurs 10 times more commonly in dogs from urban settings than in rural dogs.

ORAL MASSES

(CONTINUED)

- Squamous cell carcinoma—more prevalent in white dogs in one study.
- Any chronic oral irritation (periodontal disease, secondhand smoke) increases the risk of oral tumor development.
 - It has been suggested that the FE category develop in response to chronic inflammation/irritation
- Viral papillomas can undergo malignancy to become squamous cell carcinoma.
- It has been reported that FeLV, FIV, or FSV may play a role in squamous cell carcinoma development.
- Some researchers showed that cats that wore flea collars had 5 times the risk of developing oral squamous cell carcinoma than non-users.
- Secondhand smoke may be associated with squamous cell carcinoma in cats.
- Immunosuppressed dogs (puppies) are more commonly affected with papillomas.
- Acanthomatous ameloblastoma can very rarely transform into squamous cell carcinoma with radiation therapy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infection—viral/bacterial/fungal
- Odontoma
- Dentigerous cyst
- Radicular cyst
- Apical granuloma
- Nasopharyngeal polyps
- Eosinophilic granuloma
- Calcinosis circumscripta
- Proliferative gingival hyperplasia
- Oral ulceration (uremic ulcers, autoimmune disease, gum-chewer syndrome)
- Hypercementosis
- Apical granuloma
- Ranula
- Tonsillitis
- Lymphocytic plasmacytic stomatitis

CBC/BIOCHEMISTRY/URINALYSIS

Used to rule out other primary or secondary complications; e.g., anemia, uremia.

OTHER LABORATORY TESTS

Molecular staging of malignant melanomas can be achieved by screening lymph node aspirates for canine melanoma-associated antigens mRNA; aiding in detection of metastatic disease.

IMAGING

• Radiographs of the affected jaw for bony invasion, lungs for metastases (make sure to take three views: VD, right lateral, and left lateral).

- MRI or CT of the mass area to determine the extent of the lesion.
- MRI provides more accurate information regarding the size of the masses and invasion of adjacent structures. Since melanomas have a hyperintense signal on T1 weighted images and a hypointense signal on T2 weighted images, it facilitates identification of the extent of the local growth.
- CT provides better images of calcification and cortical bone erosion. CT images can be enhanced with the use of contrast medium (e.g., iohexol) to delineate the tumor.

DIAGNOSTIC PROCEDURES

Aspirate, biopsy, or surgically remove enlarged regional lymph nodes for cytology and/or histology to evaluate for metastasis.

PATHOLOGIC FINDINGS

- Must biopsy; sample deep tissue surrounding the mass; use excision, wedge, or needle-punch techniques.
- Cytology may also be helpful but is not as definitive as histopathology.

TREATMENT

APPROPRIATE HEALTH CARE

- Depends on the tumor type.
- Benign tumors are treatable with long-term success via surgery and sometimes with radiation therapy.
- Malignant tumors are treated surgically with varying success depending on tumor type, location, and metastasis at presentation.
- In advanced circumstances, combined therapy (surgery, chemotherapy, and radiation) may provide the best care.
- Molecularly targeted therapies provide oncologists with tools to treat cancers with greater specificity. These modalities can be used further to classify tumors, aid in predicting the prognosis, and help determine the exact treatment plan.

NURSING CARE

- Pain control
- Supportive care

ACTIVITY

N/A

DIET

Nutritional support is essential in any treatment plan. Gastrostomy, esophagostomy, nasal gastric tube placement, or peg tube placement may be required for proper nutritional support.

CLIENT EDUCATION

N/A

SURGICAL/RADIATION/

CHEMOTHERAPY CONSIDERATIONS

- Early diagnosis and treatment offer the best chance for a successful outcome.
- The first surgical resection offers the best chance for complete resection.
- Complete en bloc excision is the treatment of choice, with surgical margins ranging from 1 to 2 cm dependent on the tumor type.
- Radiation therapy should be offered in cases where complete excision is not possible and/or the mass is located in the caudal aspect of the oral cavity and precludes complete surgical excision.
- Megavoltage radiation therapy is presently considered the standard of care for treatment of oral tumors; however, intensity-modulated radiation therapy is a relatively new technology that is quickly being adopted.
- Chemotherapy is warranted in oral round cell sarcomas or in high-grade metastatic malignancies.
- Papilloma—marginal excision is the treatment of choice (mainly for histologic evaluation to rule out other forms of tumors); most will spontaneously regress in time and the use of autogenous vaccines is an effective treatment, especially when the masses are affecting mastication.
- Peripheral odontogenic fibroma (ossifying epulis)—marginal excision with removal of full-thickness gingiva down to the alveolar bone has shown success; rapid recurrence may necessitate extraction of involved tooth or slow recurrence may be managed with excising it on a yearly basis.
- Acanthomatous ameloblastoma—excision with at least 1 cm margins is usually curative; radiation has also been used successfully; the combination of surgery and radiation may be most effective (requiring less aggressive surgery), but if radiation is not readily available, surgery may be the only option; surgery must be aggressive with 2 cm margins in cases where the margins are ill defined and that extent of resection is possible; the best chance to resolve the problem surgically is the first time; extract any teeth that may impede incision healing; if the tumor reoccurs it is more aggressive and has been reported to reoccur as squamous cell carcinoma. Multiple (up to 10) injections of bleomycin (5 mg) injected at the tumor site have been effective in a small number of reported cases.
- Malignant melanoma—prognosis improves if the tumor is small and located in the rostral mandible; if surgery is chosen for therapy, it should be aggressive; typically mandibulectomy or maxillectomy; median

(CONTINUED)

ORAL MASSES

survival times average 8 months; combination of surgery, radiation, and chemotherapy (low-dose cisplatin) yielded a median survival of 14 months in one study; pigmentation does not affect the prognosis; relatively radioresistant; one study showed a median survival time of 14 months after radiation only; the problem with melanoma is not local disease management but metastasis; research indicates that vaccination is a promising cure. The DNA-based vaccine is indicated for TNM stage II—III malignant melanomas after local surgical control has been achieved. Single-agent platinum analogues used alone or with piroxicam have been shown to have antitumor activity for malignant melanoma.

- Squamous cell carcinoma—better long-term prognosis than malignant melanoma or fibrosarcoma in the dog; may be widely surgically excised or irradiated in the dog, especially if the lesion is rostral (better prognosis than those located caudally); perform a maxillectomy or mandibulectomy with a 2 cm clean surgical margin as a goal; in dogs, radiation alone delivers a median survival rate of 15–17 months; in dogs, prognosis for survival following treatment of lingual involvement is poor; dogs tolerate partial glossotomy involving 40–60% of the tongue; for tumors larger than 2 cm or those with incomplete resections, surgery, radiation, and chemotherapy (mitoxantrone or cisplatin with piroxicam) may be the best options. In cats, surgical resection gives a mean survival rate of 1 year for resectable tumors. One can use carboplatin or mitotantrone for palliative treatment. Radiation treatment locally along with aminobisphosphonate treatment is considered a good palliative treatment for cats with squamous cell carcinoma. A recent study by Fidel et al. looked at combining accelerated radiation therapy and carboplatin with better results, particularly with tonsillar SCC.
- Fibrosarcoma—surgical excision with at least 2 cm margins usually results in a 12-month median survival rate; usually requires a maxillectomy or mandibulectomy; surgical excision in combination with radiation therapy and chemotherapy offers the best prognosis; radiation or chemotherapy alone offers a poorer median survival rate than surgery alone; palatine fibrosarcomas carry the poorest prognosis because of the inability to surgically resect. Radiation therapy can be useful after surgical removal.

- Osteosarcoma—wide surgical removal with 2 cm margins is ideal. Reoccurrence can occur at metastatic sites. Radiation therapy should be considered post-surgery for microscopic disease. Palliative radiation therapy can be used alone.
- Plasmacytoma—rare; accounts for 5% of oral tumors in the dog; are locally aggressive but rarely metastasize. Surgical removal is the treatment of choice.
- Complex/compound odontoma—surgical resection en bloc is curative if all structures are removed. Surgery can be very extensive and one must remove the cystic walls of the tumor.

**MEDICATIONS****DRUG(S) OF CHOICE**

Chemotherapeutic drugs (see “Surgical/Radiation/Chemotherapy Considerations”).

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

Varies with nature of mass.

PREVENTION/AVOIDANCE

Remove or treat any oral irritation.

POSSIBLE COMPLICATIONS

- Surgical removal of part of the tongue may result in avascular necrosis if the tongue is transected just caudal to the origin of dorsal branches of the lingual arteries.
- Postoperative complications of mandibulectomy include wound dehiscence, prehension dysfunction, tongue lag, medial drift, excessive drooling, palatal ulceration secondary to malocclusion, and pressure necrosis.

- Mandibulectomies can be performed in cats, but they result in greater complications (tongue swelling, ranula formation) than in dogs. Surgery can result in aesthetic complications.

- Low-dose radiation can within the first few weeks cause diarrhea, nausea, vomiting, and hair loss (regrowth of hair is usually white); high dose has the above as well as oral ulceration/necrosis, mucositis, cataracts (these lesions occur in almost all cases and are self-limiting with supportive care), and radiation-induced tumors (mainly in young dogs that underwent radiation therapy for radioresponsive tumors). Late radiation effects can occur with bone and muscle necrosis but are unlikely. IMRT offers a more accurate dose distribution and is rapidly being accepted as the best form of radiation therapy with fewer side effects.

- Complications of chemotherapy are varied depending on the drug used.

EXPECTED COURSE AND PROGNOSIS

- Dogs with inadequate tumor-free surgical margins were 2.5 times more likely to die of the tumor than those with complete histologic excision; some surgical patients need gastrostomy tubes to facilitate nutritional supplementation during the treatment period.
- Dogs with tumors located caudal to the first premolar had 3 times greater risk of dying from the disease than those with tumors located rostral to the first premolar.
- Vaccination of dogs with malignant melanoma seems to be curative and is offered at a number of sites throughout North America.

- Staging of oral tumors using the TNM (primary Tumor, regional distant Lymph Nodes {cervical, submandibular, and parotid nodes}, and Metastasis) classification system allows for a more accurate prognosis; the higher the stage (I–IV) the worse the prognosis.

- Fibrosarcomas have four histologic types: a low-grade malignancy (best prognosis), an intermediate malignancy, a high malignancy, and a histologically low-grade yet biologically high-grade fibrosarcoma that is reported in large-breed dogs (mainly golden retrievers) and that offers a poor prognosis due to its rapid growth and metastasis.

ORAL ULCERATION

BASICS

DEFINITION

Focal or multifocal loss of mucosal integrity of the superficial epithelial layers in specific areas of the oral cavity—oral mucosal ulceration.

PATHOPHYSIOLOGY

Oral mucosal ulceration usually coincides with oropharyngeal inflammation. Oral and oropharyngeal inflammation is classified by location as:

- Gingivitis—inflammation of gingiva.
- Periodontitis—inflammation of non-gingival periodontal tissues (i.e., the periodontal ligament and alveolar bone).
- Alveolar mucositis—inflammation of alveolar mucosa (i.e., mucosa overlying the alveolar process and extending from the mucogingival junction without obvious demarcation to the vestibular sulcus and to the floor of the mouth).
- Sublingual mucositis—inflammation of mucosa on the floor of the mouth.
- Labial/buccal mucositis—inflammation of lip/cheek mucosa.
- Caudal mucositis—inflammation of mucosa of the caudal oral cavity, bordered medially by the palatoglossal folds and fauces, dorsally by the hard and soft palate, and rostrally by alveolar and buccal mucosa.
- Palatitis—inflammation of mucosa covering the hard and/or soft palate.
- Glossitis—inflammation of mucosa of the dorsal and/or ventral tongue surface.
- Cheilitis—inflammation of the lip (including the mucocutaneous junction area and skin of the lip).
- Osteomyelitis—inflammation of the bone and bone marrow.
- Stomatitis—inflammation of the mucous lining of any of the structures in the mouth; in clinical use the term should be reserved to describe widespread oral inflammation (beyond gingivitis and periodontitis) that may also extend into submucosal tissues (e.g., marked caudal mucositis extending into submucosal tissues may be termed “caudal stomatitis”).
- Tonsillitis—inflammation of the palatine tonsil.
- Pharyngitis—inflammation of the pharynx.

SIGNALMENT

Species

Dogs and cats

Breed Predilections

- Canine ulcerative stomatitis: Maltese, Cavalier King Charles spaniels, cocker spaniels, Bouvier des Flandres.
- Feline stomatitis/lymphocytic plasmacytic stomatitis (LPS)—may have predilection for Somali and Abyssinian cats (see Stomatitis, Caudal—Cats).

- Idiopathic osteomyelitis—may have predilection for cocker spaniels; complication associated with canine ulcerative stomatitis.

Mean Age and Range

None

Predominant Sex

None

SIGNS

- Halitosis.
- Gingivitis.
- Pharyngitis.
- Buccitis/buccal mucosal ulceration.
- Ptyalism (thick, ropey saliva).
- Pain.
- Anorexia.
- Mucosal ulceration—“Contact ulcers” or “kissing ulcers” common in ulcerative stomatitis.
- Plaque—with or without calculus.
- Exposed, necrotic bone—with alveolar osteitis and idiopathic osteomyelitis.
- Behavior changes secondary to oral sensitivity.
- Scar formation on lateral margins of tongue—may be seen with canine ulcerative stomatitis.
- Note: sometimes these signs will start following a routine dental cleaning on a previously “normal” patient; probably would have occurred eventually, just exacerbated by manipulation and antigenic stimulation in the oral cavity.

CAUSES

Metabolic

- Diabetes mellitus
- Hypothyroidism
- Renal disease—uremia

Nutritional

- Protein-calorie malnutrition
- Riboflavin deficiency

Neoplastic

- Dog—malignant melanoma, squamous cell carcinoma, fibrosarcoma, acanthomatous ameloblastoma, ulcerated benign tumors
- Cat—squamous cell carcinoma, fibrosarcoma, malignant melanoma

Immune Mediated

- Pemphigus vulgaris—90% have oral involvement
- Bullous pemphigoid—80% have oral involvement
- Systemic lupus erythematosus—50% have oral involvement
- Discoid lupus erythematosus
- Drug induced—toxic epidermal necrolysis, erythema multiforme
- Immune-mediated vasculitis

Infectious

- Retrovirus—FeLV/FIV
- Calicivirus—cat
- Herpesvirus—cat
- Leptospirosis—dog
- Periodontal disease—dog and cat

Traumatic

- Foreign body—bone or wood fragments
- Electric cord shock
- Malocclusion
- Gum-chewer’s disease—chronic chewing of cheek

Chemical/Toxic

- Caustic chemical ingestion
- Thallium

Idiopathic

- Eosinophilic granuloma—cats, Siberian huskies, Samoyeds
- Feline stomatitis complex—cats
- Ulcerative stomatitis—dogs; allergic, hypersensitivity reaction to plaque
- Idiopathic osteomyelitis—dogs

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- History and oral examination—foreign bodies; malocclusions; chemical, toxic, and electrical burns
- Idiopathic conditions—clinical signs; history; breed predispositions; response to therapy

CBC/BIOCHEMISTRY/URINALYSIS

- Hyperglycemia if diabetes mellitus; azotemia and isosthenuria if renal disease; leukocytosis if infections.
- Chronic conditions may have elevated serum total protein and elevated globulin levels due to chronic antigenic stimulation; T4 may be decreased secondarily.

OTHER LABORATORY TESTS

- T₄—may be low if hypothyroid or secondary to chronic inflammation
- Free T₄—may be better assessment of true thyroid function
- Serology—FeLV/FIV test, titers for specific infections
- Cultures—usually nonspecific; oral flora contaminants

IMAGING

Radiography—helps determine osseous involvement and extent of idiopathic osteomyelitis.

DIAGNOSTIC PROCEDURES

Biopsy/cytology—neoplasia, immune-mediated disease, and chronic inflammation result in predominant lymphocytes and plasmacytoid lymphocytes (feline stomatitis complex and ulcerative stomatitis in dogs).

PATHOLOGIC FINDINGS

Histopathology typically reveals nonspecific inflammation: neutrophils, macrophages, lymphocytes with varying levels of loss of mucosal epithelial integrity.

ORAL ULCERATION

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

- Supportive therapy—soft diet, fluids, hospitalization in severe cases.
- Pain management—topical analgesics/covering of ulcers, oral narcotics, serotonin reuptake inhibitors, NMDA antagonists, gabapentin.
- Nutritional support—via pharyngostomy or esophagostomy feeding tube.
- Canine ulcerative stomatitis—continuous, meticulous homecare to prevent plaque accumulation; dental cleaning initially and frequently; periodontal therapy; extraction of diseased teeth.
- Underlying metabolic or other disease—treat systemic illness appropriately.

CLIENT EDUCATION

- Warn client that prognosis is guarded, response to therapy depends on underlying cause, and prolonged treatment and/or further extractions may be necessary.
- In canine ulcerative stomatitis or feline stomatitis complex, any level of homecare that can be provided is encouraged (brushing or topical antimicrobials). Caution, these patients may have very sensitive and painful mouths.

SURGICAL CONSIDERATIONS

- Select extractions (partial, caudal, or full mouth)—may be indicated for chronic idiopathic conditions, e.g., canine ulcerative stomatitis and feline stomatitis complex, to remove the source of reaction (plaque/teeth).
- Removal of entire tooth structure—essential in extraction treatment for feline stomatitis.
- Removal of necrotic/avascular bone, gingival flap closure, and broad-spectrum antibiotics—indicated for idiopathic osteomyelitis; monitor for recurrence.

MEDICATIONS

DRUG(S) OF CHOICE

- Antimicrobials—treat primary and secondary bacterial infections; may be used intermittently between dental cleanings for therapeutic assistance, but the owner must be cautioned that chronic use could lead to antibiotic resistance; clindamycin (11 mg/kg PO q12h); amoxicillin-clavulanate (12.5–25 mg/kg PO q12h); tetracycline (10–22 mg/kg PO q8h).
- Anti-inflammatory/immunosuppressive drugs—the comfort of the patient must be weighed against potential long-term side effects of corticosteroid usage; prednisone (0.5–1 mg/kg PO q12–24h, taper dosage).

- Mucosal protectants—for chemical insults; sucralfate (1–25 kg PO q8h); cimetidine (5–10 mg/kg PO q8–12h).
- Analgesics—post-extraction; carprofen (0.5 mg/kg PO q12–24h); hydrocodone (0.22 mg/kg PO q8–12h); tramadol (2.2 mg/kg PO q8–12h).
- Topical therapy—chlorhexidine solution or gel (antibacterial): CET Oral Hygiene Rinse; zinc gluconate/ascorbic acid: Maxi/Guard Gel.

CONTRAINDICATIONS

- Do not use these medications in patients with known hypersensitivities.
- Corticosteroids are contraindicated in patients with systemic fungal infections.

PRECAUTIONS

- Some antimicrobials may upset the gastrointestinal tract.
- Avoid corticosteroids in patients that may already be immunocompromised (e.g., those with FeLV or FIV).

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

None

FOLLOW-UP

PATIENT MONITORING

Frequent oral examination to evaluate for resolution or recurrence

PREVENTION/AVOIDANCE

Meticulous homecare to prevent plaque accumulation

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Response to therapy depends on underlying cause, and prolonged treatment and/or further extractions may be necessary.
- Inflammation may take 4–6 weeks to subside after extractions due to plaque retention of sutures and tongue.
- In cats with feline stomatitis following partial (premolars and molars) and full dentition extractions: 60% significant improvement, 25% some improvement, and 15% refractory.

MISCELLANEOUS

ASSOCIATED CONDITIONS

None

AGE-RELATED FACTORS

None known

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

Avoid medications known to interact adversely with pregnant females or developing fetuses.

SYNOMYS

- Necrotizing stomatitis
- Ulcerative stomatitis
- Vincent's stomatitis

ABBREVIATIONS

- CUPS = chronic ulcerative paradental stomatitis
- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus
- LPS = lymphocytic-plasmacytic stomatitis
- NMDA antagonists = anesthetics that work to antagonize the N-methyl d-aspartate receptor
- T₄ = thyroxine

ORBITAL DISEASES (EXOPHTHALMOS, ENOPHTHALMOS, STRABISMUS)

BASICS

DEFINITION

- Abnormal position of the globe.
- Exophthalmos—anterior displacement of the globe.
- Enophthalmos—posterior displacement of the globe.
- Strabismus—deviation of the globe from the correct position of fixation, which the patient cannot correct.

PATHOPHYSIOLOGY

- Orbit cannot be examined directly; orbital disease manifested by signs that alter the position, appearance, or function of the globe and adnexa.
- Malpositioned globe—caused by changes in volume (loss or gain) of the orbital contents or abnormal extraocular muscle function.
- Exophthalmos—caused by space-occupying lesions posterior to the equator of the globe.
- Enophthalmos—caused by loss of orbital volume or space-occupying lesions anterior to the equator of the globe.
- Strabismus—usually caused by an imbalance of extraocular muscle tone or lesions that restrict extraocular muscle mobility.

SYSTEMS AFFECTED

- Ophthalmic.
- Respiratory—because of the close proximity, the nasal cavity and frontal and maxillary sinuses may be involved.

SIGNALMENT

- Dog and cat.
- Orbital abscess or cellulitis and myositis—more common in young adult dogs.
- Myositis—predisposed breeds: German shepherd, golden retriever, Weimaraner.
- Orbital neoplasia—more common in middle-aged to old dogs.

SIGNS

Exophthalmos

- Secondary signs of space-occupying orbital disease.
- Difficulty in retropulsing the globe.
- Serous to mucopurulent ocular discharge.
- Chemosis.
- Eyelid swelling.
- Lagophthalmos—inability to close the eyelids over the cornea adequately during blinking.
- Exposure keratitis—with or without ulceration.
- Pain on opening the mouth.
- Third eyelid protrusion is due to extraconal mass or late in progression of intraconal mass.
- Visual impairment caused by optic neuropathy.
- Fundic abnormalities, including retinal detachment.
- Retinal vascular congestion.
- Focal inward deviation of the posterior globe.
- Optic disk swelling.
- Neurotropic keratitis after damage to the ophthalmic branch of cranial nerve V.
- Fever and malaise—with orbital abscess or cellulitis.
- IOP—rarely high.

Enophthalmos

- Ptosis
- Third eyelid protrusion
- Extraocular muscle atrophy
- Entropion—with severe disease

Strabismus

- Deviation of one or both eyes from the normal position
- May note exophthalmos or enophthalmos

CAUSES

Exophthalmos

- Neoplasm—primary or secondary.
- Abscess or cellulitis—bacterial or fungal; fungal more likely in cats; look for foreign bodies.
- Zygomatic mucocele—not described in cats.
- Myositis—muscles of mastication or extraocular muscles (eosinophilic or extraocular polymyositis).
- Orbital hemorrhage secondary to trauma.
- Arteriovenous fistula or varix—rare.

Enophthalmos

- Ocular pain.
- Microphthalmia.
- Phthisis bulbi.
- Collapsed globe.
- Horner's syndrome.
- Dehydration.
- Loss of orbital fat or muscle.
- Conformational enophthalmos in dolichocephalic breeds.
- Neoplasia—especially those originating from rostral orbit.

Strabismus

- Abnormal innervation of extraocular muscle.
- Restriction of extraocular muscle mobility by scar tissue from previous trauma or inflammation.
- Destruction of extraocular muscle attachments after proptosis.
- Convergent strabismus—congenital; results from abnormal crossing of visual fibers in the CNS (Siamese cats).
- Shar-Pei strabismus.

RISK FACTORS

Proptosis—more readily occurs in brachycephalic dogs with shallow orbits.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Similar Signs

- Buphtalmic globe—may simulate a space-occupying mass and cause the eye to be displaced anteriorly owing to its size in relationship to the orbital volume; IOP usually high; corneal diameter is greater than normal, corneal edema, mydriatic pupil, optic nerve cupping (i.e., signs of glaucoma), blindness.
- Episcleritis—may cause severe diffuse or focal thickening of the fibrous tunic, often imitating a buphtalmic globe; corneal edema; normal or low IOP; aqueous flare.

Causes

- Acute onset of exophthalmos—often inflammatory orbital disease. Pain, especially on opening the mouth, is more likely due to inflammatory orbital disease than orbital neoplasia.
- Mucocles—more variable in speed of onset and degree of patient discomfort.
- Extraocular or eosinophilic myositis—bilateral diseases; *Neospora caninum* has caused extraocular polymyositis in a litter of German shorthaired pointers.

- Neoplasia—usually slowly progressive, not painful, unilateral exophthalmos.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Leukogram—may show inflammation with abscess or cellulitis or myositis.
- Peripheral eosinophilia—occasionally seen in dogs with eosinophilic (masticatory muscle) myositis.

IMAGING

- Orbital ultrasonography, CT, and MRI—extremely helpful in defining the extent of the lesion(s) and distinguishing between types of myositis.
- Skull radiographs (especially of the frontal sinuses and nasal cavity).
- Thoracic radiographs—may help identify metastatic disease.

DIAGNOSTIC PROCEDURES

- Lack of globe retropulsion—confirms a space-occupying mass.
- Oral examination, ocular ultrasound, and fine-needle aspiration of the orbit—may be completed after anesthetizing the patient.
- Fine-needle aspiration (18- to 20-gauge)—submit samples for aerobic and anaerobic bacterial and fungal cultures, gram staining, and cytologic examination.
- Cytology—often diagnostic for abscess or cellulitis, zygomatic salivary gland mucocele, and neoplasia.
- Biopsy—indicated if needle aspiration is non-diagnostic.
- Biopsy of masseter, temporal, or extraocular muscle if myositis suspected; assays for type 2M fibers may be helpful.
- Forced duction of the globe (strabismus)—grasp the conjunctiva with a fine pair of forceps following topical anesthesia; differentiates neurologic disease (in which the globe moves freely) from restrictive condition (in which the globe cannot be moved manually).

TREATMENT

PROPTOSIS

See Proptosis.

ORBITAL ABSCESS OR CELLULITIS

- Drainage is seen in less than half of patients, usually because the lesion is at the cellulitis stage and a true abscess has not yet formed.
- If an obvious swelling of the oral mucosa behind the last molar is not present and an ultrasound does not show an abscess, it is best to avoid incising the oral mucosa and treat with systemic antibiotics and anti-inflammatory medications; the affected globe should also be kept moist with topical lubricants q6h.
- Severe cases may require intravenous fluids to maintain hydration and replace fluid deficits until patient is able to eat.
- If a swelling of the oral mucosa behind the last molar is evident, establish ventral orbital drainage while the patient is anesthetized.
- Incise the surgically prepared mucosa approximately 1 cm behind the last

ORBITAL DISEASES (EXOPHTHALMOS, ENOPHTHALMOS, STRABISMUS)

molar. • Push a blunt-tipped forceps (e.g., Kelly or Carmalt) into the orbital space and open; in general, advance the forceps until the abscess drains, to the level of the box lock, or until movement of the eye occurs with forceps opening. • Take care to minimize retrobulbar trauma and optic nerve damage; use only blunt dissection; never cut or crush tissue. • Complications that can occur with aggressive dissection include damage to the optic nerve and ciliary nerves. • Collect samples for bacterial culture and cytologic examination through this port. • Feed soft food until globe is back in normal position and pain appears resolved. • Hot packing—q6h; helps decrease swelling and cleans discharge.

ORBITAL NEOPLASMS

- Usually primary and malignant. • Early exenteration or orbital exploratory surgery and debulking of the mass via a lateral approach to the orbit to save the globe are rational therapeutic choices. • Adjunctive chemotherapy or radiotherapy—depending on neoplasm type and extent of the lesion.
- Without adjunct therapy—survival is weeks to months if malignant because the patient is usually examined late in the course of disease.
- Consultation with an oncologist is recommended once the diagnosis is made.

ZYGOMATIC MUCOCELE

May resolve with antibiotic and corticosteroid administration; if not, surgical excision of the cyst and associated gland is usually curative.

STRABISMUS

- Neurologic—best treated by identifying the underlying cause and addressing that, if possible. • Restrictive or post-traumatic—may be treated surgically; repositioning or excising the attachments of the extraocular muscles; relieving excessive tension on those muscles; usually a very difficult procedure.

MEDICATIONS

DRUG(S) OF CHOICE

- Exophthalmos (all patients)—lubricate cornea (e.g., artificial tear ointment or gel

q6h) to prevent desiccation and ulceration.

- Ulceration—topical antibiotic (e.g., bacitracin, neomycin, polymyxin q8h) and cycloplegic (e.g., 1% atropine q12–24h), to prevent infection and reduce ciliary spasm, respectively.

Orbital Abscess or Cellulitis

- Oral or intravenous antibiotics—sodium ampicillin (20 mg/kg q6–8h) or drugs with an anaerobic spectrum (amoxicillin with clavulanic acid or metronidazole) should be considered while awaiting results of bacterial culture and cytologic examination or if client declines diagnostic testing. • Bacterial orbital infections—may be mixed; *Pasteurella multocida* and *Enterobacteriaceae* common.
- Most patients recover within approximately 2–3 weeks of treatment. • Fluconazole (2.5 mg/kg q12h or 5 mg/kg q24h) or posaconazole (5 mg/kg q12h) may be considered for orbital aspergillosis.
- Prednisone—1 mg/kg SC or IM q24h, once or twice; minimize optic neuritis and reduce orbital swelling and globe exposure.
- Alternatively, systemic NSAIDs (e.g., carprofen or meloxicam) can be used in place of prednisone but should be administered for several weeks.

Acute Myositis

- Difficult prehension—systemic corticosteroids (prednisone 2 mg/kg SC or IM); then oral corticosteroids for the following 4–6 weeks (prednisone 2 mg/kg q24h) until the swelling subsides; then taper.
- Azathioprine 1–2 mg/kg PO q24h for 3–7 days; then q48h and taper; with or without corticosteroids, may be used chronically to manage recurrent disease.

PRECAUTIONS

- Systemic corticosteroids—use with extreme caution with deep fungal orbital disease.
- Azathioprine—may be hepatotoxic and cause myelosuppression. Follow CBC platelet count and liver enzymes every 1–2 weeks for 8 weeks, then periodically thereafter.

FOLLOW-UP

PATIENT MONITORING

- Inflammatory orbital disease—examine at least weekly until clinical signs abate. • Advise client to watch for recurrence of signs, especially if an orbital foreign body is likely.
- Treat fungal infections for 60 days after signs cease.

POSSIBLE COMPLICATIONS

- Vision loss • Loss of the eye • Permanent malposition of the globe • Death

MISCELLANEOUS

AGE-RELATED FACTORS

Give a course of antibiotic therapy first prior to attempting ventral orbital drainage.

PREGNANCY/FERTILITY/BREEDING

Avoid systemic corticosteroids, antifungal medications, and azathioprine in pregnant animals.

ORGANOPHOSPHORUS AND CARBAMATE TOXICOSIS

BASICS

DEFINITION

- Results from exposure to organophosphorous compounds or carbamates. Since 2003, calls to the ASPCA APCC regarding exposure to organophosphorous compounds have decreased significantly. Currently, organophosphate and carbamate exposures represent only 4.5% of insecticide-related exposure calls to the ASPCA APCC.
- The decrease is likely related to EPA cancellations of various registrations and approval of new, less toxic formulations. Canceled products, however, often remain in homes and businesses for years.
- Animal products—organophosphate: chlorpyrifos, coumaphos, cythioate, diazinon, famphur, fenthion, phosmet, and tetrachlorvinphos; carbamate: carbaryl and propoxur (*many animal products containing phosmet, tetrachlorvinphos, carbaryl, chlorpyrifos, diazinon [all] have been discontinued*).
- Agricultural, lawn, and garden products—organophosphate: acephate, chlorpyrifos, diazinon, disulfoton, fonofos, malathion, parathion, terbufos, and others; carbamate: carbofuran and methomyl (*same comment as above for environmental products*).

PATHOPHYSIOLOGY

- Cause nervous system effects by inhibiting cholinesterase, which includes acetylcholinesterase, pseudocholinesterase, and other esterases.
- Acetylcholinesterase—normally hydrolyzes the neurotransmitter acetylcholine in nervous tissue, RBCs, and muscle, resulting in termination of nervous transmission.
- Pseudocholinesterase—found in plasma, liver, pancreas, and nervous tissue, mainly in cats.
- Cholinesterase inhibition—allows acetylcholine accumulation at the post-synaptic receptor; causes stimulation of effector organs; spontaneous reactivation after organophosphorous compound binding is very slow and once aging occurs is virtually non-existent; reversible after carbamate binding.

SYSTEMS AFFECTED

Nervous—results from overriding stimulation of parasympathetic pathways; may also result from sympathetic stimulation; acetylcholine stimulates nicotinic receptors of the somatic nervous system (skeletal muscle), parasympathetic preganglionic nicotinic and post-ganglionic muscarinic receptors (cardiac muscle, pupil, blood vessels, smooth muscles in lung and gastrointestinal tract, exocrine glands), and sympathetic preganglionic nicotinic receptors (adrenal and indirectly

cardiac muscle, pupil, blood vessels, smooth muscles in lung and gastrointestinal tract, exocrine glands).

GENETICS

- Animals with inherently low cholinesterase activity—more susceptible to cholinesterase depression.
- Cholinesterase activity—more easily inhibited in cats than in dogs.

INCIDENCE/PREVALENCE

Common in small animals

GEOGRAPHIC DISTRIBUTION

More common in areas of high flea prevalence and intense agricultural activity.

SIGNALMENT

Species

- Dog and cat
- Cats most susceptible

Breed Predilections

Lean dogs (e.g., sight hounds and racing breeds) and lean longhaired cats—more susceptible to cholinesterase inhibition because of lack of fat; many organophosphorous compounds and metabolites are stored in fat and slowly released into circulation.

Mean Age and Range

Young animals—more likely intoxicated due to lower detoxification capability.

Predominant Sex

Intact males more susceptible to some organophosphates

SIGNS

General Comments

- Parasympathetic stimulation—usually predominates.
- Sympathetic stimulation—may result in lack of specific expected signs; may note opposite signs from those expected.

Historical Findings

- Medical history—often discloses heavy or repeated applications of flea and tick insecticides; evidence of exposure to an agricultural or home and garden product.
- Carbamate insecticides (methomyl and carbofuran)—may cause rapid onset of seizures and respiratory failure and death; treat aggressively without delay.
- Organophosphate insecticides (cats, especially chlorpyrifos)—chronic anorexia, muscle weakness, and muscle twitching, with or without episodes of acute toxicosis, which may last for days to weeks.

Physical Examination Findings

- Hypersalivation
- Vomiting
- Diarrhea
- Miosis
- Bradycardia
- Depression
- Ataxia
- Muscle tremors

- Seizures
- Hyperthermia
- Dyspnea
- Respiratory failure
- Death
- Patient may not exhibit all signs
- Sympathetic stimulation—signs reversed

CAUSES

- Overuse, misuse, or use of multiple cholinesterase-inhibiting insecticides.
- Misuse of organophosphate insecticides in cats (e.g., organophosphate-containing dips labeled for dogs only, inappropriately applied to cats).
- Intentional dermal application of house or yard insecticides.

RISK FACTORS

- Concurrent exposure to multiple organophosphate- and/or carbamate-containing products.
- Exposure to floors that are damp with organophosphorous premise products.
- Incorrect dilution of insecticides.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- History of exposure, amount of exposure, and clinical signs—should be consistent with toxicosis.
- Exposure to other insecticidal products—pyrethrin/pyrethroids (flea and tick); d-limonene (citrus flea and tick); fipronil (flea and tick); imidacloprid (flea).
- Other pesticides—strychnine; fluoroacetate (1080); 4-aminopyridine (avicide); metaldehyde (snail bait); zinc/aluminum phosphide (rodenticide); bromethalin (rodenticide).
- Other toxicants—chocolate; caffeine; cocaine; amphetamine; tremorgenic mycotoxins.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Cholinesterase Activity

- Reduced to < 25% of normal in whole blood, retina, or brain—suggests exposure to a cholinesterase-inhibiting compound, must compare to normal reference values in that species generated by the same laboratory.
- Test results—must be interpreted in context of the amount of exposure and the clinical signs and the time of their onset.
- Use laboratories experienced in handling animal samples.
- Chlorpyrifos—experimentally exposed animals may remain clinically normal with no detectable cholinesterase activity.
- Carbamate inhibition—reactivation can occur during sample transport, storage, and testing, giving false-negative results.

ORGANOPHOSPHORUS AND CARBAMATE TOXICOSIS

(CONTINUED)

DIAGNOSTIC PROCEDURES

- Atropine response test—administer atropine at preanesthetic dose 0.02 mg/kg IV. Antimuscarinic response (tachycardia, mydriasis) suggests lack of anticholinesterase exposure.
- Detection of insecticides—tissue (e.g., brain, liver, kidney, and fat); stomach contents; gastrointestinal tract; fur or hair; negative results do not rule out toxicosis.
- May find pieces of chewed containers in the gastrointestinal tract.

PATHOLOGIC FINDINGS

- Histopathologic lesions—rare, no characteristic lesions likely in acute toxicosis.
- Delayed neuropathy—not usually associated with commercially available organophosphorous compounds.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—mild signs from exposure to flea and tick collars and powders; treat by simply removing the collar or brushing excess powder from the coat.
- Inpatient—continued salivation, tremors, or dyspnea.

NURSING CARE

- Basics—stabilization; decontamination; antidotal treatment with atropine (and pralidoxime chloride for organophosphate toxicosis); supportive care.
- Control seizure activity, tremors.
- Oxygen—if necessary, until respiration returns to normal.
- Fluid therapy—may be needed in anorexic cats and dehydrated animals.
- Bathing (dermal exposure)—use hand dish-washing detergent; rinse with copious amounts of water.

ACTIVITY

N/A

DIET

Chronically anorexic cats—maintain nutritional and fluid requirements.

CLIENT EDUCATION

- Stress the importance of following insecticide label directions.
- Caution client that cats with chronic anorexia and weakness may need days to weeks of supportive care for full recovery.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

- Diazepam (0.05–1 mg/kg IV to effect) used initially for seizures. Pentobarbital

(5–15 mg/kg IV to effect) added for persistent seizure activity. Phenobarbital (3–30 mg/kg IV to effect, low dosage in cats) or propofol (3–6 mg/kg IV or 0.1 mg/kg/min CRI) can be used for refractory seizures.

- Atropine sulfate—0.2 mg/kg one-quarter IV, remaining SC, as needed; administered immediately; repeated only as needed to control life-threatening clinical signs from muscarinic stimulation.

• Pralidoxime chloride (Protopam) 10–15 mg/kg IM, SC q8–12h until recovery; discontinue after three doses if no response; reduces muscle fasciculations; most beneficial against organophosphorous insecticides when started within 24 hours of exposure; even several days after dermal exposure may stimulate anorexic cats (with or without tremors) to resume eating; if refrigerated and wrapped in foil, reconstituted bottles may be successfully used for up to 2 weeks.

Emesis

- Ingestion of liquid insecticidal solution—avoid inducing emesis; risk of aspiration because many solutions contain hydrocarbon solvents.
- Liquid solvent *not* ingested, no clinical signs, and very recent ingestion—induce emesis with 3% hydrogen peroxide (2.2 mL/kg PO to a maximum of 45 mL) after feeding a moist meal.

Activated charcoal

- Evacuation of the stomach for patient with clinical signs—gastric lavage with the patient intubated, under anesthesia, with a large-bore stomach tube; then administration of activated charcoal (2 g/kg PO) containing sorbitol as a cathartic in a water slurry.
- Diarrhea—do not administer sorbitol-containing products.

CONTRAINDICATIONS

Phenothiazine tranquilizers may potentiate organophosphate toxicosis.

PRECAUTIONS

Atropine—avoid overuse; may cause tachycardia, CNS stimulation, seizures, disorientation, drowsiness, and respiratory depression.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

Monitor heart rate, respiration, and fluid and caloric intake.

PREVENTION/AVOIDANCE

- Closely follow directions on insecticide labels.

- Avoid use on sick or debilitated animals.
- Avoid simultaneous use of organophosphate and carbamate products.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Chronic organophosphate insecticide-induced weakness and anorexia (cats, chlorpyrifos exposure)—may last 2–4 weeks; most patients fully recover with aggressive nursing care.
- Acute toxicosis treated promptly—good prognosis.

ORONASAL FISTULA

BASICS

OVERVIEW

- A defect between the oral and nasal cavity.
- Communication between the mouth and nasal cavity can occur from pathology of any of the tissues surrounding the maxillary teeth or hard palate.
- The maxillary canines are most commonly involved.
- The palatal root of the maxillary fourth premolar is the next most common area involved.

SIGNALMENT

- Dogs—dolichocephalic head types are affected most often, especially dachshunds.
- Cats—rare

SIGNS

- Chronic rhinitis—with or without blood.
- Sneezing—common, especially when the maxillary canines are digitally palpated.

CAUSES & RISK FACTORS

- Usually associated with advanced -periodontitis (PD4) of the maxillary canine tooth leading to destruction of the bone separating the nasal and oral cavities.
- Other causes include trauma, penetration of a foreign body, bite wounds, traumatic tooth extraction, electrical shock, or oral cancer.
- Fistula width is related to the size of the tooth affected; fistula depth to the chronicity of the periodontal infection.
- Dogs with uncorrected lingually displaced (base-narrow) mandibular canines and those with marked mandibular distocclusion (overbite) causing the mandibular canines to penetrate the hard palate are predisposed.
- Dachshunds predisposed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Periodontal disease
- Oral neoplasia
- Trauma
- Foreign body penetration

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

- Skull radiographs rarely helpful in diagnosing oronasal fistula because the lesions are generally isolated to the palatal surface.
- Intraoral radiographs are highly recommended to evaluate the periodontal status of the patient's teeth.
- Radiographs may show foreign body entrapment or lysis consistent with neoplasia.

DIAGNOSTIC PROCEDURES

Periodontal probing—results in direct extension into the nasal cavity or epistaxis.

TREATMENT

- Extract the tooth and close the defect; after extraction, the goal of surgical closure is to place an epithelial layer in both the oral and nasal cavities.
- Full-thickness flap—after tooth extraction, a mucoperiosteal pedicle flap may be elevated from the dorsal aspect of the fistula, released, advanced to cover the defect, and sutured in place; a successful full-thickness flap requires at least 2 mm attached gingiva above the defect, sutures at the edge of the defect (not over the void), without tension on the suture line.
- Double reposition flap—used for large fistulas or repair failures where no attached gingiva remains or where periosteal tissue cannot be included; after extraction, the first flap is harvested from the hard palate and inverted so that the oral epithelium is toward the nasal passage; the second flap is mucobuccal and harvested from the alveolar mucosa and underside of the lip rostral to the fistula; it is sutured over the first flap and donor site.
- Guided tissue regeneration of the maxillary canine—may be used for repair of a deep palatal pocket if not yet fistulated; a palatal flap is elevated to approach the infrabony defect; soft tissue and calculus are removed from the defect with a curette.
- In deep infrabony pockets before fistulation, bone grafts such as PerioGlas, Consil, synthetic and natural hydroxyapatite, autogenous and heterologous bone, polylactic

acid, and Osteoallograft, (freeze dried canine cadaver bone) have been used to exclude regrowth of gingival connective tissue and epithelium, promoting regeneration of bone and periodontal ligament. Implant materials should not be used if an oronasal fistula is present.

- Oronasal fistulas located in the central portion of the hard palate may be surgically repaired with a transposition flap of the hard palate mucoperiosteum from tissue adjacent to the defect.

MEDICATIONS

DRUG(S)

N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Normal postoperative monitoring

EXPECTED COURSE AND PROGNOSIS

Even with adequate tissue, excellent release of tension on the flap, and good technique, a persistent opening may occur due to constant tension on the site during each breath. With inadequate tissue or technique, the prognosis decreases, and additional surgeries with advanced flaps may be required.

OSTEOCHONDRODYSPLASIA

BASICS

OVERVIEW

- A developmental abnormality of cartilage and bone; encompasses many disorders involving bone growth.
- Results from abnormal endochondral ossification.
- Skeletal defects—usually involve the appendicular skeleton; specifically the metaphyseal growth plates.
- Achondroplasia—failure of cartilage growth; characterized by a proportionate short-limbed dysplasia; evident soon after birth.
- Hypochondroplasia—less severe form of achondroplasia.
- Characteristic breeds—result of selection of certain desirable traits.
- Affects musculoskeletal and possibly ophthalmic systems.

SIGNALMENT

- Achondroplastic breeds—bulldog; Boston terrier; pug; Pekingese; Japanese spaniel; shih tzu.
- Hypochondroplastic breeds—dachshund; basset hound; beagle; Welsh corgi; Dandie Dinmont terrier; Scottish terrier; Skye terrier.
- Reported non-selected chondrodysplastic abnormalities—Alaskan malamute; Samoyed; Labrador retriever; English pointer; Norwegian elkhound; Great Pyrenees; cocker spaniel; Scottish terrier; Scottish deerhound; beagle; miniature poodle; French bulldog; Scottish fold cat.
- Ocular-skeletal dysplasia—diagnosed in Labrador retriever and Samoyed.

SIGNS

Historical Findings

- Phenotypically normal at birth, retardation of growth recognized in first few months of life.

Physical Examination Findings

- Usually affects the appendicular skeleton; may affect axial skeleton.
- Long bones—appear shorter than normal; often bowed.
- Major joints (elbow, stifle, carpus, tarsus)—appear enlarged.
- Radius and ulna—often severely affected owing to asynchronous growth.
- Lateral bowing of the forelimbs.
- Enlarged carpal joints.
- Valgus deformity of the paws.
- Shortened maxilla—relative mandibular prognathism.
- Spinal deviations—due to hemivertebrae.
- Retina—dysplasia; partial to complete detachment.

CAUSES & RISK FACTORS

- Achondroplastic and hypochondroplastic breeds—autosomal dominant trait.
- Nonselected chondrodysplastic breeds—autosomal recessive or polygenic trait.
- Littermates often affected.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Premature closure of the ulnar or radial physes—history of trauma; no other bones affected; unilateral or bilateral abnormalities.
- Pituitary dwarfism.

IMAGING

- Radiography of affected limbs—irregular flattening of the metaphysis; widening of the physal line; retained endochondral cores; irregularities in ossification of the affected long bone; degenerative joint disease and joint laxity owing to abnormal stress and weight-bearing on the limbs.
- Radiography of the spine—hemivertebrae; wedge-shaped vertebrae.

DIAGNOSTIC PROCEDURES

Bone biopsy of growth plate—definitive diagnosis

PATHOLOGIC FINDINGS

Histologic findings: disorganization of the proliferative zone, abnormalities within the hypertrophic zone, abnormal formation of the primary and secondary spongiosa.

TREATMENT

- Achondroplasia—considered a normal abnormality in some (chondrolystrophic) breeds.
- Surgery—usually of little benefit for non-selected chondrodysplasia.
- Corrective osteotomy to realign limb(s) or joint(s)—may have limited benefit.

MEDICATIONS

DRUG(S)

- Analgesics and anti-inflammatory agents—palliative use warranted.
 - Deracoxib (1–2 mg/kg PO q24h).
 - Carprofen (2.2 mg/kg PO q12h or q24h).
 - Etodolac (10–15 mg/kg PO q24h).
 - Meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h—liquid).
 - Firocoxib (5 mg/kg PO q24h).
 - Tepoxalin (load 20 mg/kg, then 10 mg/kg PO q24h).
 - Tramadol (1–4 mg/kg PO q8–12h).
- Chondroprotective agents—polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate; may have limited benefit in preventing articular cartilage changes.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Do not repeat dam-sire breedings that resulted in affected offspring.
- Discourage breeding affected animals.

POSSIBLE COMPLICATIONS

Intra-articular and periarticular joint structures—degenerate owing to abnormal conformation of the appendicular skeleton; leads to altered biomechanics; results in poor quality of life.

EXPECTED COURSE AND PROGNOSIS

Depends on severity

MISCELLANEOUS

SYNONYMS

- Cherubism • Dwarfism

ABBREVIATION

NSAID = nonsteroidal anti-inflammatory drug

OSTEOCHONDROSIS

BASICS

DEFINITION

A pathologic process in growing cartilage, primarily characterized by a disturbance of endochondral ossification that leads to excessive retention of cartilage.

PATHOPHYSIOLOGY

- Cells of the immature articular joint cartilage and growth plates do not differentiate normally.
- For articular cartilage, the process of endochondral ossification is retarded, presumably due to localized, focal disruption of blood supply. If blood supply is reestablished, healing occurs. Alternatively, if blood supply is not reestablished, cartilage remains thick and there is separation between the cartilage and subchondral bone. Eventually a fissure occurs through the articular cartilage that allows communication with the joint cavity. The result is creation of a cartilage flap that is separated from the underlying subchondral bone; this condition is known as osteochondritis dissecans.
- Bilateral disease common.
- Most commonly affected joints—shoulder (caudocranial humeral head); elbow (medial aspect of the humeral condyle); stifle (femoral condyle: lateral more often than medial); hock (ridge of the talus: medial more common than lateral).
- Other reported locations—femoral head; dorsal rim of the acetabulum; glenoid cavity (scapula); patella; distal radius; medial malleolus; cranial end plate of the sacrum; vertebral articular facets; cervical vertebrae.

Immature Joint Cartilage

- Thickened cartilage results in impaired metabolism, leading to degeneration and necrosis of the poorly supplied cells.
- Fissure within the thickened cartilage—may result from mechanical stress; eventually leads to the formation of a cartilage flap or OCD; may cause lameness.
- Lameness (pain)—usually becomes evident once osteochondritis dissecans develops; osteochondrosis is often asymptomatic.

Retention of Cartilage in Growth Plates

- Usually does not lead to necrosis, probably owing to nutrition provided by vessels within the cartilage.
- Failure of endochondral ossification can lead to decreased longitudinal bone growth. When this is severe and occurs in the distal ulnar physis, angular limb deformity may result.

SYSTEMS AFFECTED

Musculoskeletal

GENETICS

- Polygenic transmission—expression determined by an interaction of genetic and environmental factors.

- Heritability index—depends on breed; 0.25–0.45.

INCIDENCE/PREVALENCE

Frequent and serious problem in many dog breeds

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

- Dog

Breed Predilections

Large and giant breeds—Great Dane, Labrador retriever, Newfoundland, Rottweiler, Bernese mountain dog, English setter, Old English sheepdog.

Mean Age and Range

- Onset of clinical signs—typically 4–8 months
- Diagnosis—generally 4–18 months
- Symptoms of secondary DJD—any age

Predominant Sex

- Shoulder—males (2:1)
- Elbow, stifle, and hock—none

SIGNS

General Comments

Depend on the affected joint(s) and concurrent DJD.

Historical Findings

Lameness—most common; sudden or insidious in onset; one or more limbs; becomes worse after exercise; duration of several weeks to months; slight, moderate, or severe.

Physical Examination Findings

- Pain—usually elicited on palpation by flexing, extending, or rotating the involved joint.
- Generally a weight-bearing lameness.
- Joint effusion with capsular distention—common with OCD of elbow, stifle, and hock.
- Muscle atrophy—consistent finding with chronic lameness.
- Hock OCD—hyperextension of the tarsocrural joint.

CAUSES

- Developmental
- Nutritional

RISK FACTORS

- Diet containing three times the recommended calcium levels
- Rapid growth and weight gain
- Overfeeding

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Soft tissue trauma
- Intra-articular (osteochondral) fractures

- Elbow dysplasia

- Panosteitis

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

Radiography

- Standard craniocaudal and mediolateral views—necessary for all involved joints.
- Failure of normal endochondral ossification results in radiolucency. Thus the normal bone contour is lost, which radiographically appears as flattening of the subchondral bone or as a subchondral lucency.
- Cannot be differentiated from OCD on plain radiographs unless the cartilage flap is mineralized.
- Sclerosis of the underlying bone—common in chronic OCD lesions;
- Calcified bodies within the joint (joint mice)—indicate dislodged cartilage flap.
- Contralateral joint—comparison; check for involvement.
- Oblique views—may improve visualization, especially for hock, elbow, and shoulder lesions.
- Skyline views of the talar ridges of the hock joint—help identify medial and lateral lesions.

CT and MRI

Useful for visualizing extent of subchondral lesions. Magnetic resonance imaging is the most accurate method of detecting OC/OCD lesions, flaps, and fragments.

Ultrasonography

Can be used to detect lesions, but is very operator dependent and is the least accurate diagnostic imaging method.

Positive Contrast Arthrography

Useful for differentiating from OCD of the shoulder.

DIAGNOSTIC PROCEDURES

- Diagnosis most frequently made based on physical examination and diagnostic imaging.
- Joint tap and analysis of synovial fluid—confirms involvement; should note straw-colored fluid with normal to decreased viscosity; from cytology, should note > 90% mononuclear cells. Not specific for osteochondrosis.
- Arthroscopy—minimally invasive; excellent method for differentiating from OCD and for corrective treatment.

PATHOLOGIC FINDINGS

- Articular cartilage—initially may appear yellowish.
- Retention of articular cartilage extending into subchondral bone surrounded by increased amount of trabecular bone.
- Clefts between the underlying subchondral bone and the degenerated and necrotic deep layer of the overlying thickened (retained) cartilage.

OSTEOCHONDROSIS

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

N/A

NURSING CARE

- Cryotherapy (ice packing) of affected joint—immediately post-surgery; 5–10 minutes q8h for 3–5 days.
- Range-of-motion exercises—initiated as soon as patient can tolerate.

ACTIVITY

- Restricted.
- Avoid hard concussive activities (e.g., running on concrete).

DIET

Weight control—important for decreasing load and, therefore, the stress on the affected joint(s).

CLIENT EDUCATION

- Discuss the heritability of the disease.
- Warn client that DJD may develop.
- Discuss the influence of excessive intake of nutrients that promote rapid growth.

SURGICAL CONSIDERATIONS

- Osteochondrosis of articular cartilage is generally a nonsurgical condition..
- May progress to OCD as the patient grows. If OCD develops, surgery is generally recommended.
- Surgery is performed by arthrotomy or arthroscopy, and is indicated for most OCD patients.
- Surgical treatment usually involves removal of the cartilage flap.
- Osteochondral autografts have been described for treatment of OCD of the caudal humeral head, medial aspect of the humeral condyle, and femoral condyles. Benefit beyond surgical debridement by flap removal requires further investigation.
- Shoulder—indicated for all OCD lesions; exploratory procedure indicated for pain and lameness with radiographic evidence of osteochondrosis.
- Elbow—indicated for all OCD lesions; indicated to assess for other conditions (see Elbow Dysplasia).
- Stifle—controversial; patients develop DJD even with procedure; arthroscopy may improve the recovery rate and long-term function.
- Hock—remove osteochondral flap; controversial; all patients develop severe DJD even with procedure. Arthrodesis is considered an option for patients with severe disease.
- Sacrum—remove fragment if impinging on the cauda equina.

MEDICATIONS

DRUG(S) OF CHOICE

Anti-inflammatory drugs (NSAIDs) and analgesics—may be used to symptomatically treat DJD associated with OCD; does not promote healing of the cartilage flap (thus surgery is still indicated).

CONTRAINDICATIONS

Avoid corticosteroids owing to potential side effects and articular cartilage damage associated with long-term use.

PRECAUTIONS

NSAIDs—gastrointestinal irritation may preclude their use.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Chondroprotective drugs (e.g., polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate)—may help limit cartilage damage and degeneration; may help alleviate pain and inflammation.

FOLLOW-UP

PATIENT MONITORING

- Periodic monitoring until patient is skeletally mature—recommended to assess progression to an OCD lesion.
- Post-surgery for OCD—limit activity for 4–6 weeks; encourage early, active movement of the affected joint(s).
- Yearly examinations—recommended to assess progression of DJD.

PREVENTION/AVOIDANCE

- Discourage breeding of patients.
- Do not repeat dam-sire breedings that resulted in affected offspring.
- Restricted weight gain and growth in young dogs—may decrease incidence.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Shoulder—good to excellent prognosis for return to full function; minimal osteoarthritis development with OC and after OCD surgery.
- Elbow, stifle, and hock—fair prognosis for OC, guarded for OCD; depends on size of lesion (most important), DJD, and age at diagnosis and treatment; progressive osteoarthritis development, even after surgery.
- Sacrum—good after fragment removal.

OSTEOMYELITIS

BASICS

DEFINITION

Acute or chronic inflammation of cortical bone, endosteum, periosteum, medullary cavity and vascular channels that is usually caused by bacteria. Less common causes include fungi, parasites, viruses, foreign bodies and corrosion of metallic implants.

PATOPHYSIOLOGY

- Extension of soft tissue infections to bone—uncommon in small animals.
- Hematogenously disseminated microorganisms—from infectious foci at a distant site in the body. Bacteria localize in the metaphyseal region of long bones in young animals and vertebrae of adults. Inflammation and thrombus formation produce an ischemic environment that promotes bacterial proliferation. Mycotic infections are often due to hematogenous dissemination of inhaled spores.
- Direct inoculation of bone with pathogenic bacteria (post-traumatic)—most common route of infection. May not initiate infection unless local tissue environmental factors are affected e.g. poor vascularity due to concurrent soft tissue injury or fracture instability, necrotic bone or soft tissue, sequestration, altered tissue defenses or systemic immune response, foreign material, or surgical implants. Diminished blood supply allows for potentiation of infection as neither inflammatory cells nor antimicrobials gain access to the site of infection.
- Bacteria produce a matrix of exopolysaccharides (glycocalyx) that together with host-derived proteins and cellular debris forms a biofilm that protects bacteria from phagocytes, antibacterials and antibodies. Bacterial adherence to implants and sequestra and biofilm protection allow reinfection once antibiotic therapy is stopped.
- Resorption of bone due to infection and instability causes widening of the fracture gap and implant loosening, contributing to persistence of infection and inhibiting revascularization.

SYSTEMS AFFECTED

Musculoskeletal

GENETICS

Breeds with heritable immunodeficiency or hematogenous diseases

INCIDENCE/PREVALENCE

- Hematogenous disease—rare. • Prevalence of fracture-associated osteomyelitis—radius/ulna 41.5%; femur 28.5%.
- Discospondylitis in adult dogs and cats and fungal disease—not uncommon.

GEOGRAPHIC DISTRIBUTION

- Actinomycosis—grass awns contaminated by passage through mucous membranes or gastrointestinal tract usually cause soft tissue infections. Osteomyelitis may be an extension

of soft tissue infection. • Blastomycosis—central and eastern regions of the United States: Great Lakes region and the Mississippi and Ohio river valleys; Canadian provinces of Quebec, Manitoba and Ontario.

- Coccidioidomycosis—southwestern United States, Mexico, and Central and South America. • Histoplasmosis—Ohio, Missouri, and Mississippi river valleys and tributaries.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Breeds with immunodeficiency and hematogenous diseases

Mean Age and Range

Hematogenous metaphyseal infection—young dogs

Predominant Sex

Male dogs—for post-traumatic infection; blastomycosis

SIGNS

General Comments

- Acute postoperative wound infections after orthopedic surgery—may be indistinguishable from acute condition; may progress to chronic disease.
- Most patients have chronic disease at time of examination and diagnosis.

Historical Findings

- Lameness.
- Draining tracts.
- Previous trauma.
- Fracture or surgery—posttraumatic disease.
- Hind limb weakness and difficulty in rising—discospondylitis or vertebral osteomyelitis.
- Travel to regions endemic for mycotic infections—fungal infection.

Physical Examination Findings

- Acute hematogenous disease (dogs)—sudden onset of systemic illness; soft tissue swelling over affected site; lameness; pyrexia; lethargy; limb pain.
- Chronic condition—localized disease, usually no systemic component; chronic draining tracts, pain, muscle atrophy, muscle contracture.
- Non-union fracture with concurrent infection—instability, crepitus, limb deformity.
- Fungal infections—limb swelling, lameness, and intermittently draining tracts.
- Bone infections of the spine—pain and neurologic deficits.

CAUSES

- Open fracture.
- Traumatic injury.
- Open reduction and internal fixation of closed fracture.
- Elective orthopedic surgery.
- Prosthetic joint implant.
- Gunshot wound.
- Penetrating foreign body.
- Bite and claw wounds.
- Extension to bone of soft tissue infection—periodontitis; rhinitis; otitis media; paronychia.
- Hematogenous infection.
- *Staphylococcus* spp. reported in up to 60% of bone infections, usually *S. intermedius*; often monomicrobial infection. Polymicrobial bone infections are common—may include Gram-negative

aerobes: *E. coli*, *Pseudomonas*, *Proteus*, and *Klebsiella* spp.

- Anaerobic bacterial isolates can be as high as 70% and include *Actinomyces*, *Clostridium*, *Peptostreptococcus*, *Bacteroides*, and *Fusobacterium*.
- Fungal infection generally results from hematogenous spread—*Coccidioides immitis*, *Blastomyces dermatitidis*, *Histoplasma capsulatum*, *Cryptococcus neoformans*, *Aspergillus*.

RISK FACTORS

- Open fracture and bone contamination
- Soft tissue trauma
- Penetrating wounds
- Migrating foreign body
- Orthopedic surgery/implants
- Cortical bone allograft
- Immunodeficiency
- Nosocomial infection

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Panosteitis
- Neoplasia
- Bone cysts
- Delayed fracture union due to instability
- Hypertrophic osteodystrophy
- Hypertrophic osteopathy
- Medullary bone infarction

CBC/BIOCHEMISTRY/URINALYSIS

- Hemogram—inflammatory left shift with acute disease
- Fungal hyphae may be present in the urine of systemically ill patients with aspergillosis.

OTHER LABORATORY TESTS

- Serology—confirms some fungal infections.
- Blood cultures in dogs with suspected hematogenous infection.
- Urine excretion of antigen for blastomycosis.

IMAGING

Radiology

- Acute disease—bone architecture normal; gas may be evident if anaerobic infection present.
- Chronic disease—sequestra (avascular segment of cortical bone); periosteal new bone formation; involucrum formation (reactive bone surrounding sequestrum); bone resorption—widening of fracture gaps; cortical thinning; generalized osteopenia; implant loosening.
- Fistulogram—can help identify sequestra or radiolucent foreign bodies.

Other

- Ultrasonography—localize large fluid accumulations; guide fluid sampling by needle aspiration.
- Scintigraphy—^{99m}Tc-labeled methylene diphosphonate; highly sensitive for detecting increased vascularity of bone; not specific for osteomyelitis.

DIAGNOSTIC PROCEDURES

- Fluid aspirates of fluctuant areas or Jamshidi needle tissue biopsies for aerobic and anaerobic culture—collected by sterile techniques; identify microorganisms; determine in vitro antimicrobial drug susceptibility.
- Open surgical biopsy—indicated when needle aspirates are negative

OSTEOMYELITIS

(CONTINUED)

or when debridement is necessary for treatment; culture samples of necrotic tissue, sequestra, implants, and foreign material; histopathologic examination for suspected fungal infection and to rule out neoplasia. Request special fungal stains on pathology samples. • Samples for anaerobic culture—immediately place into appropriate transport medium. Avoid culturing purulent fluid from draining tracts—results misleading as often get contaminants from skin. • Blood cultures—indicated in acute hematogenous osteomyelitis or chronic disease with septicemia. • Urine culture to rule out urinary tract infections as a source for hematogenous disease.

PATHOLOGIC FINDINGS

- Bone sequestration—virtually diagnostic.
- Inflammation and necrosis of bone and the adjacent tissues—pyogenic bacteria.
- Cytologic or histopathologic examination of smears or sections—usually leads to diagnosis of fungal infection.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient—surgical debridement, drainage, culturing, irrigation, and wound management until infection begins to resolve; infected fractures (surgical stabilization).
- Outpatient—long-term oral antimicrobial drug therapy.

NURSING CARE

- Depends on severity, location, and degree of associated soft tissue injury. • Avoid pathogen contamination to other patients. • Physical therapy.

ACTIVITY

Restricted—with any danger of a pathologic fracture developing; with an unhealed fracture.

DIET

No restriction

CLIENT EDUCATION

- Warn the client about cost of treatment, likelihood of recurrence, possibility of repeated surgical intervention, and long duration of therapy. • Discuss prognosis.

SURGICAL CONSIDERATIONS

- Chronic disease—surgical debridement; sequestrectomy; establishment of drainage.
- Infected stable fracture—leave preexisting implants in place during healing. • Infected unstable fracture—remove implants; stabilize with external or internal skeletal fixation.
- Bone deficits—graft with autologous cancellous bone either acutely or after infection has abated and granulation tissue is present. • Large segmental deficits in long bones—bridge by Ilizarov technique or other bone segment transport. • Localized chronic infection—consider amputation (tail, digit, limb) or en bloc resection (sternum, thoracic

wall, mandible, maxilla) and primary wound closure. • Remove all implants after the fracture has healed; bacteria harbored by implant biofilm may lead to recurrence or be a pathogenic factor for fracture-associated sarcoma. • Muscle flap coverage of exposed bone early in the course of treatment greatly reduces contamination of bone and promotes fracture healing.

MEDICATIONS

DRUG(S) OF CHOICE

- Administer a broad-spectrum bactericidal antimicrobial intravenously for 3–5 days while awaiting culture and susceptibility results. Eventual antimicrobial should be selected based on in vitro determination of susceptibility of microorganisms; also consider possible toxicity, frequency, route of administration, and expense; most penetrate normal and infected bone well; must be given for 4–8 weeks; continue for at least 2 weeks beyond radiographic and clinical resolution of infection. • Staphylococci (dogs)—usually *S. intermedius*, are resistant to penicillin because of β -lactamase production; highly susceptible to cloxacillin, amoxicillin-clavulanate, cefazolin, and clindamycin.
- Antibiotics effective against anaerobes that are also available for parenteral administration: ampicillin sodium, metronidazole, and clindamycin.
- Aminoglycosides and quinolones (ciprofloxacin and enrofloxacin)—effective against gram-negative aerobic bacteria.
- Quinolones—may give orally; not nephrotoxic; to protect against resistance, use only for infections caused by gram-negative organisms or *Pseudomonas* that are resistant to other oral antimicrobial drugs. • Chronic disease—continuous local delivery of antimicrobial drugs by antibiotic-impregnated methylmethacrylate beads or biodegradable substances. • Fungal osteomyelitis—long-term therapy (months); treat at least a month beyond resolution of clinical signs; e.g., itraconazole 5–10 mg/kg PO q24h; given continuously may control disseminated aspergillosis long-term.
- Analgesics—injectable narcotics and/or nonsteroidal anti-inflammatory drugs are important to encourage limb use.

CONTRAINDICATIONS

Quinolones—avoid in immature dogs; potential for cartilage injury.

PRECAUTIONS

Aminoglycosides—may cause nephrotoxicity, especially in dehydrated patients and with electrolyte losses or preexisting renal disease.

ALTERNATIVE DRUG(S)

Identify other antimicrobial drugs by repeating cultures and susceptibility

determination if the infection becomes unresponsive to the initial agent.

FOLLOW-UP

PATIENT MONITORING

- Radiography—2–3 weeks after intervention and then sequentially as needed to monitor bone healing (every 4–6 weeks). • Reculture bone—suspected persistent infection.

POSSIBLE COMPLICATIONS

- Recurrence. • Progression to chronic disease. • Malignant neoplasia—rare sequela to chronic infection of fractures repaired by internal fixation.

EXPECTED COURSE AND PROGNOSIS

- Favorable response to treatment in 90% of affected dogs; recurrence is possible, particularly with chronic infections. • Acute infection and chronic bacterial discospondylitis—may be cured by 4–8 weeks of antimicrobial drug therapy if there is limited bone necrosis and no fracture.
- Chronic disease—resolution with antimicrobial drug therapy alone unlikely; provide appropriate surgical treatment.
- Recurrence of chronic infection weeks, months, or years after the last treatment may require repeated sequestrectomy. • Consider amputation in severe chronic cases with irreversible loss of limb function.

BASICS

DEFINITION

Osteosarcoma (OS) is a cancer derived from malignant osteoblast or stem cell, and is the most common primary bone tumor in dogs. Large to giant breed dogs most commonly develop appendicular OS, while axial OS can also affect smaller breeds. The biologic behavior of this neoplasm is malignant, with presumed microscopic lung metastases present in $\geq 85\%$ of dogs at diagnosis. This disease is less common in cats, and the biologic behavior in this species is less malignant than in dogs.

PATOPHYSIOLOGY

Genetic predisposition is likely a major contributor for the development of OS. Other factors contributing to OS development include chronic inflammation associated with metallic implants, history of prior radiation therapy to the site of tumorigenesis, and rapid bone turnover, all associated with the development of OS in dogs.

SYSTEMS AFFECTED

- Musculoskeletal—the appendicular skeleton (metaphyseal region of long bones) is most commonly affected in dogs. OS may also occur in the axial skeleton.
- Respiratory—this neoplasm metastasizes through a hematogenous route; the most common metastatic site is the lung parenchyma; however, other sites include bones, regional lymph node, skin, and visceral organs (liver, kidney).

GENETICS

There is a strong breed predilection, with some degree of heritability being identified in giant breeds such as Scottish deerhound, rottweiler, golden retriever, and Irish wolfhound.

INCIDENCE/PREVALENCE

- Dogs—OS accounts for up to 85% of primary bone tumors in dogs, representing $\sim 5\%$ of all reported malignancies in dogs.
- Cats—OS is the most common primary bone tumor in cats, accounting for $< 7\%$ of all reported cancers in this species.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dogs—large to giant breed
- Cats—domestic shorthair cats

Mean Age and Range

- Dogs—bimodal peak at 2 years and 7 years, reported to occur as young as 6 months
- Cats—average age of 8.5 years, range of 4–18 years

Predominant Sex

Dogs and cats—no strong sex predilection

SIGNS

General Comments

- Because OS occurs most commonly in the appendicular skeleton of dogs and cats, lameness and pain are common clinical findings.
- Clinical symptoms associated with OS affecting the axial skeleton can be variable depending upon the anatomic site involved.

Historical Findings

- Lameness (acute or chronic) is the most common problem.
- Signs of axial skeletal OS vary, depending on the site of the lesion.

Physical Examination Findings

- A firm, painful swelling of the affected site is common with axial skeletal OS.
- Degree of lameness varies from mild to non-weight-bearing.
- Animals can present with a pathologic fracture.
- Soft tissue swelling secondary to tumor infiltration and hemorrhage may be observed.

CAUSES

Unknown in both species

RISK FACTORS

- Dogs—large- to giant-breed dogs at greater risk
- Neutering at an early age
- Metallic implants at fracture repair sites
- History of exposure to ionizing radiation
- Cats—unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other primary bone tumor (i.e., fibrosarcoma, chondrosarcoma)
- Metastatic bone tumor (i.e., prostatic, mammary, other carcinoma)
- Infectious (i.e., fungal or bacterial osteomyelitis)

CBC/BIOCHEMISTRY/URINALYSIS

Elevated alkaline phosphatase is a poor prognostic factor.

IMAGING

Radiography of Primary Site

- At least two views of the primary lesion should be made (i.e., anterior-posterior and a lateral for appendicular sites).
- Typical findings include mixed osteolytic/osteoproducing effects involving the metaphyseal region of long bones.
- Soft tissue swelling overlying diseased bone.

Thoracic Radiography

- Three radiographic views of the thorax (right and left lateral and a dorsoventral view) should always be performed; although visible macroscopic metastatic disease is present in $< 10\%$ of cases at the time of presentation.
- If pulmonary metastases are identified at initial diagnosis, the prognosis is considered poor for long-term survival.
- Metastatic lesions typically appear as discrete, round, soft tissue density nodules.

Nuclear Bone Scans

Might be useful and more sensitive for identifying bony metastatic disease or contemporaneous primary lesions than plain radiography.

OTHER DIAGNOSTIC PROCEDURES

Bone Aspirate

- A relatively non-invasive, potentially high-yield procedure using an 18-gauge needle to withdraw cells from the tumor site.
- Cytologic evaluation may give a diagnosis of malignant mesenchymal neoplasia.
- Concurrent alkaline phosphatase positivity on cytology is sensitive and specific for OS diagnosis.

Bone Biopsy

- The gold standard for diagnosis.
- Performed with the patient under light general anesthesia or moderate sedation.
- Samples should be taken through the center of the lesion; peripheral biopsies are often nondiagnostic and contain reactive osteoblasts.
- Biopsy may be performed using a Michele trephine, jamshidi bone biopsy needle, or open (i.e., wedge) biopsy technique.

PATHOLOGIC FINDINGS

- Gross—mild to severe destruction of cortical bone with new bone proliferation.
- Histologic—malignant population of mesenchymal cells that are plump, polygonal to spindlyoid in shape. The finding of osteoid production is necessary and diagnostic for OS. Subclassifications such as osteoblastic, chondroblastic or telangiectatic have not consistently been shown to be prognostic. Parosteal (juxtacortical) OS is a rarely seen soft tissue variant that may have a less aggressive biologic behavior than other forms of OS.

TREATMENT

DIET

No specific dietary management is required, although weight loss may benefit amputees in general.

CLIENT EDUCATION

- Long-term prognosis is poor; however, a subpopulation (15%) of patients achieve long-term survival.
- Clients must understand that treatment goals are to relieve discomfort and prolong life; a cure is unlikely.
- Clients should be prepared for possible chemotherapy-induced side effects.

SURGICAL CONSIDERATIONS

Dogs—Appendicular Sites

- Conventional surgical management involves amputation of the affected limb (forequarter or hip disarticulation).
- Limb salvage therapy is available at a limited number of referral hospitals. This technique is appropriate only

OSTEOSARCOMA

(CONTINUED)

for locally confined and small distal radial lesions. The primary tumor is surgically removed, replaced by an allograft or metal prosthesis, and stabilized with a bone plate.

- Adjuvant chemotherapy recommended with either surgical procedure (see below).

Dogs—Axial Sites

• Depending on location, aggressive surgical excision and adjuvant chemotherapy are recommended (see below). • Mandibular OS may have a less aggressive biologic behavior than other sites; one study reported a 71% 1-year median survival time with surgery alone. However, recent studies would suggest that OS arising from the mandible is still highly metastatic and warrants treatment with adjunctive chemotherapy. • If surgical resection is not possible, palliative radiation is effective for the alleviation of osteolytic bone pain.

Cats—Appendicular Sites

- Amputation alone is considered appropriate.
- Adjuvant therapy not typically necessary.

Cats—Axial Sites

• Depending on site of lesion, aggressive surgical excision should be attempted. • Local recurrence appears to be the main reason for treatment failure. • If surgical resection is not possible, palliative radiation is effective for the alleviation of osteolytic bone pain.

Metastatectomy

• Pulmonary metastatectomy has been described for dogs with OS; however, is not routinely practiced. • Selection criteria for dogs to undergo this procedure include a long disease-free interval (> 300 days) and only 1–2 pulmonary nodules based on thoracic radiographs.

Inoperable Neoplasms

- Palliative (coarse fractionation) radiotherapy. • Stereotactic radiosurgery in combination with systemic chemotherapy and aminobisphosphonate therapy can provide prolonged survival times with acceptable pain control (10–12 months). • Pain management with nonsteroidal anti-inflammatory drugs, opioids or bisphosphonates may improve quality of life and thus prolong survival.

MEDICATIONS

DRUG(S) OF CHOICE

Definitive Therapy

- Chemotherapy with either platinum-based drugs (cisplatin or carboplatin) or doxorubicin is the current standard of care; a minimum of four doses is recommended.
- Cisplatin, carboplatin, or doxorubicin are standard of care. • Cisplatin 70 mg/m² IV q 3 weeks. Must be given with a saline induced diuresis to prevent nephrotoxicity: 18.3 mL/kg/h for 4 hours, administer

chemotherapy over 20 minutes, then continue diuresis for another 2 hours. Cisplatin will cause vomiting within 2 hours of administration. Antiemetics must be given before cisplatin, and the patient may need to be sent home with antiemetic therapy.

- Carboplatin 300 mg/m² IV q3 weeks.
- Doxorubicin 30 mg/m² IV q3 weeks for 5 doses is a less expensive option; may be used in combination with cisplatin.
- Chemotherapy is not effective against gross disease, less than 5% expected response rate.
- Chemotherapy typically initiated within 2 weeks of surgery.

CONTRAINdications

- Patients with preexisting renal dysfunction should not be treated with platinum-based chemotherapy drugs. • Do not give cisplatin to cats.

ALTERNATIVE DRUG(S)

Palliative Therapy

- Pain management must be addressed in patients whose owners decline definitive therapy. • Manage pain with nonsteroidal anti-inflammatory drugs, ± tramadol (2–5 mg/kg q8–12h), ± acetaminophen with codeine (0.5–2 mg/kg q8–12h), ± transdermal fentanyl (as per package instructions) ± gabapentin (3–10 mg/kg q8–24h). • Euthanasia when quality of life declines.

FOLLOW-UP

PATIENT MONITORING

- Monitor CBC for evidence of myelosuppression 7–14 days following chemotherapy. • Doxorubicin—periodic echocardiography and ECGs as cumulative cardiotoxicity may occur at > 180 mg/m².
- Thoracic radiographs every 2–3 months after surgery to assess for metastasis.
- Radiograph surgical site every 2–3 months to monitor for local recurrence following limb salvage.

POSSIBLE COMPLICATIONS

- Metastatic disease is very likely; sites of spread include lungs, other bones, soft tissue.
- Animals that undergo limb salvage may develop recurrent infections, local recurrence, or implant failure.

EXPECTED COURSE AND PROGNOSIS

Dogs

- Without treatment, with amputation alone, or with palliative radiotherapy alone, median survival is approximately 4 months. When conventional palliative radiotherapy is combined with intravenous aminobisphosphonates and oral analgesics, acceptable quality of life can be extended up to 6–9 months. The use of stereotactic radiosurgery in combination with

chemotherapy and aminobisphosphonates can extend survival times to 10–12 months.

- With surgery and chemotherapy, median survival is extended to a median of 10 months.

Cats

- Appendicular OS, with surgery, median survival of > 2 years. • Axial OS, with surgery, median survival of 5.5 months.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Do not breed animals that are undergoing chemotherapy.

SYNONYMS

- Osteogenic sarcoma

SEE ALSO

- Chondrosarcoma, Bone
- Fibrosarcoma, Bone
- Hemangiosarcoma, Bone

ABBREVIATIONS

- CT = computed tomography

OTITIS EXTERNA AND MEDIA

BASICS

DEFINITION

- Otitis externa: inflammation of the external ear canal; includes anatomic structures of the pinna, horizontal and vertical canals, and the external wall of the tympanic membrane.
- Otitis media: inflammation of the middle ear; includes anatomic structures of the medial wall of the tympanic membrane, bulla (tympanic cavity), auditory ossicles, and auditory tube. • The terms are descriptions of clinical signs; they are not diagnoses.

PATOPHYSIOLOGY

- Otitis externa—chronic inflammation results in alterations in the environment of the canal; the normal external ear canal is lined with epithelium containing modified apocrine (cerumen) glands; with inflammation, glands enlarge and produce excessive wax; the epidermis and dermis thicken and become fibrotic; thickened canal folds effectively reduce canal width; calcification of auricular cartilage is the end-stage result.
- Otitis media—often an extension of otitis externa; frequently occurs without rupture of tympanum; can occur from polyps or neoplasia within the middle ear or auditory tube; may be caused by an increase in fluid retention within the bulla or extension of infection into the bulla.

SYSTEMS AFFECTED

- Skin/Exocrine • Nervous

GEOGRAPHIC DISTRIBUTION

Environmental humidity may predispose to infection.

SIGNALMENT

Species

Dogs and cats

Breed Predilections

- Pendulous-eared dogs—especially spaniel and retriever
- Dogs with hirsute external canals—terrier and poodle
- Stenosis of the external ear canal—Shar-Pei and bulldog
- Primary secretory otitis media—Cavalier King Charles spaniel

SIGNS

Historical Findings

- Pain—shying from touching of the head, or refusing to open the mouth.
- Head shaking.
- Scratching at the pinnae.
- Malodor from canals.
- Peripheral vestibular deficits or facial nerve deficits from extension to inner ear.

Physical Examination Findings

Otitis Externa

- Redness and swelling of the external canal, leading to stenosis.
- Scaling and exudation—may result in malodor and canal obstruction.
- Vestibular signs indicate development of otitis interna.
- Deafness from obstruction.
- Purulent and malodorous exudates.

- Inflammation, pain, pruritus and erythema of the pinnae and external canals.
- Aural hematoma.
- Palpable scarring and calcification of the auricular cartilage.
- Holding of the pinna down and/or head tilt toward the affected side (if unilateral).

Otitis Media

- Chronic otitis externa (dogs)—can result in tympanic membrane rupture (71% of cases) and otitis media (82% of cases).
- Intact tympanic membrane: bulging pars flaccida.
- Evidence of fluid and/or gas behind the pars tensa; membrane may be opaque; fluid may be purulent or hemorrhagic.
- Ruptured tympanic membrane: discharge into canal or bullae filled with debris.
- Deafness.
- Pain on palpation or opening of the mouth.
- Pharyngitis, tonsillitis, or discharge through auditory tube.
- Lymphadenopathy if severe or chronic.

CAUSES

Predisposing Causes

- Predisposing causes change the environment of the ear canal facilitating inflammation and encouraging secondary infection:
 - Abnormal or breed-related conformation of the canal restricts proper air flow—see “Breed Predilections”
 - Excessive moisture (e.g., from swimming or overzealous cleaning)
 - Topical drug reaction and irritation and trauma from abrasive cleaning techniques.
 - Underlying systemic disease produces abnormalities in the environment and ear canal immune response.
 - Obstructions—neoplasia, polyps, cerumen gland hyperplasia, and accumulation of hair; may also be a secondary event.
 - Trauma to the canal.

Primary Causes

- Primary causes directly initiate or cause inflammation within the ear canal:
 - Parasites (*otitis externa*)—*Otodectes cynotis*, *Demodex* spp., *Sarcoptes* and *Notoedres*, and *Otobius megnini*.
 - Hypersensitivities—atopy, food, contact, and systemic or local drug reaction.
 - Foreign bodies—plant awns.
 - Unilateral and persistent/recurrent otitis externa/media more suspicious of an obstruction, foreign body, or growth.
 - Keratinization disorders and increased cerumen production—functional obstruction of the ear canal.
 - Endocrinopathy.
 - Auto-immune diseases may affect the pinnae and external canal.
 - Primary secretory otitis media.

Perpetuating Causes

- Perpetuating causes prevent resolution of the inflammation and/or infection of the ear canal:
 - Chronic change: stenosis of the canal, swelling from inflammation, scarring and calcification; increased retention of debris in the ear by increased cerumen production and decreased removal by epidermal migration and physical obstruction.
 - Bacterial infection: *Staphylococcus pseudintermedius*, *Pseudomonas aeruginosa*, *Enterococcus* spp., *Proteus mirabilis*, *Streptococcus* spp.,

Corynebacteria spp., and *Escherichia coli*.

- *Pseudomonas aeruginosa* commonly cultured in otitis media.
- Fungal/yeast infection: *Malassezia pachydermatis*, *Candida albicans*, and rarely other fungi (*Sporothrix schenckii*, *Cryptococcus neoformans*).

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

May indicate a primary underlying disease.

OTHER LABORATORY TESTS

Allergy Testing

- Food-elimination diet—determine cutaneous adverse reaction to food.
- Intradermal allergy testing—atopy.

IMAGING

- Bullae radiographs: may be normal; bullae may appear cloudy if filled with exudate; thickening of bulla and petrous temporal bone with chronic disease; presence of bone lysis with osteomyelitis or neoplastic disease.
- CT or MRI: detailed evidence of fluid or tissue density in the bulla, adjacent tissues, or auditory tube.

DIAGNOSTIC PROCEDURES

- Direct- or video-otoscopy: visualization of the external canal, tympanic membrane, and bulla (if tympanum ruptured).
- Skin scrapings from pinnae: parasites.
- Skin biopsy: auto-immune disease, neoplasia, cerumen gland hyperplasia.
- Culture of exudate: useful with persistent infection; most indicated when rod bacteria seen in cytology.
- Microscopic evaluation of exudate: single most important diagnostic tool after complete examination of the ear canal; physical appearance of the exudate does not permit accurate diagnosis of the type of infection; microscopic examination is necessary.
- Infections within the canal can change with prolonged or recurrent therapy; repeat examination of exudate is required in chronic cases.
- Myringotomy: spinal needle or sterile catheter is inserted through the tympanic membrane to sample fluid within the bulla for cytologic examination and culture.

Microscopic Examination

- Preparations: examine from both canals (canal contents may differ); examine both unstained and modified Wright-stained samples.
- Mites: presumptive diagnosis.
- Type(s) of bacteria or yeast: assist in the choice of therapy as well as determine if culture is needed.
- Note findings (type of organisms; cells present) in the record; rank the number of organisms and cell types present on a standardized scale (e.g., 0–4) for treatment monitoring.
- White blood cells within the exudate: indicates active infection; systemic therapy may be required.

OTITIS EXTERNA AND MEDIA

(CONTINUED)

TREATMENT

CLIENT EDUCATION

Demonstrate proper method for cleaning and medicating ears (e.g., volume of medication to instill).

SURGICAL CONSIDERATIONS

- Indicated when the canal is severely stenotic or obstructed or when neoplasia or a polyp is diagnosed.
- Severe, unresponsive otitis media may require a bullae osteotomy or total ear canal ablation.

MEDICATIONS

DRUG(S) OF CHOICE

Cleansing Solutions

- Tympanum integrity should be assessed prior to introduction of solutions and/or medications into the external ear canal.
- Tympanum not intact: saline solution or 2.5% acetic acid (1:1 vinegar/water) rinses.
- Ceruminolytics—should not be introduced into the tympanic bulla; diethyl sodium sulfosuccinate, squaline, propylene glycol.
- Antiseptics—acetic acid or 0.2% chlorhexidine gluconate. Tris-EDTA has antibacterial and synergistic properties with certain antibiotics.
- Astringents—isopropyl alcohol, boric acid, salicylic acid.
- Anti-infective/parasiticide agents specific to identified organism(s).

Ear Flushing

- Sedation may be required.
- Gentle solutions should be used initially.
- Bulb syringe or properly trimmed French red rubber catheter is used to flush in solution and remove debris.
- Repeat cleansing at a tapering frequency during therapy.

Systemic

- Cytologic examination of exudates will help to determine type of systemic medication needed.
- Otitis media and chronic/severe otitis externa should be treated with systemic medication for at least 4–6 weeks.
- Antibiotic—should be based on culture/sensitivity if recurrent.
- Coccal bacteria—cephalexin (22 mg/kg q12h), amoxicillin trihydrate-clavulanate potassium (10–15 mg/kg q12h), and chloramphenicol (25–50 mg/kg q8–12h). Clindamycin (11 mg/kg q12–24h) for bone involvement.
- Rod bacteria—based on culture/sensitivity: fluoroquinolones: enrofloxacin (dogs, 10–20 mg/kg q12h; cats, 5 mg/kg/day), marbofloxacin (5.5 mg/kg/day); Aminoglycoside: amikacin (20 mg/kg/day).
- Antifungal—should always be used with topical antifungal therapy. Ketoconazole (5 mg/kg q12–24h), fluconazole (5–10 mg/kg q24h) and itraconazole (5 mg/kg/day).

- Anti-inflammatory—often required to reduce swelling and cerumen production: tapering dosages: prednisolone (0.5–1 mg/kg/day), dexamethasone (0.1 mg/kg/day), triamcinolone (0.1 mg/kg/day).
- Antiparasite—ivermectin (300 µg/kg SC or PO 1–2 weeks for four treatments), selamectin, moxidectin (see “Contraindications” below).

Topical

- Topical therapy paramount for resolution and control of otitis externa.
- Completely clean the external ear canal of debris.
- Continue cleanings until symptoms resolve and then routinely to maintain control.
- Apply appropriate topical medications in sufficient quantity to completely treat the entire canal.
- Ointments and lotions may be occlusive unless used judiciously.
- Antibiotic—based on cytologic evaluation, culture/sensitivity, and/or empiric choice. Gentamicin, neomycin, amikacin, enrofloxacin, and silver sulfadiazine. Also chloramphenicol and tobramycin.
- Antifungal—imidazoles: clotrimazole, ketoconazole, miconazole, thiabendazole. Also nystatin, terbinafine.
- Anti-inflammatory—corticosteroids: dexamethasone, fluocinolone, betamethasone, triamcinolone, hydrocortisone aceponate, and mometasone.
- Antiparasite—ivermectin, amitraz, and thiabendazole.

CONTRAINDICATIONS

- Ruptured tympanum—use caution with topical cleansers other than sterile saline or dilute acetic acid, and aminoglycoside antibiotics; potential for ototoxicity is a concern; controversial.
- Ivermectin—not FDA approved for use systemically; herding (dog) breeds have increased sensitivity (*MDR1/ABCB1* gene mutation) to avermectins.

PRECAUTIONS

- Use caution when cleaning the external ear canals of all animals with severe and chronic otitis externa; the tympanum can easily be ruptured.
- Post-flushing vestibular complications are more common in cats, although usually temporary; warn clients of possible complications and residual effects.

POSSIBLE INTERACTIONS

- Topical medications infrequently induce contact irritation or allergic response; reevaluate all worsening cases.
- Corticosteroid use controversial with otitis media/interna.

FOLLOW-UP

PATIENT MONITORING

Repeat exudate examinations can assist in monitoring infection.

PREVENTION/AVOIDANCE

- Routine ear cleaning by the client • Control of underlying diseases

POSSIBLE COMPLICATIONS

- Deafness, vestibular disease, cellulitis, facial nerve paralysis, progression to otitis interna, and rarely meningoencephalitis.
- Post-external ear canal flushing complications in cats (vestibular signs) are not uncommon; clients should be warned of possible residual effects.

EXPECTED COURSE AND PROGNOSIS

- Otitis externa—with proper therapy, most cases resolve in 3–4 weeks; failure to correct underlying primary cause results in recurrence.
- Perpetuating factors (e.g., stenosis of the ear canal and calcification of the auricular cartilage) will not resolve and may cause recurrence.
- Otitis media—may require 6 or more weeks of systemic antibiotics until all signs resolve and the tympanic membrane has healed.
- Osteomyelitis of petrous temporal bone and bulla may require 6–8 weeks of antibiotics.
- Vestibular signs usually improve within 2–6 weeks (often with residual symptoms).

MISCELLANEOUS

ZOONOTIC POTENTIAL

- *Sarcopes* or *Notoedres* mite infestations can cause transient pruritus and dermatitis in human beings.
- Fungal infection (dermatophytosis, sporotrichosis) possible transmission to humans.

ABBREVIATIONS

- CT = computed tomography
- EDTA = ethylene diamine tetra-acetate
- MRI = magnetic resonance imaging

OTITIS MEDIA AND INTERNA

BASICS

DEFINITION

Inflammation of the middle (otitis media) and inner (otitis interna) ears, commonly caused by bacterial infection.

PATOPHYSIOLOGY

- Media—from extension of infection of the external ear through the tympanic membrane; may extend from the oral and nasopharyngeal cavities via the Eustachian tube.
- Interna—may also result from hematogenous spread of a systemic infection.

SYSTEMS AFFECTED

Nervous

- Impaired balance—from damage to the vestibular apparatus in the inner ear or to vestibular portion of vestibulocochlear nerve.
- Nausea—from dizziness due to impaired balance.
- Hearing loss—from damage to hair cells in the cochlea or to the cochlear portion of vestibulocochlear nerve.

Ophthalmic

- Corneal ulcer—from inability to blink due to damage to facial nerve.
- Keratoconjunctivitis sicca (dry eye)—from damage to parasympathetic branch of the facial nerve that travels to the lacrimal gland.
- Horner's syndrome—from damage to sympathetic nerve in middle ear.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dogs.
- Cocker spaniels and other long-ear breeds.
- Poodles with chronic otitis or pharyngitis from dental disease.
- Primary secretory otitis media (PSOM) in Cavalier King Charles spaniels.

Mean Age and Range

Any age

SIGNS

General Comments

Depend on severity and extent of inflammation; range from none to those related to bulla discomfort and nervous system involvement.

Historical Findings

- Pain when opening the mouth; reluctance to chew; shaking the head; pawing at the affected ear.
- Vestibular deficits—may be persistent, transient, or episodic.
- Unilateral involvement—head tilt, leaning, veering, or rolling.
- Bilateral involvement—wide head excursions, truncal ataxia; ± deafness.

- Vomiting and nausea—may occur during the acute phase.
- Saliva and food dropping from corner of the mouth; inability to blink; ocular discharge.
- Anisocoria (smaller pupil on affected side), protrusion of the third eyelid, enophthalmos and ptosis (Horner's syndrome) may be noted.

Physical Examination Findings

- Aural erythema, discharge, and thick and stenotic canals supports otitis externa.
- Gray, dull, opaque, and bulging tympanic membrane on otoscopic examination indicates middle ear exudate.
- Dental tartar, gingivitis, tonsillitis, or pharyngitis may be associated.
- Ipsilateral mandibular lymphadenopathy may occur with severe infections.
- Pain upon mouth opening or bulla palpation.
- Corneal ulcer—from inability to blink or keratoconjunctivitis sicca.

Neurologic Examination Findings

- Unilateral damage to vestibular portion of cranial nerve VIII—ipsilateral head tilt, leaning, veering, falling, or rolling may occur.
- Nystagmus—resting or positional and rotary or horizontal, fast phase characteristically opposite the affected side, and does not change in direction.
- Vestibular strabismus—ipsilateral ventral deviation of eyeball with neck extension.
- Bilateral damage of vestibular portion of cranial nerve VIII—patient reluctant to move, may stay in a crouched posture, wide head excursions; physiologic nystagmus poor to absent.
- Facial nerve damage—ipsilateral paresis/paralysis of the ear, eyelids, lips, and nares; reduced tear production (indicated by Schirmer tear test).
- Chronic facial paralysis—contracture of the affected face caused by fibrosis of denervated muscles.
- Deficits may be bilateral.
- Sympathetic nerve damage—ipsilateral Horner's syndrome; always miosis; may also note protrusion of third eyelid, ptosis, and enophthalmos.
- Same signs in PSOM but associated with recurrent accumulation of viscous mucus in the middle ear.

CAUSES

- Bacteria—*Staphylococcus* spp., *Streptococcus* spp., *Proteus* spp., *Pseudomonas* spp., *Pasteurella* spp., and *E. coli* and obligate anaerobes.
- Yeast (*Malassezia* spp., *Candida* spp.) and *Aspergillus*.
- Mites—predispose to secondary bacterial infections.
- Foreign bodies (e.g., grass awns, foxtail awns, or spear grass in endemic areas),

trauma, polyps, tumors (e.g., fibromas, squamous cell carcinoma, ceruminous gland carcinoma, primary bone tumors).

- Iatrogenic damage during cleaning or investigation of otitis externa.

RISK FACTORS

- Recurrent otitis externa.
- Nasopharyngeal polyps and inner, middle, or outer ear neoplasia—may predispose to bacterial infection.
- Upper respiratory infection in cats and dental disease—may be linked to otitis media.
- Vigorous ear flush.
- Ear-cleaning solutions (e.g., chlorhexidine)—may be irritating to middle/inner ear; avoid if tympanum is ruptured.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congenital vestibular anomalies—signs present from birth.
- Hypothyroidism—associated with cranial nerves VII and VIII deficits; abnormal thyroid profile supports diagnosis.
- Neoplasia and nasopharyngeal polyps—common causes of refractory and relapsing otitis media and interna; diagnosed by oral and otic exam, and imaging of the head.
- Idiopathic vestibular disease (old dogs and young to middle-aged cats), idiopathic facial paralysis, and idiopathic Horner's syndrome—diagnoses made by exclusion.
- Cryptococcus*—reported in association with peripheral vestibular disease in cats.
- Trauma—history and physical evidence of injury.
- Thiamin deficiency (cats)—bilateral central vestibular signs; history of an all-fish diet or persistent anorexia.
- Metronidazole toxicity—bilateral cerebellar involvement (vestibular portion) after high dosage or prolonged use.
- Central vestibular disease—presence of lethargy, somnolence, and other brainstem signs.

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis with left-shift may be noted.
- Globulins—may be high if chronic infection.

OTHER LABORATORY TESTS

- Blood, urine cultures—may be positive with a hematogenous source of infection.
- Low T₄, free T₄ with normal or high TSH level with hypothyroidism.

IMAGING

- Video otoscopy—detailed examination of external ear canal and tympanic membrane; membrane may appear cloudy with middle ear exudate. Helps evaluate the integrity of

OTITIS MEDIA AND INTERNA

(CONTINUED)

the tympanic membrane, obtaining samples for cytology and culture/sensitivity, and performing therapeutic lavages of the ear canal and middle ear cavity.

- Bullae radiographs—not as sensitive a test; may see thickening of the bullae and petrous temporal bone with chronic disease; may see lysis of the bone with severe cases of osteomyelitis; may be normal.
- CT or MRI—detailed evidence of fluid and soft tissue density within the middle ear and extent of involvement of adjacent structures; CT better at revealing associated bony changes; MRI better for evaluating soft tissue structures including brainstem and cerebellum.

DIAGNOSTIC PROCEDURES

- Myringotomy—insert a spinal needle (20-gauge; 2.5- to 3.5-inches) through the otoscope and tympanic membrane to aspirate middle ear fluid for cytologic examination and culture and sensitivity. Examine for bacterial and fungal causes of infection.
- BAER—test the peripheral and central auditory pathways; detect hearing loss.
- CSF analysis—if indication of intracranial extension, perform culture and sensitivity.

PATHOLOGIC FINDINGS

Purulent exudate within the middle ear cavity surrounded by a thickened bullae and microscopic evidence of degenerative neutrophils with intracellular bacteria.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient—severe debilitating infection; neurologic signs.
- Outpatient—stable patients, pending further diagnostics and surgery, if indicated.

NURSING CARE

- Fluid therapy—if unable to eat or drink due to vomiting and disorientation.
- Concurrent otitis externa—culture and clean the ear; use warm normal saline if the tympanum is ruptured.

ACTIVITY

Restrict with marked vestibular signs to avoid injury.

DIET

- Vomiting from vestibulitis— withhold food and water for 12–24 hours.
- Severe disorientation—hand-feed and water small amounts frequently; sternal during feeding to avoid aspiration pneumonia.

CLIENT EDUCATION

- Inform client that most bacterial infections resolve with an early aggressive course of

long-term broad-spectrum antibiotics and do not recur.

- Warn client that relapsing signs may occur and may require surgical drainage.

SURGICAL CONSIDERATIONS

- Do not rely on severity of neurologic signs as an indication for surgical intervention.
- Surgical treatment—for patients with evidence of middle ear exudate, osteomyelitis refractory to medical management, and nasopharyngeal polyps or neoplasia.
- Bullae osteotomy—allows drainage of the middle ear cavity.
- Ablation of ear canal—when otitis media is associated with recurrent otitis externa or neoplasia.
- Cytologic examination and culture/sensitivity of middle ear effusion and histopathology of abnormal tissue at time of surgery.

MEDICATIONS

DRUG(S) OF CHOICE

- Topical water, saline or TrizEDTA-based otic antimicrobial preparations, if tympanum is ruptured; treatment specific for bacteria, yeast, or mites present.
- Antibiotics—long-term (6–8 weeks); topical and systemic antibiotics are selected on basis of culture and sensitivity, if available.
- Amoxicillin/clavulanic acid (12.5–22 mg/kg q12h PO)—good first-choice antibiotic.
- Fluoroquinolone or third-generation cephalosporin—good second alternatives or can be used in combination, if culture and sensitivity unavailable; enrofloxacin (Baytril) 5–10 mg/kg q24h (dogs), 5 mg/kg q24h (cats), or marbofloxacin (Zeniquin 5 mg/kg q24h), or cefpodoxime (Simplicef 10 mg/kg q12h); clindamycin (Cleocin 5–30 mg/kg q12h), if anaerobes are suspected.
- Antinausea preparations—meclizine (Antivert, Antrizine, Bonine, Dramamine Less Drowsy Formula): 12.5 mg PO q24h (dogs < 10 kg and cats), 25 mg PO q24h (dogs > 10 kg); or maropitant citrate (Cerenia) 1 mg/kg SC or 2 mg/kg PO q24h (dogs), 1 mg/kg SC or 1 mg/kg PO q24h (cats); or dolasetron mesylate (Anzemet) 0.6 mg/kg IV q24h (dogs, cats).

CONTRAINDICATIONS

- Ruptured tympanum or associated neurologic deficits—avoid oil-based or irritating external ear preparations (e.g., chlorhexidine) and aminoglycosides, which are toxic to inner ear structures.
- Otitis media or interna—use topical and systemic corticosteroids judiciously; may

exacerbate infection. Reserve for cases in which flushing of the ear canal is prevented by inflammation, or to treat edema associated with intracranial spread of infection.

PRECAUTIONS

Avoid vigorous external ear flush.

FOLLOW-UP

PATIENT MONITORING

Evaluate for resolution of signs after 10–14 days or sooner if the patient is deteriorating.

PREVENTION/AVOIDANCE

- Parasite control—ear mites predispose to secondary bacterial infection.

POSSIBLE COMPLICATIONS

- Residual signs associated with vestibular (head tilt) and facial nerve damage or Horner's syndrome.
- Severe middle/inner ear infections—may spread to brainstem. Clinical signs indicate central vestibular lesion, typically preceded by peripheral vestibular or middle/inner ear signs. Aggressive surgical debridement and antibiotic therapy are required.
- Osteomyelitis of the petrous temporal bone and middle ear effusion—common sequela to severe, chronic otitis externa.
- Bulla osteotomy—postoperative complications include Horner's syndrome, facial paralysis, and onset or exacerbation of vestibular dysfunction, or deafness.

EXPECTED COURSE AND PROGNOSIS

- Otitis media-interna—usually responsive to medical management; 2- to 4-month course of antibiotic to avoid relapse.
- When medical management of otitis externa is ineffective, consider lateral ear resection.
- Vestibular signs—improvement in 2–6 weeks.

MISCELLANEOUS

AGE-RELATED FACTORS

Ear mites more common in kittens and puppies.

SEE ALSO

O

OVARIAN REMNANT SYNDROME

BASICS

OVERVIEW

- Ovarian remnant syndrome is the presence of behavioral and/or physical signs of an estrous cycle in a female dog or cat having previously undergone ovariohysterectomy.
- Caused by the presence of functional residual ovarian tissue.
- Ovarian remnant syndrome is reported to be responsible for 17% of all post-OHE complications.

SIGNALMENT

- Female dog and cat; more common in cat.
- No breed predisposition or geographic distribution.
- Signs of an estrous cycle usually occur months to years after OHE but can begin within days after surgery.

SIGNS

Bitches

Estrogen Influence

- Attraction of male dogs.
- Swelling of the vulva.
- Mucoid to sanguineous vaginal discharge.
- Passive interaction with male dogs.
- Flaggging.
- May allow copulation.
- Signs of proestrus last an average of 9 days; signs of estrus last an average of 9 days; average interval between signs of estrous cycles is 7 months.
- Signs are usually cyclical or periodic (i.e., q6 months).

Progesterone Influence

- Prominent vulva compared to patients with complete OHE.
- Enlargement of the uterine stump.
- Uterine stump pyometra can develop due to progesterone effect.

Queens

Estrogen Influence

- Vocalization.
- Lordosis.
- Restlessness.
- Head rubbing.
- Rolling.
- Tail deviation and treading the hind limbs.
- May allow copulation.
- Demonstrate typical behavioral signs of estrus in a cyclical (seasonally polyestrous) fashion.
- Estrus lasts 2–19 days, followed by an interestrous interval that lasts for 8–10 days unless ovulation and luteinization occurred, in which case the interestrous interval is at least 45 days.

Progesterone Influence

- Enlargement of the uterine stump.
- Uterine stump pyometra can develop due to the effects of progesterone.

CAUSES & RISK FACTORS

- Failure to remove both ovaries completely.
- No correlation with age at OHE, difficulty of surgery, obesity of patient, or experience of surgeon.
- Presence of anatomically abnormal ovarian tissue (fragmentation into the broad ligament) is possible, more common in queens.
- Supernumerary ovary (rare).
- Experimentally, functionality returns to ovarian tissue removed from its vascular supply and replaced into or onto the lateral abdominal wall, mesentery, or serosal surface.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inflammation or infection of the genitourinary tract.
- Vaginal hemorrhage due to foreign body (grass awn).
- Trauma.
- Uterine stump granuloma secondary to local pathology (foreign body reaction to suture material or grass awn).
- Neoplasia of a remnant portion of the tubular tract (uterine stump leiomyoma or leiomyosarcoma).
- Neoplasia of an ovarian remnant (granulosa cell tumor, carcinoma, luteoma, functional teratoma).
- Neoplasia of the urinary tract (transitional cell carcinoma).
- Vascular anomalies of the genitourinary tract.
- Coagulopathy.
- Exogenous estrogen administration (as for sphincter incompetence associated with urinary incontinence).
- Exposure to human transdermal hormone replacement therapy (most commonly small lap dogs).
- Endogenous extraovarian source of estrogen: adrenal pathology (rare).

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Chronic blood loss anemia if vaginal hemorrhage is profound; uncommon unless concurrent ovarian neoplasia, follicular cysts, coagulopathy, or other systemic disease.
- Pancytopenia is possible from estrogen toxicity.
- An inflammatory leukogram and isosthenuria can occur subsequent to uterine stump pyometra.

OTHER LABORATORY TESTS

- Observation of behavioral and physical signs of estrus together with vaginal cytology and/or measurement of serum progesterone or estradiol concentrations confirming the presence of functional ovarian tissue.
- Vaginal cytology: vaginal mucosal cornification is a bioassay for elevated plasma estradiol concentrations (see Breeding, Timing).
 - Vaginal cytology (bitch): epithelial cell cornification is generally > 90% during estrus (superficial and pyknotic or anuclear cells).
 - Vaginal cytology (queen): epithelial cell cornification ranges from 10% to 40%; clearing (absence of debris and clumping of cells) occurs in 90% of smears during estrus.
- Serum progesterone (bitch): a serum progesterone concentration > 2 ng/mL (measured 1–3 weeks after behavioral estrus) is consistent with functional luteal tissue. GnRH (50 µg IM), hCG (400 IU IV), or hCG (1,000 IU “1/2 IV, 1/2 IM”) can be used to attempt to induce ovulation or luteinization for diagnostic purposes; serum progesterone concentration is measured 2–3 weeks later. Note: pathologic ovarian tissue may not be responsive to either hormone.
- Serum progesterone (queen): ovulation and/or luteinization is stimulated most commonly by coital stimulation during behavioral estrus, and serum progesterone concentration is measured 2–3 weeks later; post-stimulation serum progesterone concentrations > 2 ng/mL are consistent with adequate coital stimulation and functional luteal tissue. GnRH (25 µg IM) can be used to attempt to induce ovulation or luteinization for diagnostic purposes; serum progesterone concentration is measured 2–3 weeks later. Pathologic ovarian tissue may not be responsive.
- Serum estradiol: peak levels triggering behavioral estrus range from 20 to > 70 pg/mL; serum estradiol concentrations are confirmatory to the diagnosis of ovarian remnant syndrome based on vaginal cytology.
- Luteinizing hormone assay (Witness LH, Zoetis): the LH assay should be positive (> 1 ng/mL) in a gonadectomized dog due to lack of pituitary feedback from a gonad. When a positive result is obtained, consider repeating in 24 hours to rule out detection of the 12–24h LH surge in an intact, estrual bitch (should have representative vaginal cytology with superficial cells predominating). If both are positive, then the dog has been gonadectomized. A negative test (< 1 ng/L) is found with intact dogs unless performed at the moment of the LH surge during estrus. The assay is licensed for use in the bitch, but

(CONTINUED)

OVARIAN REMNANT SYNDROME

likely is applicable in male dogs, toms and queens, provided that the queen is exposed to 14 hours of light/day. Note: exogenous estrogen exposure in a gonadectomized dog can cause the LH to become misleadingly negative.

- Anti-müllerian hormone (AMH) testing: A positive test in a bitch > 6 months of age supports the presence of ovarian tissue (SpayCheck®; offered by multiple endocrine laboratories in cases with a negative AMH but convincing clinical evidence supporting remnant syndrome. Some investigators advise obtaining a progesterone to identify persistent luteal structures lacking AMH).
- Cytology of vulvar discharge can be suppurative if a uterine stump granuloma or pyometra exists.
- Provocative adrenal testing (pre- and post-ACTH administration).

IMAGING

Ultrasonography

- Can be used to support a diagnosis of ovarian remnant syndrome that is based on cytology and hormonal profiles.
- Remnant ovarian tissue may be visible only during the follicular phase (anechoic, cystic structures) or the luteal phase (hypo or isoechoic cystic structures).
- Ultrasonographic imaging of ectopic ovarian tissue requires technical expertise and is best accomplished with a higher frequency, linear transducer (8–10 mHz). Ovarian remnants containing follicular or luteal structures often cause distal enhancement due to their fluid content; this can be used to locate them caudolateral to the ipsilateral kidney (Web Figure 1).
- Evaluate the region dorsal to the bladder for a uterine remnant, which can enlarge under hormonal influence or with pathology. (Web Figures 2a, 2b).
- Evaluate the adrenal glands for normal size and shape. Normal canine adrenal glands are < 0.51–0.74 cm in sagittal (Web Figures 3, 4).

DIAGNOSTIC PROCEDURES

- Exploratory laparotomy—removal of residual ovarian tissue confirms and resolves the problem.
- Identification of residual ovarian tissue is facilitated by the presence of follicles or corpora lutea; schedule procedure during times of elevated progesterone or during behavioral estrus. Unlike a routine ovariohysterectomy, this laparotomy is facilitated by hormone influence.

- Histopathology—always submit visible ovarian tissue; if no visible ovarian tissue is identified, submit all residual tissue at the ovarian pedicles. This helps confirm the diagnosis and screens for malignancy. Submit revised uterine stump tissue for aerobic and anaerobic cultures and histopathology (hormone influence, inflammatory response, malignancy).

TREATMENT

- Referral to a board-certified surgeon should be considered.
- Surgical removal of residual ovarian tissue.
- Surgical removal of significantly diseased uterine stump.
- Although not curative, restricting light exposure to < 8 hours per day can suppress signs of estrus in some, but not all, cats with ovarian tissue.

MEDICATIONS

DRUG(S)

- Progestational or androgenic compounds to suppress follicular ovarian activity—not recommended because of undesirable side effects (mammary neoplasia, diabetes, undesirable behavior, hepatopathy, dermatopathy).
- Immunocontraception or GnRH agonist (Suprelorin, Peptech Animal Health Pty Limited, Australia; Virbac, Vienna) administration will offer a viable alternative or adjunctive therapy to laparotomy when perfected and commercially available in the United States.

FOLLOW-UP

POSSIBLE COMPLICATIONS

- Removal of functional luteal tissue may induce transient signs of pseudopregnancy in dogs and cats postoperatively (see False Pregnancy).
- The use of oral antiprogestin agents (cabergoline) can be considered for pseudopregnancy.

EXPECTED COURSE AND PROGNOSIS

- Successful removal of remnant ovarian tissue should result in cessation of clinical signs of estrus/diestrus.
- Adjunctive therapy for pyometra (systemic antibiotics, supportive care) as indicated.
- Adjunctive therapy for functional ovarian neoplasia as indicated.

OVARIAN TUMORS

BASICS

OVERVIEW

- Epithelial (carcinoma), germ cell (dysgerminoma and teratoma), and sex cord stromal (granulosa cell tumor, Sertoli-Leydig cell tumor, thecoma, and luteoma) tumors.
- Dogs—rare (0.5–1.2% of tumors); 40% carcinomas, 10% germ cell, and 50% sex cord.
- Cats—rare (0.7–3.6% of tumors); 15% germ cell, and 85% sex cord.
- Metastasis common for malignant epithelial and germ cell tumors in the dog and all tumors in cats.
- Some tumors produce hormones resulting in paraneoplastic syndrome.

SIGNALMENT

- Dog and cat
- Middle-aged to old animals
- Teratoma develops in young patients

SIGNS

- Bilaterally symmetrical alopecia; pancytopenia; masculinization (hormone-secreting tumors)
- Malignant ascites or pleural effusion—occasionally
- Other signs associated with mass effects of the tumor

CAUSES & RISK FACTORS

- Intact sexual status
- Dogs: pointer, English bulldog, boxer, German shepherds and Yorkshire terrier at risk

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of abdominal effusion including vasculitis and pancreatitis.
- Other mid-abdominal masses
- Ovarian cysts, paraovarian cysts, cystic rete tubules, vascular hematomas, metastatic neoplasia

CBC/BIOCHEMISTRY/URINALYSIS

- No consistent abnormalities
- Pancytopenia in dogs with functional tumors

OTHER LABORATORY TESTS

Serum progesterone—levels > 2 mg/mL with functional tumors

IMAGING

- Abdominal radiography—may reveal unilateral or bilateral mid-abdominal mass at the caudal pole of the kidney or effusion, mineralization of tumor may be seen.
- Abdominal ultrasonography—confirm abdominal radiographic findings and provide greater certainty for the origin of mass effect.
- Advanced imaging—CT or MRI can provide detailed assessment for origin and associated tissues that might be involved in disease process.
- Thoracic radiography—may reveal distant metastasis.

DIAGNOSTIC PROCEDURES

- Cytologic evaluation of pleural or abdominal fluid—may be diagnostic for malignant effusion.
- Cytologic evaluation of tumor—tumor cells may readily implant on the body wall via fine-needle aspirate. Therefore, excisional biopsy is often recommended over fine-needle aspirate of the mass.
- Histopathologic examination—necessary for definitive diagnosis.

TREATMENT

- Ovariohysterectomy—treatment of choice for a solitary mass.
- Peritoneal transplantation during surgical removal is possible; change gloves and surgical instruments during procedure.

MEDICATIONS

DRUG(S)

- Chemotherapy—little information for dogs and cats, no standard therapy.
- Cyclophosphamide, chlorambucil, lomustine, and bleomycin—successful treatment in one patient (dog).
- Cisplatin—successful treatment reported in three dogs.

CONTRAINdications/POSSIBLE INTERACTIONS

- Cisplatin—do not use in dogs with renal disease; do not use without appropriate and concurrent diuresis; do not use in cats (fatal).
- Chemotherapy may be toxic; seek advice if unfamiliar with these agents.

FOLLOW-UP

- Abdominal and thoracic radiography—every 3 months; monitor for recurrence and metastasis.
- Ovariohysterectomy—prevention.
- Prognosis—guarded.
- Chemotherapy—has potential to lengthen survival.

ASSOCIATED CONDITIONS

- Pyometra
- Ovarian cysts
- Cystic endometrial hyperplasia
- Ovarian remnant syndrome

OVULATORY FAILURE

BASICS

OVERVIEW

- Ovulatory failure is a breakdown in the process of the release of oocytes from follicles with resultant corpus luteum formation and progesterone production.
- Ovulatory failure may present with nymphomania or prolonged anestrus.
- Bitches with nymphomania, decreased interestrous interval, have prolonged estrogen production and may present with signs of estrogen toxicity, including dermatologic or hematologic abnormalities.

SIGNALMENT

- Intact bitch or queen of any age, but there is a greater predisposition in older females.
- Ovulatory failure is reported in 1.2% of bitches presented for breeding management.
- No reported breed predisposition for anovulation; follicular cysts reported more commonly in Malamute, German shepherd, golden retriever, Bouvier des Flandres, and Labrador retriever.
- Heritability unknown.

SIGNS

- Prolonged proestrus or estrus
- Edematous vulva
- Sanguineous vulvar discharge (bitch)
- Nymphomania
- Anestrus
- Decreased interestrous interval
- Bilaterally symmetrical alopecia (progressive, non-pruritic)
- If neoplasia: enlarged abdomen ± palpable cranial-midabdominal mass ± ascites
- If chromosome abnormality: genitalia ranges from infantile or ambiguous to normal to enlarged clitoris or os clitoris; small stature; anestrus

CAUSES & RISK FACTORS

- Failure of release of gonadotropin-releasing hormone or luteinizing hormone from the hypothalamus or pituitary, respectively.
- Failure of receptors on the follicular wall to respond to LH.
- Failure of the follicles to produce adequate estrogen to illicit a surge in GnRH.
- Functional follicular cysts: may mimic a normal estrous cycle initially, but estrus persists and ovulation does not occur.
- Immune-mediated oophoritis.
- Cachexia or obesity.
- Stress (performance, travel, kennel).
- Addison's disease.
- Cushing's disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Prolonged proestrus (up to 30 days) or estrus (up to 30 days).
- Split heat: the anovulatory cycle will be followed by a normal, fertile, ovulatory cycle in 1–8 weeks.
- Hypoluteoidism.
- Granulosa cell tumor or serous cystadenoma: ± palpable abdominal mass; enlarged ovary on ultrasound, often

with a honeycomb appearance; ± ascites; ± bilaterally symmetrical alopecia, hyperpigmentation, lichenification if endocrinologically functional.

- Ovarian senescence.
- Immune-mediated oophoritis
- Chromosomal abnormality: intersex, hermaphrodites, pseudohermaphrodites, chimeras, mosaics may develop follicles that either go on to ovulate or simply regress.
- Exogenous estrogen administration or exposure.

CBC/BIOCHEMISTRY/URINALYSIS

If estrogen toxicity exists: normochromic, normocytic anemia; thrombocytopenia; initial leukocytosis followed by leukopenia

OTHER LABORATORY TESTS

- Progesterone < 4–10 ng/mL over multiple samplings once vaginal cytology exceeds 70% anucleated superficial cells. It often hovers around 3–5 ng/mL for a prolonged period of time and never exceeds 10–12 ng/mL.
- Karyotyping is indicated in cases of suspected chromosomal abnormality.

IMAGING

• Radiology may be beneficial if an ovarian mass is present. A large soft tissue density may be noted mid-abdomen. If ascites is present, a loss of general abdominal detail or ground glass appearance may be present.

• Ultrasonography is extremely helpful to evaluate ovarian structures: multiple anechoic structures on the ovary may be considered follicles; anechoic structures > 1 cm are considered cystic; enlarged ovaries may be neoplastic; anechoic structures with thickened walls may indicate luteinization (partial or complete) of follicular structures; serial (daily) ultrasonography is necessary to document ovulation; use of color doppler to assess ovarian follicular blood flow (increased with follicles, minimal with luteal structures).

DIAGNOSTIC PROCEDURES

Exploratory laparotomy to examine the ovaries or to obtain ovarian biopsies: the ovarian bursa must be opened to visualize the ovary.

TREATMENT

MEDICATIONS

DRUG(S)

- Ovulation induction may be attempted once cytology reaches > 70% anucleated cells and follicles are > 4–5 mm (toy to small-breed canine), 5–7 mm (medium to large-breed canine), 7–10 mm (giant-breed canine), or 2–3 mm (feline).
- Ovulation-inducing agents: GnRH 1.1–2.2 µg/kg IM or IV or 25 µg/cat IM. May repeat daily for 1–3 days in bitches, single dose for queens; hCG

500–1,000 IU/dog IM or 500 IU/queen IM, may repeat in 2–3 days if ovulation does not occur; GnRH and hCG may be given concurrently; deslorelin implant (2.1 mg implant; Ovuplant®) placed in the mucosa of the vulvar lip using a lidocaine block and removed with a similar block and sharp dissection, remove implant once ovulation is documented (progesterone > 10 ng/mL); cervical stimulation in queens, may be performed starting at the time of initial induction medication and repeated several times daily for 24–48 hours.

FOLLOW-UP

- Monitoring of progesterone concentrations during pregnancy is advised as luteal failure or hypoluteoidism are more common with induced ovulation.
- Progesterone should be monitored after induction medications are administered to confirm a normal rise in progesterone.
- Serial ultrasound examinations (using color doppler) may be useful to document ovulation.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Bilaterally symmetrically non-pruritic alopecia with significantly prolonged estrus.

PREGNANCY/FERTILITY/BREEDING

- Depending on etiology, anovulation may be hereditary; discuss with owner prior to breeding.
- The cycle after an anovulatory cycle may be normal, necessitating no treatments.

SEE ALSO

- Infertility, Female—Dogs
- Sexual Development Disorders

ABBREVIATIONS

- GnRH = gonadotropin-releasing hormone
- hCG = human chorionic gonadotropin
- LH = luteinizing hormone

PAIN (ACUTE, CHRONIC, AND POSTOPERATIVE)

BASICS

DEFINITION

- Unpleasant sensory or emotional experience associated with actual or potential tissue damage (adaptive pain) or altered sensory neurobiology (chronic pain).
- The inability for the animal to communicate does not negate presence of pain and the need for appropriate pain-relieving treatment.

PATHOPHYSIOLOGY

- With physiologic pain, an application of a noxious stimulus activates specialized nerve endings called nociceptors; nociceptors transduce noxious chemical, mechanical, or thermal stimuli into electrochemical potentials that are transmitted via sensory nerves, from the affected tissue to the spinal cord.
- In the dorsal horn of the spinal cord, the incoming first-order peripheral nerve synapses with ascending spinal neurons, which terminate in the brainstem. Incoming noxious information can be modulated in the dorsal horn by other incoming information, descending inhibitory nerve impulses, or pharmacologic inhibition by several classes of drugs. The ascending neurons synapse in the brainstem to form ascending tracts that end in the cortex, where sensation occurs.
- Neuroendocrine and physiologic responses (e.g., tachycardia, elevated cortisol) to noxious stimuli may originate from the brainstem and do not necessarily correlate with the perceived intensity of pain.
- Nociceptive processes (i.e., transduction, transmission, and modulation) appear to be similar anatomically and physiologically in most mammalian and many non-mammalian species. The perception of pain may vary between species and individuals of the same species since anatomic differences in cortical development exist and integration of past experiences and learned behaviors varies.
- Prolonged activity in nociceptive pathways (e.g., days, weeks, or months) from chronic injury or disease, or injury to nervous system tissues, may cause altered neuroprocessing resulting in sensitization of these pathways and hyper-responsiveness. This may cause an increased response to a stimulus not normally considered noxious (allodynia).

SYSTEMS AFFECTED

- Pain may originate from any tissue, including the nervous system itself. In humans, certain pain syndromes may be associated with fear, anxiety, or depression in the absence of any observable injury.
- The physiologic response to pain can include decreased immune function, increased catabolism, and elevated neuroendocrine markers of stress. Pain can result in a loss of function of affected tissues.

GENETICS

Age, sex, breeding strain, and species can influence responses to noxious stimuli. Genes have been described that modify individual behavioral responses to noxious stimuli in several species. Genes may also be variably expressed depending on stimulus intensity and duration, which can lead to altered neuroprocessing and maladaptive or chronic pain.

INCIDENCE/PREVALENCE

- Evolutionarily, aversion to noxious stimuli was protective to organisms, keeping them away from harm.
- While acute pain is beneficial to warn or teach an animal about potential harmful objects in its environment, persistent acute pain associated with surgery or injury does not benefit the patient and should be treated appropriately.
- Any form of chronic pain syndrome does not serve a protective function and should be treated.

SIGNS

- Behavioral signs of pain and distress vary considerably among individuals.
- Experience, environment, age, species, and other factors can modify the intensity of the reaction to noxious stimuli or to an altered neurobiology associated with maladaptive or chronic pain.
- The most obvious clinical signs of distress in the dog and cat can include vocalization, agitation, abnormal posture or gait, thrashing, hyperesthesia or hyperalgesia.
- More subtle signs shared by many conditions include trembling, lethargy, reduced appetite, stupor, and biting.
- Tachypnea, tachycardia, mydriasis, and hypertension are signs observed with the stress response that may also accompany pain; these are nonspecific and present in many

non-painful conditions. The stress response is often not associated with chronic pain due to adaptation.

- Clinical signs associated with chronically painful conditions may be very subtle or difficult to evaluate since homeostatic mechanisms tend to help the animal compensate. Chronically painful conditions are often associated with decreased activity, lameness, and/or depression.

CAUSES

- Physiologic or adaptive pain can be caused by perceived or actual tissue disruption associated with trauma or surgery and also by chronic degenerative changes and inflammation associated with conditions such as osteoarthritis.
- Pain that extends beyond the initial tissue damage and healing processes is pathologic (maladaptive) and may indicate that the initiation of altered nervous system processing has occurred.

RISK FACTORS

- All animals that experience surgical or traumatic tissue damage or have recently altered behavior should be evaluated for the presence of pain.
- Due to the increasing prevalence of degenerative diseases in older patients, routine examination should include evaluation for pain.
- Pain intensity may not always correlate with the degree of tissue damage. However, more invasive soft tissue and orthopedic procedures or inflammatory disease progression in older patients are likely associated with greater pain.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Identifying pain in veterinary patients is a diagnosis, and the medical record should reflect the veterinarian's clinical diagnostic and treatment plan.
- Acute pain is almost always accompanied by tissue damage or disease, and diagnosis and treatment of the primary disorder should be done before or concomitantly with treatment of pain. The presence or absence of pain is sometimes used as a way of monitoring and diagnosing some conditions, and treatment should be in accordance with good medical

(CONTINUED)

PAIN (ACUTE, CHRONIC, AND POSTOPERATIVE)

practice. Pain should be differentiated from distress associated with other factors, such as restraint, restrictive bandaging, and separation from owners. Drugs used to treat pain, particularly opioids and dissociative anesthetics, may cause dysphoria, which often resembles and can be confused with signs of pain and distress.

CBC/BIOCHEMISTRY/URINALYSIS

- Cortisol release associated with acute pain may appear as a stress leukogram.
- Hyperglycemia may also be observed in some patients, but can also be seen with anesthesia in the absence of tissue trauma.
- Normal laboratory test values do not rule out the presence of pain.

OTHER LABORATORY TESTS

N/A

IMAGING

- Many painful patients have underlying changes in anatomic structures observable on ultrasound, radiography, computed tomography or magnetic resonance imaging.
- Chronic pathologic tissue changes such as the degree of osteophyte formation with osteoarthritis do not necessarily always correlate with the degree of pain and dysfunction experienced by the patient. Some patients can be painful without observable tissue or structural changes.

DIAGNOSTIC PROCEDURES

- Perform a thorough diagnostic evaluation for an underlying condition (e.g., ruptured cruciate ligament) when an animal appears painful. If an underlying condition is diagnosed it should be treated appropriately. Pain is most commonly caused by an underlying medical or surgical condition that when properly treated will eventually alleviate pain associated with the abnormality.
- Begin evaluation of pain with the signalment, history, and physical examination. Next, the animal's behavior is observed from a distance, and then behavior is noted during human interaction. Finally, gentle palpation of the body region of interest is performed, if necessary, to determine the animal's response.
- When analgesics are administered, the process should be repeated periodically to assess effectiveness. Do not assume administration of an analgesic will result in acceptable relief of pain.

- Complete abolition of pain may not be possible or desirable if analgesic administration results in excessive adverse effects. Therapy should aim to make pain tolerable.

TREATMENT

APPROPRIATE HEALTH CARE

- Analgesic drug selection depends on species, pain intensity, and underlying cause.
- Treat the underlying cause at the same time if possible.
- Acupuncture, prescribed activity (e.g., physical therapy), mesenchymal stromal cell or platelet-rich plasma injection, and physical manipulation (massage, trigger point manipulation, chiropractic) may be useful adjunctive treatment modalities for certain types of painful musculoskeletal conditions.
- If the patient's quality of life is not acceptable after all reasonable therapeutic options have been explored, euthanasia may be the most humane option.

NURSING CARE

- General good nursing practices.
- Non-pharmacologic, including bandaging and hydrotherapy, may be appropriate.

ACTIVITY

- Rehabilitation medicine and weight loss is a useful adjunct for some musculoskeletal conditions.
- Cage rest or limited activity may be useful for certain types of pain.

DIET

- Dietary changes to help treat the underlying condition (e.g., weight reduction for hip dysplasia) may be beneficial.
- Many supplements and nutriceuticals have been marketed that may have beneficial effects on articular cartilage or modify inflammatory disease progression.
- Commercial veterinary diets are marketed specifically for animals with mobility issues.

CLIENT EDUCATION

- When pain medication is dispensed, educate the client on what to look for with effective treatment, as well as adverse effects.
- Inform the client that analgesic effectiveness varies and several drugs may need to be tried

before an effective treatment is found. Pain management must be individualized because of the neurobiologic complexity of pain perception.

- Clients should be asked to participate in evaluation of their pet's pain, especially chronic pain. Simplified assessment tools for both acute and chronic pain in dogs and acute pain in cats are now available and can help document treatment effectiveness.

SURGICAL CONSIDERATIONS

- Surgical treatment of the underlying condition causing pain may be the best treatment in some circumstances.
- Ablative procedures (neurectomy) to halt pain transmission is not always associated with positive results and may result in worsening of the painful condition. These procedures are rarely performed in veterinary patients.

MEDICATIONS

DRUG(S) OF CHOICE (SEE APPENDIX VII)

- Opioids, alone or in combination with other classes of drugs, such as sedative/tranquilizers or NSAIDs, are widely used for the management of acute postoperative pain. Full μ -opioid receptor agonists, such as morphine, hydromorphone, and fentanyl, are usually effective for moderate to severe pain. Partial agonist or agonist-antagonist drugs, such as buprenorphine and butorphanol, are usually reserved for mild to moderate pain. Opioids generally have poor oral bioavailability, and oral doses should be adjusted accordingly. Full μ -opioid receptor agonists can be used safely in cats. However, doses are usually reduced relative to dog doses. Should dysphoria develop, tranquilization with an α_2 -agonist or acepromazine may be beneficial.
- NSAIDs are used most commonly for the chronic treatment of painful conditions in dogs. NSAIDs can be safe when administered chronically, but gastrointestinal, hepatic and renal adverse effects are possible. The best strategy appears to be reducing the dose to the lowest effective dose in an individual. If chronic administration is anticipated serum chemistries should be considered to monitor for hepatic and renal adverse effects.

PAIN (ACUTE, CHRONIC, AND POSTOPERATIVE)

(CONTINUED)

• Most NSAIDs have not been approved for cats (exceptions include robenecoxib and meloxicam in the US and ketoprofen, carprofen, and tolfenamic acid in Canada and Europe). Additional information is available for many drugs and should be referred to when considering extra-label use. Owners should be informed of the risks of analgesic drug therapy in their pet before consenting to treatment.

• Treatment of neuropathic pain is a subcategory of pathologic pain. It may originate from brain or spinal masses, injury (such as with intervertebral disc disease), inflammation, or the repetitive stimulation of the pain transmission system by a chronic injury outside the central nervous system. Classic signs that accompany neuropathic pain are allodynia and hyperalgesia. Neuropathic pain does not always respond well to traditional analgesics, such as NSAIDs and opioids, although these drugs are usually tried initially (except for NSAIDs when neurosurgery is imminent). Tricyclic antidepressants, antiepileptic drugs (e.g., gabapentin), *N*-methyl-d-aspartate (NMDA) receptor antagonists, and other alternative (complementary) therapies may be effective. Most of these treatments consist of extra- or off-label use of human medications and require careful client communication and approval.

CONTRAINDICATIONS

• Opioids may be associated with severe respiratory depression in human patients, but in most dogs and cats cause only minimal respiratory depression. In patients with severe respiratory compromise or intracranial hypertension, opioids may be contraindicated. Most μ -opioid receptor agonists can also alter gastrointestinal and urinary tract motility, resulting in constipation, urinary retention, and vomiting.

• NSAIDs can cause gastrointestinal ulceration, hepatopathies, and impaired renal function. Preexisting gastrointestinal, hepatic, or renal disease may be a contraindication to their use. Concomitant glucocorticoid therapy, severe stress, or anorexia may predispose many animals to adverse effects. NSAIDs that significantly inhibit cyclooxygenase (COX-1) may also alter platelet function and may result in increased

surgical blood loss. Acetaminophen or acetaminophen-containing analgesics should not be used in cats.

PRECAUTIONS

- Carefully monitor patients for adverse effects and clinical effectiveness following administration of analgesic drugs.
- Opioid-induced hyperthermia has been reported in feline patients, most commonly after fentanyl patch application or hydromorphone administration.
- Opioid administration may result in altered gastrointestinal motility (constipation), inappetence, and urine retention. These signs usually appear soon after initiation of opioid therapy and should resolve within 12–36 hours of stopping opioid administration. In the interim supportive care such as passing a urinary catheter may be necessary.
- In consultation with the pet owner, the veterinarian may feel the need to prescribe NSAIDs to a particular patient even if the risk for adverse events is deemed increased due to disease or preexisting conditions. The veterinarian should strive to ethically balance the long-term therapeutic risk of drugs such as NSAIDs against the benefit of improved quality of life.

POSSIBLE INTERACTIONS

- Opioids can reduce the anesthetic requirements for most species, especially when combined with α_2 -agonists or acepromazine as a premedication before anesthesia. In humans the combination of certain opioids such as meperidine with serotonin altering drugs may result in toxicity (e.g., l-deprenyl, amitriptyline, tramadol, trazadone) and are occasionally prescribed to veterinary patients.
- Concurrent glucocorticoid therapy may enhance NSAID toxicity.
- Other drugs that predispose animals to gastrointestinal or renal impairment, such as aminoglycoside antimicrobials, should be used with caution when NSAIDs are also being administered.

ALTERNATIVE DRUG(S)

- Adjunctive analgesic drugs (e.g., gabapentin, amantadine, amitriptyline, tramadol) may be beneficial for patients that have altered neuroprocessing associated with chronic disease changes or nervous system

injury. To select and administer an adjuvant analgesic properly, the veterinarian should be aware of the drug's clinical pharmacology. The following information about the drug is necessary: (1) approved indication, (2) unapproved indication (e.g., as an analgesic) widely accepted in veterinary medical practice, (3) common side effects and potentially serious adverse effects, (4) pharmacokinetic features, and (5) specific dosing guidelines for pain (see Appendix VII).

- Non-traditional medical treatments are common, but should be evaluated for safety and effectiveness before recommendation.
- Regenerative medicine (i.e., mesenchymal stromal cell therapy) has become more common. The effectiveness of many therapies used for chronic painful conditions appears to be unpredictable, but in a small number of patients the results can be life-altering.

FOLLOW-UP

PATIENT MONITORING

- Frequent evaluation of analgesic drug effectiveness should be performed.
- Patients receiving chronic analgesic medication, especially NSAIDs, should be evaluated periodically to monitor gastrointestinal, liver, and renal function.
- It is the responsibility of the veterinarian to ensure that the information about the effects of prescribed drugs is disseminated to clients.

PREVENTION/AVOIDANCE

Although some degree of pain is usually an unavoidable consequence of surgery or trauma, when possible, the preemptive administration of analgesic drugs may provide better pain control and reduce the potential for central nervous system wind-up. Use of proper anesthetic techniques incorporating analgesic premedications and local and regional analgesic techniques where appropriate, are effective ways of practicing preemptive analgesia.

EXPECTED COURSE AND PROGNOSIS

Acute pain associated with surgery or trauma usually resolves with tissue healing. Opioids may be most effective for the 12–24 hours

(CONTINUED)

PAIN (ACUTE, CHRONIC, AND POSTOPERATIVE)

following surgery, whereas NSAIDs may be better after that period. Some NSAIDs are effective analgesics immediately after surgery. When pain signs persist beyond the normal course of a few days to weeks, suspect persistent disease, injury, or central nervous system changes and consult an anesthesiologist or a board-certified specialist trained in pain management for suggestions about appropriate therapy.

**MISCELLANEOUS****PREGNANCY/FERTILITY/BREEDING**

- Opioids may cause fetal respiratory depression following delivery. NSAIDs may alter maternal or fetal prostaglandin production, resulting in pregnancy complications.

- The effects on the fetus of many of the analgesic drugs approved for use in dogs and cats are not widely reported.

ABBREVIATIONS

- COX = cyclooxygenase
- NMDA = *N*-methyl-d-aspartate
- NSAID = nonsteroidal anti-inflammatory drug

PANCREATITIS—CATS

BASICS

DEFINITION

• Inflammation of the pancreas most often of unknown cause(s). • Acute pancreatitis— inflammation of the pancreas that occurs abruptly with little or no permanent pathologic change. • Chronic pancreatitis— continuing inflammatory disease that is accompanied by irreversible morphologic change such as fibrosis.

PATHOPHYSIOLOGY

• Host defense mechanisms normally prevent pancreatic autodigestion by pancreatic enzymes, but under select circumstances, these natural defenses fail; autodigestion occurs when these digestive enzymes are activated within acinar cells. • Local and systemic tissue injury is due to the activity of released pancreatic enzymes and a variety of inflammatory mediators such as kinins, free radicals, and complement factors are released by infiltrating neutrophils and macrophages. The most common pathologies involving the feline pancreas include acute necrotizing pancreatitis (ANP) and acute suppurative pancreatitis.

SYSTEMS AFFECTED

• Gastrointestinal—altered GI motility (ileus) due to regional chemical peritonitis; local or generalized peritonitis due to enhanced vascular permeability; concurrent inflammatory bowel disease may be seen in some cats. • Hepatobiliary—lesions due to shock, pancreatic enzyme injury, inflammatory cellular infiltrates, hepatic lipidosis, and intra/extrahepatic cholestasis. Feline gastrointestinal inflammatory disease (concurrent cholangitis ± inflammatory bowel disease) may be seen in some cats. • Respiratory—pulmonary edema or pleural effusion. • Cardiovascular—cardiac arrhythmias may result from release of myocardial depressant factor. • Hematologic—activation of the coagulation cascade and systemic consumptive coagulopathy (DIC) occur.

GENETICS

No genetic basis for disease pathogenesis in cats has been identified.

INCIDENCE/PREVALENCE

• True prevalence is unknown but is a relatively common clinical disorder in cats. • Necropsy surveys suggest an increased prevalence in cats with cholangitis, and inflammatory bowel disease. The unique feline pancreaticobiliary anatomy and intestinal microbiota likely contribute to multi-organ inflammatory disease in this species.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Cat of any age

Breed Predilections

Siamese cats

Mean Age and Range

Mean age for acute pancreatitis is 7.3 years.

Predominant Sex

None

SIGNS

General Comments

Vague, nonspecific, and nonlocalizing signs. Anorexia, lethargy, and vomiting are reported most frequently.

Historical Findings

- Lethargy/anorexia
- Vomiting
- Weakness
- Abdominal pain
- Diarrhea – small bowel and large bowel diarrhea and fever are less common in cats than dogs

Physical Examination Findings

- Severe lethargy.
- Dehydration—common; due to GI losses.
- Abdominal pain—may adopt a “prayer position” and/or resist abdominal palpation. Abdominal pain is recognized much less frequently in cats compared to dogs.
- Mass lesions may be palpable.
- Fever—Observed in 25% of cats.

CAUSES

Etiology is most often unknown; possibilities include:

- Hepatobiliary tract disease—both inflammatory and degenerative (hepatic lipidosis)
- Pancreatic trauma/ischemia
- Duodenal reflux
- Drugs/toxins (organophosphates)
- Pancreatic duct obstruction
- Hypercalcemia
- Inflammatory gastrointestinal disease
- Nutrition—excessive lean body mass is associated with ANP

RISK FACTORS

- Breed?
- Obesity?
- Organophosphate poisoning
- Concurrent hepatic/intestinal inflammatory disease
- See “Causes”

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of acute abdomen:

- GI disease (obstruction, foreign body, perforation, infectious gastroenteritis, ulcer disease)—exclude with CBC/biochemistry/urinalysis, diagnostic imaging, and paracentesis. Gastrointestinal or hepatic neoplasia—exclude with tissue biopsy.
- Urogenital disease (pyelonephritis, prostatitis or abscessation, pyometra, urinary tract rupture or obstruction, acute renal failure)—exclude with CBC/biochemistry/urinalysis, urine culture/sensitivity, and imaging.
- Hepatobiliary disease (cholangitis and EHBO) exclude with CBC/biochemistry/urinalysis, bile acids, imaging, and liver

biopsy.

- Abdominal neoplasia—exclude with imaging and cytology or biopsy.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—often reveals nonregenerative anemia (40%), leukocytosis (38%), and/or leukopenia (15%).
- Serum biochemistries—often show prerenal azotemia; liver enzyme activities (ALT, ALP) are often elevated because of hepatic ischemia or exposure to pancreatic enzymes; hyperbilirubinemia with intra/extrahepatic biliary obstruction; hyperglycemia with necrotizing pancreatitis due to hyperglucagonemia; hypoalbuminemia, hypercholesterolemia and hypertriglyceridemia are common.
- Hypocalcemia is more common in cats than dogs, and a low ionized calcium concentration is a negative prognostic indicator in cats.
- Urinalysis—increased urine SG associated with dehydration or can be unremarkable.

OTHER LABORATORY TESTS

- Serum amylase and lipase activities are unreliable serologic markers—may be elevated, but are nonspecific; can also increase with hepatic, renal, or neoplastic disease in the absence of pancreatitis.
- Serum pancreatic lipase immunoreactivity (fPL) is a highly sensitive and specific serologic marker of acute pancreatic inflammation. A cage-side fPL assay (SNAP fPL) has been developed as a useful screening tool. Elevation in SNAP fPL should be followed up by laboratory measurement of serum Spec fPL to quantitate the degree of elevation.

IMAGING

- Abdominal radiographs—may include increased soft tissue opacity in the right cranial abdominal compartment; loss of visceral detail (“ground glass appearance”) due to abdominal effusion; static gas pattern in the proximal duodenum.
- Abdominal ultrasound—nonhomogeneous solid or cystic mass lesions suggest pancreatic abscess; may be a pancreatic mass or altered echogenicity (hypoechoic) in the area of the pancreas; pancreas is usually enlarged with irregular borders, surrounding mesentery may be hyperechoic due to focal peritonitis, may see peritoneal effusion and extrahepatic biliary obstruction.
- fPL assay and pancreatic ultrasound in combination have the highest specificity for an antemortem diagnosis of acute pancreatitis.

DIAGNOSTIC PROCEDURES

- Ultrasound-guided needle-aspiration biopsy may confirm inflammation (cytology), abscess, or cyst.
- Laparoscopy with pancreatic forceps biopsy for histologic diagnosis.
- Histopathologic evaluation may miss focal or segmental pancreatic inflammation and results should be interpreted with caution.

PATHOLOGIC FINDINGS

- Gross findings (acute pancreatitis)—mild swelling with edematous pancreatitis.
- Gross

(CONTINUED)

findings (chronic pancreatitis)—pancreas is reduced in size, firm, gray, and irregular; may contain extensive adhesions to surrounding viscera. • Microscopic changes (acute pancreatitis)—include edema, parenchymal necrosis, hemorrhage, and neutrophilic cellular infiltrate with acute lesions. • Microscopic changes (chronic pancreatitis)—pancreatic fibrosis around ducts, ductal epithelial hyperplasia, atrophy, and mononuclear cellular infiltrate.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient medical management most often.
- Aggressive IV fluid therapy. • Fluid therapy goals—correct hypovolemia and maintain pancreatic microcirculation. • A balanced electrolyte solution such as lactated Ringer's solution (LRS) is the first-choice rehydration fluid. • Correct initial dehydration (mL = % dehydration × weight in kg × 1,000) and give over 4–6 hours. • May need colloids (oxyglobin, hetastarch) to improve pancreatic circulatory needs and prevent ischemia.
- Following replacement of deficits, give additional fluids to match maintenance requirements (2.5 × weight in kg) and ongoing losses (estimated). • Potassium chloride (KCl) supplementation usually needed because of potassium loss in the vomitus; base potassium supplementation on measured serum levels (use 20 mEq of KCl/L of IV fluid if serum potassium levels are not known; do not administer faster than 0.5 mEq/kg/h).

ACTIVITY

Restrict

DIET

- Continue to feed orally unless vomiting is intractable; feeding maintains intestinal epithelial integrity and minimizes bacterial translocation. • Initiate enteral feeding via esophagostomy, gastrostomy enteral feeding device, or nasoesophageal tube placement.
- NPO in animals with persistent vomiting for the shortest time possible; when there has been no vomiting for 12 hours, offer small volumes of water; if tolerated, begin small, frequent feedings of a diet that does not contain excessive amounts of dietary fat. Most nutritionists agree that excessive dietary fat restriction is not necessary in cats with pancreatitis.

CLIENT EDUCATION

- Discuss the need for extended hospitalization. • Discuss the expense of diagnosis and treatment. • Discuss possible short-term and long-term complications (see "Associated Conditions").

SURGICAL CONSIDERATIONS

- May need surgery to remove pseudocysts, abscesses, or devitalized tissue seen with necrotizing pancreatitis. • May need laparotomy and pancreatic biopsy to confirm pancreatitis and/or rule out other, nonpancreatic diseases such as hepatic cholangitis, lipidosis, and/or IBD.
- Extrahepatic biliary obstruction from pancreatitis requires ductal decompression with surgical correction.

MEDICATIONS

DRUG(S)

- Animals with intermittent vomiting should be treated with antiemetics—chlorpromazine (0.2–0.4 mg/kg IM or SC q8h) or ondansetron (0.1–0.2 mg/kg IV q12h) are reasonable first-choice options. Maropitant (Cerenia) is approved for parenteral administration in cats older than 16 weeks and is given IV at 1 mg/kg q24h for 5–7 consecutive days. • Antibiotics if evidence of sepsis from bacterial translocation and to prevent pancreatic infection—cefotaxime (50 mg/kg IM q8h). • Analgesics to relieve abdominal pain, e.g., butorphanol (0.2–0.4 mg/kg SC q6h), buprenorphine (0.01–0.02 mg/kg IM, IV, or SC q6–12h) or fentanyl CRI (2–4 µg/kg/h) as needed.

CONTRAINdications

- Anticholinergics (e.g., atropine)
- Azathioprine • Chlorothiazide • Estrogens
- Furosemide • Tetracycline • L-asparaginase

PRECAUTIONS

Only use antibiotics if a clear clinical condition exists, such as infection.

FOLLOW-UP

PATIENT MONITORING

- Evaluate hydration status closely during first 24 hours of therapy; twice daily check physical examination, body weight, hematocrit, total plasma protein, BUN, and urine output. Evaluate the effectiveness of fluid therapy after 24 hours and adjust flow rates and fluid composition accordingly; repeat biochemistries to assess electrolyte/acid-base status. • Watch closely for systemic complications involving a variety of organ systems; perform appropriate diagnostic tests as needed (see "Associated Conditions").
- Gradually taper fluids down to maintenance requirements if possible. Maintain oral alimentation or enteral nutrition as described above, being careful to feed diets that do not contain excessive amounts of dietary fat.
- Monitor for clinical evidence of IBD and treat accordingly. • Monitor for progression to diabetes mellitus, exocrine pancreatic

PANCREATITIS—CATS

insufficiency (EPI), and/or hepatic lipidosis in cats with ANP.

PREVENTION/AVOIDANCE

- Weight reduction if obese • Avoid high-fat diets

POSSIBLE COMPLICATIONS

- Failed response to supportive therapy.
- Life-threatening associated conditions such as EPI, diabetes mellitus, and hepatic lipidosis. • Progression of acute pancreatitis to chronic pancreatitis.

EXPECTED COURSE AND PROGNOSIS

- Guarded for most patients with ANP; cats with multi-organ inflammation may be less responsive to treatment. • More guarded to poor for patients with severe necrotizing pancreatitis, decreased ionized calcium fraction, and systemic conditions.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Life-Threatening

- Pulmonary edema (e.g., adult respiratory distress syndrome) • Cardiac arrhythmias
- Peritonitis • DIC

Non-Life-Threatening

- Diabetes mellitus • EPI • Chronic pancreatitis • Cholangitis and hepatic lipidosis • Inflammatory bowel disease

SEE ALSO

- Acute Abdomen • Cholangitis/Cholangiohepatitis Syndrome • Exocrine Pancreatic Insufficiency • Inflammatory Bowel Disease

ABBREVIATIONS

- ALP = alkaline phosphatase • ALT = alanine aminotransferase • ANP = acute necrotizing pancreatitis • DIC = disseminated intravascular coagulation
- EHBO = extrahepatic biliary obstruction
- EPI = exocrine pancreatic insufficiency
- FPL = feline pancreatic lipase immunoreactivity • GI = gastrointestinal
- IBD = inflammatory bowel disease
- NPO = nothing per os

PANCREATITIS—DOGS

BASICS

DEFINITION

- Inflammation of the pancreas most often of unknown cause(s). Acute pancreatitis— inflammation of the pancreas that occurs abruptly with little or no permanent pathologic change. Chronic pancreatitis— continuing inflammatory disease that is accompanied by irreversible morphologic change such as fibrosis and atrophy.

PATHOPHYSIOLOGY

- Local and systemic tissue injury is due to the activity of released pancreatic enzymes and a variety of inflammatory mediators such as kinins, free radicals, and complement factors are released by infiltrating neutrophils and macrophages.

SYSTEMS AFFECTED

- Gastrointestinal—altered GI motility (ileus) due to regional chemical peritonitis; local or generalized peritonitis due to enhanced vascular permeability.
- Hepatobiliary—lesions due to shock, pancreatic enzyme injury, inflammatory cellular infiltrates, hepatic lipidosis, and intra/extrahepatic cholestasis.
- Respiratory—pulmonary edema or pleural effusion; adult respiratory distress syndrome is an uncommon but potentially fatal sequela with systemic complications.
- Cardiovascular—cardiac arrhythmias may result from release of myocardial depressant factor.
- Hematologic—activation of the coagulation cascade and systemic consumptive coagulopathy (DIC) occur.

GENETICS

Possible genetic basis in miniature schnauzers where select mutations in the *SPINK1* gene may confer increased susceptibility.

INCIDENCE/PREVALENCE

- True prevalence is unknown but a relatively common clinical disorder.
- Up to 1% of normal dogs may have histologic evidence of pancreatitis.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog of any age

Breed Predilections

- Miniature schnauzer • Yorkshire terrier
- Cocker spaniel

Mean Age and Range

Acute pancreatitis is most common in middle-aged and older (> 7 years) dogs; mean age at presentation is 6.5 years.

Predominant Sex

Female

SIGNS

General Comments

- Predominantly GI tract signs that are

nonlocalizing and abdominal pain. Dogs with chronic pancreatitis may not exhibit abdominal pain.

Historical Findings

- Lethargy/anorexia • Vomiting • Weakness
- Abdominal pain • Diarrhea—small or large bowel type

Physical Examination Findings

- Severe lethargy. • Dehydration—common; due to GI losses.
- Abdominal pain—may adopt a “prayer position” and/or resist abdominal palpation.
- Mass lesions may be palpable.
- Fever—common with more severe acute pancreatitis.
- Less common systemic abnormalities include respiratory distress, bleeding disorders, and cardiac arrhythmias.

CAUSES

Etiology is most often unknown; possibilities include:

- Nutritional factors (e.g., dietary indiscretion, hyperlipoproteinemia)
- Pancreatic trauma/ischemia • Duodenal reflux • Drugs/toxins (see “Contraindications”)
- Pancreatic duct obstruction • Hypercalcemia • Infectious agents—babesiosis

RISK FACTORS

- Breed (potential genetic predisposition—miniature schnauzers) • Obesity
- Concurrent disease (e.g., diabetes mellitus, hyperadrenocorticism, hypothyroidism, chronic renal failure, and neoplasia) • Recent drug administration (see “Contraindications”)
- See “Causes”

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of acute abdomen:

- GI disease (obstruction, foreign body, perforation, gastroenteritis, ulcer disease)—exclude with CBC/biochemistry/urinalysis, diagnostic imaging, and paracentesis.
- Splenic torsion—exclude with imaging.
- Hypoadrenocorticism—exclude with CBC/biochemistry/urinalysis, resting cortisol, ACTH stimulation test.
- Urogenital disease (pyelonephritis, prostatitis or abscessation, pyometra, urinary tract rupture or obstruction, acute renal failure)—exclude with CBC/biochemistry/urinalysis, urine culture/sensitivity, and imaging.
- Hepatobiliary disease—exclude with CBC/biochemistry/urinalysis, bile acids, ultrasound imaging, and liver biopsy.
- Abdominal neoplasia—exclude with ultrasound imaging and cytology or biopsy.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—acute pancreatitis often associated with hemoconcentration with increased PCV, leukocytosis with a left shift, and toxic neutrophils with severe inflammation; thrombocytopenia.
- Serum biochemistries—

often show prerenal azotemia; liver enzyme activities (ALT, ALP) are often increased because of hepatic ischemia or exposure to pancreatic toxins; hyperbilirubinemia with intra/extrahepatic biliary obstruction; electrolyte abnormalities associated with vomiting; hyperglycemia with necrotizing pancreatitis due to hyperglucagonemia; hypoalbuminemia; hypercholesterolemia and hypertriglyceridemia are common.

- Urinalysis—increased urine SG associated with dehydration. Urinalysis may show evidence of proteinuria or may be unremarkable.

OTHER LABORATORY TESTS

- Serum amylase and lipase activities are unreliable serologic markers—may be elevated but are nonspecific; also increase with hepatic, renal, or neoplastic disease in the absence of pancreatitis; dexamethasone may increase serum lipase concentrations in dogs.
- Serum pancreatic lipase immunoreactivity (cPL) is a highly sensitive and specific serologic marker of acute pancreatic inflammation, although is less sensitive for detecting chronic pancreatic inflammation. A cage-side cPL assay (SNAP cPL) has been developed as a useful screening tool. Elevation in SNAP cPL should be followed up by laboratory measurement of serum Spec cPL to obtain a quantitative value.

IMAGING

- Abdominal radiographs—may include increased soft tissue opacity in the right cranial abdominal compartment; loss of visceral detail (“ground glass appearance”) due to abdominal effusion; static gas pattern in the proximal duodenum; widened angle between pyloric antrum and proximal duodenum.
- Abdominal radiographs are a relatively insensitive diagnostic procedure for pancreatitis and are of greater value for helping to rule out other causes of chronic vomiting in the dog such as gastric or intestinal foreign bodies.
- Thoracic radiographs—may reveal mild pleural effusion or more severe pulmonary complications.
- Abdominal ultrasound—nonhomogeneous solid or cystic mass lesions suggest pancreatic abscess; pancreas is usually enlarged with an irregular border, may be a pancreatic mass or altered echogenicity (hypoechoic) in the area of the pancreas secondary to edema; surrounding mesentery is typically hyperechoic secondary to focal peritonitis; may see peritoneal effusion and extrahepatic biliary obstruction.
- cPL assay and pancreatic ultrasound in combination have the highest sensitivity for an antemortem diagnosis of acute pancreatitis.

DIAGNOSTIC PROCEDURES

- Ultrasound-guided needle-aspiration biopsy may confirm inflammation (cytology), abscess, or cyst.
- Laparoscopy with pancreatic biopsy forceps for histologic diagnosis.
- Histopathologic evaluation may

(CONTINUED)

miss focal or segmental pancreatic inflammation; thus this diagnostic tool must be interpreted with caution.

PATHOLOGIC FINDINGS

- Gross findings (acute pancreatitis)—mild swelling with edematous pancreatitis; grayish yellow areas of pancreatic necrosis with varying amounts of hemorrhage with necrotizing pancreatitis.
- Gross findings (chronic pancreatitis)—pancreas is reduced in size, firm, gray, and irregular; may contain extensive adhesions to surrounding viscera.
- Microscopic changes (acute pancreatitis)—include edema, parenchymal necrosis, hemorrhage, and neutrophilic cellular infiltrate with acute lesions.
- Microscopic changes (chronic pancreatitis)—pancreatic fibrosis around ducts, ductal epithelial hyperplasia, atrophy, and mononuclear cellular infiltrate.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient medical management most often required.
- Aggressive IV fluid therapy.
- Fluid therapy goals—correct hypovolemia and maintain pancreatic microcirculation.
- A balanced electrolyte solution such as lactated Ringer's solution (LRS) is the first-choice rehydration fluid.
- Correct initial dehydration ($\text{mL} = \% \text{ dehydration} \times \text{weight in kg} \times 1,000$) and give over 4–6 hours.
- May need colloids (oxyglobin, hetastarch) to improve pancreatic circulatory needs and prevent ischemia.
- Following replacement of deficits, give additional fluids to match maintenance requirements ($2.5 \times \text{weight in kg}$) and ongoing losses (estimated).
- Potassium chloride (KCl) supplementation usually needed because of potassium loss in the vomitus; base potassium supplementation on measured serum levels (use 20 mEq of KCl/L of IV fluid if serum potassium levels are not known; do not administer faster than 0.5 mEq/kg/h).

ACTIVITY

Restrict

DIET

- Continue to feed orally unless vomiting is intractable; feeding maintains intestinal epithelial integrity and minimizes bacterial translocation.
- Initiate enteral feeding via esophagostomy, gastrostomy enteral device, or nasoesophageal tube placement.
- NPO in animals with persistent vomiting for the shortest time possible; when there has been no vomiting for 12 hours, offer small volumes of water; if tolerated, begin small, frequent feedings of a carbohydrate (e.g., boiled rice); gradually introduce a protein source of high biologic value such as cottage cheese or lean meat.
- Avoid high-protein and high-fat diets and use fat-restricted low-residue diets.

CLIENT EDUCATION

- Discuss the need for extended hospitalization.
- Discuss the expense of diagnosis and treatment.
- Discuss possible short-term and long-term complications (see "Associated Conditions").

SURGICAL CONSIDERATIONS

- May need surgery to remove pseudocysts, abscesses, or devitalized tissue seen with necrotizing pancreatitis.
- May need laparotomy and pancreatic biopsy to confirm pancreatitis and/or rule out other, nonpancreatic diseases.
- Extrahepatic biliary obstruction from pancreatitis requires surgical correction.

MEDICATIONS

DRUG(S)

- Animals with intermittent vomiting should be treated with antiemetics—maropitant (1 mg/kg SC q24h for 5 days maximum) or ondansetron (0.1–0.2 mg/kg IV q12h) are reasonable first choice options.
- Anti-inflammatory agents—corticosteroids are indicated for treatment of shock. Anti-inflammatory doses of corticosteroids can be used for management of acute pancreatitis, although published evidence for benefit is lacking.
- Antibiotics if evidence of sepsis—penicillin G (20,000 U/kg q6h), ampicillin sodium (20 mg/kg q8h), and enrofloxacin (10 mg/kg IV q24h in dogs).
- Analgesics to relieve abdominal pain, e.g., buprenorphine (0.01–0.02 mg/kg IM, IV, or SC q6–12h) or fentanyl CRI (2–5 µg/kg/h) as needed.

CONTRAINdications

- Anticholinergics (e.g., atropine)
- Azathioprine
- Chlorothiazide
- Estrogens
- Furosemide
- Tetracycline
- L-asparaginase

PRECAUTIONS

Only use antibiotics if a clear clinical condition exists, such as infection.

FOLLOW-UP

PATIENT MONITORING

- Evaluate hydration status closely during first 24 hours of therapy; twice daily check physical examination, body weight, hematocrit, total plasma protein, BUN, and urine output.
- Evaluate the effectiveness of fluid therapy after 24 hours and adjust flow rates and fluid composition accordingly; repeat biochemistries to assess electrolyte/acid-base status.
- Repeat plasma enzyme concentrations (cPL assay) after 7 days to evaluate the inflammatory process and response to therapy.
- Watch closely for systemic complications involving a variety of organ systems; perform appropriate diagnostic tests as needed (see "Associated Conditions").

PANCREATITIS—DOGS

- Gradually taper fluids down to maintenance requirements if possible.
- Maintain oral alimentation or enteral nutrition as described above being careful to feed only low-fat diets.
- A clinical index for pancreatitis may be used to define initial disease severity and response to treatment.

PREVENTION/AVOIDANCE

- Weight reduction if obese.
- Avoid high-fat diets.
- Avoid drugs that may precipitate disease (see "Contraindications").

POSSIBLE COMPLICATIONS

- Failed response to supportive therapy
- Life-threatening associated conditions
- Progression of acute pancreatitis to chronic pancreatitis

EXPECTED COURSE AND PROGNOSIS

- Good for most patients with acute pancreatitis; these patients usually respond to appropriate symptomatic therapy.
- More guarded to poor for patients with necrotizing pancreatitis and systemic conditions

MISCELLANEOUS

ASSOCIATED CONDITIONS

Life-Threatening

- Pulmonary edema (e.g., adult respiratory distress syndrome)
- Cardiac arrhythmias
- Peritonitis
- DIC

Non-Life-Threatening

- Diabetes mellitus
- EPI
- Chronic pancreatitis

PANCYTOPENIA

BASICS

DEFINITION

Simultaneous leukopenia, nonregenerative anemia, and thrombocytopenia; not a disease itself—rather, a group of laboratory findings that can result from multiple causes.

PATHOPHYSIOLOGY

- Mechanisms may include decreased production of cells in the bone marrow or increased peripheral use, destruction, or sequestration; one or more of these mechanisms may occur together.
- Decreased production occurs when pluripotent, multipotent, or committed stem cells are destroyed, their proliferation or differentiation is suppressed, or the maturation of differentiated cells is delayed or arrested.
- If pluripotent stem cells are affected, pancytopenia develops; if committed stem cells are involved, cytopenia of the specific cell type develops.
- Increased use and destruction of cells typically results in increased production in the bone marrow. At least 2–3 days are required before increased production begins to have an effect on peripheral blood cell counts, and peak output usually takes about a week; thus, the rate of use or destruction necessary to cause cytopenia is not as great during the first few days of disease as it is later.
- Sequestration of cells in the microcirculation, especially that of the spleen, intestine, and lungs, can cause cytopenia of the cell type involved.

P

SYSTEMS AFFECTED

Hemic/Lymphatic/Immune—bone marrow, spleen, lymph nodes, and other lymphocytic tissues; depending on the cause, these organs can be affected by cellular depletion, degeneration, necrosis, hyperplasia, dysplasia, or dyscrasia; changes may occur alone or in combination.

INCIDENCE/PREVALENCE

Pancytopenia is an uncommon occurrence and does not always occur with the causes listed below. One study (Weiss et al. 1999) determined an incidence of 2.4% in dogs.

GEOGRAPHIC DISTRIBUTION

Unless the cause of pancytopenia is due to an infectious agent that is localized to a certain region (e.g., leishmaniasis, histoplasmosis), no specific geographic distribution exists.

SIGNALMENT

- Dogs and cats
- No age, sex, or breed predilection

SIGNS

Historical Findings

- History reflects the underlying cause.
- Lethargy or pallor from anemia.
- Petechial hemorrhage or mucosal bleeding from thrombocytopenia.
- Repeated febrile episodes or frequent or persistent infections from leukopenia.

Physical Examination Findings

- Lethargy, weakness
- Pale mucous membranes
- Petechial hemorrhages
- Mucosal hemorrhage (e.g., hematuria, epistaxis, hemoptysis, melena)
- Fever

CAUSES

Infectious Diseases/Agents

- FeLV
- FIV
- FIP
- ICH
- Canine and feline parvovirus
- Histoplasmosis
- Ehrlichiosis
- Cytauxzoonosis
- Leishmaniasis
- Endotoxemia or septicemia

Drugs, Chemicals, and Toxins

- Chloramphenicol
- 2nd generation cephalosporins
- Trimethoprim-sulfadiazine
- Albendazole
- Fenbendazole
- Griseofulvin
- ACE inhibitors (e.g. captopril)
- Methimazole
- Phenobarbital
- Phenylbutazone
- Estrogen (exogenous administration, Sertoli cell tumor, interstitial cell tumor)
- Chemotherapeutic drugs (azathioprine, carboplatin, cyclophosphamide, cytosine arabinoside, doxorubicin, hydroxyurea, vinblastine)
- Fusarium* T-2 toxin
- Thallium
- Ionizing radiation

Proliferative and Infiltrative Diseases

- Hematopoietic neoplasia (e.g., acute and chronic leukemias, lymphoma, histiocytic tumors, myelodysplasia)
- Myelofibrosis
- Myelophthysis
- Osteosclerosis

Immune-Mediated Diseases

- Aplastic anemia (also known as aplastic pancytopenia).
- Immune-mediated hemolytic anemia and thrombocytopenia (when precursor cells are targeted by the immune system).

RISK FACTORS

Vary with individual cause

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute onset with severe clinical signs—more consistent with conditions that cause necrosis, destruction, or sequestration of cells.
- Slow, insidious onset—more consistent with conditions that cause bone marrow suppression.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

Glucocorticoids often mildly to moderately increase the segmented neutrophil count, which may then obscure the presence of neutropenia.

Disorders That May Alter Laboratory Results

Phlebotomy technique may result in platelet clumping and hemolysis, leading to spuriously low platelet count and PCV, respectively.

CBC/BIOCHEMISTRY/URINALYSIS

- Leukopenia—characterized by neutropenia with or without lymphopenia.
- Nonregenerative anemia—severity depends on duration and underlying cause.
- Thrombocytopenia.
- Blood smear evaluation—may reveal infectious agents (e.g., *Ehrlichia* spp. *Histoplasma capsulatum*); may reveal abnormal cells of any lineage, suggesting myeloproliferative or lymphoproliferative diseases.
- Toxic changes in leukocytes—may suggest bone marrow injury (e.g., from parvovirus or chemical agent), septicemia, or endotoxemia.
- Biochemical alterations—depends on organ and degree of involvement (e.g., increased liver enzymes may be seen with certain infectious diseases, toxins, and infiltrative diseases).

OTHER LABORATORY TESTS

- Reticulocyte count—a regenerative response to anemia suggests destruction, use, or sequestration of RBCs; a nonregenerative response suggests bone marrow suppression and merits bone marrow examination.
- Immunologic tests for infectious diseases (e.g., FeLV, FIV, *Ehrlichia* spp.).
- PCR for infectious agents.

DIAGNOSTIC PROCEDURES

- Bone marrow examination—indicated when cause of pancytopenia cannot be determined with other tests.

(CONTINUED)

PANCYTOPENIA

- Hypercellular bone marrow associated with myelodysplasia, neoplasia, myelophthisis, or recovery from parvovirus.
- Hypocellular bone marrow associated with necrosis, myelofibrosis, and suppression (e.g., drugs, estrogen, aplastic anemia).
- If a bone marrow aspirate cannot be obtained, myelofibrosis, necrosis, or marked hypocellularity should be suspected and a core biopsy should be evaluated.

PATHOLOGIC FINDINGS

Bone marrow core biopsy—may see replacement of normal hematopoietic tissue with necrotic, neoplastic, fibrous, or adipose tissue, depending on the underlying cause.

**TREATMENT**

- Supportive treatment depends on the clinical situation and includes aggressive antibiotic therapy and blood component transfusions.
- Treatment of the underlying condition is paramount.

**MEDICATIONS****DRUG(S) OF CHOICE**

Treatment should be appropriate for the clinical situation (i.e., the degree to which each cell population is decreased, presence of fever or infection, and established or suspected specific diagnoses); see specific causes.

CONTRAINDICATIONS

- Drugs that may suppress hematopoiesis further (see "Causes").
- NSAIDs, clopidogrel, or other drugs that may interfere with platelet function.

PRECAUTIONS

Because of the patient's compromised immune status, glucocorticoids and other immunosuppressive drugs should be used only when absolutely necessary and with extreme care and frequent monitoring.

ALTERNATIVE DRUG(S)***Recombinant Hematopoietic Growth Factors***

- rhG-CSF—1–5 µg/kg/day SC; stimulates neutrophil production.
- rhEPO—initial dosage: 100 U/kg SC 3 times/week; stimulates erythropoiesis.

**FOLLOW-UP****PATIENT MONITORING**

- Daily physical examination, including frequent monitoring of body temperature.
- Periodic CBC—frequency depends on severity of cytopenia, age, general physical condition of the patient, and underlying cause.

PREVENTION/AVOIDANCE

- Castration of cryptorchid males.
- Vaccination for infectious diseases.
- Frequent monitoring of CBC in cancer patients receiving chemotherapy or radiation.

POSSIBLE COMPLICATIONS

- Hemorrhage
- Sepsis

EXPECTED COURSE AND PROGNOSIS

- Depends on the underlying cause
- Often a guarded prognosis is warranted

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Secondary infections—in patients with neutropenia.

ZOONOTIC POTENTIAL

- Tularemia.
- An owner can contract histoplasmosis from the same source as the patient.

PREGNANCY/FERTILITY/BREEDING

Stress of underlying disease may cause abortion; see respective topics for the effects of different causes on pregnancy.

SEE ALSO

- Anemia, Aplastic
- Anemia, Nonregenerative

PANNICULITIS/STEATITIS

BASICS

OVERVIEW

Inflammation of the subcutaneous fat tissue.

SYSTEMS AFFECTED

Skin/Exocrine

SIGNALMENT

Species

Steatitis—predominantly cats, but can occur in dogs with concurrent diseases.

Mean Age and Range

- Panniculitis—any age.
- Steatitis—young to middle-aged cats; older dogs.

SIGNS

- Uncommon in dogs and cats.
- Single or multiple subcutaneous nodules or draining tracts.
- May be painful and fluctuant to firm.
- Nodules—few millimeters to several centimeters in diameter.
- Involved fat may necrose.
- Exudate—usually a small amount of oily discharge; yellow-brown to bloody.
- Multiple lesions (dogs and cats)—systemic signs common (e.g., anorexia, pyrexia, lethargy, and depression).

CAUSES & RISK FACTORS

- Infectious—bacterial, fungal (deep mycosis or dermatophyte), opportunistic mycobacteria, *Nocardia*, viral.
- Immune-mediated—lupus panniculitis, erythema nodosum, vasculitis or drug reaction.
- Idiopathic—sterile nodular panniculitis, thromboembolism.
- Trauma.
- Neoplastic—multicentric mast cell tumors, cutaneous lymphoma, pancreatic carcinoma.
- Foreign bodies.
- Post-injection—corticosteroids, vaccines, other subcutaneous injections.
- Nutritional—vitamin E deficiency in cats, oily fish-based diet (steatitis).

P

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Infectious

- More common than sterile/immune-mediated panniculitis.
- Deep pyoderma.
- FIP.

Cutaneous Cyst

- Usually non-painful, non-inflamed
- Well demarcated

Lipoma

- Soft; usually well demarcated
- No inflammation or draining tracts
- Usually solitary

Mast Cell Tumors/Epitheliotropic Lymphoma

- Multifocal
- Often erythematous
- Variable presentations

Sterile Nodular Panniculitis

Diagnosis made by ruling out other causes of panniculitis.

CBC/BIOCHEMISTRY/URINALYSIS

- Panniculitis—no abnormalities.
- Most steatitis cases and occasional panniculitis: moderate to severe neutrophilia with mild eosinophilia; mild to moderate leukocytosis; mild nonregenerative anemia; hypoalbuminemia and proteinuria, possible hypocalcemia.

OTHER LABORATORY TESTS

- Antinuclear antibody—lupus panniculitis
- Serum protein electrophoresis • Serum lipase/amylase levels • FeLV/FIV testing

IMAGING

- Abdominal ultrasound:
- Panniculitis—pancreatitis may be a contributing factor.
- Steatitis—may see mottled subcutaneous, inguinal or falciform fat, loss of contrast in abdominal cavity.

DIAGNOSTIC PROCEDURES

- Aspirates and impression smears:
- Pyoderma—numerous neutrophils and variable numbers of mononuclear cells and bacteria.
- Fungal infections—fungal organisms and variable numbers of mononuclear cells may be noted.
- Blastomycosis—urine antigen testing.
- Bacterial culture and sensitivity testing (tissue)—necessary for identifying primary or secondary bacterial infection.
- Fungal and opportunistic mycobacteria culture (tissue).
- Biopsy with negative cultures for diagnosis of sterile nodular panniculitis.
- Special stains of histopathologic samples—may help identify causative agent.

PATHOLOGIC FINDINGS

- Surgical excisional biopsies—more accurate than punch biopsy specimens in most cases.
- Histopathology required for diagnosis:
- Panniculitis—lobular or diffuse infiltrate (granulomatous, pyogranulomatous, suppurative, eosinophilic, necrotizing or fibrosing) of panniculus; may identify if vasculitis present. Special stains will aid in identifying infectious agents.
- Steatitis—lumpy, granular fat, normal to yellowish/orange coloration of body fat may be noted.

TREATMENT

Diet: Steatitis—remove fish products from diet; feed nutritionally complete, balanced commercially prepared food; may require parenteral feeding (e.g., PEG tube, esophagostomy feeding tube).

MEDICATIONS

DRUG(S)

Positive culture results require appropriate antibacterial, antifungal, or antimycobacterial treatment.

Sterile nodular panniculitis

- Systemic treatment with corticosteroids; prednisone (2.2 mg/kg daily in dogs or 4.4 mg/kg daily in cats; taper based on response: may require low dose to maintain remission). • Oral vitamin E—200 IU q12h < 10 kg, 400 IU q12h > 10 kg.
- Azathioprine (Dogs: 1 mg/kg PO daily initially)—can be used if corticosteroids are contraindicated or insufficient response to corticosteroids alone.
- Cyclosporine can be beneficial in some dogs (initially 5 mg/kg q24h for 4–8 weeks, then tapered).

Steatitis

Oral vitamin E—200 IU q12h < 10 kg, 400 IU q12h > 10 kg; corticosteroids at an anti-inflammatory dosage; S-adenosylmethionine PO on an empty stomach.

FOLLOW-UP

- Depends on underlying etiology type and duration of treatment.
- Monitor CBC, platelet count, chemistry profile, and urinalysis/urine bacterial culture and sensitivity if immune-suppressive agents or long-term corticosteroids are used.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Pancreatic carcinoma, chylous ascites, peritonitis

ABBREVIATIONS

- FeLV = feline leukemia virus
- FIP = feline infectious peritonitis
- FIV = feline immunodeficiency virus
- PEG tube = percutaneous endoscopically-placed gastrostomy tube

PANOSTEITIS

BASICS

DEFINITION

A self-limiting, painful condition affecting one or more of the long bones of young, medium- to large-breed dogs that is characterized clinically by lameness and radiographically by high density of the marrow cavity.

PATHOPHYSIOLOGY

- Cause unknown.
- Attempts to isolate microorganisms have failed.
- Metabolic, allergic, or endocrine aberrations—without support.
- Pain—may owe to the disturbance of endosteal and periosteal elements, vascular congestion, or high intramedullary pressure.

SYSTEMS AFFECTED

Musculoskeletal—lameness of variable intensity; may affect a single limb or become a shifting leg lameness.

GENETICS

- No proven transmission.
- Predominance of German shepherds in the affected population strongly suggests an inheritable basis.

INCIDENCE/PREVALENCE

No reliable estimates; common

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog

Breed Predilections

- German shepherds and German shepherd mixes—most commonly affected.
- Medium to large breeds—most commonly affected.

Mean Age and Range

- Usually 5–18 months of age
- As young as 2 months and as old as 5 years

Predominant Sex

Male

SIGNS

General Comments

Lameness—if no distinct abnormalities noted on physical examination or radiographs, repeat examinations 4–6 weeks later.

Historical Findings

- No associated trauma.
- Lameness—varying intensity; usually involves the forelimbs initially; may affect the hind limbs; may see shifting leg lameness; may be non-weight-bearing.
- Severe disease—mild depression; inappetence; weight loss.

Physical Examination Findings

- Pain—on deep palpation of the long bones (diaphysis) in an affected limb; distinguishing characteristic; palpate firmly along the entire shaft of each bone while carefully avoiding any pinching of nearby muscle.
- Bones—ulna most commonly affected; may affect radius, humerus, femur, and tibia (in decreasing order of frequency) either concurrently or subsequently.
- May note low-grade fever.
- May see muscle atrophy.

CAUSES

Unknown

RISK FACTORS

Purebred German shepherd or German shepherd mix

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Always consider the diagnosis with lameness in a young German shepherd or German shepherd mix.
- May occur alone or with other juvenile orthopedic diseases.
- Osteochondritis dissecans.
- Fragmented medial coronoid process.
- Un-united anconeal process.
- Hip dysplasia.
- Fractures and ligamentous injuries from unobserved trauma.
- Shifting leg lameness—immune-mediated arthritides; Lyme disease; bacterial endocarditis.
- Coccidioidomycosis.
- Bacterial osteomyelitis.
- Hypertrophic osteodystrophy.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal
- May note eosinophilia early in disease

OTHER LABORATORY TESTS

N/A

IMAGING

- Radiographic densities within the medulla of long bones—characteristic; confirm diagnosis.
- Early, middle, and late radiographic lesions.
- Early—trabecular pattern of the ends of the diaphysis becomes more prominent; may appear blurred; may see granular opacities.
- Middle—patchy sclerotic opacities first around the nutrient foramen and later throughout the diaphysis; widened cortex; thickened periosteum with increased opacity.
- Late—during resolution, diminished overall opacity of the medullary canal (toward normal); a coarse trabecular pattern and some granular opacity may remain; may be a period in which the medullary canal becomes more lucent than normal.

- Bone scintigraphy may reveal subtle lesions that later become more apparent on follow-up radiographs.

DIAGNOSTIC PROCEDURES

Bone biopsy—occasionally indicated to rule out neoplasia and bacterial or fungal osteomyelitis that have similar radiographic appearances.

PATHOLOGIC FINDINGS

- Biopsy or necropsy—rarely performed because of excellent prognosis for recovery.
- No gross pathologic lesions.
- Degeneration of the marrow adipocytes surrounding the nutrient foramen followed by proliferation of vascular stromal cells within the marrow sinusoids.
- Osteoid formation and endosteal new bone formation—progress proximally and distally.
- Vascular congestion—may accompany the proliferation of new bone, secondarily stimulating endosteal and periosteal reaction.
- Remodeling of the endosteum—occurs during resolution; reestablishes normal endosteal and marrow architecture.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient

NURSING CARE

Maintenance and replacement fluid therapy—occasionally owing to prolonged periods of inappetence and pyrexia.

ACTIVITY

- Limited—not shown to hasten recovery; lessens pain.
- Moderate to severe disease—pain may cause self-limited movement leading to muscle atrophy.

CLIENT EDUCATION

- Warn client that patient may develop other juvenile orthopedic diseases.
- Inform client that signs of pain and lameness may last for several weeks.
- Warn client that recurrence of clinical signs is common up to 2 years of age.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

NSAIDs

- Minimize pain; decrease inflammation.
- Symptomatic therapy has no bearing on the duration of the disease.
- Carprofen (2.2 mg/kg PO q12h), etodolac (10–15 mg/kg PO q24h), meloxicam

PANOSTEITIS

(CONTINUED)

(0.2 mg/kg PO, IV, or SC first day—then 0.1 mg/kg q24h), deracoxib (1–2 mg/kg PO q24h for OA, 3–4 mg/kg for postoperative pain PO q24h; do not exceed 7 days), firocoxib (5 mg/kg PO q24h), buffered or enteric-coated aspirin (10–25 mg/kg PO q8–12h).

- Glucocorticoids.
- May give anti-inflammatory dosage—prednisone (0.1–0.5 mg/kg PO).
- Potential side effects well documented.
- Goal for chronic use—low-dose and alternate-day therapy.

PRECAUTIONS

NSAIDs—gastrointestinal upset may preclude use.

PRECAUTIONS

NSAIDs—most cause some degree of gastric ulceration.

POSSIBLE INTERACTIONS

NSAIDs—do not use in conjunction with glucocorticoids; risk of gastrointestinal tract ulceration; consider appropriate washout times when switching from one NSAID to another.

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

Recheck lameness every 2–4 weeks to detect more serious concurrent orthopedic problems.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Self-limiting disease.
- Treatment—symptomatic; appears to have no influence on duration of clinical signs.
- Multiple limb involvement—common.
- Lameness—typically lasts from a few days to several weeks; may persist for months.
- Occasional case has unrelenting pain and lameness that is unresponsive to therapy. Euthanasia has been recommended in these dogs.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Typically affects immature and young dogs

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Females reported to be more susceptible to panosteitis during estrus; no proven relationship to reproductive hormones or pregnancy.

SYNOMYS

- Enostosis
- Eosinophilic panosteitis
- Fibrous osteodystrophy
- Juvenile osteomyelitis

ABBREVIATION

- NSAID = nonsteroidal anti-inflammatory drug

PANTING AND TACHYPNEA

BASICS

DEFINITION

- Tachypnea—increased respiratory rate.
- Panting—rapid, shallow, open-mouth breathing that is usually not associated with gas exchange issues.

PATHOPHYSIOLOGY

• Respiratory rate, rhythm, and effort are controlled by the respiratory center in the brainstem in response to numerous afferent pathways, both central and peripheral in origin. These include the cerebral cortex, central chemoreceptors, peripheral chemoreceptors, stimulation of mechanoreceptors in the airways that sense lung inflation and deflation, stimulation of irritant receptors of the airways, stimulation of C-fibers in the alveoli and pulmonary blood vessels that sense interstitial congestion, and baroreceptors that sense changes in blood pressure. • Tachypnea and panting can occur in response to stimulation of any of the above receptor pathways.

SYSTEMS AFFECTED

Respiratory

SIGNALMENT

- Dog and cat; no age, or sex predilection.
- Older, large breed dogs predisposed to panting associated with laryngeal paralysis.
- Brachycephalic dogs prone to panting due to upper airway obstruction.

SIGNS

Historical Findings

- Patients with primary respiratory or cardiac disease usually have associated coughing or exercise intolerance.
- Non-respiratory causes—clinical complaints associated with the primary disease, e.g., PU/PD/PP with hyperadrenocorticism, intermittent signs of systemic hypertension with pheochromocytoma.

Physical Examination Findings

- Brachycephalic syndrome (stenoic nares, stertorous respirations associated with soft palate elongation or saccular eversion) may be observed.
- Stridor can be evident on inspiration with upper airway diseases.
- Lower airway disease—cough, expiratory wheezes on auscultation, abdominal effort.
- Pulmonary parenchymal disease—may have crackles on auscultation; harsh or moist lung sounds common, may be normal.
- Cardiogenic pulmonary edema—heart murmur or arrhythmia, tachycardia, gallop sound, hypothermia, pale mucous membranes, poor capillary refill time.
- Pleural space disease—diminished breath sounds: ventrally—fluid; dorsally—air; unilaterally—space-occupying lesions, pyothorax, chylothorax.
- Thoracic wall disease—visible and/or palpable trauma.

- Non-respiratory diseases—findings will depend on the other diseases, e.g., pale mucous membranes if anemic, hepatomegaly with hyperadrenocorticism.
- Other signs could indicate trauma.

CAUSES & RISK FACTORS

Panting

- Pain, anxiety, hyperthermia.
- Brachycephalic airway syndrome.
- Central nervous system disease causing abnormal ventilatory control.
- Cardiovascular compromise (shock), hypertension, arrhythmia.
- Drug therapy (opioids)
- Metabolic acidosis.
- Laryngeal disease.
- Cortisol or norepinephrine excess.
- Can be a normal behavioral pattern in some dogs.

Tachypnea

- Hypoxemia, hypercapnia, hypotension, hyperthermia, anemia, acidosis, systemic inflammation, brainstem disease.
- Airway pathology—inhaled irritant, bronchoconstriction, airway compression, airway infection.
- Interstitial pathology—edema, hemorrhage, inflammation, neoplasia, fibrosis.
- Larynx—laryngeal paralysis, edema, collapse, foreign body, neoplasia, inflammation, trauma, webbing.
- Trachea—collapse, stenosis, trauma, foreign body, neoplasia, parasites.
- Lower airway disease—allergic disease, inflammation, infection (*Mycoplasma*), parasites, neoplasia.
- Pulmonary parenchymal disease—edema (cardiogenic or non-cardiogenic), pneumonia or pneumonitis, neoplasia (primary or metastatic), hemorrhage.
- Pulmonary thromboembolism associated with—IMHA, PLE, PLN, cardiac disease, neoplasia, heartworm disease.
- Pericardial effusion.
- Pleural effusion or pneumothorax.
- Abdominal distention—organomegaly; neoplasia, pregnancy; obesity; ascites; gastric dilatation, torsion.
- CNS disease—compression or infarct near the respiratory center.
- Metabolic acidosis—diabetic ketoacidosis, diarrhea, uremia, renal tubular acidosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Tachypnea without respiratory distress—may be a non-respiratory problem.
- Stertor and stridor are features of upper airway disease—auscultation over the trachea can help delineate upper airway noises from lower airway noises.
- Thoracic auscultation and percussion—most useful for distinguishing pleural disease (dampened lung sounds, dull percussion) from parenchymal disease (normal, harsh or moist lung sounds, crackles on auscultation).
- Wheezes on auscultation are suggestive of narrowed lower airway (bronchi, bronchioles).
- Crackles on auscultation are features of airway collapse, bronchitis, edema, or other pulmonary parenchymal diseases.
- Congestive heart failure—murmur, tachycardia, poor pulse quality, jugular pulses.

auscultation are features of airway collapse, bronchitis, edema, or other pulmonary parenchymal diseases.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia—can cause non-respiratory tachypnea.
- Polycythemia—chronic hypoxia.
- Inflammatory leukogram—pneumonia, pneumonitis, pyothorax, or non-respiratory causes (SIRS, sepsis).
- Eosinophilia—hypersensitivity or parasitic airway disease.
- Thrombocytosis—hyperadrenocorticism predisposes to PTE; alternatively, could indicate iron deficiency anemia.
- Sodium: potassium ratio < 27 —can be seen with pleural or abdominal effusions.
- High alkaline phosphatase—hyperadrenocorticism predisposes to panting and PTE.
- Hypoproteinemia—may suggest protein losing disease that can predispose to PTE.
- Proteinuria—can predispose to PTE.
- Azotemia—if severe can lead to uremic pneumonitis.
- Hyperglycemia, glucosuria, and ketonuria—could indicate ketoacidosis as cause of tachypnea.

OTHER LABORATORY TESTS

- Fecal examinations if indicated.
- Low dose dexamethasone suppression test to assess adrenal cortical function, if indicated.
- Pleural fluid analysis.
- Serum antigen or antibody titers—heartworm, toxoplasmosis, distemper, FeLV, FIV.
- Pulse oximetry or arterial blood gas—can help differentiate pulmonary from non-respiratory causes.
- Hemoglobin saturation with oxygen $< 95\%$ supportive of hypoxemia.
- PaO_2 —partial pressure of oxygen dissolved in arterial blood; normoxemia: PaO_2 80–120 mmHg (room air, sea level), hypoxemia: $\text{PaO}_2 < 80$ mmHg; F_1O_2 —fraction of inspired oxygen ranges from 0.21 (room air) to 1.0; $\text{PaO}_2/\text{F}_1\text{O}_2$ ratio—measure of lung efficiency; $\text{PaO}_2/\text{F}_1\text{O}_2 \geq 500$ —normal lung efficiency; 300–500—mild insufficiency; 200–300—moderate insufficiency; < 200 —severe insufficiency.
- Reduction in lung efficiency is most commonly due to pulmonary parenchymal disease.
- PaCO_2 or PvCO_2 —partial pressure of CO_2 dissolved in arterial or venous blood; measure of ventilation; normal 30 mmHg $< \text{PCO}_2 < 40$ mmHg.
- Hypercapnia = hypoventilation = decreased alveolar minute ventilation.
- Hypocapnia = hyperventilation = increased alveolar MV.
- Hypoventilation can be due to upper airway obstruction, pleural space disease, thoracic wall disease and abdominal distention; respiratory muscle fatigue from a prolonged period of tachypnea can lead to hypoventilation.
- Blood gas may reveal metabolic acidosis as a cause.
- Coagulation testing—if suspect hemothorax and/or pulmonary hemorrhage.

PANTING AND TACHYPNEA

(CONTINUED)

IMAGING

- Cervical and thoracic radiography: *laryngeal disease*—increased density could suggest edema or soft tissue mass lesion. Also can see large airway narrowing, lymphadenopathy, intraluminal abnormalities. *Lower airway disease*—bronchial thickening, middle lung lobe consolidation (cats), atelectasis, hyperinflation and diaphragmatic flattening (primarily cats). *Pneumonia*—alveolar infiltrates; aspiration pneumonia usually cranoventral distribution or middle lobe affected. *Cardiogenic pulmonary edema*—enlarged cardiac silhouette, pulmonary venous distention, enlarged left atrium with perihilar pulmonary infiltrates in dogs; infiltrates can be of any distribution in cats. *Noncardiogenic pulmonary edema*—caudodorsal distribution. ARDS—diffuse, symmetrical alveolar infiltrates. *Pulmonary vascular abnormalities*—PTE, heartworm disease. *Pleural space disease*—pneumothorax, pleural effusion, mass lesions, diaphragmatic hernias. *Thoracic wall disease*—rib fractures, neoplasia.
- Thoracic ultrasonography: evaluation of distribution of pleural effusion (excellent as guide for thoracocentesis), pneumothorax (absence of “glide sign”), and parenchymal disease (presence of “comet tail” artifact). Pulmonary mass identification—guide fine-needle aspiration; mediastinal evaluation.
- Echocardiography: evaluate cardiac function if cardiogenic pulmonary edema or pleural effusion suspected; elevated pulmonary artery pressure and right ventricular overload can support diagnosis of PTE; visualize heart-based masses, rule out pericardial effusion.
- Abdominal ultrasound: evaluation of abdominal distention, assess adrenal gland size. • Fluoroscopy: evaluate tracheal and/or large airway collapse; evaluate diaphragmatic function.
- Computed tomography: airway, pulmonary parenchymal, and pleural space disease can be evaluated; can detect lesions not clearly defined on radiographs but requires general anesthesia.
- Pulmonary vascular angiography: gold standard for diagnosis of PTE but requires general anesthesia.
- Perfusion scintigraphy: abnormal perfusion scan is considered supportive of PTE.
- May need CNS imaging.

DIAGNOSTIC PROCEDURES

- Laryngoscopy/nasopharyngoscopy/tracheoscopy—to evaluate laryngeal function and visualize foreign bodies and masses; visualize caudal nasopharyngeal region with flexible endoscope or spay hook and dental mirror.
- Bronchoscopy—evaluate large and small airways; take biopsies; perform bronchoalveolar lavage for cytology and culture.
- Thoracocentesis—fluid analysis and culture.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient care if life-threatening; therapy depends on underlying cause.
- Administer oxygen and see if tachypnea resolves—this would be supportive of a primary respiratory problem.
- Upper airway disease—use sedation to reduce inspiratory effort. Check body temperature frequently and actively cool patients as needed. Severe upper airway disease requires intubation to stabilize; if the problem cannot be immediately cured, placement of a temporary tracheostomy tube is indicated. Remove foreign bodies; perform surgical excision/biopsy of masses, surgical correction for laryngeal paralysis and brachycephalic syndrome; give anti-inflammatory medications for laryngeal edema.
- Lower airway disease—bronchodilators; oxygen therapy until stable; systemic corticosteroids may be required to stabilize cats with acute bronchoconstriction.
- Pulmonary parenchymal disease—oxygen therapy, antibiotics if pneumonia; treat coagulation disorders; cardiogenic edema requires furosemide ± vasodilators. Non-cardiogenic edema requires oxygen therapy, may require positive-pressure ventilation if oxygen therapy alone is not adequate to stabilize the patient.
- Pleural space disease—thoracocentesis for air and fluid. Place a chest tube if repeated chest taps are needed to keep patient stable.
- Abdominal distention—drain ascites only as needed to keep the patient comfortable; relieve gastric distention.
- Non-respiratory diseases—treat primary problem.

NURSING CARE

- Oxygen therapy via cage, nasal cannula, E-collar covered in plastic wrap, mask, or flow-by. Humidify oxygen source if giving oxygen therapy for more than a few hours.
- Monitor temperature regularly, as hyperthermia will worsen respiratory difficulty.

DIET

Weight-reducing diet if obesity is a contributing cause.

SURGICAL CONSIDERATIONS

- Anesthesia must be carefully tailored to the patient. Securing an airway is essential and rapid intravenous induction is important. Have multiple sizes of endotracheal tubes available if upper airway obstruction is suspected.
- If laryngeal paralysis or

brachycephalic syndrome is suspected, prepare for surgical correction at the time of diagnosis. Warn owners of increased likelihood of aspiration pneumonia in dogs with laryngeal disease.

MEDICATIONS

DRUG(S)

Varies with underlying cause (see “Appropriate Health Care”).

PAPILLOMATOSIS

BASICS

OVERVIEW

- Cutaneous mucous membrane lesions of dogs and cats caused by various papilloma viruses.
- Dogs: oral papillomatosis, venereal papillomatosis, exophytic cutaneous papillomas, cutaneous inverted papillomas, multiple papillomas of the footpad, canine pigmented viral plaques.
- Cats: feline cutaneous papillomas, feline cutaneous fibropapillomas (feline sarcoids), feline viral plaques.
- Viral plaques may progress to BISC, SCC or invasive carcinoma.

SIGNALMENT

Dogs

- Puppies and young adult dogs—oral papillomatosis, venereal papillomatosis, multiple papillomas of the footpad, cutaneous inverted papillomas, canine pigmented viral plaques (breed predisposition).
- Older dogs—exophytic cutaneous papillomas, cutaneous inverted papillomas.
- Miniature schnauzers and pugs—pigmented viral plaques; associated with immunosuppression in other breeds.

Cats

- More common in older cats; associated with immunocompromise (e.g., FIV).
- Feline sarcoids: younger cats, especially those with outdoor exposure.

SIGNS

Dogs

- Cutaneous papillomas—pedunculated, fronds of epithelium, up to 1 cm in diameter located anywhere.
- Canine papillomavirus—most often oral mucosa, hard palate, epiglottis; may interfere with prehension, swallowing; trauma results in halitosis and ptalism; may be confined to genital or eyelid regions.
- Cutaneous inverted papillomas—less common, multiple lesions often found with a central pore; on ventral abdomen; caused by distinctly different papilloma virus from COPV.
- Multiple papillomas affecting footpads in younger dogs—firm, hyperkeratotic lesions causing discomfort and lameness.
- Canine pigmented viral plaques—miniature schnauzers, pugs; Boston terriers, French bulldogs; rarely transform to SCC; ventral abdomen and inner thigh region.

Cats

- Feline cutaneous papillomas—rare.
- Feline viral plaques—more common; may progress to BISC or invasive carcinoma.
- Feline sarcoid lesions—uncommon.
- Cats 10 years or older; other systemic disease causing immunosuppression (e.g., FIV).

CAUSES & RISK FACTORS

- Oral papillomas affecting naive dogs and recovered animals develop lifelong immunity.
- Dogs—cutaneous papillomas thought to

involve cell-mediated immunologic defects.

- Older, immunosuppressed cats develop plaques and BISC.
- Canine pigmented viral plaques—strong breed predisposition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dogs

- Oral cavity, oropharynx—fibromatous epulis, transmissible venereal tumor, SCC.
- Cutaneous—sebaceous hyperplasia, acrochordon.
- Pigmented plaque—melanocytoma.
- Inverted—infundibular keratinizing acanthoma.

Cats

Eosinophilic granuloma, complex, actinic keratoses, cutaneous lesions of FeLV, multicentric SCC *in situ*, SCC.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

Cats: FeLV, FIV

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Gross lesions have a typical appearance.
- Biopsy for histopathology; immunohistochemistry demonstrates viral antigens within lesions; PCR not definitive.

PATHOLOGIC FINDINGS

- Dependent upon syndrome; all lesions share cytopathic effects of papillomavirus infection: hyperkeratosis, acanthosis, koilocytes in stratum spinosum, abnormal, large keratohyalin granules in stratum granulosum.
- Viral pigmented plaques may lack koilocytes and viral inclusion bodies.

TREATMENT

- Most lesions regress spontaneously (especially oral forms).
- Surgery if needed (excision, cryosurgery, or electrosurgery).
- Persistent disease (dogs)—COPV vaccine reported to induce epithelial tumors and SCC at vaccination sites; latency period 11–34 months; autogenous vaccination: treatment controversial.
- Cats—diagnosis for visceral diseases or causes of immunosuppression.

MEDICATIONS

DRUG(S)

- α -Interferon—30 units/cat PO q24h.
- Imiquimod—applied to individual lesions three times/week for 4 weeks.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Imiquimod—potential for human exposure when applying to patient; causes severe localized reaction; use with caution at mucocutaneous junctions.

FOLLOW-UP

PATIENT MONITORING

Monitor for signs of malignant transformation to SCC.

PREVENTION/AVOIDANCE

- Separate dogs with oral papillomas from susceptible animals.
- Commercial kennels—may consider autogenous vaccination.

EXPECTED COURSE AND PROGNOSIS

- Dogs—prognosis good; incubation period 1–8 weeks; regression usually 1–5 months; lesions persist 24 months or more.
- Cats—long-term prognosis for plaques and BISC depends on concurrent diseases.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Dependent upon viral strain

ZOONOTIC POTENTIAL

Papillomaviruses: species specific

PREGNANCY/FERTILITY/BREEDING

- Venereal lesions may preclude breeding.
- Transmission of viral infection likely; especially when active lesions present.

PARALYSIS

BASICS

DEFINITION

- Paresis—weakness of voluntary movement.
- Paralysis—lack of voluntary movement.
- Quadripareisis (tetraparesis)—weakness of voluntary movements in all limbs.
- Quadriplegia (tetraplegia)—absence of all voluntary limb movement.
- Paraparesis—weakness of voluntary movements in pelvic limbs.
- Paraplegia—absence of all voluntary pelvic limb movement.
- Schiff-Sherrington syndrome may occur with severe spinal cord trauma below T2—patient in lateral recumbency, front limbs and neck in extension, with paralysis of pelvic limbs; front limb function is normal; prognosis based on presence or absence of pain perception in pelvic limbs.
- Spinal shock may occur with severe spinal cord trauma, usually located near the thoracolumbar spine—paralyzed pelvic limbs with initially areflexic pelvic limb reflexes that become exaggerated (and more indicative of a T3–L3 lesion localization) within minutes to a few hours after the trauma.

PATOPHYSIOLOGY

- Weakness—caused by lesions in the upper motor neuron (UMN) or lower motor neuron (LMN) systems.
- UMN system—cell bodies or nuclei located within the brain and responsible for initiating voluntary movement; axons from these cell bodies form the tracts (rubrospinal, corticospinal, vestibulospinal, reticulospinal) that descend from the brain to synapse on the interneurons in the spinal cord. Interneuronal axons synapse on large alpha motor neurons in the ventral gray matter of the spinal cord; these are cell bodies of origin for the LMN system, which is responsible for spinal reflexes.
 - LMN system—collections of lower motor neurons in the cervical and lumbar intumescences that give rise to axons that form the ventral nerve roots, spinal nerves, and (ultimately) the peripheral nerves that innervate limb muscles.
 - Evaluation of limb reflexes—determines which system (UMN or LMN) is involved.
 - UMN and their axons—have inhibitory influence on the large alpha motor neurons of the LMN system; maintain normal muscle tone and normal spinal reflexes.
 - If UMN is injured, spinal reflexes are no longer inhibited or controlled and spinal reflexes become exaggerated or hyperreflexic.
 - If LMN system is injured, spinal reflexes cannot be elicited (areflexic) or are reduced (hyporeflexic). Large alpha motor neurons or their processes (peripheral nerves) also maintain normal muscle tone. With LMN injury, muscle wasting is usually severe and within 5–7 days of injury.

SYSTEMS AFFECTED

Nervous

SIGNALMENT

Dog and cat

SIGNS

General Comments

Limb weakness—acute or gradual onset

Historical Findings

- Owner may describe the patient as being “down,” unable to move, walk, or get up.
- Many focal compressive spinal cord diseases begin with ataxia and progress to weakness, then to paralysis.

Physical Examination Findings

- Usually normal, unless the disease is systemic.
- If in pain, patient may resent handling and manipulation.
- Aortic emboli (ischemic neuromyopathy)—patient may be paraplegic and areflexic or hyporeflexic; femoral pulses absent; limbs often cold; nail beds often blue.

Neurologic Examination Findings

- Confirm that the problem is weakness or paralysis.
- If limbs are paralyzed—likely bladder is also paralyzed, negating voluntary urination.
- Localize problem to either LMN or UMN system.
- Tetraparesis with exaggerated spinal reflexes in all limbs—lesion located at C1–C5 spinal segments or in the brain.
- Tetraparesis with normal or depressed front limb spinal reflexes and exaggerated pelvic limb spinal reflexes—lesion located at C6–T2 spinal segments.
- Tetraparesis with depressed spinal reflexes and muscle tone in all limbs—lesion is diffuse involving muscles or peripheral nerves, or, the cervical (C6–T2 spinal cord segments) and lumbar spinal cord intumescences (L4–S2 spinal segments).
- Normal front limbs but paraparesis/paraplegia with exaggerated pelvic limb spinal reflexes—lesion located at T3–L3 spinal segments.
- Normal front limbs but paraparesis/paraplegia with depressed to absent pelvic limb spinal reflexes—lesion located at L4 spinal segment and caudally.
- Normal front limb and pelvic limb motor activity but flaccid tail/anus and urinary and/or fecal incontinence—lesion located at S2 spinal segment and caudally.
- Normal front limbs but paraparesis/paraplegia and depressed patellar reflexes—lesion involves spinal segments L4–6, located in vertebral bodies L3–4.
- Normal front limbs but paraparesis/paraplegia, exaggerated patellar reflexes, and weak flexor and sciatic reflexes—if only the spinal cord is affected (no root involvement), lesion involves spinal segments L6–S2, located in vertebral bodies L4–L6.

CAUSES

Quadriplegia

- If LMN system—acute onset: coonhound paralysis, botulism, tick paralysis, fulminating form of myasthenia gravis, protozoal

myoneuritis.

- If LMN system—more gradual onset: polyneuropathies and polymyopathies from toxicity, infection, inflammation, endocrinopathy, metabolic disease, or congenital/inherited disease.
- If UMN system—acute onset: disc herniation; fibrocartilaginous embolism; trauma; neoplasia; myelitis of many causes.
- If UMN system—gradual onset: disc herniation; discospondylitis; neoplasia; myelitis of many causes; malformations of the spine or spinal cord.

Paraplegia

- If UMN system—disc herniation; discospondylitis; fibrocartilaginous embolism; neoplasia; trauma; congenital malformations of spine or spinal cord; degenerative myelopathy.
- If LMN system—fibrocartilaginous embolism; disc herniation; lumbosacral instability; discospondylitis; trauma; neoplasia; spina bifida.

Quadriplegia with Cranial Nerve Deficits, Seizures, or Stupor

- UMN system—diseases of the brainstem: encephalitis; neoplasia; trauma; vascular accidents; congenital or inherited disorders.

RISK FACTORS

- Degenerative disc disease—dachshunds, poodles, cocker spaniels, and beagles.
- Hunting dogs—coonhound paralysis.
- Roaming animals—spinal cord and vertebral trauma.
- Atlantoaxial luxation—toy and small breeds.
- Lumbosacral instability—large breeds; working breeds; German shepherds.
- Cervical spondylomyelopathy (wobbler syndrome)—large breeds; Doberman pinschers; Great Danes.
- Syringomyelia—Cavalier King Charles spaniels, brachycephalic toy breeds and many others.
- Spinal arachnoid diverticulum: rottweilers, pugs, small breeds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Weak or paralyzed pelvic limbs—ensure femoral pulses are present and normal; aortic or femoral artery emboli may lead to LMN paraparesis or paraplegia.
- Spinal reflexes—localize weakness to the cervical, thoracolumbar, or lower lumbar cord segments.
- Acute onset—be careful when moving patient if possibility of trauma.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal, unless inflammatory diseases involved.

OTHER LABORATORY TESTS

- Urinary tract inflammation—urine culture may be positive in discospondylitis or in any dog that has had chronic bladder paralysis or repeated urinary catheterizations.
- Discospondylitis—diagnose by spinal

(CONTINUED)

PARALYSIS

radiography (intervertebral disc space lysis); perform *Brucella* titer; consider blood and urine bacterial cultures. • Exercise-induced weakness—determine acetylcholine receptor antibody titers (test for myasthenia gravis); check serum creatine kinase concentration (polymyositis or polymyopathy), RBC count (anemia or polycythemia), and blood glucose concentration (hypoglycemia); check for cardiac arrhythmia and hypoxia via ECG, thoracic radiography, Holter monitoring, and echocardiography; muscle biopsy. • LMN weakness or muscle pain, muscle atrophy, or hypertrophy—determine creatine kinase concentration to help diagnose polymyositis; perform muscle and nerve biopsy; evaluate *Neospora caninum* and *Toxoplasma gondii* serum titers. • Myelitis or meningitis—dog: perform titers for *N. caninum*, *T. gondii*, Rocky Mountain spotted fever, *Ehrlichia* spp., and canine distemper virus; cat: perform serum titers for *T. gondii* and *Cryptococcus neoformans* and evaluate spinal fluid for signs of feline infectious peritonitis virus and *C. neoformans*.

IMAGING

- Spinal radiography—may reveal disc herniation, discospondylitis, bony tumor, congenital vertebral malformation, and fracture or luxation.
- Myelography—required if survey radiography not diagnostic and CT or MRI not available.
- CT or MRI—has replaced myelography where technology is available.

DIAGNOSTIC PROCEDURES

- CSF—before myelography to detect myelitis and meningitis; if high protein or cell numbers consider infectious disease titer analysis.
- Needle electromyography and motor nerve conduction velocity—may help with diagnosis and characterization of generalized LMN.
- Muscle and nerve biopsy—generalized LMN weakness.
- Aspirate intervertebral disc space under fluoroscopy; perform cytology and culture to isolate an infectious agent if discospondylitis is observed on imaging studies.

**TREATMENT**

- Inpatient—with severe weakness or paralysis until bladder function can be ascertained.
- Hand feeding—with diffuse LMN, swallowing can be affected.
- Feeding from an elevated platform or installation of a feeding

tube—recommended for animals with megaesophagus until resolution occurs.

- Activity—restrict until spinal trauma and disc herniation can be ruled out.
- Physical therapy—important for paralyzed patients; tone muscles and keep joints flexible.
- Bedding—check and clean frequently to prevent urine scalding and superficial pyoderma; use padded bedding or waterbed to help prevent decubital ulcer formation.
- Turn quadriplegic patients from side to side four to eight times daily—prevents hypostatic lung congestion and decubital ulcer formation.
- Surgery—for disc herniation, fracture, and some neoplasias and congenital conditions; often the quickest and most effective method of improving the neurologic status.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Medications depend on underlying cause of weakness.
- Corticosteroid use, even in known diseases like spinal trauma or disc herniation, is controversial. May help to allay pain associated with some causes of paralysis, but do not expedite spinal cord recovery.
- Dexamethasone 0.1–0.2 mg/kg q48h for pain relief for two to three doses.
- Prednisolone 0.5–1 mg/kg q12–24h for pain relief for 3–5 days.
- Pyridostigmine bromide 0.5–3 mg/kg PO q8–12h for suspected myasthenia gravis; administer cautiously at low dose while waiting for titer results.
- If acute generalized LMN signs—check for ticks; use appropriate insecticides.

CONTRAINdicATIONS

Corticosteroids—do not use with discospondylitis or fungal or protozoal myelitis/meningitis; do not use with myasthenia gravis if aspiration pneumonia is present.

PRECAUTIONS

Corticosteroids—associated with gastrointestinal ulceration and hemorrhage, delayed wound healing, and heightened susceptibility to infection.

ALTERNATIVE DRUG(S)

- NSAIDS for spinal diseases associated with bone discomfort or pain.
- Tramadol 2 mg/kg q12h PO (dogs or cats), up to 4–5 mg/kg q12h (dogs only) for pain relief. Avoid using with antidepressants.
- Gabapentin 3–10 mg/kg q12h PO for neuropathic pain.
- Butorphanol 0.2–0.6 mg/kg q2–4h for pain control.

**FOLLOW-UP****PATIENT MONITORING**

- Neurologic examinations—daily to monitor status.
- Bladder—evacuate (via manual expression or catheterization) three to four times a day to prevent overdistention and subsequent bladder atony; once bladder function has returned, patient can be managed at home.

POSSIBLE COMPLICATIONS

- Urinary tract infection, bladder atony, urine scalding and pyoderma, constipation, decubital ulcer formation.
- Aspiration pneumonia—with generalized LMN disease or in any quadriplegic patient.
- Myelomalacia—with severe spinal cord trauma or disc herniations.
- Respiratory compromise or paralysis—with myelomalacia or generalized LMN disease.

**MISCELLANEOUS****SEE ALSO**

- Schiff-Sherrington Phenomenon
- Neck and Back Pain
- Syringomyelia and Chiari-like Malformation
- Exercise-Induced Weakness/Collapse in Labradors

PARANEOPLASTIC SYNDROMES

BASICS

OVERVIEW

Paraneoplastic syndromes (PNS) are a diverse group of systemic disorders resulting from the metabolic effects of cancer in tissues remote from the tumor. These disorders are usually caused by production and release of substances not normally released by the tumor cell of origin or in amounts not normally produced by those cells. Other etiologies of PNS aside from production of metabolically active substances include autoimmune disease stimulation, immune complex formation, immunosuppression, and ectopic receptor production/competitive blockade of normal hormones. PNS may also occur secondary to substances produced by normal cells due to the presence of the tumor (e.g., tumor necrosis factor production by reticuloendothelial cells contributing to cancer cachexia). Many PNS in veterinary medicine have an unknown etiology. Pathophysiology depends on the specific PNS (see Table 1).

SIGNALMENT

Any dog or cat with a histologically malignant (most common) or benign cancer (rare).

SIGNS

Vary with tumor type and organ systems affected but include:

- Alopecia (feline paraneoplastic syndrome)
- Anemia
- Cachexia
- Cutaneous flushing
- Diencephalic syndrome
- Disseminated intravascular coagulation
- Eosinophilia
- Gastroduodenal ulceration
- Hypercalcemia
- Hypertrophic osteopathy
- Hypoglycemia
- Myelofibrosis
- Neutrophilic leukocytosis
- Nodular dermatofibrosis
- Polycythemia
- Superficial necrolytic dermatitis
- Thrombocytopathy
- Thrombocytopenia
- Thrombocytosis

P

CAUSES & RISK FACTORS

Production and release of substances not normally released by the tumor cell of origin or in amounts not normally produced by those cells and the substances' subsequent effects on target tissues.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Varies with syndrome

CBC/BIOCHEMISTRY/URINALYSIS

Helpful in identifying and monitoring several of the reported syndromes.

OTHER LABORATORY TESTS

Ionized calcium and parathormone levels—assess patients with hypercalcemia; hypercalcemia of malignancy usually characterized by high ionized calcium and low PTH, may occasionally have elevated PTH-rP.

IMAGING

- Radiography—detect hypertrophic osteopathy
- Advanced imaging (CT or MRI)—detect occult tumor

DIAGNOSTIC PROCEDURES

Biopsy—diagnose paraneoplastic skin lesions

TREATMENT

- Varies based on the underlying tumor and the clinical manifestations of the paraneoplastic syndrome.
- The only definitive treatment is to treat the underlying neoplasia rather than to try to control the clinical signs of the paraneoplastic syndrome. If the primary tumor cannot be treated, then management of clinical signs, as best as possible, is indicated for palliation.

MEDICATIONS

DRUG(S)

Depends on underlying tumor type

FOLLOW-UP

PATIENT MONITORING

As for underlying tumor type

MISCELLANEOUS

ABBREVIATIONS

- CT = computed tomography
- MRI = magnetic resonance imaging
- PTH = parathormone

PARANEOPLASTIC SYNDROMES

Table 1

Syndrome	Primary Tumor Association (Dog)	Primary Tumor Association (Cat)	Primary Mechanism
Alopecia	Adrenal carcinoma		Dogs: due to an excess of cortisol production; most often associated with hyperadrenocorticism Cats: mechanism unknown. See Adenocarcinoma, Pancreas; Hyperadrenocorticism (Cushing's Syndrome—Cats); and Feline Paraneoplastic Alopecia
Alopecia (feline paraneoplastic alopecia)		Pancreatic carcinoma and carcinoma of the biliary tree	
Cachexia	Assorted—true cancer cachexia is relatively rare	Assorted—true cancer cachexia is relatively rare	Severe metabolic derangements likely caused by cytokines and hormones; may result from alterations in lipid, protein, and carbohydrate metabolism that create a net energy loss in spite of adequate caloric intake; anaerobic metabolic pathways of cancer cells may play a role. See Weight Loss and Cachexia
Cutaneous flushing syndrome	Pheochromocytoma; mast cell tumor	Not reported	Inappropriate release of vasoactive substances, such as histamine, causes paroxysmal flushing of the skin
Diencephalic syndrome	Astrocytoma, anaplastic ependymoma	Not reported	Tumor is present in the diencephalon region of the brain; excess of growth hormone results in dramatic weight loss (without acromegaly) despite adequate caloric intake
Disseminated intravascular coagulation	Hemangiosarcoma; many others	Myeloproliferative disease	See Disseminated Intravascular Coagulation
Eosinophilia	Assorted, including lymphoma and mast cell tumors	Assorted, including lymphoma and mast cell tumors	May be due to stimulation of eosinophil precursors by products such as interleukin-2, -3, and -5 and granulocyte-macrophage colony-stimulating factor
Exfoliative dermatitis (feline thymoma associated exfoliative dermatitis)	Not reported	Thymoma	Not completely elucidated, likely due to the induction of autoreacting T-lymphocytes
Feminization syndrome	Testicular tumors—especially Sertoli cell tumors		Due to hyperestrogenism or a relative testosterone:estrogen imbalance that is uncomplicated by myelosuppression
Gastroduodenal ulceration	Non-islet cell pancreatic neoplasia; mast cell tumor	Rare	Inappropriate gastrin secretion (non-islet cell tumor) or excess histamine secretion (mast cell)
Hypercalcemia	Lymphoma; apocrine gland adenocarcinoma of the anal sac (AGASACA); multiple myeloma; others	Relatively rare; lymphoma; squamous cell carcinoma; others	Dogs: multiple secreted factors involved; with lymphoma and AGASACA may involve parathyroid hormone-related protein (PTHrP) production Cats: mechanisms unexplored. See Hypercalcemia
Hypertrophic osteopathy	Metastatic and primary tumors of the lung, intra-abdominal tumors also	Metastatic and primary tumors of the lung, intra-abdominal tumors also	Characterized by distal limb soft tissue swelling followed by periosteal new bone growth. The etiology is unknown. Several mechanisms likely play a role, including vagally-mediated changes in limb perfusion, cytokine and growth factor secretion, immune mechanisms, vascular thrombi caused by platelets and antiphospholipid antibodies, and interaction between activated platelets and the endothelium

P

PARANEOPLASTIC SYNDROMES

(CONTINUED)

Table 1

(Continued)

Syndrome	Primary Tumor Association (Dog)	Primary Tumor Association (Cat)	Primary Mechanism
Hyperviscosity syndrome	Immunoglobulin-secreting tumor (e.g., multiple myeloma, lymphoma)	Immunoglobulin-secreting tumor	Accumulation of large immunoglobulin proteins or polymerized small immunoglobulin proteins in the blood that result in decreased blood flow from increased viscosity. See Multiple Myeloma and Paraproteinemia
Hypoglycemia	Insulinoma; benign and malignant smooth muscle tumors; large mesenchymal tumors; others	Rare; insulinoma	Involves the excess production of insulin or insulin-like factors or excessive glucose utilization. See Insulinoma
Immune complex disorders	Lymphocytic leukemia; primary erythrocytosis	Lymphoma	Secondary to antigen-antibody-immune complex activation; glomerulonephritis is most recognized problem
Myasthenia gravis	Thymoma; others	Very rare; thymoma	Exact mechanism is unknown, likely immune-mediated, may be due to effects of follicular helper T-cells. See Myasthenia Gravis
Myelofibrosis	Assorted	Assorted	See Myelodysplastic Syndromes
Neutrophilic leukocytosis	Hemangiosarcoma; lymphoma; others	Assorted; lymphoma, carcinomas and sarcomas	Production of a granulocyte-monocyte stimulating cytokine is likely cause
Nodular dermatofibrosis	Renal cystadenoma or cystadenocarcinoma primarily in German shepherds and shepherd crosses. Also reported in one golden retriever	Not reported	Mechanism is unknown but involves proliferation of fibroblasts. Propensity to develop is inherited in an autosomal dominant pattern. May be linked to chromosome 5. Loss of heterozygosity/function of the <i>FLCN</i> gene may contribute to neoplastic transformation of renal epithelial cells. Renal tumors are usually slowly progressive and almost always bilateral
Pemphigus	Rare, reported in one case of mediastinal lymphoma and one splenic sarcoma	Not reported	Autoimmunity to target antigens (periplakin and envoplakin) in the skin
Peripheral nerve syndromes	Various	Not reported	Unknown, but usually subclinical and secondary to changes in myelination
Polycythemia	Renal sarcoma and carcinoma; others	Renal carcinoma	Inappropriate secretion of erythropoietin or erythropoietin-like peptides. See Polycythemia and Polycythemia Vera
Superficial necrolytic dermatitis (metabolic epidermal necrosis, hepatocutaneous syndrome, necrolytic migratory erythema)	Hepatic neoplasia; pancreatic neoplasia (glucagonoma)	Pancreatic neoplasia (glucagonoma)	Many names used to describe similar clinical entities; usually observed in patients with hepatic disease and less commonly with glucagon-secreting pancreatic tumors; sometimes referred to as glucagonoma syndrome; exact mechanism is unclear; may see associated glucose intolerance or diabetes mellitus
Thrombocytopenia	Immunoglobulin-secreting tumors	Immunoglobulin-secreting tumors	Immunoglobulin molecules inhibit normal platelet aggregation. See Thrombocytopathies
Thrombocytopenia	Lymphoma, multiple myeloma, hemangiosarcoma, others	Lymphoma, others	Thrombocytopenia, primary immune mediated or secondary to myelophthisis. See Thrombocytopenia
Thrombocytosis	Myeloproliferative disorders	Myeloproliferative disorders	Overproduction of cytokines that stimulate thrombopoietin production (e.g., interleukin-1, -3, -6, -11)

PARAPHIMOSIS, PHIMOSIS, AND PRIAPIST

BASICS

OVERVIEW

- Phimosis—inability to protrude the penis beyond the preputial orifice.
- Paraphimosis—exteriorized penis cannot be retracted back into the sheath. • Priapism—prolonged extrusion of an erect penis not associated with sexual arousal; can result from excessive parasympathetic stimulation or decreased venous outflow from the corpus cavernosum penis; relatively uncommon condition in dogs and rare in cats.

SIGNALMENT

- Dog and cat. • German shepherd and golden retriever—observed congenital preputial stenosis causing phimosis; possibly hereditary. • Siamese cat—one report noted six of seven cases of priapism were Siamese.

SIGNS

- Phimosis—may be undetected until unsuccessful in attempts to copulate; severe defects in the neonate interfere with urination; may cause pooling of urine in preputial cavity, can lead to balanoposthitis, and even septicemia. • Paraphimosis—if recent only sign may be licking of an exteriorized penis; after hours of exposure, may see ischemic necrosis and urethral obstruction; edema and swelling may make differentiation from priapism difficult.
- Priapism—persistent penile erection lasting > 4 hours; bulbus glandis firm and swollen.

CAUSES & RISK FACTORS

- Phimosis—abnormally small preputial orifice; congenital or acquired (e.g., caused by injury or disease); may be associated with a persistent penile or preputial frenulum (thin band of connective tissue joining the penis and prepuce along the ventral glans).
- Paraphimosis—usually associated with erection and/or copulation; preputial hair at the orifice can entrap the penis, especially the bulbus glandis, preventing retraction; moderately stenotic preputial orifice may contribute; injuries; os penis fractures; neurologic disease (encephalomyelitis, intervertebral disc disease); balanoposthitis; penile swelling (neoplasia, strangulation with foreign body); incompetent preputial muscles.
- Priapism—non-ischemic: (arterial, high flow) trauma, vasoactive drugs, neurologic conditions, canine distemper; ischemic (veno-occlusive, low flow): trauma during mating, chronic distemper encephalomyelitis, penile thromboembolism, amphetamine use, penile neoplasia, perineal abscess, cause often unknown; humans (sickle cell disease, hematologic dyscrasias, hemodialysis, fluid therapy, heparin therapy, vasoactive drugs,

spinal cord injury, anesthesia, urethral obstruction due to uroliths).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Paraphimosis—exposure of the glans penis caused by abnormality of the retractor penis muscles or prepuce muscles, large preputial opening, short prepuce, or priapism.
- Priapism—urethral obstruction by uroliths (dysuria).

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal. • Phimosis in neonates—may note severe balanoposthitis and evidence of septicemia (e.g., leukocytosis, neutrophilia progressing to neutropenia, positive urine cultures).

OTHER LABORATORY TESTS

- Penile blood gas analysis to differentiate types of priapism in dogs: ° Ischemic: pH < 7.25, a P_{O_2} < 30 mmHg, P_{CO_2} > 60 mmHg ° Non-ischemic: pH of 7.4, a P_{O_2} > 90 mmHg, P_{CO_2} < 40 mmHg.

DIAGNOSTIC PROCEDURES

- Ultrasonography—visualization of engorged penile vessels. • Neurologic exam, radiographs, magnetic resonance imaging—to evaluate spinal cord.

TREATMENT

PHIMOSIS

- Surgical enlargement of the preputial orifice. • Persistent penile frenulum (dogs)—remove band of tissue holding the glans penis to the parietal lamina of prepuce.

PARAPHIMOSIS

- Requires immediate treatment—after 24 hours, tissue damage and urethral obstruction may necessitate penile amputation; goal: replace the penis in a normal position. • Indwelling urinary catheter—if urethral patency is in question.
- Remove foreign objects. • Lubricate the penis. • Compresses of hypertonic glucose solutions. • Surgically enlarge the preputial orifice, if necessary. • Phalloplasty has reportedly been successful in correcting the condition. • Castration not effective; paraphimosis is not testosterone-dependent.

PRIAPIST

- Aspiration of penile blood may be therapeutic (temporary pain relief) and diagnostic (blood gas analysis to differentiate ischemic from non-ischemic conditions).
- Identifying the underlying cause is often not possible before ischemia of the penis occurs;

penile amputation and perineal urethrostomy usually required due to irreparable ischemic necrosis of the penis; castration not effective.

- Penile amputation and perineal urethrostomy—indicated for cats with difficulty urinating. • Abdominal compression bandage and indwelling urinary catheter—maintain the penis within the prepuce; may also reduce localized edema. Ischemic priapism may be treated with intrapenile injections of phenylephrine (100–500 µg diluted into 1 mL of saline solution).

MEDICATIONS

DRUG(S)

- Antibiotic ointments—maintain treatment; prevent adhesions between penis and prepuce.
- None approved or proven safe.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Phimosis—fair to good if identified prior to development of septicemia. • Paraphimosis and priapism—guarded to poor for return to breeding activity; fair to good for life with early successful medical and/or surgical management.

PARAPROTEINEMIA

BASICS

OVERVIEW

- The presence in the blood of an abnormal protein (paraprotein or M component) produced by a single clone of cells. The paraprotein may be composed of whole immunoglobulin molecules, subunits, light chains, or heavy chains. This disorder is commonly seen with plasma cell neoplasms, such as multiple myeloma, or other immunoglobulin secreting B-cell lymphoproliferative diseases, such as CLL or lymphoma.
- Primary signs are related to the underlying neoplasm and could be related to bony invasion or bone marrow infiltration.
- Markedly elevated serum paraprotein levels can produce signs of HVS.

SYSTEMS AFFECTED

- Musculoskeletal—bone lysis by the neoplastic cells can cause lameness and pathologic fractures.
- Nervous—bone lysis of the vertebrae can cause neurologic signs; disorientation, seizures, cranial nerve deficits, or vestibular signs may be associated with HVS.
- Hemic/Lymphatic/Immune—myelophthisis and secondary immune-mediated destruction may cause anemia, leukopenia, or thrombocytopenia. Hemostasis may be compromised by paraprotein interference with platelet and coagulation factor function; inhibited normal immunoglobulin production leads to decreased immunoglobulin levels, thus an increased susceptibility to infection.
- Ophthalmic—HVS can cause dilated and tortuous retinal vessels, retinal detachment, or retinal hemorrhage.
- Cardiovascular—HVS can cause tachycardia, hypertrophic cardiomyopathy, and gallop rhythm, as well as cardiac failure in cats more often than dogs.
- Renal/Urologic—renal failure is possible secondary to tumor infiltration, HVS causing renal hypoxia, proteinuria, hypercalcemia of malignancy, or infection.

SIGNALMENT

- Dogs—middle-aged to older
- Cats (rare)—older
- No sex predilection

SIGNS

- Lethargy and weakness
- Lameness, paresis
- Epistaxis or gingival bleeding
- Petechia or ecchymoses
- Blindness or retinal hemorrhage
- Polyuria and polydipsia
- Seizures

CAUSES & RISK FACTORS

- Factors contributing to multiple myeloma—genetic predisposition, viral infections, chronic immune stimulation, and exposure to carcinogens have been suggested.
- Retroviruses in cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Monoclonal gammopathy—extramedullary plasmacytoma, lymphoma, chronic and acute lymphocytic leukemia, ehrlichiosis, leishmaniasis, bartonellosis, dirofilariasis, plasmacytic gastroenteritis, feline stomatitis and FIP.
- Polyclonal gammopathy—chronic infectious/inflammatory disorders (e.g., hepatitis/hemoparasites/FIP/fungal), stomatitis, chronic autoimmune disease, and neoplasia.
- Bleeding—in most cases, due to paraproteinemia and thrombocytopenia; other possibilities: paraneoplastic, infectious, or autoimmune immune-mediated thrombocytopenia/pathia and vasculitis.
- HVS—see Hyperviscosity Syndrome.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia/leukopenia/thrombocytopenia—secondary to myelophthisis or autoimmune mechanisms; marked lymphocytosis associated with CLL or lymphoma within the bone marrow.
- Total protein and globulin—elevated.
- Albumin—may be low.
- Calcium—may be high secondary to malignancy, renal failure, or bone lysis.
- Urea and creatinine—may be elevated secondary to primary renal azotemia.
- Proteinuria—caused by light chains (i.e., Bence-Jones protein); not detected on routine test; immunoassay or electrophoresis on the urine sample is needed.

OTHER LABORATORY TESTS

- Protein electrophoresis—identify a monoclonal spike/oligoclonal/polyclonal pattern.
- Immunoelectrophoresis—helps to define the type of gammopathy (i.e., IgG, IgA, or IgM).
- Infectious disease testing.
- Flow cytometry—lymphocytosis.

IMAGING

- Radiology of affected bones—to identify a potential site to aspirate or biopsy.
- Skeletal survey or bone scan—to define extent of lytic lesions. Most common location for multiple myeloma lesions includes vertebral bodies, ribs, pelvis, skull, and proximal long bones.
- Thoracic and abdominal radiography or abdominal ultrasonography—for evidence of enlarged lymph nodes or organomegaly suggestive of lymphoma.

OTHER DIAGNOSTIC PROCEDURES

- Bone marrow aspiration/biopsy—plasma cells < 5% is considered normal, > 20% in dogs or > 10% with special attention to cell morphology in cat is consistent with multiple myeloma; myelophthisis associated with other lymphoproliferative diseases.
- Bone biopsy of lytic lesion—rarely required to diagnose multiple myeloma.
- Lymph node aspiration—to identify neoplastic population of lymphocytes with lymphoma; to identify

amastigotes of *Leishmania* or morulae of *Ehrlichia*.

- Organ cytology, PARR or histopathology and immunohistochemistry—for neoplastic populations of cells, infectious agents (e.g., immunofluorescence for FCoV in macrophages), or amyloid; note: coagulopathies may prevent invasive diagnostics.

TREATMENT

- Supportive care depending on the manifestation of disease and the organ systems affected.
- HVS—see Hyperviscosity Syndrome.
- Chemotherapy for neoplastic processes, such as multiple myeloma.

MEDICATIONS

DRUG(S)

- See specific diseases for appropriate chemotherapy or antibiotic choices.

FOLLOW-UP

- See specific diseases.
- Electrophoresis may be monitored as an indication of response to therapy.

PATELLAR LUXATION

BASICS

DEFINITION

Medial or lateral displacement of the patella from its normal anatomic position in the femoral trochlea.

PATHOPHYSIOLOGY

- Clinical signs may be mild to severe; different degrees of clinical and pathologic changes; classified into grades I—IV.
- Common musculoskeletal changes—tibial rotation on its long axis; bowing of the distal femur and proximal tibia; shallow to absent femoral trochlea; dysplasia of the femoral and tibial epiphysis; displacement of the quadriceps muscle group.

SYSTEMS AFFECTED

Musculoskeletal

GENETICS

- Recessive, polygenic, and multifocal inheritances proposed.
- Hereditary factor in Devon Rex cats.

INCIDENCE/PREVALENCE

- One of the most common stifle joint abnormalities in dogs.
- Medial—> 75% of cases (large and small dogs and cats).
- Bilateral involvement—50% of cases.
- Uncommon in cats, but may be more common than suspected because most affected cats are not lame.

SIGNALMENT

Species

- Predominantly dog
- Rarely cat

Breed Predilections

- Most common in toy and miniature dog breeds.
- Dogs—miniature and toy poodles; Yorkshire terriers; Pomeranians; Pekingese; Chihuahuas; Boston terriers.

Mean Age and Range

Clinical signs—may develop soon after birth; generally after 4 months of age.

Predominant Sex

Risk for females 1.5 times that for males

SIGNS

General Comments

Clinical expression depends on grade (severity), amount of degenerative arthritis, chronicity of disease, and occurrence of other stifle joint abnormalities (e.g., cruciate ligament rupture).

Historical Findings

- Persistent abnormal hind limb carriage and function in neonates and puppies.
- Occasional skipping or intermittent hind limb lameness—worsens in young to mature dogs.

- Sudden signs of lameness—owing to minor trauma or worsening DJD in mature animals.

Physical Examination Findings

- Grade I—patella can be manually displaced from the trochlea, but immediately resumes a normal position when pressure is released.
- Grade II—patella can be manually displaced or can spontaneously do so with flexion of the stifle joint; patella remains malpositioned until it is manually reduced or the patient extends the stifle joint. Patient intermittently carries the affected limb with the stifle joint flexed.
- Grade III—patella remains luxated most of the time but can be manually reduced with the stifle joint in extension; movement of the stifle joint results in relaxation of the patella.
- Grade IV—patella is permanently luxated and cannot be manually repositioned; may be up to 90° of rotation of the proximal tibial plateau; shallow or missing femoral trochlea.
- Grades III and IV—crouching, bowlegged (genu varum) or knock-kneed (genu valgum) stance for medial or lateral luxations, respectively; most of the body weight is transferred to the front limbs.
- Pain—occurs as the patella relocates or if abrasion creates contact with exposed bone.

CAUSES

- Congenital
- Rarely, traumatic

RISK FACTORS

Coxa vara—lateral displacement of the proximal femur; vastus medialis pulls patella medially.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cranial cruciate ligament rupture—positive cranial drawer; concurrent in 15–20% of cases.
- Avulsion of the tibial tubercle—patellar alta.
- Rupture of the patellar tendon—patella alta.
- Malunion and malalignment of fractures of the femur or tibia—may result in displacement of the quadriceps muscle group.

IMAGING

Patella luxation is diagnosed based on clinical signs and physical examination. Computed tomography or orthogonal radiography of the femur and tibia may be indicated in Grade III and IV luxations to assess bowing and torsion of the femur and tibia.

DIAGNOSTIC PROCEDURES

Palpation of patellar position and movement during flexion and extension of the stifle. Medial and lateral force exerted on patella to relocate the patella into the trochlear groove (if luxated) or luxate the patella (in Grade I or II luxations).

PATHOLOGIC FINDINGS

- Gross—cartilage wear lesions of the patella and femoral trochlea; joint capsule redundancy on the side opposite to luxation; fibrosis and contracture on the side of luxation.
- Microscopic—cartilage fibrillation and loss of glycosaminoglycan content; synovitis.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—all grade I and some grade II luxations.
- Inpatient (surgery)—most grade II and all grade III and IV luxations.

NURSING CARE

- Cryotherapy (ice packing)—immediately after surgery; 5–10 minutes q8h for 3–5 days.
- Passive stifle range-of-motion exercises—as soon as tolerated.

ACTIVITY

Normal to restricted, depending on severity and if surgical correction was performed.

DIET

Weight control—decreases the load and stress on the patella support mechanism.

CLIENT EDUCATION

- Discuss the heritability of the condition.
- Warn about relapse potential after surgery. Retrospective studies indicate that 8%–19.8% of patellas relaxate after surgery. Revision surgery is necessary in 13% of cases.
- Inform about increased risk of cranial cruciate ligament disease.
- Warn that the condition could worsen over time (e.g., from grade I to grade II).

P

SURGICAL CONSIDERATIONS

- Malalignment is the underlying cause—tibial crest transposition is the definitive realignment procedure, but often needs to be combined with other techniques such as sulcoplasty.
- Retinacula and joint capsule tension on the side of luxation prevents realignment—medial capsulotomy (release) is essential.
- Shallowness of the trochlea sulcus is assessed and managed with one of the following:
 - Trochleoplasty—rasp or burr to deepen the sulcus.
 - Trochlea chondroplasty—only indicated in very young dogs; lift the surface hyaline cartilage and curette out cancellous bone to deepen the sulcus; lay the cartilage back over exposed bone.
 - Recession sulcoplasty—remove a pie-shaped wedge; deepen the defect, replace the wedge; preferred technique for most patients since the surface cartilage is mostly intact.

PATELLAR LUXATION

(CONTINUED)

- Block recession sulcoplasty—remove a block instead of a wedge; increases surface area of cartilage in contact with patella.
- Transposition of the tibial tubercle—realign the longitudinal axis of the quadriceps mechanism so that it is centered over the femoral trochlea; osteotomize the tibia tubercle leaving it attached distally, transpose it opposite the direction of luxation, and stabilize it with K-wires and, in larger dogs, a tension band wire.
- Imbricate the joint capsule and supporting soft tissues on the side opposite the luxation—to help keep the patella in the sulcus. Imbrication as a sole procedure is not sufficient to permanently correct the position.
- Corrective osteotomies of the distal femur and proximal tibia—realigns the longitudinal axis of the hind limb; generally indicated for only grade IV luxations with significant bowing and torsion.

MEDICATIONS

DRUG(S) OF CHOICE

- NSAIDs—minimize pain; decrease inflammation; meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg daily PO—liquid), carprofen (2.2 mg/kg PO q12h), etodolac (10–15 mg/kg PO q24h), deracoxib (3–4 mg/kg PO q24h—chewable) for 7 days (for postoperative pain).

CONTRAINDICATIONS

Avoid corticosteroids because of potential side effects and articular cartilage damage associated with long-term use.

P

PRECAUTIONS

NSAIDs—gastrointestinal irritation may preclude their use.

ALTERNATIVE DRUG(S)

Supplementation with omega-3 fatty acids (fish oils) is useful to decrease joint inflammation. Chondroprotective drugs (e.g., polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate)—may help limit cartilage damage and degeneration, but recent evidence suggests they are not or are only minimally efficacious.

FOLLOW-UP

PATIENT MONITORING

- Post-trochleoplasty—encourage early, active use of the limb.
- Leash walk exercise for 4 weeks; prevent jumping. When corrected with tibial crest transposition, cage rest is indicated until follow-up radiographs indicate the crest is healed in its new position.
- Yearly examinations—to assess progression.

PREVENTION/AVOIDANCE

- Discourage breeding of affected animals.
- Do not repeat dam-sire breedings that result in affected offspring.

POSSIBLE COMPLICATIONS

Infection, recurrence, tibial crest avulsion, pin migration.

EXPECTED COURSE AND PROGNOSIS

- With surgical treatment—> 90% of patients are free from lameness and clinical dysfunction.
- DJD—radiographic evidence in almost all affected stifle joints after surgery. Clinical impact appears minimal in small dogs.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Cranial cruciate ligament disease

SEE ALSO

Arthritis (Osteoarthritis)

ABBREVIATIONS

- DJD = degenerative joint disease
- NSAID = nonsteroidal anti-inflammatory drug

PATENT DUCTUS ARTERIOSUS

BASICS

DEFINITION

Persistent patency of the fetal ductus arteriosus connecting the descending aorta to the pulmonary artery.

PATHOPHYSIOLOGY

The ductus arteriosus fails to close following birth permitting persistent communication between the aorta and pulmonary artery. Blood typically shunts from left to right. Hemodynamic consequences depend on the size of the shunt, pulmonary vascular resistance, and concurrent heart defects. Small shunt volumes are well tolerated; moderate-to-large shunt volumes cause left-sided CHF from volume overload of the left ventricle. Much less frequently, a large-diameter PDA causes severe pulmonary vascular injury, high pulmonary vascular resistance, pulmonary hypertension, and reversal of the shunt (Eisenmenger's pathophysiology or "reversed" PDA), with bidirectional shunting across the ductus. Patients affected with right-to-left shunting suffer from arterial desaturation and hypoxia-triggered erythrocytosis.

SYSTEMS AFFECTED

- Cardiovascular—volume overload (left-to-right shunt) or pulmonary vascular disease and erythrocytosis (right-to-left shunt).
- Hemic/Lymph/Immune—increased red cell mass and hyperviscosity if erythrocytosis develops.
- Respiratory—symptoms of cough or labored breathing if pulmonary edema or pulmonary hypertension develop.

GENETICS

Genetically transmitted ("polygenic" model) defect in many canine breeds, including the bichon frise, Cavalier King Charles spaniel, Chihuahua, cocker spaniel, collie, English springer spaniel, German shepherd, Labrador retriever, Maltese, miniature (and toy) poodle, Pomeranian, Shetland sheepdog, and others.

INCIDENCE/PREVALENCE

Very common congenital heart defect in dogs; prevalence estimated to be up to 2.5 cases/1,000 live births. Uncommon in cats.

SIGNALMENT

Species

Dog and cat

Breed Predilections

See "Genetics"

Mean Age and Range

- Vast majority are identified during the initial vaccination sequence
- Onset of signs related to CHF—weeks to many years

Predominant Sex

Dogs—females predisposed in many breeds

SIGNS

General Comments

- Onset of reversed PDA—quite sudden in dogs (usually before 4 months of age); might develop more gradually in cats.
- No significant documentation that shunt reversal begins after 6 months of age in dogs, but signs related to reversed shunting might be overlooked for years. The onset of clinical signs has been reported in dogs older than 5 years of age.

Historical Findings

- Most affected animals are asymptomatic at initial evaluation.
- Respiratory distress, coughing, exercise intolerance with development of CHF.
- Stunted growth in some.
- Right-to-left shunting PDA—exertional rear limb weakness and complications of erythrocytosis and hyperviscosity (seizures or sudden death related to arrhythmias or microvascular thrombi).
- Signs usually precipitated by or worsened by exercise.

Physical Examination Findings

- Typically, continuous, machinery-type murmur loudest over pulmonary artery at the left craniodorsal cardiac base; localized in some dogs; murmur can be loud near the manubrium sterni in small dogs; often a concurrent systolic murmur of mitral regurgitation at the left apex. The murmur in puppies < 6 weeks of age or in cats of any age might not be obviously continuous, but more resemble a long systolic and early diastolic murmur.
- Loud murmurs—associated with a palpable precordial thrill.
- Arterial pulses—hyperkinetic ("waterhammer").
- Caudodorsal displacement of the ventricular apex indicating LV enlargement.
- Tachypnea, respiratory distress, and inspiratory crackles—can indicate left-sided CHF or concurrent primary respiratory disease such as pneumonia.
- Rapid, irregular cardiac rhythm with variable-intensity arterial pulses if atrial fibrillation develops—this is more common in larger breed dogs.
- In right-to-left shunting ("reversed") PDA the findings differ—no continuous murmur, normal arterial pulses, and a prominent right ventricular impulse; systolic ejection murmur and a tympanic, or split, second heart sound might be evident; jugular pulse is possible.
- Classic feature of right-to-left shunting PDA is differential cyanosis—pink cranial, but cyanotic caudal, mucous membranes. Severe secondary erythrocytosis or an intracardiac shunt (septal defect or patent foramen ovale) can cause cyanosis of the cranial mucous membranes.

CAUSES

Genetically predisposed in most cases

RISK FACTORS

Genetic (breed) predisposition in dogs; risk

factors in cats are unknown; a large diameter PDA is a risk factor for shunt reversal.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Principal auscultatory differentials are congenital aortic stenosis with aortic insufficiency (to-and-fro systolic/diastolic murmurs) and ventricular septal defect with aortic valve prolapse into the defect (causing a systolic murmur of VSD and diastolic murmur of aortic regurgitation).
- Other rare causes of continuous thoracic murmurs—arteriovenous fistula of the lung, aortopulmonary communication, rupture of the aorta into the right atrium or right ventricle, or coronary artery fistula.
- Systemic arterial to pulmonary artery fistula(s) can result in similar imaging findings to those of PDA; murmurs are often soft or absent.
- Rear limb weakness of right-to-left shunting PDA if often misdiagnosed as a neuromuscular disease, especially myasthenia gravis.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal unless right-to-left shunting in which case variable degrees of erythrocytosis (PCV 58–80%) might be present.

OTHER BLOOD TESTS

Reversed PDA—low femoral arterial pO_2 compared to a pO_2 obtained by careful puncture of the carotid or brachial artery using a 25-gauge needle. This is rarely if ever needed for diagnosis. Pulse oximetry of the cranial membranes compared to the rectum might document the disparity in hemoglobin saturation.

IMAGING

Thoracic Radiographic Findings

- Lateral projection—left heart enlargement; typically pulmonary overcirculation; frequently the lobar pulmonary veins are slightly larger than the attendant arteries.
- Dorsoventral view (preferable to accentuate the descending aorta) demonstrates cardiac elongation (left ventricular enlargement), left auricular enlargement, and dilation of the descending aorta (called a "ductus bump"); the main pulmonary artery is dilated.
- Left-sided CHF—distended pulmonary veins, increased interstitial/alveolar densities.
- Reversed PDA—heart usually normal sized, but the contour of the right cardiac border is more prominent on the DV view, and the pulmonary circulation appears normal to reduced; the main pulmonary artery and proximal lobar branches are dilated; a ductus bump often is evident on the DV view; lung fields are clear.

PATENT DUCTUS ARTERIOSUS

(CONTINUED)

Echocardiographic Findings

- Left atrium, left ventricle, and main pulmonary artery are dilated; right ventricle is normal, except in cats, in which it is more likely to be hypertrophied; the ductal ampulla and the distal ductus can generally be imaged from the right and left cranial hemithorax.
- Left ventricular systolic function (fractional shortening) is normal to reduced; can be markedly decreased in large dogs with long-standing PDA.
- Doppler studies demonstrate continuous flow into the main pulmonary artery (from the ductus); often concurrent pulmonary insufficiency from dilation of the pulmonary artery, and mitral regurgitation caused by left-sided cardiac dilatation; transmural flow velocity and transaortic flow velocity are high because of increased volume and left atrial pressure; aortic velocities can be augmented substantially (up to 2.5–3 m/second), mimicking findings of mild subvalvular aortic stenosis. Trivial aortic regurgitation often evident likely from aortic dilatation and increased flow across the valve.
- Right-to-left shunting PDA—small left heart chambers, right atrial dilation, right ventricular hypertrophy, and dilation of the main and branch pulmonary arteries; contrast echocardiography is useful to confirm the diagnosis; inject saline in the cephalic vein while imaging the abdominal aorta. Color and spectral Doppler studies can identify low velocity bidirectional shunting across ductus. High velocity pulmonary and tricuspid regurgitation jets indicative of pulmonary hypertension might be detected.

Angiographic Findings

- Echocardiography has completely supplanted angiography for the diagnosis.
- Standard angiography is useful for the differential diagnosis of rare aortic or coronary arterial malformations, abnormal aortic arch (with right-sided ductus arteriosus), systemic arterial to pulmonary artery fistulas, and during interventional catheterization procedures. Injection of contrast media into the descending aorta demonstrates ductal morphology, information crucial to catheter-based ductal occlusion techniques. Computed tomography angiography is an alternative for delineation of some of these lesions.

DIAGNOSTIC PROCEDURES

Electrocardiography

- ECG—mainly used in PDA to diagnose auscultable arrhythmias. • Typical abnormalities include wide P waves and tall R waves in the caudal leads (II, aVF, III) and left precordial leads.
- Atrial fibrillation—observed infrequently, related to marked dilatation of the left atrium; more common in large-breed dogs.
- Right-to-left shunting PDA—findings of right ventricular

enlargement, S waves in leads I, II, III and right axis deviation are more typical but variable.

PATHOLOGIC FINDINGS

- Persistent patency of the ductus arteriosus between descending aorta and origin of the left pulmonary artery.
- Left-to-right shunting PDA—pulmonary edema, cardiomegaly (left sided), and dilation of the aorta and pulmonary artery.
- Right-to-left shunting PDA—right ventricular hypertrophy, dilation of the pulmonary artery, and prominent bronchial arteries; ductal diameter is invariably very wide, similar to the descending aorta. Pulmonary arterioles are thickened; there are often histologic changes of pulmonary vascular disease (medial hypertrophy, plexiform lesions or necrotizing arteritis).

TREATMENT

APPROPRIATE HEALTH CARE

- Manage pulmonary edema with furosemide and, if necessary, oxygen, nitrates, and cage rest; following stabilization, promptly occlude the PDA.
- Ductal closure involves surgical ligation or occlusion with a canine ductal occluder device, thrombogenic coil, or vascular plug device—refer to an experienced surgeon or to a cardiologist for these procedures.
- Schedule stable animals for elective surgery or device closure without delay; asymptomatic dogs as young as 7–8 weeks of age show no higher operative mortality than older dogs.
- Treat dogs with erythrocytosis caused by right-to-left shunting PDA with rehydration or, if needed, by periodic phlebotomy to maintain the PCV < 65% (typically 62–65%). Rarely hydroxyurea is used for intractable erythrocytosis.

ACTIVITY

- Restrict activity until the ductus is closed and in all dogs with CHF.
- After removal of any sutures and first follow-up examination, resume normal activity.

DIET

Normal; but restrict sodium intake if CHF.

CLIENT EDUCATION

- Surgical or transcatheter ductal closure—do not delay; mortality is higher and left ventricular function impaired if clinical signs or atrial fibrillation develop.
- Following successful closure of the PDA and a 2-week convalescence, the dog can be treated normally.

SURGICAL CONSIDERATIONS

- Closure of a PDA can be achieved through surgical ligation or by placement of a catheter-delivered, occluding or thrombogenic device

within the ductal lumen. Smaller patient sizes (< 2.5 kg) are a limiting factor with current PDA devices, but new, lower-profile devices have been developed and tested recently.

- Surgery can generally proceed within 24–48 hours of medical stabilization.
- Standard therapy involves ductal ligation via left thoracotomy; surgical and perioperative mortality should be < 3% for all cases.
- Mortality with devices is even lower, but some complications including failure to achieve closure are reported.
- Results obtained with catheter-delivered occlusion devices are very good when done by experienced operators.
- Never correct right-to-left PDA surgically; the right ventricle will not be able to eject against the pulmonary vascular resistance without the “pop-off valve” of the PDA.
- PDA with moderate pulmonary hypertension can sometimes be closed, especially in cats, provided pulmonary vascular resistance is not fixed and predominant shunting is left to right. Refer to a cardiologist for evaluation.

MEDICATIONS

DRUG(S) OF CHOICE

- Treat pulmonary edema with furosemide (2–4 mg/kg q6–12h PO, SC, IM, or IV as required); can be discontinued when the PDA is closed.
- When surgery is not an option—if CHF, prescribe furosemide, ACE inhibitor such as enalapril (0.5 mg/kg q12–24h PO), and pimobendan (0.25–0.3 mg/kg q12h PO).
- When atrial fibrillation has developed add digoxin and diltiazem (see Atrial Fibrillation and Atrial Flutter). An alternative is electrical cardioversion—this is a reasonable therapy provided the ductus can be closed—refer to a cardiologist.
- To control severe, life-threatening CHF—can use direct vasodilators such as hydralazine (1–2 mg/kg q12h PO) or sodium nitroprusside (1–5 µg/kg/minute IV) to reduce left-to-right shunting. Maintain systolic blood pressure at 85–90 mmHg.

CONTRAINDICATIONS

- Left-to-right PDA—drugs that increase systemic vascular resistance and arterial blood pressure, except as needed for anesthesia and surgery.
- Right-to-left PDA—drugs that lead to systemic arterial vasodilation and reduce systemic arterial blood pressure, including drugs with arterial vasodilating effects.

PRECAUTIONS

- Measure digoxin levels if prescribed.
- Monitor arterial blood pressure, renal function, and serum electrolytes to identify problems related to diuretic and vasodilator therapies.

(CONTINUED)

PATENT DUCTUS ARTERIOSUS**POSSIBLE INTERACTIONS**

Aggressive diuresis leading to dehydration or hypokalemia exacerbates the risk for digoxin toxicity.

ALTERNATIVE DRUG(S)

- Prostaglandin inhibitors (e.g., indomethacin) do *not* close PDAs effectively in dogs.
- Sildenafil—a minimum 2- to 3-week trial course should be given to dogs with reversed PDA; clinical signs can improve significantly in some dogs on long-term therapy.
- Hydroxyurea—consider for treatment of severe erythrocytosis unresponsive to phlebotomy; not always effective and adverse effects are possible.

**FOLLOW-UP****PATIENT MONITORING**

- Pain management is appropriate post-thoracotomy and shortens the recovery time. Opiate therapy is generally administered perioperatively for 24–48 hours. Instill long-acting local anesthetic in the surgical wound prior to closure. Analgesic therapy following catheter-based closure is less aggressive but also continued for 24–48 hours.
- Postoperative—monitor vital signs and respiratory rate; dyspnea can indicate pneumothorax.
- Cardiac auscultation postoperatively and at suture removal; if heart sounds are normal, no further follow-up or diagnostic studies are required unless preoperative echocardiography showed moderate to severe LV dysfunction. There is no basis for recommending annual cardiac reevaluation of uncomplicated cases.
- Persistent, continuous murmur indicates either incomplete closure of the ductus, recanalization (rule out infection or device migration), or a concurrent cardiac or vascular defect.
- Systolic murmurs are variably heard postoperatively; these should abate by the time of suture removal. Reinvestigate unexpected murmurs by Doppler echocardiography. When only partial ligation at surgery is achieved, consider referral to a cardiologist for device occlusion.
- Sudden illness, fever, or acute respiratory signs postoperatively—consider bacterial infection of the closure site with hematogenous pneumonia; aggressive antibiotic therapy

needed. • An unusual complication is acquired stenosis of the main or branch pulmonary artery following surgery to correct PDA.

PREVENTION/AVOIDANCE

Do not breed affected animals.

POSSIBLE COMPLICATIONS

- Left-sided CHF.
- Cardiac arrhythmias (atrial fibrillation).
- Pulmonary vascular disease with pulmonary hypertension, reversed shunting, exercise intolerance, and erythrocytosis.
- Perioperative death (from torn ductus or aortic aneurysm), bleeding, or infection.
- Recanalization of the ductus.
- Pulmonary or systemic embolization from a dislodged occluding device; hemolysis from device-induced RBC fragmentation; sepsis from infected surgical site or implanted device.

EXPECTED COURSE AND PROGNOSIS

- Infrequently dogs remain asymptomatic for life. PDA closure adds an estimated 10 years to median lifespan in dogs (12 years with closure, 2 years without). In other reports, ~50–60% of dogs died from CHF within 1 year of diagnosis if the PDA is not closed.
- Surgery performed prior to onset of moderate-to-severe CHF—excellent prognosis with approximately 2–3% surgical/perioperative mortality in the most experienced hospitals. Even lower mortality and excellent closure results are obtained in *experienced* hospitals using ductal occluding devices.
- Moderate-to-severe CHF is related to left ventricular myocardial failure or atrial fibrillation—guarded prognosis; referral to a cardiologist is advised.
- Dogs with right-to-left shunting PDA can live for several years but often die suddenly; occasionally, dogs live beyond 5 years of age (especially cocker spaniels).
- Cats—varies from rapidly progressive left-sided CHF to gradual development of pulmonary vascular disease; even right-sided CHF can develop with PDA and pulmonary vascular disease.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Typically an isolated defect, but is recognized in conjunction with other congenital heart

lesions; these seem more likely in larger breeds. Occasionally a vascular ring anomaly is evident, such as persistent right fourth aortic arch.

AGE-RELATED FACTORS

Presentation is typically young animals, median age of presentation reported as 5 months in dogs.

PREGNANCY/FERTILITY/BREEDING

Carries greater risk for CHF in pregnant bitches; offspring carry greater risk for large PDA or reversed shunting due to pulmonary vascular disease; do not breed affected dogs.

SYNOMYNS

Duct of Botallo, or ductus Botalli

PECTUS EXCAVATUM

BASICS

OVERVIEW

- Deformity of the sternum and costal cartilages that results in a dorsal to ventral narrowing of the chest, primarily in the caudal aspect.
- Can have secondary abnormalities of respiratory and cardiovascular function from restriction of ventilation and cardiac compression.
- Considered congenital in origin although an acquired case has been reported.
- Upper respiratory obstruction at a young age could cause abnormal respiratory gradients and subsequent pectus excavatum.
- Uncommon defect.
- Concurrent cardiac defects common.
- Some patients demonstrate swimmer syndrome—neonatal dogs lack the ability to posture properly and remain in sternal recumbency, which can lead to invagination of the sternum.

SIGNALMENT

- Dog and cat.
- Brachycephalic breeds and Bengal cats may be predisposed.
- Most common age of presentation: 4 weeks–3 months.
- Male cats more often reported than females, no gender predisposition noted in dogs.

SIGNS

- Thoracic defect, easily palpated or seen.
- Varying degrees of respiratory distress.
- Exercise intolerance.
- Weight loss.
- Recurrent respiratory infections.
- Cough.
- Vomiting.
- Cyanosis.
- Poor appetite.
- Cardiac murmurs associated with concurrent cardiac defects or compression of the heart.
- Muffled heart sounds.
- No correlation between severity of signs and severity of anatomic or physiologic abnormalities.
- Vertebral deformities.
- Swimmer syndrome—limbs not adducted properly; ambulation impaired.

CAUSES & RISK FACTORS

- Genetic predisposition—may exist.
- Unknown etiology—suspected causes include intrauterine pressure abnormalities, shortening of central tendon of the diaphragm, cranial abdominal muscle

deficiency, and abnormal osteogenesis or chondrogenesis.

- Dogs predisposed to respiratory obstructive processes have a higher risk than others.
- Single report in a geriatric Golden retriever with laryngeal paralysis.
- Puppies raised on surfaces causing poor footing may be predisposed to swimmer syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congenital diaphragmatic hernia (pleuroperitoneal or pericardioperitoneal)
- Tracheal malformations or collapse
- Congenital heart defects
- Pulmonary edema
- Hemothorax
- Pyothorax
- Pneumonia
- Tracheobronchitis/bronchitis
- Brachycephalic airway syndrome

IMAGING

Thoracic Radiography

- Confirm sternal and costal skeletal abnormalities.
- Decreased thoracic volume.
- Cardiac malpositioning—left and cranial displacement of cardiac silhouette.
- Concurrent secondary pulmonary disease.
- Measure frontosagittal and vertebral indices to characterize degree of deformity as mild, moderate, or severe and help predict response to treatment.

Echocardiography

Rule out concurrent congenital cardiac defects or other cardiac disease.

TREATMENT

- Decision to repair deformities—made on the basis of clinical signs. If incidental finding with minimal to no clinical signs, then intervention may not be indicated.
- Treatment options include external coaptation, partial sternectomy, or both. Decision based on age of the animal and degree of deformity.
- Surgery benefits patients with concurrent respiratory distress; benefits unknown in patients with no respiratory distress but with moderate or severe deformity.
- Non-clinical patients can develop signs at later date; patients with clinical signs of disease may show progression.

- Puppies with swimmer syndrome—place on surfaces with excellent footing; careful toggling of front and rear legs may improve adduction.

- Brachycephalic breeds with concurrent upper airway obstruction may benefit from surgery directed at these problems.
- Anesthesia—patients require constant monitoring; ventilatory support should be available.

MEDICATIONS

DRUG(S)

Treat underlying or secondary medical conditions.

FOLLOW-UP

- Examinations—dictated by clinical signs or when surgical intervention has been precluded.
- No specific actions for avoiding disease; genetic factors may sometimes be involved.
- Progression of respiratory signs—can develop in nonclinical or mildly clinical patients.
- Prognosis—guarded to good depending on properly timed and expertly administered intervention.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Cardiac defects
- Swimmer syndrome

PEDIATRIC BEHAVIOR PROBLEMS AND TRAINING—DOGS

BASICS

DEFINITION

These problems include behaviors that are normal and common to most puppies but not acceptable to the family. They require some degree of modification by training and shaping to become acceptable. Training and behavior issues include confinement training, house training, destructive chewing (see *Destructive Behavior—Dogs*), playbiting, jumping on people (see *Unruly Behaviors: Jumping, Pulling, Chasing, Stealing*), and getting on counters or furniture.

SYSTEMS AFFECTED

Behavioral

GENETICS

- Activity levels and behaviors of young pups are likely to be similar to those of their parents.
- Some problems may be more prevalent in certain breeds such as those with a high need for exercise and mental stimulation.

INCIDENCE/PREVALENCE

Common to most puppies

GEOGRAPHIC DISTRIBUTION

May be more frequent in urban environments or where opportunities to exercise are less available.

SIGNALMENT

Species

Dog

Breed Predilections

Breeds selected for high-energy, stamina, and working functions (e.g., retrieve, hunt, herd).

Mean Age and Range

3–9 months of age but some may persist through adulthood.

Predominant Sex

May be higher frequency and intensity in males.

SIGNS

Confinement training

N/A

House training

N/A

Playbiting

- The pet bites hands, legs, and/or clothing. Bites are usually inhibited but can cause injuries due to sharp teeth or insufficient bite inhibition.
- Growling and barking may be present but usually a higher pitch with lower tones associated with other types of aggression (e.g., fear-related, possessive).
- Attacks are usually triggered by movement or play with a family member but can be spontaneous.

Getting on Counters/Furniture

- The pet gets on furniture and counters to explore and access objects to chew or eat.

- The pet may also climb onto furniture during play, to get attention, or to rest.

CAUSES

General

- Normal puppy play and exploration
- Inadequate owner supervision, management, training, socialization, mental stimulation or environmental enrichment
- Owner responses may reinforce or exacerbate the behaviors.

Confinement training

N/A

Housetraining

N/A

Playbiting

- A normal behavior, but rough play, teasing, and encouraging the pet to bite hands and feet may cause or contribute to problems.

Getting on Counters/Furniture

- Insufficient outlets for normal play and exploration
- Tempting objects or food left on counters/furniture
- Desire for social interaction
- No acceptable alternative bedding on which to rest

RISK FACTORS

See "Causes"

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Confinement training

N/A

House training

N/A (rule out medical)

Playbiting

- Fear-related aggression*—aggressive behavior is accompanied by signs of fear and/or submission (lowered body, ears and tail down/tucked, horizontal retraction of oral commissures). ° The behavior occurs when the pet is in a situation it perceives as threatening. ° Vocalization might include growling or yelping.
- Possessive aggression*—the behavior occurs in specific situations in which there is competition for a resource.
- The pet stiffens and hovers over the guarded object.
- An increase in the speed of eating or quickly grasping an object tightly in the mouth may also be observed.
- Growling has a deep tone.
- Piloerection may occur, as might lunging, snapping, and biting.
- The pet learns that aggressive behavior is effective at achieving goals (avoid being picked up, pushed off couch, restrained by collar, nails trimmed).
- Conflict-related aggression*—the pet bites in situations where it is frustrated or uncertain how to respond due to inconsistent outcomes (reward/punishment).
- Medical*, e.g., viral encephalitis, toxins, congenital disorders, usually accompanied by other signs of illness.

Getting on Counters/Furniture

N/A

CBC/BIOCHEMISTRY/URINALYSIS

Refractory house training problems may require a urinalysis, fecal exams or other testing as suggested by physical exam and history. If neurologic signs or pain, further medical assessment including imaging would be required.

DIAGNOSTIC PROCEDURES

N/A unless showing concurrent signs of illness.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient

NURSING CARE

N/A

ACTIVITY

Provide a regular daily routine of exercise, play, and mental stimulation.

DIET

- Provide sufficient food and chew toys to reduce the motivation to steal and chew.
- Use food-dispensing toys to slow feeding and provide oral and mental stimulation.

CLIENT EDUCATION

General

- Family members should constantly look for and reward acceptable behaviors.
- Avoid harsh verbal or physical punishment (e.g., striking the pet, shaking by the scruff, rolling on the back, squeezing lips against teeth). This may worsen problems, negatively impacts the bond with the pet, and can lead to more serious problems (such as fear, aggression).
- Teach the pet to sit on command by using food-lure training, and ask him to sit prior to getting anything he wants or needs.

Confinement training

- The goal is to acclimate the pup to being confined in a safe, comfortable area to prevent housesoiling, destructiveness, injury, and provide a safe haven for rest, chew toys, and perhaps eating, also accustoms him to confinement for traveling and boarding.
- Choose an appropriate confinement area (CA). A crate is good for intermittent confinement but no longer than the puppy can control its urine and stools (gradually increasing from 1–2 to 4–5 hours). If the pet must be confined for > 5 hours on a daily basis, a larger housing area should be provided with an elimination area within.
- Introduce the pup to the CA early. Place treats, toys, or food in the area so that he is motivated to enter. Whenever the pup is tired or sleepy, place him in his CA. To maintain a positive association, the pup should never be scolded or roughly forced in.
- Some degree of distress

PEDIATRIC BEHAVIOR PROBLEMS AND TRAINING—DOGS (CONTINUED)

vocalization may occur the first few times the pup is confined. A radio, TV or CD may help calm the pet and mask environmental noises that trigger barking. A calming pheromone (Adaptil) sprayed in the crate or a diffuser in the room may help the puppy adapt. Avoid releasing the pup when he cries or whines. Wait until he is quiet, or squeak a toy from out of sight to get the pup to quiet before he is released.

House training

• The puppy should be taken out to eliminate each hour when awake during the daytime when the family is home. If he does not eliminate within 5 minutes, return indoors, supervise closely for 15–30 minutes and try again. Take the pet out when he is most likely to need to eliminate: after play, exercise, naps, eating, drinking, confinement, as well as prior to confinement, as well as when he exhibits pre-elimination circling and sniffing. Offer food 2–3 times each day for 20 minutes at the same time to help establish an elimination routine. • Until the puppy has completed 4 consecutive weeks without soiling, it should either be within eyesight of the family or confined to its CA. A leash will help keep the pet close and can be used to interrupt an attempt to eliminate indoors. Most pups can control elimination through the night by 3–4 months of age. By 4 months of age, most puppies will have 2–3 hours or more of control during the daytime. Soiling can be prevented by closing doors or moving furniture to limit access to areas and by making locations aversive with a motion-activated alarm. • Punishment should not be used. If urine or stool is found in the home after the act, the owner was not sufficiently supervising. If caught in the act of eliminating indoors, the puppy should calmly be interrupted, and taken outdoors. Urine and stool odors should be removed. • If the puppy eliminates in its crate: he may have been left there longer than he can control eliminating; the crate may be so large that he sleeps in one end and eliminates in the other; the puppy did not eliminate prior to confinement; the feeding schedule was not matched to the elimination schedule; there is anxiety about confinement or being left alone (see separation distress); or there is an underlying medical cause. • If it is not practical to take the puppy outside frequently enough (apartment dweller, long work days), indoor training is similar to conventional housetraining, i.e., supervision, confinement, reward desirable behavior, but the elimination site would be on paper or a litter pad. When the family is out of the home, the puppy should be confined to a large enough confinement area (e.g., pen or large crate) with the paper within. • Medical issues may

cause or contribute to house training problems, including problems that cause increased volume of urine or stool (e.g., renal disease, malabsorption), increased frequency of elimination (e.g., lower urinary tract disease, colitis) or CNS problems that interfere with learning or mobility.

Playbiting

- Exercise often enough and with appropriate outlets to meet the pet's needs. • Have toys available at all times to toss and distract the pet. • Use food-laced toys to keep the pet occupied. • Keep a leash attached to the supervised pup to prevent and interrupt undesirable behaviors. • Use confinement if the puppy is out of control and the family cannot effectively engage the pet in alternate acceptable activities. • Avoid games that encourage biting hands or feet. • Make all interactions structured and predictable by training sit before giving toys, food, play, and attention. • Ignore attention-seeking behavior such as whining, barking, or pawing for attention. • Say "Ouch" very loudly and immediately walk away to interrupt any hard bites during play. • Physical corrections should be avoided as they can cause fear, anxiety, and aggression or inadvertently encourage further rough play. • Consider a head halter for difficult pups. • Enroll in puppy classes early (8–10 weeks of age).

Getting on Counters/Furniture

- Keep food and appealing objects off counters and furniture • Constantly supervise
- Confine the pup when he can't be supervised • Block access to potential problem areas • Provide interesting toys on the floor for mental stimulation • Provide a bed/rest area on the floor • Meet the pet's needs for food, chewing, mental stimulation and exploration • Decrease the appeal of furniture or trash bins with bitter tasting sprays, or motion-activated sprays or alarms.

MEDICATIONS

DRUG(S) OF CHOICE

- Drugs are generally not indicated. • If signs of anxiety see other appropriate sections in the text (e.g., Separation Distress Syndrome).

ALTERNATIVE DRUG(S)

A dog-appeasing pheromone may help the pup in stressful situations.

FOLLOW-UP

PATIENT MONITORING

- Phone follow-ups at approximately 10 days, 20 days, and 6 weeks following the initial visit

are usually helpful. • This can be done by a trained support staff member.

PREVENTION/AVOIDANCE

- Discuss supervision and confinement strategies. • Begin food-lure-reward training in the home at 7–8 weeks of age. • Enroll in a puppy class at 8–10 weeks of age. • Provide regular sessions of physical exercise and mental stimulation. • Provide information and guidance about normal behavior to insure needs are adequately met (e.g., mental stimulation, socialization, exercise, object play). • Suggest safe and interesting toys for chewing, play, and mental stimulation.
- Make all interactions predictable by teaching sit before giving anything of value.

Possible Complications

- Damaged household objects and clothing
- Food stealing • Intestinal foreign bodies/obstructions • Minor injuries from play-bites
- A guest is knocked down and injured
- Owner frustration, a weakened bond, and possible relinquishment to a shelter.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is generally good. • The frequency and intensity of the behaviors will decrease with age, consistency and by providing sufficient outlets. • Play-biting can usually be quickly controlled if the family is consistent with training. • Confinement training should take a few days to several weeks to accomplish. • Housetraining can be accomplished in a few weeks, but may take longer if the family is not consistent in supervision and training or the family schedule does not address the dog's needs.

PEDIATRIC BEHAVIOR PROBLEMS—CATS

BASICS

DEFINITION

- Undesirable behaviors exhibited by kittens between birth and puberty.

PATHOPHYSIOLOGY

- Most pediatric behavior problems are normal, species-typical behaviors.
- Lack of appropriate social interactions and environmental stimulation can contribute to abnormal or unwanted behaviors.

SYSTEMS AFFECTED

Behavioral

GENETICS

Paternal influences on friendliness to people and boldness to unfamiliar or novel objects have been supported.

SIGNALMENT

Species

Cats

Mean Age and Range

Generally 6–52 weeks

SIGNS

General Comments

Play Aggression

- Elements of predation including stalking, chasing, attacking, pouncing, swatting, and biting. Play can be solitary, with objects, or social to another kitten, animal or person.
- With normal play, bites are inhibited and claws retracted. Vocalizations are rare compared to other forms of feline aggression.
- Inappropriate play behaviors may be uninhibited, leading to bite and scratch injuries.

Excessive Play/Activity and/or Destructive Play

High level of solitary play (running, jumping, climbing, object play) may result in household damage and disruption of owner sleep.

Scratching

- Use of claws to scratch on household items and/or people.
- Scratching is a normal behavior for both claw maintenance and territorial marking but becomes problematic when scratched objects include walls, furniture, carpets, and other household items.

Fearful Behaviors

Includes hiding, hissing, scratching, unsocial behaviors and can include varying manifestations of aggression to another animal or person.

Historical Findings

Aggressive Play Directed toward People or Other Pets in the Household

- Attacks directed toward people or other pets in the household.
- Ambushes are common and occur without vocalizations. Bites are generally inhibited but may indent the skin and light scratches with claws may occur.

Uninhibited Aggressive Play Directed toward People

- Signs similar to above except more intense.
- Bites and scratches are not as inhibited and can break skin.

Play Directed toward Household Objects

- Bursts of solitary play that include intense running, jumping, climbing across and up household furnishings.
- Knocks or swipes objects from surfaces.

Scratching

Household items and family members.

Fear and Defensive Behaviors Due to Lack of Socialization

- No exposure to people before 7 to 9 weeks of age.
- Behaviors associated with fear, e.g., dilated pupils, piloerection, defensive postures, hissing, hiding, fleeing, aggression.

Fear and Defensive Behaviors Related to Early Trauma

Normal until experienced traumatic event, e.g., abuse, attack by another animal.

Fear and Defensive Behaviors Related to Correction Techniques

- History of punishment by owner(s).
- Kitten shows defensive postures including hissing, fleeing, hiding, dilated pupils, piloerection in presence of owner or in response to corrections.

CAUSES

Aggressive Play Directed toward People or Other Cats in the Household

- Normal species-typical behavior but without appropriate social interaction with conspecifics, the behavior can become uninhibited and injurious.
- Owners may encourage inappropriate interactive play by promoting play with human body parts (fingers, hands, feet).
- Lack of outlets for appropriate play.

Play Directed toward Objects in the Household

Normal species-typical behavior beginning at 7–8 weeks of age.

Fear and Defensive Behaviors Due to Lack of Early Socialization

No or minimal amount of exposure to people before 7–9 weeks of age.

Fear and Defensive Behaviors Related to Early Trauma

Early traumatic event

Fear and Defensive Behaviors Related to Correction Techniques

Normal until “corrected” by person, e.g., spanked, swatted, flicked on nose, yelled at, chased.

RISK FACTORS

Aggressive Play Directed toward People

- Only cat in the household, orphan hand-reared kitten or adoption prior to 6 weeks of age.
- Insufficient appropriate outlets for normal play and exploration.
- Encouragement of inappropriate play (e.g., with hands, fingers, feet).

Play Directed toward Objects in the Household

- Lack of sufficient enrichment including toys and interactive play with people or other animals.
- Only pet in household.

Scratching

Lack of appropriate scratching outlets.

Fear and Defensive Behaviors

- Lack of appropriate socialization with people, use of punishments and other traumatic experience(s).
- Removing kittens less than 2 weeks of age from queen may result in markedly fearful and overly aggressive kittens towards humans and other cats

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Play Aggression toward People

Differentiate normal play from the more serious, uninhibited play aggression.

Excessive Play/Destructive Behaviors

None

Scratching

Nail maintenance, marking, or play-related

Fearful and Defensive Behaviors

Central nervous system diseases, pain, metabolic disorders, endocrinopathies (e.g., hyperthyroidism), pain.

CBC/BIOCHEMISTRY/URINALYSIS

Frightened kittens may have elevated glucose levels.

TREATMENT

ACTIVITY

Many pediatric behavior problems can be alleviated or reduced by enriching the kitten's environment (e.g., provide movable toys, variety of toys, rotating them regularly); engage the kitten in interactive play directed away from the owner's body parts; provide access to window sills, boxes, perches; offer a variety of enticing scratching surfaces; possibly get second kitten.

DIET

Provide multiple small meals.

CLIENT EDUCATION

Most of these problems are normal kitten behaviors that the owners perceive as abnormal or excessive and inappropriate for their lifestyle. Many kittens will mature out of these problem behaviors.

Aggressive Play Directed toward People

- Owner needs to provide and initiate regular interactive play that allows for hunt, stalk and attack behaviors directed at appropriate toys or objects. Ensure owners never use hands, fingers, feet to encourage play.
- Most

PEDIATRIC BEHAVIOR PROBLEMS—CATS

(CONTINUED)

effective treatment may be to acquire an additional kitten of the same size and temperament. • Redirection: Identify the situations in which the attacks may occur. Watch for signs of dilated pupils, stalking, crouching, tail swishing. Be prepared to redirect the play to another object (e.g., tossing a wadded piece of paper or chasing a toy) or to cue and reward alternative desirable behaviors that the kitten has learned (e.g., go to mat, sit/watch, let's eat, let's play). • Educate the client to not hit, or swat, on nose with fingers as this may encourage rougher play from the kitten. • Immediately stop play for inappropriate behaviors. • May use a startling noise or hiss to distract the kitten, then stop all play by withdrawing from and then ignoring the kitten. • Frequent trimming of tips of claws helps reduce damage caused by nails. • If injuries are being caused by claws, declawing may be considered in severe cases where kitten is at risk of relinquishment, or for immunocompromised owners.

Aggressive Play Directed toward Other Cats in the Household

- Acquire additional kitten of the same size and temperament of the problem kitten.
- Watch for signs and redirect into alternative acceptable behaviors (sit/watch, go to mat)
- Problem kitten and other cat should have restricted access to each other at times when problems might arise • Startling, punitive techniques may aversively affect the other cat and are not recommended. • Provide appropriate outlets for predatory behaviors with the problem kitten on a regular, daily basis using toys or objects.

Play That Is Excessive and/or Destructive, and Scratching

- Put valuable, breakable, or dangerous objects away. • Provide appropriate toys for the kitten and rotate every few days to maintain novelty and interest. • Interactive play with kitten using toys or objects on a daily basis. • "Booby traps" may be used to keep kitten from a few select objects or areas. Excessive use of such items might result in generalized anxiety. • Provide scratching posts of variable materials and assure they are long enough and stable enough for the cat to stretch and scratch. • Place scratching stations in commonly used areas and encourage use with catnip, treats, and integrating perches and resting areas. • Make inappropriately scratched areas less desirable (e.g., double sided sticky tape, plastic). • Frequent trimming of claws. • Declawing is a humane concern; however several studies indicate that declawing is not psychologically harmful to cats. Therefore, declawing may be preferable to relinquishment.

Fear and Defensive Behaviors Due to Lack of Early Socialization or from Early Trauma

- Gradual exposure to people without forcing interactions. • The kitten should be housed where it is comfortable and where it can remove itself from view but be frequently aware of people. • Counter-conditioning generally required. Highly enticing food and treats should be offered. Initially, food can be put in or near hiding area. Gradually food is placed farther from hiding area and closer to where a person is stationary. No attempt should be made to grab or hold the kitten. Eventually the food may be given by hand or on the person's lap. Toys on strings can be used to entice the kitten to play. • Important principles to remember are to let the kitten make the advances—not the person—and avoid scaring the kitten by forcing interaction or preventing escape.

Fear and Defensive Behaviors Related to Correction Techniques

Identify and cease inappropriate punishment.

MEDICATIONS

DRUG(S)

- None needed unless extreme fear and anxiety. See also Fears, Phobias, and Anxieties—Cats. • May consider use of feline pheromone products for fearful kittens

FOLLOW-UP

PATIENT MONITORING

- Telephone follow-up support helpful. • Be sure clients are not using aversive techniques that may induce fear and aggression in the kitten and/or exacerbate intensity of play aggression.

PREVENTION/AVOIDANCE

- Kitten behavior problems are often a result of owner's unrealistic expectations and misunderstanding of normal kitten behavior, as well as lack of enrichment and appropriate predatory play outlets. • Most problem behaviors can be prevented or redirected.
- Between 3 and 7 weeks of age, kittens should experience positive interactions with people to reduce fear and develop appropriate social bonds with humans. • Between 4 and 18 weeks, helpful to have exposure to tolerant (and playful) conspecifics to learn effective bite and play inhibition. • Advise family members to avoid roughhousing and body part play with kittens. • Punitive corrections should be discouraged.

EXPECTED COURSE AND PROGNOSIS

Normal Play Behaviors Directed toward People, Other Cats, and Household Objects

Reduction or resolution of problem when appropriate treatment protocols are followed. As the kitten ages, many of these behaviors begin to wane.

Uninhibited Aggressive Play Directed toward People

- Guarded prognosis • Aggression may become more severe and injurious with maturity. A better prognosis is given to those cases that are caught early and appropriately counseled or by obtaining a second compatible cat.

Scratching

Generally, if can successfully divert and reward for using appropriate scratching surfaces, the prognosis is good, and as the kitten matures, the behaviors wane. For cats with a high drive to scratch, long-term management is needed.

Fear and Defensive Behaviors Due to Lack of Early Socialization or Related to Early Trauma

- Kittens will vary in the degree to which they acclimate to people; maximal improvement may take months or even years; some may never be comfortable around people. • The longer the interval from 3 weeks of age to exposure to people, the poorer the prognosis.
- The more intense the early trauma, the poorer the prognosis.

Fear and Defensive Behaviors Related to Correction Techniques

- Can resolve quickly if corrections have not been used frequently, have not been severe, and the clients follow advice to replace these techniques with reward-based, avoidance, and redirection procedures.

MISCELLANEOUS

AGE-RELATED FACTORS

Fear and Defensive Behaviors Due to Lack of Early Socialization

During the sensitive period, between 3–7 weeks, the kitten must be exposed to people to prevent fearful and defensive responses to them.

PELGER-HUËT ANOMALY

BASICS

OVERVIEW

- Congenital hereditary disorder that has been seen in several breeds of dogs and domestic shorthair cats.
- An autosomal dominant inheritance pattern is likely.
- Nuclear hyposegmentation of many to all granulocytes (neutrophils, eosinophils and basophils) is seen.
- Hypolobulation of monocytes and megakaryocytes has also been reported.
- Chromatin patterns of leukocytes are normochromatic, or occasionally hyperchromatic.
- Cytoplasm of cells is unremarkable (i.e., no toxic changes are observed).
- Cellular function remains normal in heterozygotes.
- Heterozygous animals are asymptomatic.
- Care should be taken not to misinterpret a leukogram in a patient with Pelger-Huët anomaly as a severe left shift or vice versa.

SIGNALMENT

- Dogs—Pelger-Huët anomaly has been reported in mixed-breed dogs as well as numerous purebred animals. Overall the incidence is low; however, Australian shepherd dogs have been shown to have a 9.8% incidence rate.
- Cats—Pelger-Huët anomaly has only been reported in domestic shorthair cats. The overall incidence in cats is unknown; however, it is likely rare when compared to dogs.
- An autosomal dominant mode of inheritance is likely; however, incomplete penetrance has been seen in Australian shepherd dogs.

SIGNS

- No clinical signs observed in heterozygous animals, as the leukocytes are fully functional.
- Homozygous animals either die *in utero* or are stillborn with significant chondrodysplastic changes.

CAUSES AND RISK FACTORS

- Caused by an inherited defect of terminal differentiation due to a mutation in the laminin B receptor in humans.
- Australian shepherd dogs may have a higher incidence of the anomaly than other breeds; however, incidence rates in other breeds have not been thoroughly investigated.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

- The primary differential diagnosis to rule out is a severe regenerative or degenerative left shift, indicating severe inflammation and/or endotoxemia.
- An inflammatory leukogram may show a leukocytosis or leukopenia. Immature leukocytes exhibit an open, pale chromatin pattern.
- Toxic changes (e.g., Döhle bodies, blue foamy cytoplasm, toxic granulation) are frequently seen with severe inflammation and/or endotoxemia.
- Pelger-Huët cells have a nucleus that shows a mature, condensed chromatin pattern and exhibit no toxic changes.
- Animals with Pelger-Huët anomaly are clinically well, whereas animals with severe left shifts tend to be systemically ill and exhibit laboratory test abnormalities consistent with underlying inflammation and/or endotoxemia and possible organ system dysfunction.

CBC/SERUM BIOCHEMISTRY/ URINALYSIS

- The blood smear reveals a persistent varying hyposegmentation of all granulocytes and often monocytes.
- Granulocyte nuclei may be round, oval, peanut, dumbbell, horseshoe and bilobed in shape.
- A key finding is the mature, condensed chromatin pattern.
- The serum biochemistry profile and

urinalysis are unremarkable in cases of Pelger-Huët anomaly.

OTHER LABORATORY TESTS

No other tests are indicated to diagnose Pelger-Huët anomaly.

IMAGING

Imaging is not useful in diagnosing Pelger-Huët anomaly.

DIAGNOSTIC PROCEDURES

- Establishment of a hereditary pattern typically an academic exercise, but potentially useful.
- No additional diagnostic procedures are indicated to diagnose Pelger-Huët anomaly.

TREATMENT

No treatment is indicated for Pelger-Huët anomaly.

FOLLOW-UP

No follow-up is necessary.

Consulting Editor Alan H. Rebar

PELVIC BLADDER

BASICS

OVERVIEW

Also known as "intrapelvic bladder," as the urinary bladder neck is caudal to the pubic bone, causing most of the urethra and a variable amount of the bladder to remain inside the bony pelvis. The association of a short urethral length and urethral sphincter mechanism incompetence is common.

SIGNALMENT

- Dog and rarely cat.
- Primarily young female dogs (<1 year of age); incontinence often worsens after ovariectomy/ovariohysterectomy.
- Incontinence usually detected in male dogs after neutering.

SIGNS

- May be asymptomatic
- Incontinence can be continuous or intermittent
- Conscious voiding patterns often present
- Urgency with small volume elimination
- Perineum stained/soaked with urine; urine scalding; wet vulva/prepuce

CAUSES & RISK FACTORS

The position of the bladder in incontinent female dogs has been shown to be more intrapelvic and associated with a shorter urethral length, suggesting that an intrapelvic bladder neck and a short urethra together encourage urinary incontinence.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Urinary incontinence—ectopic ureter, USMI, inappropriate urination, urge incontinence, urinary tract infection, neurogenic incontinence (lower motor neuron disease).
- The degree of incontinence often exceeds that seen with USMI but is not as severe as that seen with ectopic ureters.
- Often associated with ectopic ureters.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC and biochemistries typically unremarkable.
- Urinalysis may reveal evidence of UTI (including pyuria, bacteriuria, and hematuria) or polyuria (USG < 1.035).
- Urine culture and sensitivity via a cystocentesis should be performed. Urine culture is often positive.

IMAGING

- Abdominal radiographs may reveal a caudally displaced bladder, but this should be interpreted carefully without bladder distension.
- Excretory urography may allow visualization of the kidneys, ureteral terminations, urinary bladder, and urethra but does not provide bladder distension. Without appropriate bladder distension, interpretation of bladder neck location should be made with caution.
- Retrograde vaginourethrogram or urethrocystography allows visualization of the vaginal vault, urethra, urethral length, prostate, urinary bladder shape, and bladder neck location.
- If the urinary bladder and urethra are inside the bony pelvis, double contrast cystourethrography may be required for full visualization. After maximum dilation with infusion of carbon dioxide or contrast medium, much of the bladder, bladder neck, and entire urethra remain within the pelvic canal, caudal to the bony pelvic brim. There is often a short wide urethra.
- Ultrasonography of the kidneys, ureters, and urinary bladder can aid in documentation of concurrent urologic anomalies, hydronephrosis concurrent pyelonephritis, or concurrent ectopic ureters.
- The diagnostic combination of choice is urethrocystoscopy and cystourethrography. This combination allows careful investigation of urethral, ureteral, cystic, vaginal, and vestibular defects. It also allows more accurate measurement of urethral length and width and aids in formulating therapy.

DIAGNOSTIC PROCEDURES

- Neurologic exam should be normal.
- Urodynamic procedures—consider cystometrography and urethral pressure profilometry to evaluate urinary bladder and urethral function, as well as urethral functional length. Detrusor function is usually normal, though higher threshold pressures may be generated at lower fluid volumes. The functional urethral length is shortened, and intraurethral pressure is frequently decreased, resulting in USMI.

TREATMENT

- Identify UTI and treat appropriately.
- Goal is to increase urethral resistance (artificial urethral sphincters, intraurethral injections of bulking agents, etc.), increase urethral length (bladder neck reconstruction),

and/or relocate the bladder neck to an intra-abdominal position (colposuspension, urethropexy, prostatoxexy, or vas deferensopexy).

- Detrusor relaxation has been suggested to treat refractory incontinent dogs as an overactive bladder could contribute to incontinence or urgency.
- Medical management for traditional USMI is typically successful in 75–90% of female dogs.

SURGICAL CONSIDERATIONS

- Colposuspension is the traditional surgical approach. A cure rate of 53% has been reported.
- Placement of an artificial urethral sphincter, or hydraulic occluder, has been successful and is the currently surgical treatment of choice if other minimally invasive or medical interventions fail. Experience with this procedure has been limited and the risk of urethral strictures can be up to 20%. Cystopexy can also be considered.

MINIMALLY INVASIVE TREATMENT

Transurethral submucosal bulking agent therapy (e.g., collagen implantation) has been described for the treatment of patients refractory to medical management and is associated with relatively good success. This is accomplished via cystoscopic guidance. This aids in improving incontinence but does not affect the location of the urinary bladder.

MEDICATIONS

DRUG(S)

- Phenylpropanolamine: an α -agonist (1–1.5 mg/kg PO q8h) will improve continence for USMI in a majority of cases.
- Diethylstilbestrol: initially 0.1–0.3 mg/kg q24h for 7 days, then once weekly; 0.1–1 mg PO for 3–5 days, then 1 mg per week thereafter. Gradually reduce to the lowest effective dose. DES can be toxic to the bone marrow in dogs and cats and can cause blood dyscrasias. This can progress, in rare cases, to fatal aplastic anemia. In some dogs, a combination of estrogen and PPA therapy may be more effective.
- Estriol: can be used for estrogen-responsive urinary incontinence. The dose is 2 mg once daily per dog (regardless of body weight) for 14 days, followed by the lowest effective daily dose tapered every 7 days.

(CONTINUED)

PELVIC BLADDER**FOLLOW-UP****PATIENT MONITORING**

- Every 3–6 months for UTI.
- Patients receiving an α -agonist should have serial blood pressure evaluations, as this is contraindicated in hypertensive patients or those with renal or heart disease.
- Patients receiving estrogen therapy should have serial CBC evaluations to monitor for bone marrow dyscrasias.

- Use all medications at the lowest effective dose.

**MISCELLANEOUS****ABBREVIATIONS**

- DES = diethylstilbestrol
- PPA = phenylpropanolamine
- USMI = urethral sphincter mechanism incompetence
- UTI = urinary tract infection

PEMPHIGUS

BASICS

OVERVIEW

- A group of auto-immune dermatoses characterized by varying degrees of erosion, ulceration, crusting, and pustule and vesicle formation.
- Affects the skin and sometimes mucous membranes.
- Forms identified in animals: pemphigus foliaceus (PF), pemphigus erythematosus (PE), pemphigus vulgaris (PV), panepidermal pustular pemphigus/vegetans (PEP), canine benign familial chronic pemphigus (Hailey-Hailey disease), paraneoplastic pemphigus (PP).

PATHOPHYSIOLOGY

- Tissue-bound auto-antibody directed at intraepidermal cell antigens (desmogleins) and acetylcholine receptors is deposited within the intercellular spaces, causing epidermal cell separation and cell rounding (acantholysis).
- Severity of ulceration and disease—related to depth of auto-antibody deposition within the skin.
- PF—auto-antibody deposition in the superficial layers of the epidermis.
- PV—lesions more severe; mediated by auto-antibody deposition just above the basement membrane zone; rapidly leads to ulcer formation.
- Implicated trigger factors are varied—genetics, hormonal, neoplasia, drugs, nutrition, viral, emotional stress, and physical factors (burns, UV radiation).

P SYSTEMS AFFECTED

Skin/Exocrine

GENETICS

Benign familial chronic pemphigus (Hailey-Hailey disease)—may have a genetic predisposition (autosomal dominant genodermatosis in humans).

INCIDENCE/PREVALENCE

- Uncommon group of diseases.
- PF—most common type.
- PE—relatively common; may be a more benign variant of PF or may be a crossover syndrome of pemphigus and lupus erythematosus.
- PV—second most common type; most severe form.
- PEP—rarest type; course of disease may be more severe than PF.
- PP—rare, clinical signs vary from severe to relatively benign crusted lesions.

SIGNALMENT

Species

- Dogs and cats—PF, PV, PE
- Dog—PEP

Breed Predilections

- PF—Akita, bearded collie, chow chow, dachshund, Doberman pinscher, Finnish spitz, Newfoundland, and schipperke.
- PE—collie, German shepherd dog, and Shetland sheepdog.

Mean Age and Range

Usually middle-aged to old animals

Predominant Sex

None reported

SIGNS

PF

- Scales, crust, pustules, epidermal collarettes, erosions, erythema, alopecia, and footpad hyperkeratosis with fissuring.
- Occasional vesicles are transient.
- Common involvement—head, ears, and footpads; often becomes generalized.
- Mucosal and mucocutaneous lesions uncommon.
- Cats—nipple and nailbed involvement common.
- Lymphadenopathy, edema, depression, fever, and lameness (if footpads involved) when severe or generalized.
- Variable pain and pruritus.
- Secondary bacterial infection possible.

PE

- Similar to PF.
- Lesions usually confined to head, face, and footpads.
- Depigmentation more common than with other forms often precedes crusting.

PV

- Oral ulceration frequent and may precede skin lesions.
- Ulcerative lesions, erosions, epidermal collarettes, blisters, and crusts.
- More severe than PF and PE.
- Affects mucous membranes, mucocutaneous junctions, and skin; may become generalized.
- Axillae and inguinum often involved.
- Positive Nikolsky sign (new or extended erosive lesion created when lateral pressure is applied to the skin near an existing lesion).
- Variable pruritus and pain.
- Anorexia, depression, and fever.
- Secondary bacterial infections common.

PEP

- Pustule groups become eruptive papillomatous lesions and vegetative masses with exudation.
- No oral involvement.
- No systemic illness.

CAUSES

Undetermined—genetics and a possible triggering event (e.g., viral infection, drug).

RISK FACTORS

Undetermined

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

PF

- Bacterial folliculitis
- Dermatophytosis
- Demodicosis
- Candidiasis
- Keratinization disorders
- Lupus erythematosus
- Pemphigus erythematosus
- Subcorneal pustular dermatosis
- Drug eruption
- Zinc-responsive dermatitis
- Dermatomyositis
- Tyrosinemia
- Mycosis fungoides
- Lymphoreticular malignancies
- Metabolic epidermal necrosis
- Sterile eosinophilic pustulosis
- Linear IgA dermatosis

PE

- Pemphigus foliaceus
- Lupus erythematosus
- Mucocutaneous pyoderma
- Demodicosis
- Dermatophytosis
- Epidermolysis bullosa simplex
- Uveodermatologic syndrome

PV

- Bullous pemphigoid
- Systemic lupus erythematosus
- Toxic epidermal necrolysis
- Drug eruption
- Mycosis fungoides
- Lymphoreticular neoplasia
- Ulcerative stomatitis causes
- Erythema multiforme

PEP

- Pemphigus vulgaris
- Bacterial folliculitis
- Pemphigus foliaceus
- Lichenoid dermatoses
- Cutaneous neoplasia

CBC/BIOCHEMISTRY/URINALYSIS

- Abnormalities uncommon.
- Leukocytosis and hyperglobulinemia with chronicity and/or secondary infection.

OTHER LABORATORY TESTS

Antinuclear antibody—may be weakly positive in PE only.

DIAGNOSTIC PROCEDURES

- Cytology of aspirates or impression smears from pustules or crusts—acantholytic keratinocytes and neutrophils; occasionally with eosinophils.
- Bacteriologic culture—identify secondary bacterial infections.

PATHOLOGIC FINDINGS

- Biopsies of lesional or perilesional skin required for diagnosis—acantholysis and

(CONTINUED)

PEMPHIGUS

- intraepidermal clefting; microabscess or pustule formation; rafts of acantholytic keratinocytes.
- Location of epidermal lesions—varies with disease; PF and PE have subcorneal or intragranular clefting and acantholysis; PV and PEP have suprabasilar clefting.
- Immunopathology of biopsied skin via immunofluorescent antibody assays or immunohistochemical testing—may demonstrate positive staining in the intercellular spaces in 50–90% of cases; results can be affected by concurrent or previous corticosteroid (or other immunosuppressive drug) administration; indirect immunofluorescence usually negative; PE may demonstrate staining of basement membranes and intercellular spaces.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Initial inpatient supportive therapy for severely affected patients.
- Outpatient treatment with initial frequent hospital visits (every 1–3 weeks); taper to every 1–3 months when remission is achieved and the patient is on a maintenance medical regimen.

NURSING CARE

Severely affected patients may require antibiotics and hydrotherapy/soaks.

DIET

Low-fat—to avoid pancreatitis predisposed by corticosteroids and (possibly) azathioprine therapy.

CLIENT EDUCATION

Sun avoidance/use of sunblock—ultraviolet light may exacerbate lesions (PE).

**MEDICATIONS****DRUG(S)****PF and PV****Corticosteroids**

- Prednisone or prednisolone—1.1–2.2 mg/kg/day PO divided q12h to initiate control.
- Minimum maintenance—0.5 mg/kg PO q48h to twice weekly.
- Taper dosage at 2- to 4-week intervals by 5–10 mg/week.

Cytotoxic Agents

- Most patients require additional immunomodulating drugs.
- Work synergistically with corticosteroids to allow reduction in dose and side effects.
- Azathioprine 2.2 mg/kg PO q24h, then q48h (dogs); infrequently used in cats, owing to potential for marked bone marrow suppression; feline dose 1 mg/kg q24–48h.

- Chlorambucil 0.2 mg/kg daily; best choice for cats.
- Cyclophosphamide 50 mg/m² BSA PO q48h (dogs).
- Cyclosporine 5–15 mg/kg PO q24h; limited application.
- Dapsone 1 mg/kg PO q8h; then as needed (dogs); limited application.

Chrysotherapy

- Used in conjunction with prednisone; very expensive.
- Auranofin 0.1–0.2 mg/kg PO q12–24h.

PE and PEP

- Oral prednisone or prednisolone 1.1 mg/kg PO q24h; then q48h; then to the lowest maintenance dose possible; may be stopped when in remission.
- Topical steroids may be sufficient in mild cases.

PRECAUTIONS

- Corticosteroids—polyuria, polydipsia, polyphagia, temperament changes, diabetes mellitus, pancreatitis, and hepatotoxicity.
- Azathioprine—pancreatitis, bone marrow suppression.
- Cytotoxic drugs—leukopenia, thrombocytopenia, nephrotoxicity, and hepatotoxicity.
- Chrysotherapy—leukopenia, thrombocytopenia, nephrotoxicity, dermatitis, stomatitis, and allergic reactions.
- Cyclophosphamide—hemorrhagic cystitis.
- Immunosuppression—can predispose animal to demodicosis, cutaneous and systemic bacterial and fungal infection.

ALTERNATIVE DRUG(S)**Alternative Corticosteroids**

- Use instead of prednisone if undesirable side effects or poor response noted.
- Methylprednisolone 0.8–1.5 mg/kg PO q12h; for patients that tolerate prednisone poorly.
- Triamcinolone 0.2–0.3 mg/kg PO q12h; then 0.05–0.1 mg/kg q48–72h.
- Glucocorticoid pulse therapy—11 mg/kg IV methylprednisolone sodium succinate for 3 consecutive days to induce remission; limited application.

Topical Steroids

- Hydrocortisone cream.
- More potent topical corticosteroids—0.1% betamethasone valerate, flucinolone acetonide, or 0.1% triamcinolide; q12h; then q24–48h.

Miscellaneous

- Tetracycline and niacinamide 500 mg PO q8h (dogs > 10 kg); half doses for dogs < 10 kg; limited application (especially PE).

**FOLLOW-UP****PATIENT MONITORING**

- Monitor response to therapy.

- Monitor for medication side effects—routine hematology and serum biochemistry, especially patients on high doses of corticosteroids, cytotoxic drugs, or chrysotherapy; check every 1–3 weeks, then every 1–3 months when in remission.

EXPECTED COURSE AND PROGNOSIS**PV and PF**

- Guarded (PV) to fair (PF): life-long or long-term therapy with corticosteroids and cytotoxic drugs usually needed.
- Regular monitoring necessary.
- Side effects of medications may affect quality of life.
- May be fatal if untreated (especially PV).
- Secondary infections cause morbidity and possible mortality (especially PV).

PE and PEP

- Fair: relatively benign and self-limiting.
- Oral corticosteroids may eventually be tapered to low maintenance doses; may be discontinued in some patients.
- Cutaneous lesions persist if untreated, but systemic symptoms rare.

**MISCELLANEOUS****PREGNANCY/FERTILITY/BREEDING**

Avoid steroids and cytotoxic drugs during pregnancy

ABBREVIATIONS

PERIANAL FISTULA

BASICS

OVERVIEW

- Chronic inflammatory condition characterized by multiple, painful, progressive, ulcerating sinuses or, much less frequently, true fistulous tracts involving the perianal region.
- Synonyms: anal furunculosis, perianal sinus, pararectal fistulae, fistulae-in-ano.

SIGNALMENT

- Dog • German shepherd dogs primarily; Irish setters • Middle-aged dogs with mean age of 5–7 years; range, 7 months–14 years
- Males more commonly affected in most studies

SIGNS

- Dyschezia • Tenesmus • Hematochezia
- Constipation • Diarrhea • Malodorous mucopurulent anal discharge • Ulceration of the perianal skin with sinus tract formation
- Licking and self-mutilation • Reluctance to sit; posturing difficulties; personality changes
- Pain on manipulation of tail and examination of perianal area • Fecal incontinence • Anorexia • Weight loss

CAUSES & RISK FACTORS

- Cause not clearly defined, but a multifactorial immune-mediated mechanism is strongly suspected. • Appears to be an inappropriate T-cell mediated response. • An association with colitis has also been proposed, particularly in German shepherd dogs. • A genetic predisposition, based on breed incidence, has been proposed but not proven. • Anatomic factors have been implicated, particularly in German shepherds.
- Low tail carriage and a broad tail. • High density of apocrine sweat glands in the cutaneous zone of the anal canal of German shepherd dogs.

P

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other inflammatory processes—e.g., anusitis, hidradenitis suppurativa • Chronic anal sac abscess • Perianal adenoma or adenocarcinoma with ulceration and drainage
- Squamous cell carcinoma • Atypical bacterial infection • Oomycosis • Rectal fistula

CBC/BIOCHEMISTRY/URINALYSIS

- Usually unremarkable. • Patients with inflammation may have an inflammatory leukogram.

DIAGNOSTIC PROCEDURES

- Presumptive diagnosis—based on clinical signs and results of physical examination.
- Definitive diagnosis—made by biopsy of

the affected area.

- Colonoscopy with biopsy—may reveal associated colitis.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient medical therapy recommended initially in all cases.
- Clipping and cleaning the perianal area facilitates local therapy.
- Bathing with an antimicrobial shampoo may be helpful.

DIET

- Dietary modification—novel protein elimination diet such as venison or fish and potato. Hypoallergenic hydrolyzed diets should also be considered.
- Stool softeners—with pain or tenesmus.

SURGICAL CONSIDERATIONS

- Surgery is primarily indicated for patients with incomplete resolution or pseudohealing of sinuses following appropriate medical therapy.
- Anal sacculectomy—perform if anal sac involvement is confirmed.
- Surgical options—resection of inflammatory tissue and/or ablation of remaining sinuses with carbon dioxide laser is preferred.
- Surgical debridement (deroofing) with fulguration by chemical cautery or electrocautery; surgical resection followed by primary closure or second intention healing are other options.
- Radical excision of the rectal ring with modified rectal pull-through is not commonly necessary and is associated with a higher risk of fecal incontinence.

MEDICATIONS

DRUG(S) OF CHOICE

- Cyclosporine (CsA) ± ketoconazole is treatment of choice but is expensive.
- Cyclosporine A microemulsion as a single agent—give 4–8 mg/kg PO per day as induction dose, then taper dose based on clinical response.
- Cyclosporine A and ketoconazole—give CsA orally at 2–5 mg/kg/day PO and ketoconazole at 5–10 mg/kg/day PO as induction dose and then taper CsA as clinical signs resolve.
- Ketoconazole reduces dose of cyclosporine required by inhibiting CsA metabolizing enzymes.
- Continue treatment at least 4 weeks after complete resolution of fistula(e), but many patients require chronic treatment at reduced frequency to prevent recurrences.
- Tacrolimus (0.1% ointment) applied topically as maintenance therapy may be sufficient to control lesions; begin application as dose of oral medications is reduced.
- Apply topically q12h with gloved hand, then taper to q24–72h.

OR

- Oral prednisone and topical tacrolimus, appears to be efficacious and economical in less severe cases.
- Prednisone—2 mg/kg PO q24h for 2 weeks, decrease to 1 mg/kg q24h for 4 weeks and then 1 mg/kg q48h for 10 weeks.
- 0.1% tacrolimus ointment—(see protocol above)
- Chronic maintenance therapy with tacrolimus and possibly prednisone likely necessary for long-term control.
- Azathioprine alone or combined with prednisone using a decreasing dosage regimen is another treatment option.
- Metronidazole—10 mg/kg q12h for 2 weeks at initiation of therapy to control secondary infection.
- Elimination or hypoallergenic dietary therapy must be strictly enforced.
- Fecal softener if needed.

ALTERNATIVE DRUG(S)

Analgesics may be necessary, especially during induction phase, to facilitate local therapy.

FOLLOW-UP

PATIENT MONITORING

- Assess cyclosporine trough levels especially when ketoconazole is used if toxicity is suspected.
- Re-examine to assess healing, signs of recurrence, and associated complications.

POSSIBLE COMPLICATIONS

- Reversible alopecia • Vomiting, diarrhea, anorexia • Weight loss • Recurrence • Failure to heal • Dehiscence of surgical site
- Tenesmus • Fecal incontinence • Anal stricture • Flatulence • Iatrogenic Cushing's disease from corticosteroids

EXPECTED COURSE AND PROGNOSIS

- Guarded for complete resolution except in mildly affected patients.
- Chronic treatment may be necessary.
- If all treatment is discontinued, patient should be closely monitored for recurrence.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Colitis • Constipation and/or obstipation may develop

Consulting Editor Stanley L. Marks

PERICARDIAL EFFUSION

BASICS

DEFINITION

Abnormally high volume of fluid within the pericardial sac; cardiac tamponade refers to the clinical syndrome that results from reduced cardiac output due to mechanical compression of the heart.

PATOPHYSIOLOGY

Accumulation of effusion exceeds the elastic capabilities of the pericardial sac resulting in elevated intrapericardial pressure. Cardiac tamponade occurs when intrapericardial pressure exceeds cardiac diastolic filling pressures. The compliant right atrium and right ventricle normally have the lowest filling pressures and are thus predominantly affected. The resultant reduction in cardiac venous return diminishes cardiac output. In animals with chronic pericardial disease, low cardiac output activates compensatory mechanisms that lead to fluid accumulation, typically manifested as right-sided CHF. Animals with acutely developing effusions typically exhibit signs of weakness or collapse.

SYSTEMS AFFECTED

- Cardiovascular—signs of low cardiac output and CHF
- Hepatobiliary—chronic passive congestion with mildly to moderately high liver enzymes
- Renal/Urologic—prerenal azotemia
- Respiratory—tachypnea or pleural effusion

INCIDENCE/PREVALENCE

Pericardial disorders comprise approximately 8% of the canine cardiology caseload at referral institutions.

GEOGRAPHIC DISTRIBUTION

Increased incidence of coccidioidomycosis-induced effusive constrictive pericarditis in the southwestern United States, Mexico, and Central and South America.

SIGNALMENT

Species

Dog; pericardial effusion in cat is typically secondary to CHF.

Breed Predilections

- Golden retrievers and German shepherds are predisposed to both right atrial hemangiosarcoma and idiopathic effusion.
- Brachycephalic breeds are predisposed to aortic body tumors.

Mean Age and Range

Middle-aged to older dogs are predisposed.

Predominant Sex

Male dogs may be predisposed to idiopathic effusion.

SIGNS

General Comments

Chronic pericardial effusion often causes

jugular distension and ascites without a cardiac murmur.

Historical Findings

- Lethargy
- Anorexia
- Weakness
- Exercise intolerance
- Abdominal distension
- Respiratory distress; occasionally cough
- Syncope or collapse
- Vomiting

Physical Examination Findings

- Jugular vein distension
- Ascites (especially with chronic effusion)
- Muffled heart sounds
- Weak arterial pulses
- Pulsus paradoxus
- Pallor or slow capillary refill time
- Tachypnea and/or tachycardia

CAUSES

- Neoplasia—hemangiosarcoma, heart base tumor, thyroid adenoma or adenocarcinoma, mesothelioma, metastatic neoplasia, and lymphoma (especially cats)
- Idiopathic—pericarditis (benign hemorrhagic effusion vs. effusive constrictive pericarditis with pericardial fibrosis)
- Coagulopathy—intoxication with vitamin K antagonist rodenticide, other coagulopathies
- CHF (especially cats)
- Infection—feline infectious peritonitis, coccidioidomycosis, bacterial pericarditis
- Congenital disorders—pericardioperitoneal diaphragmatic hernia, intrapericardial cysts
- Left atrial tear or cardiac trauma
- Pericardial foreign body

RISK FACTORS

- Cardiac neoplasia
- Advanced chronic valvular disease
- Coagulopathy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- CHF secondary to other causes (e.g., valvular disease, cardiomyopathy, congenital heart disease), hepatic failure, abdominal neoplasia with hemorrhage, protein-losing nephropathy or enteropathy, Budd-Chiari-like syndrome.
 - Other causes of ascites (e.g., hepatic failure, hypoproteinemia, intra-abdominal neoplasia, and hemorrhage)—characteristically result in remarkable abnormalities on CBC and biochemistry profile, with a lack of jugular venous distension. Jugular vein examination can be helpful in differentiating these conditions from heart failure.
- CBC/BIOCHEMISTRY/URINALYSIS**
- CBC—usually normal; anemia possible in animals with hemangiosarcoma, lymphoma,

or coagulopathy; red cell morphology may be abnormal; may see thrombocytopenia in animals with neoplasia or DIC.

- Biochemistry profile—often normal; may see mild to moderately elevated liver enzymes (in animals with chronic passive hepatic congestion), mild azotemia (typically prerenal), hypoproteinemia, and mild electrolyte abnormalities (e.g., hyponatremia, hypochloremia, and hyperkalemia).
- Urinalysis—usually normal with normal renal concentrating ability unless a diuretic has been administered.

OTHER LABORATORY TESTS

- Elevated serum concentrations of cardiac troponin I (cTnI) have been demonstrated in dogs with pericardial effusion, especially in those with hemangiosarcoma.
- Clotting times (e.g., activated partial thromboplastin time and one-stage prothrombin time)—prolonged in animals with vitamin K antagonist rodenticide intoxication or DIC.
- Pericardial fluid analysis, although limited in diagnostic sensitivity and specificity, may be helpful in identifying certain neoplastic etiologies (e.g., lymphoma) or infectious causes.
- Feline infectious peritonitis testing or feline leukemia virus testing may be useful in cats.

IMAGING

Thoracic Radiographic Findings

- Mild-to-severe cardiac enlargement; cardiac silhouette often globoid with very sharp edges often evident on the dorsoventral view due to lack of cardiac motion artifact.
- Pleural effusion in some patients.
- Ascites in many patients.
- Large caudal vena cava in some patients.
- Nodular pulmonary infiltrates may be evident in patients with metastatic neoplasia.

Echocardiography

- Superior diagnostic test to evaluate for a cardiac mass; though only moderately accurate in predicting histopathologic diagnosis of mass lesions.
- Echo-free space clearly identified between the parietal pericardium and the epicardial surface of the heart.
- Often demonstrates the cause of pericardial effusion in patients with neoplasia (e.g. right atrial hemangiosarcoma or heart base tumor) or PPDH.
- Left atrial rupture may be suspected based on concurrent findings of pericardial effusion and advanced chronic valvular disease, especially if an intra-atrial or intra-pericardial thrombus is visualized.
- Pericardial effusion facilitates the detection of intrapericardial masses; echocardiography is ideally performed prior to pericardiocentesis if patient stable.
- Diastolic collapse of the right atrium or ventricle are indicative of cardiac tamponade.

PERICARDIAL EFFUSION

(CONTINUED)

Magnetic Resonance Imaging

Cardiac MRI has not been found to be superior to echocardiography in improving the diagnosis of cardiac neoplasia; however, advanced imaging may be helpful in detecting pulmonary, hepatic, or splenic metastases.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

- Sinus tachycardia in many patients; occasionally ventricular or supraventricular arrhythmias.
- Low-voltage QRS complexes (< 1 mV in leads I, II, III, aVR, aVL, and aVF) in some.
- ST segment elevation in some patients.
- Electrical alternans, a regular (1:1 or 2:1) variation in QRS-T wave height or morphology, results from the heart swinging back and forth within the pericardial sac in some patients.

PATHOLOGIC FINDINGS

- Pathologic findings will vary based on the underlying cause of pericardial effusion.
- Small cardiac masses may be identified that were not visible on antemortem testing.
- Dogs with left atrial tears will have advanced mitral endocardiosis with thickened and irregular mitral and/or tricuspid valve leaflets, left atrial enlargement and endocardial jet lesions, and possible ruptured chordae tendinae.

TREATMENT

APPROPRIATE HEALTH CARE

Cardiac tamponade warrants immediate pericardiocentesis; if uncomfortable with performing pericardiocentesis, referral to individuals with competence in this technique is strongly advised. Repeated pericardiocentesis may be needed; surgery may be indicated in selected dogs. Pericardiocentesis is rarely required in the cat.

Pericardiocentesis

- Place the patient in sternal recumbency. Clip haircoat on the right thorax between the third and eighth intercostal spaces from above the costochondral junction ventrally to the sternum. The right side of the thorax is preferred over the left due to decreased likelihood of coronary artery laceration. Simultaneous ECG monitoring is advised to detect arrhythmias. Echocardiography is useful to identify the best intercostal space, but if not available, perform pericardiocentesis at the fifth intercostal space just below the costochondral junction. After aseptic skin preparation and local anesthetic block with lidocaine, advance a long (~2 cm), large-bore (~16–18 gauge) catheter into the pericardial sac; may obtain a small amount of clear pleural fluid before advancement of the catheter into the pericardial sac. In dogs,

pericardial effusion is usually hemorrhagic, but some patients have a serous or serosanguinous effusion. Remove as much effusion as possible (unless a left atrial tear is suspected). If arrhythmias develop, reposition the needle or catheter and be prepared to administer IV lidocaine.

- Unless the patient has active hemorrhage into the pericardial sac, the effusion obtained by pericardiocentesis should not clot and should have a packed cell volume that differs from that of peripheral blood. The supernatant of chronic effusions is often xanthochromic.

NURSING CARE

Unless the patient has marked dehydration, fluids are generally not required or recommended for chronic pericardial effusion. Mild volume expansion may be useful in selected animals with acute pericardial effusion. Administer oxygen to dogs with tachypnea or signs of hemodynamic instability.

ACTIVITY

Cage rest, followed by exercise restriction

DIET

N/A

CLIENT EDUCATION

Clients should be informed that pericardial effusions are typically recurrent in nature, though the prognosis may vary greatly depending on the underlying cause. Clients should be educated about the importance for close monitoring for recurrent effusion and warned of the potential for sudden death.

SURGICAL CONSIDERATIONS

- Pericardectomy may be useful in the treatment of pericardial effusion accompanying heart base tumors and prolongs survival; this may also be considered for palliation of right atrial hemangiosarcoma but it is unknown whether it has any impact on survival.
- If idiopathic—may respond to pericardiocentesis; pericardectomy is indicated for recurrent effusion.
- Right auricular appendage masses may be treated surgically but resection alone without adjuvant chemotherapy is unlikely to significantly prolong survival.
- Thoracoscopy allows for partial pericardectomy with reduced risk and reduced postoperative pain.

MEDICATIONS

DRUG(S) OF CHOICE

- Drugs should not be used in place of pericardiocentesis.
- Diuretics—may help reduce ascites but can lead to progressive azotemia and patient weakness; generally not advised.

- Vitamin K—indicated for patients with rodenticide anticoagulant intoxication.
- Appropriate antibiotics are indicated in animals with infectious pericarditis.
- Chemotherapy—may be useful to treat effusion caused by lymphoma; partially effective in the treatment of atrial hemangiosarcoma and generally ineffective for heart-base tumor; adjuvant doxorubicin-based chemotherapy following right atrial mass resection has been shown to increase survival times but dogs rarely survive more than 6 months postoperatively.

CONTRAINdications

Digitalis, vasodilators, and angiotensin-converting enzyme inhibitors—reported to be relatively or absolutely contraindicated.

PRECAUTIONS

Diuretic administration often leads to exacerbation of weakness and azotemia.

ALTERNATIVE DRUG(S)

- Intracavitary chemotherapy may be attempted to treat mesothelioma.
- Anti-inflammatories or colchicine may be useful in selected dogs with idiopathic pericardial effusion.
- Additional immunosuppressives or intracavitary chemotherapy can be considered for recurrent effusions, especially in cases with recurrent pleural effusion after pericardectomy.

FOLLOW-UP

PATIENT MONITORING

- ECG—advised during first 24 hours as pericardiocentesis often leads to ventricular arrhythmias.
- Pericardial effusion may recur at any stage; examination and echocardiography at 10–14 days and every 2–4 months recommended to detect recurrent idiopathic pericardial effusion.

POSSIBLE COMPLICATIONS

- Hypotension or shock.
- Pneumothorax, arrhythmias, and myocardial perforation or coronary laceration secondary to pericardiocentesis.

EXPECTED COURSE AND PROGNOSIS

- Right atrial hemangiosarcoma—poor; tumor is highly malignant, usually not resectable at the time of diagnosis; may respond transiently to adriamycin-based chemotherapy; the benefit of palliative pericardectomy is unproven.
- Chemodectoma—fair; slow-growing tumor, late to metastasize; pericardectomy often resolves clinical signs; may respond to chemotherapy or radiation therapy; survival of up to 3 years has been reported following pericardectomy alone.

(CONTINUED)

- Prognosis is good with idiopathic pericardial effusion; approximately 50% of cases resolve after one or two pericardiocenteses; pericardectomy is often curative in persistent cases.

PERICARDITIS

BASICS

OVERVIEW

- Pericardial disease accounts for about 5% of cardiovascular disease in dogs (far less in cats), but it is a common cause of emergency presentation, since dogs with pericardial disease often experience serious clinical signs. Clinical signs of pericardial disease are usually caused by cardiac tamponade, which occurs when fluid accumulates in the pericardial space fast enough to increase the intrapericardial pressure above the central venous pressure during part of the respiratory cycle. If the intrapericardial pressure exceeds the central venous pressure continuously for more than a few minutes, death occurs. Pericardial constriction (elevated intrapericardial pressure in the absence of significant effusion) is fortunately rare in both dogs and cats, and occurs most often as a long-term complication of infectious or effusive pericarditis.

- Clinical signs of pericardial disease generally depend on the severity of tamponade (or rarely, constriction), and are independent of the underlying disease (i.e., inflammatory pericardial diseases (pericarditis) cannot usually be distinguished from neoplastic pericardial diseases based on the clinical signs they produce).

SIGNALMENT

- Idiopathic hemorrhagic pericarditis is more common in young to middle-aged, large-breed dogs (e.g., Great Pyrenees, Great Dane, Saint Bernard, golden retriever).
- Infectious pericarditis is relatively rare, but it occurs most often in young, active dogs (occasionally cats), associated with a penetrating injury (e.g., twig, plant awn).
- Pericarditis is rare as an important cause of clinical signs in cats, but the most common cause is feline infectious peritonitis (FIP), which has a "dual peak" age incidence in young and old cats.
- Small amounts of pericardial effusion in the absence of cardiac tamponade occur commonly in cats with hypertrophic cardiomyopathy, most often with other signs of heart failure—this should not be confused with pericarditis.

SIGNS

- Cats—clinical signs are rare, but similar to dogs when they occur.
- Dogs—clinical signs are caused by tamponade, and include signs of low cardiac output (e.g., collapse, weakness, anorexia, prerenal azotemia) as well as those caused by high central venous pressure (e.g., ascites). Diminished arterial pulse strength with noticeable weakening of the pulse on

inspiration is called pulsus paradoxus, a physical finding highly suggestive of tamponade. Dogs with tamponade also commonly have muffled or distant heart sounds, jugular venous distension, and rapid heart rates (tachycardia), but these findings are not pathognomonic.

- Clinical signs of pericardial constriction tend to be more chronic, with ascites prominent among them. Rarely, dogs with chronically elevated central venous pressures develop intestinal lymphangiectasia, with subsequent protein-losing enteropathy.

CAUSES & RISK FACTORS

- The cause of idiopathic hemorrhagic pericarditis is unknown; it may constitute the benign end of a spectrum that on its malignant end may include mesothelioma, when mesothelial cells that line the pericardium (or other body cavity) become malignant.
- Infectious pericarditis can be caused by either bacterial or fungal infection (e.g., tuberculosis, coccidioidomycosis, actinomycosis, nocardiosis, and infection with *Pasteurella* spp.). Infectious pericarditis may result from migrating porcupine quills, plant awns, projectiles, or other objects introduced into the chest.
- Cats—trauma or infection (e.g., FIP, *Staphylococcus aureus*, *Escherichia coli*, *Streptococcus*, *Actinomycetes*, *Cryptococcus*, and possibly *Toxoplasma*).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of pericardial effusion and tamponade (e.g., neoplasia, left atrial rupture, heart failure, peritoneal-pericardial diaphragmatic hernia, and pericardial cysts).
- Other causes of heart failure (e.g., cardiomyopathy, myocarditis, tricuspid or pulmonary valve disease, congenital heart disease, cor pulmonale, and severe left-sided CHF).
- Other causes of abdominal effusion (e.g., neoplasia, hemorrhage, severe hypoalbuminemia).
- Other causes of weak arterial pulse or collapse (e.g., cardiomyopathy, shock, hypoadrenocorticism, arrhythmias).

CBC/BIOCHEMISTRY/URINALYSIS

Most often unhelpful, with nonspecific changes common to many chronic conditions, including mild anemia, relatively nonreactive neutrophilia, and monocytosis.

IMAGING

Thoracic Radiography

Often unhelpful, although a rounded cardiac silhouette may suggest pericardial effusion,

particularly when the slow accumulation of chronic effusion permits significant expansion of the pericardium before the onset of tamponade; absence of this finding does not rule out pericardial effusion or pericarditis.

Echocardiography

The best single test to rule out pericardial effusion. Two-dimensional echocardiography reveals an echo-free space inside the parietal pericardium when effusion is present. Cardiac tamponade is recognized by the diastolic collapse of the right atrium, which is relieved during inspiration. The identification of intracardiac neoplasia is best left to highly trained and experienced echocardiographers.

Hemodynamic Measurements

- In the absence of volume contraction or treatment with diuretics, cardiac tamponade is associated with high central venous pressures (> 10 mmHg), and even if marginally elevated (e.g., 5–10 mmHg), these pressures spike to high levels (> 10 mmHg) and remain elevated on fluid challenge (e.g., 10 mL/kg IV bolus of LRS administered IV in less than 5 minutes).
- Constrictive pericardial physiology is rare and difficult to diagnose even by simultaneous pressure measurements from the right and left ventricles showing pressure equalization at an elevated end-diastolic pressure. Atrial pressure tracings classically show a rapid drop in pressure in early diastole followed by an early rise to a plateau at an elevated end-diastolic pressure.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

Potentially, low-voltage QRS complexes (< 0.9 mV in all leads in the dog), electrical alternans, ST segment elevation in the caudal and leftward leads (e.g., II, aVF, V3, I), P-mitrale (even in the absence of left atrial enlargement) and occasionally, arrhythmias. These changes lack sensitivity, and are not pathognomonic even when present.

Fluid Analysis

Cytologic examination of pericardial effusion cannot reliably differentiate among the common neoplastic (e.g., hemangiosarcoma, mesothelioma) and idiopathic causes of effusion. Cytology can identify (and thus rule out if they are not present) some potential causes of effusion (e.g., lymphosarcoma, FIP, sepsis).

Other Procedures

- If an infectious agent is suspected, aerobic and anaerobic cultures of the effusion are indicated.
- Histopathologic examination of the pericardium.
- Significant elevation of serum cardiac troponin I is not typical of benign effusion and suggests hemangiosarcoma.

(CONTINUED)

PERICARDITIS**TREATMENT**

- Pericardiocentesis is the only effective treatment for pericardial effusion causing tamponade. Until pericardiocentesis can be performed, IV fluids are beneficial to support cardiac output; diuretics are contraindicated in the management of cardiac tamponade.
- Effusion caused by idiopathic pericarditis in dogs may spontaneously subside after one or more pericardiocenteses. For chronically recurrent (e.g., more than twice) pericardial effusion in the absence of an echocardiographically identifiable cause, thoracic exploration with partial pericardectomy permits histopathologic examination, removal of foreign material, and evaluation for neoplastic or granulomatous disease. Thoracoscopic pericardectomy may provide similar diagnostic and therapeutic benefits in experienced hands. Surgery may help prevent subsequent constrictive disease. Infectious pericarditis should be treated surgically as soon as the diagnosis is made, in an effort to avoid subsequent pericardial constriction.
- Constrictive pericarditis may require epicardial stripping to relieve the constriction and adhesions between the visceral and parietal layers of the pericardium; this is a difficult and potentially dangerous procedure that should be attempted only by experts.

**MEDICATIONS****DRUG(S)**

- Treat infectious disease with appropriate antibiotics or antifungals based on culture and sensitivity testing.
- While anti-inflammatory, immunosuppressive, or anti-fibrotic strategies have been tried in dogs (e.g., therapy with corticosteroids, azothioprine, or colchicine) the efficacy of these strategies for preventing recurrent effusion is unknown.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Diuretics and preload reducers are contraindicated in tamponade.
- Corticosteroids or other immunosuppressive agents may exacerbate infection.

**FOLLOW-UP**

Pericardial effusion may recur if the pericardium is intact. Pleural effusion may occur months or even years after pericardiocentesis or pericardectomy, often associated with mesothelioma; periodic echocardiographic monitoring following treatment is recommended.

**MISCELLANEOUS****ABBREVIATIONS**

- CHF = congestive heart failure
- FIP = feline infectious peritonitis

PERINEAL HERNIA

BASICS

OVERVIEW

- The term *Perineal hernia* refers to a spectrum of diseases in which the perineal diaphragm is weakened or ruptured, resulting in abnormal function during defecation and progressing to herniation of pelvic and abdominal viscera.
- Weakening of the perineal diaphragm is postulated to result from hormonal influences on the perineal musculature in male dogs, but may also follow from conditions causing chronic and excessive straining, or neuropathic weakness of the perineal muscles.
- Separation of the perineal muscles (levator ani and coccygeus) from the anal sphincter and rectum allows lateral bulging of the rectum when the animal strains, thereby preventing coordinated defecation. Separation of the muscles also allows pelvic and abdominal viscera to migrate caudally.
- Retroflexion of the bladder may occur, and the subsequent incarceration may lead to ureteral or urethral obstruction. Strangulation of herniated viscera may occur in the severest cases.

SIGNALMENT

- This disease is seen most commonly in dogs, but also sporadically in cats.
- Older, intact male dogs are most at risk, however it can occur in females.

SIGNS

- Straining to defecate or urinate.
- Constipation is the main feature, although some patients present for supposed diarrhea, when liquid feces escapes around the firmer stool.
- Unilateral or bilateral perineal bulge due to fecal impaction and/or herniation: this is often the only presenting sign in cats.

CAUSES & RISK FACTORS

- Intact status in older male dogs.
- Underlying pathology leading to excessive straining: prostatomegaly in male dogs, while megacolon and malunion of pelvic fractures can predispose to perineal laxity in cats.
- Caudal neuropathy, malformation or injury such as tail traction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other conditions leading to obstipation and straining. Perineal neoplasia (adenoma, adenocarcinoma), sub-lumbar lymphadenomegaly secondary to anal sac adenocarcinoma, rectal tumor, perineal lipoma, paraprostatic cyst. Perineal abscess (anal sac abscess, foreign body).

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities on blood work, except azotemia and elevated creatinine if urinary obstruction occurs.

IMAGING

- Abdominal radiography: confirm constipation, prostatomegaly, sublumbar lymphadenomegaly, megacolon in cats.
- Pelvic radiography: confirm pelvic fracture malunion or intrapelvic mass.
- Abdominal ultrasonography: evaluate the size and consistency of the prostate.
- Perineal ultrasonography: evaluate presence of viscera or mass lesions.

DIAGNOSTIC PROCEDURES

- Thorough rectal palpation should confirm accumulation of feces in the dilated rectum, and perineal laxity.
- Insert a finger into the rectum and hook it laterally. If it is possible to pinch the rectal mucosa and skin together between the tip of the forefinger and thumb, without palpating a muscle shelf in between, the integrity of the pelvic diaphragm has been compromised.
- It is important to thoroughly evaluate both sides of the perineum: bilateral perineal laxity is often present even when herniation has only occurred on one side. Also evaluate the position of the anal sphincter in relation to the tuber ischii.
- In a normal patient, the sphincter is held in position dorsal and slightly cranial to the caudal extent of the tuber ischii. When the perineal diaphragm breaks down, the anus migrates caudally.
- Endoscopy or fine-needle aspiration biopsy may be indicated if a mass lesion is present extra or intraluminally.

TREATMENT

- Low residue diet and fecal softeners may ameliorate clinical signs temporarily, but surgical repair of the perineal diaphragm is required for definitive treatment.
- Castration of male dogs should always be performed simultaneously with herniorrhaphy in male dogs, due to the high rate of recurrence in intact dogs.
- Bladder retroflexion is considered an emergency; either due to urinary obstruction or the potential for strangulation and devitalization. In these patients, the urethra should be catheterized and the bladder decompressed if possible.
- In some cases, percutaneous cystocentesis is required to decompress and reposition the bladder before a urethral catheter can be passed.
- A balanced electrolyte solution should be administered intravenously prior to and during surgery in patients suffering from azotemia and hyperkalemia following urinary obstruction.
- Prior to surgical correction, impacted feces should be gently removed from the rectum. Enemas are not recommended as liquid feces may not be completely evacuated, leading to more contamination during surgery.
- Intraoperative antibiotics may be given, but there is no indication to continue antibiotic treatment postoperatively.
- The anal sacs are expressed and flushed, and a purse-string suture placed at the anocutaneous junction. The entire perineum and tail base is clipped, with the clip extending cranially past the greater trochanter of the femur on each side.
- In intact male dogs, the scrotum and surrounding skin is prepped for either a prescrotal or caudal castration approach. Depending on the preferred approach, the dog is castrated in dorsal recumbency and then flipped and placed in a perineal stand for the hernia repair, or placed in the perineal stand and castration performed via a caudal approach to the scrotum.
- A curvilinear incision is made 1–2 cm lateral to the anus, extending from the ventral tail base to the tuber ischium. The subcutaneous tissues are dissected in order to expose the hernia sac. This sac is perforated, at which point a small amount of serosanguinous fluid is usually encountered.
- Omentum is the most common organ within the hernia, and it may contain organizing hematomas or areas of saponification: these can be resected if necessary. The loose connective tissue is dissected to expose the coccygeus muscle (lateral), the anal sphincter (medial) and the internal obturator (ventral).
- Take care to avoid damaging the pudendal nerve and artery as it crosses the dorsal aspect of the internal obturator toward the anus. Most surgeons prefer to elevate the internal obturator from the ischium in order to close the hernia ring with minimal tension.
- Three simple interrupted sutures (nonabsorbable or long-acting absorbable, appropriately spaced) are placed between the following muscles: dorsal anal sphincter and dorsal coccygeus, ventral anal sphincter and medial internal obturator, ventral coccygeus and lateral internal obturator. The surgical wounds are then closed routinely. Ensure that the purse-string suture is removed!
- It may be helpful in large dogs with large bilateral hernias, especially if bladder retroflexion with urinary obstruction has occurred, to initially perform exploratory celiotomy, reposition the bladder and colon, and perform incisional colopexy and cystopexy.
- Staging the procedure, so that herniorrhaphy can be performed a few days later, when the patient's condition has stabilized and the perineal edema has resolved, may facilitate definitive hernia repair.

(CONTINUED)

- This technique has not been shown to affect recurrence rates, but does simplify the definitive herniorrhaphy by allowing local edema to settle, and reducing the tendency of abdominal contents to migrate into the field during surgical correction.
- In patients with very poor perineal muscle development, the repair may be supported by using a flap from the superficial gluteal muscle, incorporating prosthetic mesh into the repair, or in very severe cases, elevating and rotating the semitendinosus muscle. A superficial gluteal muscle flap is recommended in cats and very small dogs.
- The incisions are iced postoperatively to reduce pain and swelling. An Elizabethan collar is placed to prevent self-trauma to the incisions and appropriate analgesia given. A moist, low-residue diet is usually sufficient to maintain sufficiently soft stool to prevent straining or constipation postoperatively. Fecal softeners may be administered, but may lead to diarrhea and fecal soiling in the first days after surgery, especially if a bilateral repair has been performed. The patient's activity should be restricted for at least 3–4 weeks after surgery.

- The main risks of perineal herniorrhaphy are recurrence (greatly reduced by castration and use of internal obturator flap), and temporary dysfunction of the anal sphincter due to stretching following bilateral herniorrhaphy.
- Fecal and urinary incontinence can occur if excessive dissection around the pudendal nerve or peritoneal reflections are performed.

MEDICATIONS

N/A

FOLLOW-UP

PATIENT MONITORING

The patient should be evaluated thoroughly for the first 48 hours following surgery, with particular attention paid to urination and defecation. A rectal examination should be performed at the time of suture removal if feasible.

PREVENTION/AVOIDANCE

The major factor known to reduce the risk of recurrence following surgery is castration.

PERINEAL HERNIA

POSSIBLE COMPLICATIONS

Constipation and bladder retroflexion/obstruction if left untreated.

EXPECTED COURSE AND PROGNOSIS

Recovery and function following surgery is usually excellent. There is a 10–50% risk of recurrence depending on presence of underlying conditions, surgical approach, and intact status of the dog.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Cats should also be evaluated for primary conditions causing excessive straining (e.g., megacolon due to neurologic dysfunction or outflow obstruction).

PERIODONTAL DISEASES

BASICS

DEFINITION

Inflammation of some or all of the tooth's support structures (gingiva, cementum, periodontal ligament, and alveolar bone); compared with gingivitis (inflammation of the marginal gingiva), periodontitis indicates some degree of periodontal attachment tissue loss.

PATHOPHYSIOLOGY

• An intact epithelial barrier, high rate of epithelial turnover and surface desquamation prevent bacteria from gaining direct access to underlying tissue. • Normal host defense mechanisms limit the penetration of these products and their damaging effects. • Fluctuations in the host—parasite equilibrium may result in cycles of either diminished or increased intensity of the inflammatory response; it may be possible to think of periodontitis as the outcome of an imperfectly balanced host—parasite interaction. • Caused by bacteria located in the gingival crevice; initially a pellicle forms on the enamel surface of a clean tooth; the pellicle is composed of proteins and glycoproteins deposited from saliva and gingival crevicular fluid; the pellicle attracts aerobic gram-positive bacteria (mostly *Actinomyces* and *Streptococcus*); more bacteria soon adhere, forming plaque; within days the plaque thickens, becomes mineralized, and transforms into calculus. Calculus is rough and can be irritating to the gingiva. In time an anaerobic environment occurs subgingivally, allowing anaerobic motile rods and spirochetes to populate the subgingival area; more plaque builds on top of the calculus; endotoxins released by anaerobic bacteria cause tissue destruction and bone loss (periodontitis).

SYSTEMS AFFECTED

• Gastrointestinal—oral cavity. • Microscopic hepatic, renal, and CNS lesions are found in some animals.

GENETICS

Dogs and cats (less common)

Breed Predilections

Toy breeds especially Maltese and Yorkshire terriers are predisposed to developing periodontal disease.

Mean Age and Range

More common in older animals

Predominant Sex

None

SIGNS

Malodor, face rubbing, dropping food, oral bleeding

Examination Findings

- The degree of severity of periodontal disease relates to a single tooth; a patient may have teeth that have different stages of periodontal disease. Attachment loss may involve gingiva and/or alveolar bone loss (as well as periodontal ligament). Either periodontal pockets or recession of tissue with exposure of roots and/or furcation area may occur.
- Normal (PD 0): clinically normal—no gingival inflammation or periodontitis clinically evident.
- Stage 1 (PD 1): gingivitis without attachment loss. The height and architecture of the alveolar margin are normal. Bleeding on probing may be present.
- Stage 2 (PD 2): early periodontitis—less than 25% of attachment loss, or at most, there is a Stage 1 furcation involvement in multirooted teeth. There are early radiologic signs of periodontitis. The loss of periodontal attachment is less than 25% as measured either by probing of the clinical attachment level or radiographic determination of the distance of the alveolar margin from the tooth's cementoenamel junction relative to the length of the root. Stage 1 furcation involvement may be present in multirooted teeth.
- Stage 3 (PD 3): moderate periodontitis—25–50% of attachment loss as measured either by probing of the clinical attachment level, radiographic determination of the distance of the alveolar margin from the cementoenamel junction relative to the length of the root, and/or there is a Stage 2 furcation involvement in multirooted teeth.
- Stage 4 (PD 4): advanced periodontitis—more than 50% of attachment loss as measured either by probing of the clinical attachment level, radiographic determination of the distance of the alveolar margin from the cementoenamel junction relative to the length of the root, or there is a Stage 3 furcation involvement in multirooted teeth.

CAUSES

- Gingivitis—dogs; *Streptococcus* and *Actinomyces* spp.
- Periodontitis—dogs; pigmented and non-pigmented *Bacteroides*, *Porphyromonas denticanis*, *Porphyromonas salivosa*, *Porphyromonas gulae*, *Prevotella* spp., *Fusobacterium* spp.
- Cats—*Peptostreptococcus*, *Actinomyces*, and *Porphyromonas* spp.

RISK FACTORS

- Toy breeds with crowded teeth
- Dogs that groom themselves—causes hair to be embedded in the gingival sulcus
- Other debilitating illnesses
- Poor nutritional state

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pemphigus • Lupus • Oral neoplasia
- Stomatitis

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

DETECTION

- The Visual Awake Exam significantly underestimates the presence and severity of periodontal disease and there is no correlation between the visual awake exam and the presence or absence of periodontal disease.
- OraStrip QuickCheck Canine is a quick, point-of-care test that provides early detection of periodontal disease within 10 seconds and can be used in every wellness exam. • A positive OraStrip test has been shown to correlate with the presence of periodontal disease.

IMAGING

- Radiography—important diagnostic tool; as much as 60% of disease is hidden below the gum line.
- No radiographic changes in Stage 1 disease (gingivitis).
- Early radiographic signs of Stage 2/3 disease include loss of density and sharpness of the alveolar margin; as periodontal disease progresses, loss of lamina dura mineralization apically and furcation involvement in multirooted teeth.
- Advanced periodontal disease appears radiographically as loss of bone support around one or more roots; bone loss may be horizontal (a decrease in bone height around one or more teeth), vertical (infrabony defect), or oblique (a combination of both).

DIAGNOSTIC PROCEDURES

- Exam room—diagnostic strip (OraStrip) measures the amount of thiol levels which correlate to presence of periodontal disease necessitating care.
- Periodontal probing—“probing depth”: distance between free gingival margin and apical extent of pocket; probing depths > 2 mm in the medium-sized dog and 1 mm in the cat are abnormal.
- “Attachment loss” measures between the cementoenamel junction (CEJ) and apical extent of pocket; normally the gingival sulcus is located at the CEJ; any attachment loss is abnormal.

TREATMENT

- The ultimate goal of periodontal therapy is to eliminate periodontal pocket(s) and prevent further attachment loss; a willing patient and a client who can provide

(CONTINUED)

PERIODONTAL DISEASES

homecare are important considerations in creating a therapy plan. • Stages 1 or 2—professional cleaning, hand scaling, polishing, irrigation, application of dental sealant (SANOS). In cases of periodontal pockets locally applied antimicrobials may be helpful in reducing the pocket depth when combined with daily home care to control plaque. After thoroughly cleaning a moderate pocket, placement of a local antibiotic gel Clindoral or Doxirole Gel can help rejuvenate periodontal tissues and may reduce pocket depth. • Stage 3—above plus closed-root planing and subgingival curettage. If client can not provide home care or pet will not accept it consider extraction. • Stage 4—surgery needed to either expose the root for treatment (open-flap curettage) with a guarded prognosis or extract. • If 2–3 mm of healthy, attached gingiva is present—apically reposition flap to decrease pocket depth in areas of alveolar bone loss; if not enough healthy gingiva remains to apically reposition flap; rotated flap (from adjacent gingiva), free gingival flap, or extraction. • Bone replacement procedures—with two-, three-, four-walled infrabony pockets. • Guided tissue regeneration—use tissue barriers to separate gingival tissue and root surface.

MEDICATIONS

DRUG(S) OF CHOICE

Clindamycin and amoxicillin/clavulanic acid are antimicrobials approved for periodontal disease; may be used for a week before periodontal treatment, prior to anesthesia, postoperatively for 7–10 days. Systemic use of antimicrobials is not indicated in the treatment of periodontal diseases without surgical attention to the underlying cause.

HOMECARE

- The Veterinary Oral Health Council was created to accept products that significantly (> 20%) retarded the accumulation of plaque and/or tartar. Those products that are accepted by the VOHC carry the VOHC seal of acceptance. • Fluoride—stannous fluoride preparations (Omni Gel and Gel-Kam) help control periodontal disease by reducing plaque deposition on the surface of enamel and also decrease dental pain; use 0.4% strength in patients with Stage 3 and 4 periodontal disease, especially those with exposed root surfaces. • Chlorhexidine—the most effective product to inhibit plaque

formation in humans; bacteriostatic and bactericidal against bacteria, fungi, and some viruses; once absorbed it continues to be effective for up to 24 hours; in humans, to be maximally effective, it is swished in the mouth for 1 minute twice daily; the contact time of application is important for binding to the tooth and gingival sulcus; 1 minute of oral rinsing is difficult to accomplish in animals; chlorhexidine can be applied with a gauze sponge or cotton-tipped applicators, as a spray, or with finger brushes. Chlorhexidine is incorporated in CEH Hextra Chews (Virbac). • Novadent—chlorhexidine acetate 0.1%. • DentAcetic wipes-(Dechra) contains sodium hexametaphosphate used daily to remove plaque and decrease accumulation of tartar. • OraVet (Merial) plaque prevention gel applied weekly. • Diet—hard biscuit foods are preferable to soft sticky foods. • t/d tartar control diet (Hill's)—specifically indicated to control tartar (calculus) in dogs and cats. • Amount and type of homecare products dispensed depends on dental periodontal pathology. • Stages 1 and 2—daily brushing with dentifrice and VOHC accepted home care products used daily. • Stage 3, established periodontal disease—daily brushing with fluoride-containing toothpaste plus twice-weekly application of stannous fluoride gel. • Stage 4, advanced periodontal disease—zinc ascorbate gel (Maxi/Guard) 3–4 times daily to help regenerate cellular collagen, plus 0.2% chlorhexidine spray twice daily; or CHX-Guard, chlorhexidine gluconate, and zinc.

CONTRAINdications

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

Do not use chlorhexidine and fluoride products concurrently; binding both products may inactivate them; better to wait 30 minutes to 1 hour between use of a dentifrice-containing fluoride and a chlorhexidine rinse or gel.

ALTERNATIVE DRUG(S)

- Tetracycline • Metronidazole

FOLLOW-UP

PATIENT MONITORING

The degree of periodontal pathology dictates recall interval; some patients are checked

monthly, while others can be evaluated every 3–6 months. OraStrip can be used at recall to determine if the periodontal disease has recurred or worsened.

PREVENTION/AVOIDANCE

Good dental homecare

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Due to the multifactorial aspect of periodontal disease and individual response, the expected course and prognosis can be highly variable, but early assessment, diagnosis, adequate treatment, and therapy can minimize the destructive effects of this disease.

P

PERIPHERAL EDEMA

BASICS

DEFINITION

Edema is focal or diffuse excessive accumulation of tissue fluid within the interstitium; often at gravitational surfaces, whether localized or generalized.

PATHOPHYSIOLOGY

- High capillary hydrostatic pressure
- Increased capillary permeability
- Lymphatic drainage abnormality
- Low plasma colloid osmotic pressure

SYSTEMS AFFECTED

- Musculoskeletal
- Skin/Exocrine

GENETICS

- Dominantly inherited primary lymphedema has been described in poodles.
- Lethal congenital edema has been documented in bulldogs.

INCIDENCE/PREVALENCE

Variable

GEOGRAPHIC DISTRIBUTION

Pertinent when considering infectious disease mechanisms

SIGNALMENT

Species

Dogs and cats

Breed Predilections

Primary or congenital lymphedema has been reported in bulldogs, poodles, Old English sheepdogs, Labradors, and myriad other canine breeds as well as cats.

P

SIGNS

Historical Findings

- Allergic or other immune, cardiac, hepatic, or other organic disease.
- Trauma.
- Exposure to toxic (venomous) or infectious agents such as ticks or other arachnids.

Physical Examination Findings

- Unexplained weight gain may be noted initially; otherwise, early detection is unlikely.
- Non-inflammatory subcutaneous edema is often first recognized at the dependent thorax or abdomen or distal limbs.
- Inflammatory edema may be noted in non-dependent foci of the interstitium.

CAUSES

Localized or Single-Limb Edema

- High capillary hydrostatic pressure
- Venous or arterial obstruction, e.g., thrombosis or post-caval syndrome
- Arteriovenous fistula
- Increased capillary permeability
- Focal or multifocal immune, infectious, or toxic (chemical or biologic) insults (e.g., snake bite or bee sting)
- Trauma
- Burns

- Lymphatic obstruction
- Sterile (juvenile pyoderma) or infectious lymphangitis
- Primary or metastatic neoplastic invasion of lymphatic tissue
- Congenital aplasia or dysgenesis of the lymphatic system

Regional or Generalized Edema

- High capillary hydrostatic pressure
- CHF
- Cardiac tamponade
- Cranial or caudal vena caval thrombosis
- Renal failure and hypernatremia (salt retention)
- Paralysis or prolonged recumbency with subsequent failure of the venous pump
- Tourniquet effect of a bandage
- Increased capillary permeability
- Systemic immune, infectious, or toxic insults (e.g., sepsis or vasculitis)
- Lymphatic abnormalities
- Acquired regional traumatic, immune, infectious, or neoplastic process
- Congenital aplasia or other lymphatic dysgenesis
- Low plasma colloid osmotic pressure
- Protein-losing disease (e.g., nephrotic syndrome or intestinal lymphangiectasia)
- Failure to produce protein (e.g., cirrhosis)
- Exudative protein loss (e.g., severe burn)

RISK FACTORS

Variable

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Peripheral edema secondary to myxedema or inflammation is typically non-pitting.
- Bilateral forelimb edema with jugular venous distention implies cranial vena caval syndrome.
- Bilateral rear limb edema with or without ascites implies either hypoalbuminemia or caudal vena caval obstruction.
- Fore and/or rear limb edema with jugular venous distension, hydrothorax, and/or ascites implies cardiac disease.
- Focal edema with bruit and fremitus implies an arteriovenous fistula.
- Focal edema with erythema may be secondary to an insect or other bite.
- Multifocal or diffuse edema with petechiation and/or ecchymosis may be associated with a coagulopathy or vasculitis.
- CBC/BIOCHEMISTRY/URINALYSIS
- Leukocytosis suggests inflammatory or infectious disease.
- Thrombocytopenia may be secondary to vasculitis (e.g., RMSF), SLE, or a coagulopathy (e.g., DIC).
- Panhypoproteinemia is consistent with gastrointestinal disease, but diarrhea is not an obligatory clinical sign.

- Panhypoproteinemia and hypocholesterolemia are seen with intestinal lymphangiectasia.
- Hypoalbuminemia may occur with hepatic failure.
- Hypoalbuminemia with proteinuria suggests glomerular disease.
- Hypoalbuminemia with proteinuria and hypercholesterolemia in an edematous patient defines nephrotic syndrome.

OTHER LABORATORY TESTS

- Antithrombin III assay indicated in conditions with albumin loss.
- Further delineate thrombocytopenia with a bone marrow biopsy, ANA, screen for *Ehrlichia* and RMSF, and a coagulation profile.
- Panhypoproteinemia may dictate a need for intestinal biopsy.
- Hypoalbuminemia may warrant liver function testing (e.g., bile acid test, hepatic biopsy).
- Confirm proteinuria with a urine protein:creatinine ratio.
- Bacterial and fungal cultures of blind fistulae may prove useful.
- Fungal or other assays of infectious disease may be warranted; patient's primary residence and patient's travel history need to be considered.
- Pleural or peritoneal fluid analysis is suggested, if effusion is present.
- Low resting thyroid hormone (T_4) should be elaborated with a TRH stimulation test, free T_4 by equilibrium dialysis, or TSH concentration.

IMAGING

- Suspected heart disease necessitates thoracic radiographs and echocardiogram.
- Angiography (e.g., venacavogram) may help to define a vascular obstruction.
- Diagnostic ultrasound may help to delineate a vascular occlusion.
- Thermography and perfusion scans (e.g., scintigraphy) are esoteric but have been used to diagnose occlusive vascular disease.

DIAGNOSTIC PROCEDURES

- Fine-needle aspiration of an affected area for cytology and culture may be helpful.
- Biopsy and deep culture may help define an underlying cause for edema.

PATHOLOGIC FINDINGS

Depend on cause of the edema

TREATMENT

APPROPRIATE HEALTH CARE

Depends on the cause of the edema

NURSING CARE

- Application of warm compresses is recommended for patients with edema secondary to infection.

(CONTINUED)

- Good nursing care required to prevent decubital ulceration in recumbent patients.

ACTIVITY

Depends on cause of edema—e.g., exercise restriction is recommended in patients with congestive heart failure.

DIET

Depends on the cause of edema—e.g., patients with protein-losing nephropathy require a restricted protein diet.

CLIENT EDUCATION

Depends on the cause of edema

SURGICAL CONSIDERATIONS

- Surgery such as lymphangioplasty, thrombectomy, or lymphaticovenous shunt may be palliative.
- Amputation of the edematous limb is sometimes indicated.
- Arteriovenous fistulae may be treated by various surgical methods.

**MEDICATIONS****DRUG(S)**

- Anaphylaxis—epinephrine (1 mg/mL) at 0.01 mL/kg IM or SC to a maximum of 0.02–0.05 mL; prednisone sodium succinate, 10–30 mg/kg IV; antihistamines are of equivocal benefit once anaphylaxis ensues.
- Lymphedema—benzopyrone use yields variable results in veterinary medicine; rutin, 50 mg/kg PO q8h, has been mixed with food for cats with chylothorax.
- Cardiogenic edema—combinations of positive or negative inotropes, vasodilators, and diuretics commonly used in patients with CHF.
- Immune-mediated edema requires immunosuppressive therapy (e.g., prednisone).
- Vasculitis and edema secondary to rickettsial disease typically respond to tetracycline (22 mg/kg PO q8h) or doxycycline (5 mg/kg PO q12h).
- Edema in association with other infectious agents requires antifungal therapy or antibiotic therapy (ideally dictated by culture and sensitivity).
- Myxedema secondary to hypothyroidism should respond gradually to T₄ supplementation.
- Edema associated with toxic insults may be slowed with antidotes (e.g., antivenom).
- Anticoagulant therapy (e.g., heparin, warfarin, or clopidigrel) may benefit patients with DIC or AT III.
- Vascular volume expanders such as hydroxyethyl starch or plasma often benefit patients with low plasma oncotic pressure; very-low-dose furosemide in a constant-rate infusion of 0.1 mg/kg/hour has been effective in conjunction with a volume expander.

CONTRAINDICATIONS

- Diuretics generally aggravate edema of non-cardiogenic origin.
- Steroids may worsen edema secondary to infectious disease.
- Epinephrine—generally contraindicated in shock except in anaphylaxis.
- Propranolol (beta-blocker)—contraindicated in patients predisposed to bronchospasm.

PRECAUTIONS

- Avoid IM injections in patients with thrombocytopenia.
- Taper patients on long-term steroid therapy so that endogenous steroid production resumes.
- Use epinephrine cautiously in patients predisposed to ventricular fibrillation.
- Use enalapril and other ACE inhibitors cautiously in patients with renal disease.
- Long-term antibiotic therapy may facilitate a superinfection by a fungus (e.g., *Candida*) or resistant bacteria.
- Monitor anticoagulants closely to avoid fatal hemorrhage.

**FOLLOW-UP****PATIENT MONITORING**

- Repeat complete blood counts, chemistries, and urine protein:creatinine ratios for blood dyscrasias and serum and urine protein concentrations.
- Weekly assessment of prothrombin or partial thromboplastin time for patients on warfarin or heparin.
- Serial biopsies of affected tissue such as kidney in glomerulonephritis may help to prognosticate.
- Repeat cultures or acute and convalescing titers for patients suffering from an infectious disease.
- Periodic TSH assay or T₄ assay (4–6 hours post-pill) for patients receiving thyroid supplementation.

PREVENTION/AVOIDANCE

Depends on the cause of the edema

POSSIBLE COMPLICATIONS

- Decubital ulceration
- Fatal hemorrhage
- Fatal thrombosis
- Refractory cardiac, gastrointestinal, hepatic, or renal failure
- Malnutrition
- Cerebral edema and herniation
- Resistant infection and sepsis

EXPECTED COURSE AND PROGNOSIS

Depends on cause of the edema

PERIPHERAL EDEMA**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Pericardial, pleural, or peritoneal effusion

AGE-RELATED FACTORS

Vascular anomalies or primary lymphedema are generally documented in juvenile patients (e.g., anasarca).

ZOONOTIC POTENTIAL

- Recent tick exposure is a common element in pets and their owners who may suffer simultaneously from rickettsial disease.
- Certain protozoal (*Leishmania*), fungal (*Sporothrix*), and bacterial (*Brucella*) organisms may transfer to people via direct contact.

PREGNANCY/FERTILITY/BREEDING

Brucellosis has been associated with vulvar edema, necrotizing vasculitis, and embryonic death or fetal abortion.

SYNONYMS

Anasarca

PERIRENAL PSEUDOCYSTS

BASICS

OVERVIEW

- Capsulogenic renal cyst, capsular cyst, pararenal pseudocyst, capsular hydronephrosis, perirenal cyst, and perirenal pseudocyst are terms used to describe renomegaly caused by accumulation of fluid between the kidney and its surrounding capsule. One or both kidneys are affected.
- The tissue adjacent to the fluid accumulation is not lined with secretory epithelium; and thus the name "pseudo"-cyst is appropriate.

SIGNALMENT

- Primarily older male cats (> 8 years).
- When detected in young cats, the disease is usually unilateral.
- Rare in dogs; the difference in prevalence between species may be related to the prominent network of subcapsular veins that characterize feline kidneys.

SIGNS

- May be asymptomatic
- Non-painful, enlarged abdomen is common
- Signs of concomitant renal failure in some patients

CAUSES & RISK FACTORS

- Cause of perirenal accumulation of fluid is not completely understood.
- Accumulation of pseudocyst fluid is a dynamic, not a static, process.
- Cytologic and biochemical evaluation of pseudocyst fluid may aid understanding of pathophysiologic mechanisms.
- Fluid with characteristics of a transudate may accumulate because of high capillary hydrostatic pressure or lymphatic obstruction. Some cats have light microscopic evidence of renal fibrosis. However, it is not known whether progressive renal parenchymal contraction occludes lymphatics and blood vessels, promoting transudation of fluid.
- Perirenal accumulation of transudate can also result from rupture of renal cysts.
- Accumulation of perirenal urine may indicate disruption of the renal pelvis or the proximal ureter.
- Accumulation of blood in pseudocysts can result from external trauma, surgery, neoplastic erosion of blood vessels, rupture of aneurysms, coagulopathies, or paracentesis.

P

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Causes of renomegaly include renal neoplasia, hydronephrosis, polycystic kidney disease (common), feline infectious peritonitis, and mycotic or bacterial nephritis (less common).
- Ascites and enlargement of other abdominal organs can cause non-painful distension of the abdomen.

CBC/BIOCHEMISTRY/URINALYSIS

- Results unremarkable until patient develops renal insufficiency.
- Azotemia and inappropriately low urinary specific gravity (< 1.035) indicate concomitant chronic kidney disease (CKD).

OTHER LABORATORY TESTS

N/A

IMAGING

- Renomegaly is commonly detected by abdominal radiography.
- Excretory urography and ultrasonography can be used to determine whether the underlying renal parenchyma is normal or abnormal. Small kidneys beneath an abnormally wide fluid-filled intracapsular space is a common finding.

DIAGNOSTIC PROCEDURES

Cytologic examination of pseudocyst fluid may provide evidence of the underlying disease process resulting in fluid accumulation (e.g., transudation, hemorrhage, lymphatic obstruction, inflammation, urine, etc.) or secondary complications (e.g., infection). Creatinine concentrations that are higher in pseudocyst fluid compared to serum are consistent with urinary tract rupture.

TREATMENT

- Perirenal pseudocysts are not immediately life-threatening.
- Some patients need no treatment.
- Many patients require further diagnostic evaluation and treatment of concomitant CKD.
- Capsulectomy or pseudocyst fenestration (remove greater than 1-cm × 1-cm section of capsule to minimize spontaneous closure of the fenestration) is generally associated with amelioration of abdominal distention and abdominal organ displacement. Early stages

of CKD may resolve; however, progression of CKD commonly occurs.

- Long-term response is unknown.
- Avoid nephrectomy to maximize kidney function.
- Decompression by paracentesis with a needle and syringe provides temporary relief.
- If pseudocysts refill with fluid (often in 1–2 weeks), paracentesis can then be repeated.

MEDICATIONS

DRUG(S)

Consider appropriate antimicrobial (i.e., lipid-soluble antibiotic chosen on the basis of antimicrobial susceptibility) if pseudocysts become infected.

FOLLOW-UP

- Monitor patients periodically (every 2–6 months) for development and progression of CKD.
- Short-term prognosis appears favorable with or without pseudocyst decompression in patients with no evidence of CKD.
- Long-term prognosis is unknown because it has not been determined whether perirenal pseudocysts are associated with underlying lesions in the renal parenchyma that may be progressive. It is also unknown whether perirenal pseudocysts are associated with hypertension.
- Survival is related to the severity and progression of CKD.

PERITONEOPERICARDIAL DIAPHRAGMATIC HERNIA

BASICS

OVERVIEW

- Embryologic malformation of the ventral midline allowing communication between the pericardial and peritoneal cavities.
- May be associated with other congenital malformations including sternal deformities (especially in cats), cranial abdominal hernia, and ventricular septal defects.
- Signs may be due to large amounts of abdominal viscera compressing the heart or lungs and incarceration of abdominal organs (e.g., liver and small bowel).

SIGNALMENT

- Dog and cat.
- Age when clinical signs first occur varies; more than one-third of patients are 4 years of age or older.
- Weimaraners and Persians may be predisposed.
- No evidence that lesions are hereditary, but they have been reported in littermates.

SIGNS

General Comments

- Depend on the nature and amount of abdominal contents that herniated.

Historical Findings

- Vomiting.
- Diarrhea.
- Weight loss.
- Abdominal pain.
- Coughing.
- Dyspnea.

Physical Examination Findings

- Muffled heart sounds.
- Displaced or attenuated apical cardiac impulse.
- Palpable sternal deformity or cranial abdominal hernia.
- Cardiac tamponade and signs of right-sided congestive heart failure (rare).

CAUSES & RISK FACTORS

- Embryologic malformation.
- Prenatal injury of the septum transversum and pleuroperitoneal folds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Never an acquired traumatic defect because no natural direct communication exists

between the peritoneal and pericardial cavities after birth.

- Pericardial effusion.

CBC/BIOCHEMISTRY/URINALYSIS

No associated hematologic or biochemical alterations

OTHER LABORATORY TESTS

N/A

IMAGING

- Radiographic findings depend on size of defect and amount of herniated abdominal contents; caudal heart border and diaphragm may overlap; thoracic radiographs may show an "empty" abdomen and possible multiple radiographic densities.
- Positive and negative contrast peritoneography have been used to evaluate the diaphragm. Injection of 1–2 mL/kg body weight of water-soluble positive-contrast into the peritoneal cavity followed by right and left lateral, sternal, and dorsal recumbent radiographs allows complete evaluation of the diaphragm. Identification of contrast within the pleural space confirms the diagnosis of diaphragmatic rupture. Air, carbon dioxide, or nitrous oxide may also be used.
- Barium series may demonstrate bowel loops crossing the diaphragm and within the pericardial sac.
- Non-selective angiography outlines the cardiac chambers within the large cardiac silhouette.
- Echocardiography gives a definitive diagnosis.

DIAGNOSTIC PROCEDURES

Electrocardiogram may show small complexes if abdominal contents have herniated or if marked effusion is present.

TREATMENT

Surgical closure of the hernia after returning viable organs to their normal location is usually curative. In asymptomatic adult patients with small hernias, treatment may not be indicated.

MEDICATIONS

DRUG(S)

- Myocardial contractility is unaffected in most patients; drugs for improving cardiac output are not indicated.

- Can give symptomatic treatment based on nature and amount of abdominal contents that are herniated.

CONTRAINDICATIONS/POSSIBLE

INTERACTIONS

Drugs that reduce ventricular afterload (e.g., arteriolar vasodilators) or preload (e.g., venous dilators and diuretics) are not useful and can cause reduction of ventricular filling, hypotension, and low cardiac output.

FOLLOW-UP

Prognosis after surgery is excellent in animals with no other significant congenital anomalies or complicating factors.

Author Larry P. Tilley

Consulting Editors Larry P. Tilley and Francis W.K. Smith, Jr.

PERITONITIS

BASICS

DEFINITION

An inflammatory process involving the serous membrane of the abdominal cavity.

PATHOPHYSIOLOGY

- Insult to the peritoneal cavity, whether localized or generalized, leads to an inflammatory process characterized by vasodilation, cellular infiltration, stimulation of pain fibers, and development of adhesions.
- Extent and severity depend on type and severity of the insult. • Bacterial peritonitis is commonly associated with Gram-negative bacterial endotoxin. The lipopolysaccharide (LPS) binds to macrophages, inducing cytokine release such as interleukin 1 (IL-1) and tumor necrosis factor (TNF). Gram-positive bacteria contain peptidoglycan, teichoic acid, and hyaluronic acid. Resultant cytokine release includes IL-1, TNF, and nitric oxide (NO). NO causes vasodilation and can promote hypotension.
- Release of vasoactive substances (histamine, serotonin, protease, nitric oxide, endotoxin) cause vasodilation and increased vascular permeability. Cytokine release from mast cells, neutrophils, macrophages, and lymphocytes result in chemotaxis, activation of the complement system, and further accumulation of fluid. Activation of the complement system also results in fibrin degradation, damage to the mesothelium in the face of decreased fibrinolysis results in adhesion formation. • Bile damages mesothelial cells and inhibits PMN function. Blood in the peritoneal cavity interferes with chemotaxis and phagocytosis and promotes bacterial growth. The result of significant abdominal inflammation can be systemic inflammatory response syndrome (SIRS) and sepsis. With time, SIRS can progress to multiple organ dysfunction (MODS) and can affect the respiratory system (acute respiratory distress syndrome [ARDS] or pulmonary thromboembolism [PTE]), or cause renal dysfunction, reduced cardiac function, and neurologic signs.

SIGNS

General Comments

Signs may be vague and nonspecific and signs depend on the time of evaluation in relation to severity of the inflammation and systemic response present.

Historical Findings

Lethargy, depression, anorexia, vomiting, diarrhea, collapse

Physical Examination Findings

- Abdominal discomfort or pain—localized or generalized; patient usually resents palpation; less common in cats. • A “prayer” position—due to abdominal discomfort.
- Compensatory shock—tachycardia, tachypnea, injected mucus membranes, rapid capillary refill time (CRT). • Early decompensatory shock—tachycardia, poor pulse quality, depressed mentation, pallor, prolonged CRT. Cats often show a normal to decreased heart rate (< 140/min).
- Decompensatory shock—bradycardia, weak or absent pulses, severely depressed mentation, pallor or cyanosis, prolonged CRT. • Vomiting common. • Arrhythmias may be detected. • Fever—not consistent; when noted with other signs of peritonitis strongly suggests bacterial contamination of the abdominal cavity. • Weight loss—reported in one-third of dogs and cats with secondary peritonitis.

CAUSES

Primary Peritonitis

- Uncommon. • Primary peritonitis results from hematogenous or lymphatic spread, or due to translocation from the gastrointestinal tract. Feline infectious peritonitis (FIP) is a form of peritonitis in cats.

Secondary Peritonitis

- Predominant form. • Secondary peritonitis is the most common form of the condition and results due to contamination of the peritoneal cavity originating in one of the abdominal organs. Sources include the gastrointestinal tract (up to 75%), perforation of ulcerations, GI tract tumors, perforation secondary to GDV, leakage following GI surgery, penetrating trauma, biliary tract trauma or rupture due to obstruction or mucocele formation, abscessation of the pancreas, kidney, prostate, spleen or liver, ruptured pyometra, and urine leakage. Uroabdomen and bile peritonitis may or may not be septic; regardless, chemical peritonitis is present.

RISK FACTORS

- Trauma. • Gastrointestinal surgery.
- Undetected abscess of liver, pancreas,

prostate, or uterus. • Prior NSAID use is associated with perforation occurring at the pylorus compared to other sites.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of abdominal pain or distention, sepsis, and shock.

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilic leukocytosis most common finding; may be a left shift; degenerative left shift or development of neutropenia may portend a worsening prognosis.
- Hemoconcentration or anemia.
- Hypoproteinemia—owing to exudation of albumin. • Hypo- or hyperkalemia and hyponatremia. • Azotemia—associated with prerenal, renal, or post-renal causes.
- Metabolic acidosis. • Hypoglycemia—may indicate sepsis; hyperglycemia may be present in cats. • Liver enzyme elevations—associated with hepatic causes of peritonitis or due to MODs. • Hyperlactatemia—due to poor perfusion associated with shock.

OTHER LABORATORY TESTS

- Coagulation abnormalities may develop—prolonged activated partial thromboplastin time (aPTT) and prothrombin time (PT).
- Thromboelastography to evaluate for hyper- or hypoagulability. • DIC may also develop—prolonged aPTT, PT, and thrombocytopenia, elevated D-dimers (> 1,000 U), low protein C levels.

IMAGING

Radiography

- Findings inconsistent and depend on cause.
- Loss of serosal detail (ground-glass appearance suggests fluid in the abdominal cavity)—rule out lack of intra-abdominal fat.
- Generalized ileus may be present.
- Consider making right and left lateral projections of the abdomen.
- Pneumoperitoneum—gas in the abdomen may be slight, closely evaluate the region of the diaphragm; consider making lateral beam images in a sternally recumbent or lateral recumbency. • Can be diagnostic for GDV, GI foreign bodies, mass lesions, enlargement of organs with abscessation. • Contrast procedures—rarely warranted; may complicate management if contrast material enters the abdominal cavity; avoid barium if gastrointestinal perforation is suspected.

Ultrasound

May identify smaller volumes of peritoneal effusion; abscesses of the pancreas, liver, or prostate; rupture of the gallbladder, tumors or mass lesions. Important for aspiration of small volumes of fluid.

DIAGNOSTIC PROCEDURES

- Abdominocentesis and diagnostic peritoneal lavage—safe and reliable and should be

(CONTINUED)

PERITONITIS

performed as soon as possible.

- Abdominocentesis—empty the urinary bladder; aseptically clip and prepare the abdomen. Utilize ultrasound guidance if desired. Use a 22- or 20-gauge needle, butterfly catheter or over-the-needle catheter to penetrate the abdominal cavity. Collect the first few drops of fluid for cytology. Use a 3 mL syringe to apply gentle negative pressure if free flow of fluid does not occur; tap all four quadrants (i.e., four separate needle punctures), with the left side last in an attempt to avoid inadvertent splenic puncture. Ultrasound guidance may be necessary to avoid the falciform fat and spleen and is required when small volumes of fluid are present.
- Diagnostic peritoneal lavage—if abdominal fluid not recovered by abdominocentesis and the index of suspicion is high (e.g., postoperative complication). Empty the urinary bladder and aseptically prepare the abdomen. Infuse 20 mL/kg warm sterile saline through an 18- or 16-gauge over-the-needle catheter using gravity; gently roll patient from side to side to distribute the lavage fluid. Move the infusion bag to a position below the patient to recover fluid. There is no need to recover entire amount of infused fluid.
- Cytology—first collect samples into EDTA tube; note color and clarity of the fluid and presence of fibrin.
- Culture and sensitivity—next, collect sample in a sterile clot tube.
- Suspected chemical peritonitis—finally, analyze abdominal fluid for creatinine (for uroabdomen), amylase (for pancreatitis), and bilirubin (for bile leakage).
- Suspected FIP—submit abdominal fluid for protein electrophoresis and globulin determination.

PATHOLOGIC FINDINGS

- Intra- or extracellular bacteria, degenerative neutrophils, and plant material are diagnostic of septic peritonitis.
- Normal peritoneal fluid contains < 2,500 cells/ μ L; peritoneal fluid glucose levels more than 20 mg/dL below that of the peripheral blood are highly suggestive of septic peritonitis.
- Fluid lactate > 2.5 mmol/L in dogs is suggestive of septic peritonitis, but is not useful in cats.
- Recent surgery results in < 10,000 cells/mL; primary peritonitis usually results in 7,000 cells/ μ L in dogs and 3,000 cells/ μ L in cats.
- Fluid bilirubin or creatinine levels higher than that of peripheral blood indicate bile peritonitis or uroabdomen, respectively.
- Acellular homogenous, laminated, basophilic material on cytology may be mucoid material associated with bile peritonitis.

**TREATMENT****APPROPRIATE HEALTH CARE**

Inpatient—intensive monitoring and supportive care are required.

Intravenous Fluid Therapy

- Critical for correction of hemodynamic disturbances and electrolyte and acid-base abnormalities prior to considering surgery.
- Balanced electrolyte solution—lactated Ringer's solution or Normosol-R for initial treatment; evaluate the response to therapy frequently.
- Potassium and glucose—may need to supplement.
- Replacement rate—may initially be as high as 55 mL/kg (cats) and 90 mL/kg (dogs); adjust rate frequently as patient status changes; if supplemented with potassium, the rate should not exceed 0.5 mEq/kg/h of potassium.
- Colloid administration is highly recommended in acute and/or severe cases (up to 20 mL/kg/d in dogs and 15 mL/kg/d in cats).
- Goals—blood pressure > 90 mmHg, heart rate 80–140/min (dogs) and 140–225/min (cats), CRT < 2 sec, urine output > 1–2 mL/kg/h, serum lactate < 2.5 mmol/L in dogs.
- Inadequate response to therapy prompts vasopressor administration (dopamine, dobutamine, vasopressin, norepinephrine).
- Whole blood or packed red blood cells (PRBC)—as required for anemia.
- DIC—remove the inciting cause, support with plasma; consider heparin therapy.
- Consider canine albumin transfusion in cases of severe hypoalbuminemia.

NURSING CARE

- Significant and dependent upon the severity of systemic signs, SIRS, MODS, ARDS, sepsis.
- Continue intravenous fluid therapy and maintenance of goals per the above.

ACTIVITY

- Will be significantly decreased depending on the severity of systemic illness.
- Depends on the inciting cause and surgery necessary.

DIET

- Dictated by cause, when identified, and any concurrent conditions (e.g., heart disease).
- Feeding tube placement should be considered and placed at the time of surgery for early nutritional support (e.g., esophagostomy, gastrostomy, jejunostomy).
- Adequate nutrition—essential to optimize outcome; may attenuate the hypermetabolic state, preserve hepatic antioxidant defenses, prevent protein-calorie malnutrition, and maintain the gastrointestinal barrier function.

CLIENT EDUCATION

- Advise client of the high rate of morbidity and in most cases of septic peritonitis, mortality.
- Inform client that extensive monitoring and intensive care may be costly.

SURGICAL CONSIDERATIONS

- Decision to treat medically or surgically—dictated by etiology, patient's response to initial treatment, and owner's financial constraints.
- Known bacterial contamination or suspected chemical peritonitis—surgical intervention necessary.
- Perform surgery as soon as the patient is stable.
- Exploratory

laparotomy—prepare for incision extending from xiphoid to pubis; goals of surgery are to remove the source of contamination, debride and clean the abdomen, collect fluid or tissue for Gram stain and aerobic and anaerobic culture, and providing nutritional support; use monofilament absorbable or non-absorbable suture within the abdomen (avoid multifilament, non-absorbable suture and catgut); before closing, thoroughly lavage the abdomen with 200–300 mL/kg sterile saline solution, warmed to body temperature. Do not add antimicrobials or other products (povidone iodine) to the lavage solution; remove all lavage solution from the abdomen.

- Surgeon must be able to assess organ viability and resection. Anastomosis of the GI tract should utilize healthy tissue; consider serosal patching, perform omental patching if serosal patching not done.
- Consider omentectomy of pancreatic abscesses, perform omentectomy for prostatic abscessation. Remove affected organ or part in other cases of abscessation.
- Consider open abdominal drainage—based on degree of contamination, ability to debride the abdomen, severity of the illness, and anticipation of septic complications. Allow continued removal of fluid, bacteria, and toxins. Forms include closed suction drains, vacuum-assisted peritoneal drainage (VAPD), and closure of the caudal abdomen with partial closure of the cranial abdomen. Sterile bandaging is required in each form; less external materials for VAPD, but regulate suction and specialized foam and connections to suction required. Requires anesthesia for abdominal closure unless closed suction drains are used.

P

**MEDICATIONS****DRUG(S) OF CHOICE**

- Antimicrobials—early and aggressive therapy for suspected septic peritonitis; broad-spectrum (against Gram-positive and Gram-negative, aerobic, and anaerobic organisms); final therapy must be based on culture and susceptibility testing.
- Initial therapy—gram negative (enrofloxacin, cefotaxime, amikacin); gram positive (ampicillin, clindamycin); anaerobes (metronidazole).
- Ampicillin 22 mg/kg IV q8h.
- Clindamycin 12 mg/kg IV q12h.
- Cefotaxime 20–80 mg/kg IV q8h.
- Enrofloxacin 10–20 mg/kg IV q12h (5 mg/kg/d IV in cats).
- Amikacin 10–15 mg/kg IV q24h.
- Metronidazole 10 mg/kg IV q8–12h.
- Pain control—depending on the severity of pain; may be intermittent or via continuous rate infusion (CRI). Significant pain is usually present; opioids recommended.
- Multimodal CRI for pain; dogs, morphine—0.05–0.2 mg/kg/h,

PERITONITIS

(CONTINUED)

- ketamine (0.2–0.6 mg/kg/h), lidocaine (2–4 mg/kg/h); cats, fentanyl (2–4 µg/kg/h), ketamine (0.05–0.2 mg/kg/h). • GI protectants—often recommended due to poor perfusion and stress. Required for cases of GI ulceration.
- Famotidine—0.5–1.0 mg/kg IV q12–24h for rapid onset of action.
- Pantoprazole 1 mg/kg IV q24h for more complete decrease in gastric acid.
- Sucralfate: dogs, 0.5–1.0 mg PO q8h; cats, 0.25–0.5 mg PO q8h.

CONTRAINDICATIONS

- Glucocorticoids—use is controversial.
- NSAIDs are not recommended.
- Heparin therapy for the treatment of DIC—less effective in the case of insufficient antithrombin levels.

PRECAUTIONS

- Aminoglycosides—use with caution if renal function is impaired.
- Adequate hydration—essential to enhance safety of these drugs.
- Antiemetic use should be avoided if gastrointestinal foreign body or rupture is at all suspected. Use indicated when GI cause is eliminated.

POSSIBLE INTERACTIONS

Time sucralfate and gastric acid reducer so that sucralfate is given when the pH is lower. Also avoid oral medications at the same time as sucralfate as required.

ALTERNATIVE DRUG(S)

Fluoroquinolone—enrofloxacin or orbifloxacin; substitute for an aminoglycoside, especially with impaired renal function.

FOLLOW-UP

PATIENT MONITORING

- Fluid balance, electrolyte balance, acid-base status—depending on the severity of the condition.. Blood gas, electrolyte, lactate measurements as necessary.
- Frequency of monitoring—varies with severity of the condition and response to treatment. May be frequent (1h).
- Maintain urine output 1–2 mL/kg/h and goals described in fluid therapy section above.
- Replace fluid losses (vomiting, diarrhea) as necessary.
- Change recumbency every 4–6h as necessary.
- Enteral nutrition as soon as possible via oral feeding or nasoesophageal, gastrostomy, or jejunostomy tube feeding promotes enterocyte health and decreases bacterial migration through the intestinal wall.
- Repeat ultrasound and cytologic evaluation depending on index of suspicion for leakage of intestinal surgery sites.
- CBC, chemistry profile, urinalysis—every 1–2 days during

periods of intensive monitoring, even in patients that are responding.

PREVENTION/AVOIDANCE

Prevention—difficult except when specific risk factors are identified (e.g., pyometra).

POSSIBLE COMPLICATIONS

- If underlying cause is not identified and managed, patient is at risk for complications.
- Open peritoneal drainage—increased cost and required intensive care, repeated sedation or anesthesia for aseptic bandage changes, ascending/nosocomial infection, hypoproteinemia, electrolyte imbalances, enterocutaneous fistulation, and abdominal hernia formation.
- Adhesions.

EXPECTED COURSE AND PROGNOSIS

• Prognosis—depends on rapid identification and successful management of the underlying cause and appropriate follow-up care.

- Septic peritonitis—mortality of 30–68%. Prognosis worse in animals with pre-existing septic peritonitis, incorrectable hypotension, low serum albumin and total protein, respiratory dysfunction, DIC, low protein C, low antithrombin, MODS, and better survival in patients with lower pre-operative alanine aminotransferase, gamma-glutamyl transferase, packed cell volume, total solids, thromboelastography consistent with hypercoagulation, and albumin.
- Septic peritonitis—open peritoneal drainage may improve survival.
- Septic bile peritonitis—27% survival compared to 100% with non-septic bile peritonitis.
- Antibiotic treatment within the first hour in cases of suspected septic peritonitis per a specific treatment protocol based on hospital cultures reduced mortality from approximately 80% to 42%.
- Plasma lactate > 2/5 mmol/L or inability to normalize plasma lactate—poorer survival in septic peritonitis.
- Feeding tube complications depend on the site of placement. Esophagostomy (localized infection or abscessation), gastrostomy and jejunostomy (leakage or premature dislodgement associated peritonitis), nasoesophageal (sneezing, epistaxis). Refeeding syndrome—decreased magnesium, phosphorus, potassium. Warrants close monitoring.
- Bradycardia and hypothermia in cats with primary septic peritonitis were associated with mortality.

PETECHIA, ECCHYMOSIS, BRUISING

BASICS

DEFINITION

Pinpoint (petechia) or larger (ecchymosis) hemorrhage in the skin or mucous membranes most often secondary to abnormal primary hemostasis (platelet or vessel-wall mediated); may appear spontaneously or following minimal trauma. Spontaneous development often occurs at sites of increased capillary trauma or increased pressure, e.g., ventrum.

PATHOPHYSIOLOGY

- Thrombocytopenia and/or defective platelet function (i.e., thrombocytopathia) cause impaired primary hemostasis (failure of platelet plug formation). Platelet numbers below $50 \times 10^9/L$ and more often below $25 \times 10^9/L$ are associated with an increased risk of spontaneous hemorrhage.
- Main mechanisms of thrombocytopenia—increased destruction, e.g., immune mediated (ITP); decreased production, e.g., myelophthisis or chemotherapy-induced myelosuppression; increased consumption, e.g., DIC; and sequestration in the spleen or liver, e.g., splenic torsion or neoplasia.
- Main mechanisms of congenital thrombocytopathia—deficient or abnormal von Willebrand factor (most common); defects in platelet membrane glycoproteins, e.g., Glanzmann's thrombasthenia in otter hounds and Great Pyrenees (rare); defects in platelet storage granules, e.g., storage pool disease (Chédiak Higashi) in Persian cats or American cocker spaniels (rare); defects in signal transduction, e.g., in basset hounds or spitzes (rare).
- Main mechanisms of acquired platelet dysfunction are drugs (e.g., NSAIDs) or uremia-induced inhibition of prostaglandin metabolism. Other causes are anti-platelet antibodies, paraproteinemia, liver disease, immune-mediated causes, some snake venoms, and various other drugs/exogenous agents.
- Vascular hemostatic defects—generally caused by increased capillary permeability, e.g., RMSF or FIP-associated vasculitis, or altered dermal vascular support, e.g., hyperadrenocorticism or Ehlers-Danlos syndrome.

SYSTEMS AFFECTED

- Gastrointestinal—melena/hematochezia/hematemesis
- Hemic/Lymphatic/Immune—ITP may be associated with IMHA; concurrent gastrointestinal bleeding can cause significant anemia.
- Neurologic—variable depending on location of bleeding.
- Ophthalmic—scleral/retinal hemorrhage, secondary glaucoma, and uveitis.
- Renal/Urologic—hematuria.
- Respiratory—epistaxis/hemoptysis.
- Skin/Exocrine—petechia/ecchymosis/bruising.

SIGNALMENT

- Doberman pinschers and Scottish terriers are overrepresented for von Willebrand deficiency. Many other breeds have vWD. Note bruising and mucosal hemorrhage is common and petechiation is rare in association with vWD.
- See specific thrombopathias for breed-associated disorders.
- Note: an inherited macrothrombocytopenia (giant platelets) is seen in Cavalier King Charles spaniels and several other breeds; it does not cause bruising. Greyhounds have a lower than normal platelet count causing a mild thrombocytopenia.
- ITP shows a possible genetic predisposition because of the high prevalence in cocker spaniels, toy poodles, and Old English sheepdogs. Middle-aged female dogs also are at increased risk.
- Cats—Primary ITP is rare.

CAUSES

Thrombocytopenia

- Immune mediated—idiopathic, drug induced (e.g., antibiotics), paraneoplastic, and infection induced (e.g., viral, rickettsial, bacterial, protozoal, or fungal).
- Infectious—e.g., *Ehrlichia* spp. (*E. canis*, *E. ewingii*), *Anaplasma platys*, RMSF, babesiosis, leptospirosis, leishmania, *Borrelia*, *Dirofilaria* spp., *Bartonella vinsonii*, *Mycoplasma* spp., *Histoplasma*, *Candida*, FIP, FeLV, Cytauxzoonosis, parvovirus, herpesvirus, or septicemia.
- Bone marrow suppression—e.g., hyperestrogenism or chemotherapy.
- Drug related—procainamide, sulfonamide, azathioprine, methimazole, albendazole, griseofulvin, and chloramphenicol.
- Bone marrow infiltration—myeloproliferative or lymphoproliferative diseases.
- Sequestration in liver and/or spleen secondary to vascular neoplasia, or torsions.
- Consumption—e.g., DIC or recent extensive mucosal and serosal hemorrhage e.g., rodenticide poisoning or splenic tumor rupture.

Thrombocytopathy

- Congenital or acquired disorders affecting platelet adhesion, aggregation; see "Pathophysiology."

Vascular Disease

- Vasculitis secondary to inflammation, neoplasia, drug reactions, infection (e.g., RMSF or FIP); immune-mediated; see specific disease(s).

Coagulation Factor Deficiency

Clinical signs are not usually associated with petechia or ecchymosis but epistaxis is noted. Most commonly hemorrhage occurs within body cavities as well as hemarthrosis and hematomas.

RISK FACTORS

- The occurrence of any of the aforementioned diseases or breed predispositions. Severe vWD is seen in German shorthaired pointers, Shetland

sheepdogs, Scottish terriers, and Chesapeake Bay retrievers.

- History of NSAID use.
- Recent vaccination has not been proven but remains a concern for ITP.
- Geography/travel history, e.g., arthropod-borne diseases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Petechia are generally not mistaken for anything else. Some inflammatory skin lesions may look like petechia. Diascopy can be used to help distinguish between the two. Vasculitis lesions may have associated edema. Unwitnessed trauma may cause ecchymoses/bruising.

CBC/BIOCHEMISTRY/URINALYSIS

- Platelets are low, either by direct count or by estimation on a well-made blood smear. One platelet per high power field (hpf) represents approximately $15 \times 10^9/L$. An average of 10–30 platelets per hpf corresponds to a normal platelet count. If the platelet count is greater than $100 \times 10^9/L$, consider other causes of primary hemostasis abnormalities.
- RBC fragmentation is associated with DIC or microangiopathies.
- Ehrlichia* morulae or other hemoparasites may be seen on a peripheral blood smear.
- Patients with myeloproliferative or lymphoproliferative disease, myelofibrosis, or a history of chemotherapy or administration of drugs such as estrogens may be concurrently leukemic or have other cytopenias.
- Biochemical analysis—identify renal or liver disease as well as hyperglobulinemia.
- Urinalysis—identify hematuria. Proteinuria—may suggest concurrent immune-mediated disease, such as glomerulonephritis, and increase the suspicion of systemic lupus erythematosus.

OTHER LABORATORY TESTS

- Coagulation studies (APTT, PT, FDP, D-dimer, antithrombin III concentration) help diagnose DIC. Platelet counts less than $10 \times 10^9/L$ will interfere with ACT assay.
- Von Willebrand factor antigen assay—necessary to confirm vWD.
- Platelet function tests—may be necessary to rule out platelet function disorders, e.g., BMBT, thromboelastography, platelet aggregometry, flow cytometry, and DNA testing at Auburn University.
- Antiplatelet antibody tests will not distinguish primary from secondary ITP.
- Serum and urine protein electrophoresis (looking for Bence-Jones proteins)—indicated if hyperglobulinemia noted.
- Protein: creatinine ratio—if proteinuria noted on urine analysis. An elevated ratio > 1 may be suggestive of concurrent glomerulonephritis.
- FeLV/FIV testing—underlying cause of thrombocytopenia.
- Antinuclear antibody titer—helps to diagnose systemic lupus erythematosus if there is evidence of other

PETECHIA, ECCHYMOSIS, BRUISING

(CONTINUED)

immune-mediated disease. • Adrenal function testing may be indicated if hyperadrenocorticism is suspected.

- Serology—aid to diagnose ehrlichiosis, *Anaplasma platys*, *Bartonella vinsonii*, or RMSF. • PCR—for underlying infections such as *Ehrlichia* spp., *Anaplasma platys* or *Babesia* spp., *Mycoplasma* spp.

IMAGING

• Three-view thoracic radiography—look for evidence of metastasis or primary neoplasia/effusion. Identify enlarged lymph nodes or signs suggestive of underlying infectious disease. • Abdominal radiography to assess spleen and liver size/abdominal detail. Identify enlarged sublumbar lymph nodes or an abdominal mass consistent with hemangiosarcoma. • Abdominal ultrasonography to note architectural abnormalities in various organs that suggest underlying neoplasia, infection, or inflammation and to evaluate organ blood flow. Evaluate mesenteric lymph nodes for signs of neoplasia, infection, or inflammation.

DIAGNOSTIC PROCEDURES

• BMBT is indicated if the platelets are above $100 \times 10^9/L$; prolonged BMBT suggests a thrombopathia. Thrombocytopenic patients also have a prolonged BMBT. Normal range is < 4 minutes in dogs and < 2 minutes in cats. • Most invasive procedures are contraindicated in patients with bleeding disorders, except bone marrow aspiration and core biopsy. These procedures are indicated if there are cytopenias, hypergammaglobulinemia, or evidence of leukemia. • Invasive diagnostic procedures may be performed with less risk if platelet concentrate can be administered during the procedure to decrease the risk of hemorrhage.

TREATMENT

• Usually as an inpatient until a definitive diagnosis has been made. • Minimize activity to reduce the risk of even minor trauma. • Discontinue any medications that may alter platelet function, e.g., aspirin and other NSAIDs. • Discontinue medication that is associated with immune-mediated thrombocytopenia, such as methimazole in cats or trimethoprim sulfa in dogs. • Maintain fluid volume with a balanced electrolyte solution. • Avoid subcutaneous and intramuscular injections as well as venipuncture from the jugular vein. • Fresh whole blood or platelet transfusions may be necessary and life saving before a definitive diagnosis is made. Ensure blood samples are collected prior to transfusion for diagnostic

testing such as coagulation tests, serology, or PCR. • No specific treatment is available for congenital thrombopathias, other than DDAVP, which can be used for Type I vWD to help control bleeding and possibly other thrombopathias. It can also be given to blood donors prior to blood collection if the recipient needs surgery. See von Willebrand Disease for additional details. Acquired thrombopathias need to have the underlying disease corrected. The underlying disease needs to be treated when treating vasculitis/vasculopathies. See specific chapters.

MEDICATIONS

DRUG(S)

- Depends on the underlying diagnosis.
- Prednisone ± vincristine for immune-mediated thrombocytopenia.
- Doxycycline ± enrofloxacin/pradofloxacin (cats) for infectious causes or until infectious causes have been ruled out.
- Desmopressin acetate (DDAVP) for mild platelet function defects, e.g., Type 1 VWD.

CONTRAINDICATIONS

Avoid subcutaneous and intramuscular injectable medications whenever possible.

PRECAUTIONS

Avoid NSAIDs and other drugs that inhibit hemostasis, other than heparin in DIC.

FOLLOW-UP

Daily platelet count for patients with thrombocytopenia until an adequate response is seen. See specific diseases for details.

POSSIBLE COMPLICATIONS

- Death or morbidity caused by hemorrhage into brain, gut, lung, or other organs. • Shock caused by hemorrhagic hypovolemia.
- Blindness secondary to hyphema, retinal detachment, and/or glaucoma.

PETROLEUM HYDROCARBON TOXICOSES

BASICS

DEFINITION

• Petroleum hydrocarbons are a diverse group of products derived or synthesized from crude oil. • Certain non-petroleum-origin hydrocarbons, such as turpentine and linseed oil, are toxicologically similar enough to be considered with petroleum-origin products of similar molecular weight. Halogenated hydrocarbons, such as carbon tetrachloride or methylene chloride, are sufficiently unique to warrant separate consideration. • Small animal poisoning most commonly results from exposure to refined commercial products including such disparate mixtures as fuels, solvents, lubricants, and waxes. • Petroleum-based solvents are often used as “inert” carriers for other potential toxicants (e.g., pesticides, paints, medications). • Most petroleum hydrocarbons can be “lumped” into a relatively few broad categories on the basis of volatility, viscosity, and surface tension. Mixtures with high boiling points (low volatility), such as asphalt, mineral oil, and waxes, are relatively non-toxic. Products with relatively low boiling points and low viscosities, such as benzene or turpentine, are more readily aspirated, penetrate further into airways, and are more likely to cause chemical pneumonitis. In general, products that are more volatile also tend to be more lipophilic and more readily absorbed, systemically. Products with high aromatic content are also predisposed to cause systemic toxicity.

PATHOPHYSIOLOGY

• In general, the most acutely life-threatening effects of hydrocarbon ingestion result from aspiration-induced pneumonitis. • Viscosity and surface tension are reliable determinants of pneumotoxic potential. Low viscosity permits hydrocarbons to penetrate further into smaller airways. Low surface tension increases their tendency to “wet” pulmonary surfaces. For example, aspiration of as little as 0.1 mL of a low-viscosity hydrocarbon (e.g., hexane) may produce severe pneumonitis, whereas a high-viscosity product (e.g., motor oil) would not penetrate past the major airways. • Inhalation of hydrocarbon vapors (as opposed to aspirating liquid) may compromise pulmonary immune function and displace oxygen. • Topical exposure to hydrocarbon-based solvents (e.g., petroleum distillates, turpentine) may result in irritation and necrosis of skin and cornea. • Systemic toxicity is possible after oral or topical exposure. Although there are no quantitative data readily applicable to small animals, systemic toxicity should be considered when evaluating pets that have received a heavy topical exposure, or if the hydrocarbon is aromatic (e.g. benzene) or of a low molecular weight (e.g. hexane). Topical exposure is

especially important in very small animals (e.g., puppies, kittens, rodents), which have a relatively high body surface area to mass ratio. Systemic uptake and thus toxicity are also enhanced by factors such as a long hair coat, which traps the product against the skin.

SYSTEMS AFFECTED

- Cardiac
- Gastrointestinal
- Nervous
- Respiratory
- Skin
- Hematopoietic

INCIDENCE/PREVALENCE

In the author's experience, the incidence of small animal poisonings has decreased in recent years

SIGNALMENT

Species

Dogs and cats

SIGNS

General Comments

• Pneumonitis is the most serious complication associated with ingesting the more volatile (e.g., gasoline) hydrocarbons. Respiratory signs usually occur within a few minutes to 1–2 hours post-ingestion. The central nervous and gastrointestinal systems may also be affected, but death usually results from respiratory failure. • If aspiration occurs simultaneously with ingestion, there will be choking, coughing, gagging, and varying degrees of dyspnea. Direct damage of airway components and bronchospasm may result in hypoxia. Cyanosis may also develop immediately as alveolar oxygen is displaced by hydrocarbon vapor. • There is some evidence that *some* hydrocarbons sensitize the myocardium to both endogenous and exogenous catecholamines, precipitating arrhythmias; hemolytic anemia has been occasionally reported in children.

Historical Findings

• A history of (possible) exposure is essential to the diagnosis of hydrocarbon intoxication. Signs of hydrocarbon poisoning are seldom sufficiently characteristic to permit diagnosis. • Respiratory involvement, when present, is usually progressive over the first 24–48 hours, then gradually resolves 3–10 days following exposure. Animals that remain completely asymptomatic for 6–12 hours after ingestion are unlikely to develop respiratory illness.

Physical Examination Findings

• Astute observers may note a characteristic hydrocarbon odor on the animal's breath or coat. • Animals appear to experience a burning sensation in the mouth and pharynx after ingesting hydrocarbons, evidenced by slobbering, champing the jaws, shaking the head, and pawing at the muzzle. • Fever usually occurs in 3–4 hours following aspiration, but may occur in less than an hour or as much as 24 hours. • Vomiting, colic, and diarrhea after oral exposure. The severity and presence of such signs are a function of the dose and the individual hydrocarbon. Heavy aliphatic hydrocarbons (e.g., mineral

oil) may produce mild diarrhea but little else. Lighter hydrocarbons (e.g., gasoline) are more likely to produce colic and vomiting.

• Intoxicated animals may exhibit vertigo, ataxia, and mental confusion. Hydrocarbons produce depression and narcosis in most cases, but tremors and convulsions have also been reported in a few. If the dose is very high, the animal may become comatose and die prior to exhibiting signs of pneumonitis, although this is very rare. • Arrhythmias and syncope may occur as a result of myocardial sensitization to endogenous catecholamines. Myocardial sensitization may persist for as much as 24–48 hours after apparent recovery from the neurologic effects of intoxication.

CAUSES

- Storage in inappropriate containers and failure to clean up spills are common causes of exposure in pets. • Folk remedies using gasoline, kerosene, and other solvents as tonics or vermicifuges have poisoned pets.
- Using gasoline or other solvents in an attempt to remove sticky material from an animal's coat may also result in poisoning. Cats may ingest significant amounts of gasoline or other hydrocarbons by grooming themselves after topical contamination.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Infectious diseases, toxins, and/or injuries may result in respiratory signs similar to hydrocarbon aspiration, but only very acute processes (e.g., trauma, chylothorax) exhibit a similar rapidity of onset. • The diverse spectrum of neurologic effects may be confused with those of acute ethylene glycol, ethanol, or drug intoxication.

CBC/BIOCHEMISTRY/URINALYSIS

• Urine and serum will be negative for ethylene glycol; serum osmolality will be normal. • CBC may indicate stress, but this usually does not occur early in the course.

OTHER LABORATORY TESTS

- A simple spot test involves mixing vomitus or gastric contents vigorously with warm water. If gasoline or other petroleum distillates are present, they will float to the surface. Care must be taken to distinguish between petroleum products and dietary lipids. The former usually have a characteristic odor. • Most petroleum products lighter than kerosene, if isolated and absorbed onto a paper towel, evaporate relatively quickly with little residue and have a characteristic odor.
- Chemical analysis of ingestants or post-mortem tissues is useful forensically but is not practical for clinical evaluation. If chemical analysis is conducted, samples must be taken quickly and frozen in airtight containers to prevent loss due to volatilization.

PETROLEUM HYDROCARBON TOXICOSES

(CONTINUED)

IMAGING

Radiographic findings are typical of aspiration pneumonia and consist of fine, perihilar densities and extensive infiltrates in ventral portions of the lungs. These are worst at 3–4 days, then gradually improve. Not all animals with radiographic signs of hydrocarbon aspiration develop respiratory signs, and radiographic changes usually persist past the resolution of clinical signs.

PATHOLOGIC FINDINGS

- If aspiration has occurred, the principal lesions will be in the respiratory tract. Pulmonary lesions are bilateral and typically involve caudoventral portions of the lung. The earliest lesions include hyperemia, edema, and hemorrhage into the airways. Foreign matter may be grossly visible in the smaller airways. Later, there is bronchospasm, emphysema, and atelectasis. Pneumatoceles, pneumothorax, and subcutaneous emphysema result from airway collapse. There may be ulcerations in the mucosa of the trachea and larger airways.
- Bacterial pneumonia occasionally supervenes and may result in abscesses.
- Systemic toxicity very occasionally results in hepatic, myocardial, and/or renal tubular necrosis if the animal survives > 24 hours.

TREATMENT

APPROPRIATE HEALTH CARE

P In all cases of uncomplicated (i.e., not contaminated with some other, more toxic substance) petroleum hydrocarbon ingestion, the primary goal is to minimize the risk of aspiration. • If the amount ingested was small and the hydrocarbon ingested was one of the less volatile, more viscous products (e.g., motor oil, grease), cage rest and observation may be all that is required. • If the volume ingested was substantial and the product involved known to cause systemic toxicity (e.g., gasoline), activated charcoal is indicated within the first 4–6 hours post-exposure. Retrospective studies indicate that lavage is not beneficial after 60 min post-ingestion. • If the product contains other, highly toxic substances (e.g., pesticide), gastric decontamination may be indicated, despite

the risk of aspiration. It is essential that precautions (e.g., tracheal intubation) be taken to prevent possible aspiration of stomach contents. Emetics are contraindicated unless a last resort.

- Respiratory effects should be treated symptomatically. Supplemental oxygen and mechanical ventilation should be used as needed. Pneumomediastinum, pneumatoceles, and pneumothorax are common complications so positive pressure systems must be used with caution. High frequency jet ventilation reportedly results in fewer adverse sequelae than conventional mechanical ventilation. Since the lungs are the major route of systemic elimination for volatile hydrocarbons, closed or semiclosed systems should be purged frequently.
- Topical exposure may be treated by gently bathing with warm water and a mild detergent shampoo. If the hair coat is heavy or matted, it may be necessary to clip the contaminated areas.
- Symptomatic treatment of petroleum burns may involve topical antibacterials or other agents.
- Very viscous hydrocarbons (e.g., tar, waxes) may also be removed with mild detergents. They are not readily absorbed, pose only a cosmetic and skin irritation problem, and removal is not critical. Lipophilic materials (e.g., butter, lard, mechanic's hand cleaner) may also be useful, but the use of solvents is not recommended.

NURSING CARE

Cage rest is indicated, both for promotion of healing and to minimize the effects of excitement-induced catecholamines on a potentially sensitized myocardium.

CLIENT EDUCATION

Pet owners should be educated about proper storage and use of petroleum products.

MEDICATIONS

DRUG(S)

• Historically, oral mineral or vegetable oil was recommended to increase the viscosity of petroleum hydrocarbons and decrease the risk of aspiration. Retrospective studies suggest that such treatment increases the likelihood of aspiration pneumonia, and the use of such oils is no longer recommended.

- The routine use of antibiotics is of questionable value. Hydrocarbon pneumonitis is largely non-bacterial in origin; however, given the potentially severe consequences of bacterial complications and the relatively small downside to antibiotic use, it may be prudent to use antimicrobial prophylaxis if vomiting has occurred.

- Corticosteroids have been associated with increased numbers of positive lung cultures and are contraindicated.
- Bronchospasm may be treated with a beta adrenergic agonist such as albuterol.

PRECAUTIONS

Emesis should only be used when there is a high degree of certainty that leaving the foreign material in the gut poses a greater hazard than aspiration.

FOLLOW-UP

PATIENT MONITORING

Monitor patients for 3–4 days to ensure that ingested hydrocarbons have cleared the gastrointestinal tract and no pulmonary sequelae will occur.

EXPECTED COURSE AND PROGNOSIS

The diversity of this class of products precludes absolute prediction, but most hydrocarbon exposures respond well to conservative, supportive therapy.

PHEOCHROMOCYTOMA

BASICS

DEFINITION

APUDomas are tumors of the cells known as amine precursor uptake and decarboxylation (APUD) cells. APUDomas are peptide-secreting cells that synthesize and metabolize biogenic amines; they are located throughout the body (thyroid, adrenal medulla) and the gastrointestinal tract. Pheochromocytomas consist of chromaffin cells that originate from neural crest cells within the adrenal medulla or sympathetic ganglia (paragangliomas).

PATHOPHYSIOLOGY

Clinical signs develop as a result of the space-occupying nature of the tumor and its metastases or from excessive secretion of catecholamines (e.g., hypertension, tachycardia). Signs of hypertension and tachycardia may be constant or paroxysmal.

SYSTEMS AFFECTED

- Cardiovascular
- Neurologic
- Renal
- Respiratory

INCIDENCE/PREVALENCE

Uncommon disease in dogs; rare in cats

SIGNALMENT

Species

Dog and rarely cat

Breed Predilections

Boxer, miniature poodle, and German shepherd dog

Mean Age and Range

- Median age in dogs is 11 years; range is 1–16 years
- Older cats

SIGNS

General Comments

- The predominant signs result from alpha-mediated vasoconstriction and beta-mediated cardiac effects that cause systemic hypertension or tachyarrhythmias.
- Signs of hypertension may be constant or paroxysmal. Signs may be present for more than a year or develop suddenly resulting in death.
- Thirty percent of cases are asymptomatic and only identified at necropsy.

Historical Findings

- Clinical signs are often episodic or acute
- Generalized weakness and lethargy are common
- Anorexia
- Vomiting
- Weight loss
- Panting, dyspnea
- Diarrhea
- Whining, pacing
- Ascites, edema

- PU/PD
- Shakes/shivers
- Epistaxis
- Adypsia

Physical Examination Findings

- May be normal
- Lethargy, depression
- Tachypnea, dyspnea
- Thin, emaciated
- Weakness
- Peripheral edema
- Ascites
- Cardiac arrhythmias
- Systolic murmur
- Rales
- Pale or hyperemic mucous membranes
- Abdominal mass
- Dehydration
- Blindness
- Abdominal pain

CAUSES

Chromaffin cell tumor

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hyperadrenocorticism
- Hyperaldosteronism
- Essential hypertension (cats)
- Renal disease with secondary hypertension

CBC/BIOCHEMISTRY/URINALYSIS

- Nonregenerative anemia
- Hemoconcentration
- Leukocytosis
- Mild hyperglycemia
- Mild uremia
- Increased liver enzymes
- Hypoalbuminemia
- Hypocalcemia
- Proteinuria

OTHER LABORATORY TESTS

Arterial Blood Pressure

Systolic > 180 or diastolic > 95 mmHg is diagnostic for hypertension. Only 50% of animals with pheochromocytoma are hypertensive when blood pressure is measured because of the episodic nature of secretion of some tumors.

Electrocardiography

Sinus tachycardia is the most common arrhythmia; ventricular premature contractions less common.

IMAGING

Abdominal Radiography

- Abdominal mass (30%)
- Calcification of the adrenal mass (10%)
- Hepatomegaly
- Renal displacement
- Abnormal renal contour
- Ascites
- Enlargement of the caudal venal cava

Thoracic Radiography

- Generalized cardiomegaly
- Pulmonary congestion or edema

Abdominal Ultrasonography

- Unilateral adrenal mass
- Tumor invasion of the caudal vena cava and other adjacent structures
- Intra-abdominal and liver metastasis

Other Imaging Modalities

- CT scan and MRI
- Scintigraphy using ^{123}I -metaiodobenzylguanidine scan

DIAGNOSTIC PROCEDURES

- Plasma catecholamines:
 - > 2,000 pg/mL supports diagnosis of pheochromocytoma.
- Urinary catecholamine and catecholamine metabolites:
 - Total excretion over 24 hours is required or catecholamine/metanephrine to creatinine ratio.
 - No vanilla ingestion, drugs, or radiographic contrast agents prior to obtaining the urine sample.
 - 10–15% false positives.
 - Urine must be acidified ($\text{pH} < 3$).
 - Low sensitivity (0.42) compared with plasma catecholamines (0.97).
 - Metanephrine/normetanephrine—normal < 1.3 $\mu\text{g}/\text{day}$.
 - Catecholamine/metanephrine to creatinine ratio: normal = 53–323.
 - Total urinary catecholamines—normal < 250 $\mu\text{g}/\text{day}$.
- Phentolamine test:
 - Used in hypertensive patients to evaluate the dependence of catecholamines on maintaining hypertension.
 - After a stable arterial blood pressure is obtained, an IV bolus of phentolamine (0.5–1.5 mg) is given.
 - Blood pressure is recorded every 30 seconds for the first 3 minutes and every minute thereafter for an additional 7 minutes.
 - Test is positive if the fall in blood pressure is > 35 mmHg systolic or 25 mmHg diastolic and the decline lasts at least 5 minutes.
 - High incidence of false-positives and hypotension.
- Provocative tests:
 - Histamine, tyramine, glucagon may cause hypertensive crisis.

P

PATHOLOGIC FINDINGS

Immunohistochemical staining of tumor tissues with chromogranin A or synaptophysin allows differentiation of pheochromocytomas from other tumor types.

PHEOCHROMOCYTOMA

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

- Surgical removal of the tumor is the treatment of choice.
- Medical therapy is most commonly used to stabilize patients prior to surgery.

CLIENT EDUCATION

Survival times may be as long as 3 years following successful resection of tumor. In cats, removal of tumor is often curative; these are often benign as opposed to the malignant tumors seen in dogs.

SURGICAL CONSIDERATIONS

Preoperative Care

- Phenoxybenzamine (0.2–1.5 mg/kg PO q12h) 1–2 weeks prior to surgery.
- Atenolol, a β -1 selective antagonist (0.2–1 mg/kg PO q12–24h), can be used to control clinically significant supraventricular tachycardia.

Complications and Patient Monitoring

Common complications—hypertension, severe tachycardia, other cardiac arrhythmias, and hypovolemia/hypotension.

Anesthesia

- Induce anesthesia with a narcotic agent or propofol.
- Maintain anesthesia with isoflurane.

Surgery

Unilateral adrenalectomy and often thrombectomy. Manipulation of the tumor may cause severe hypertension if patient is not properly premedicated.

- Cardiac arrhythmias and severe tachycardia—common problems; usually respond to β -blocking agents such as esmolol (0.5 mg/kg slow IV bolus followed by 0.05–0.2 mg/kg/minute IV infusion).

CONTRAINdications

- Anesthetic agents—morphine, meperidine, xylazine, and ketamine.
- Severe hypertension can develop if a nonselective β -blocker (e.g., propranolol) is used without prior alpha-adrenergic blockade (e.g., phentolamine, phenoxybenzamine).

PRECAUTIONS

Nonselective beta blockade can lead to fatal hypertension.

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

Blood pressure, central venous pressure, and ECG are closely monitored in the immediate postoperative period (24–72 hours).

POSSIBLE COMPLICATIONS

Postoperative— intra-abdominal hemorrhage, hypotension, peritonitis, sepsis.

EXPECTED COURSE AND PROGNOSIS

Prognosis is guarded to fair.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Multiple endocrine neoplasia types II and III

PREGNANCY/FERTILITY/BREEDING

N/A

Consulting Editor Deborah S. Greco

MEDICATIONS

DRUG(S) OF CHOICE

- Pre- and intraoperative hypertension can be treated with phentolamine (0.02–0.1 mg/kg IV to effect).

BASICS

DEFINITION

- An inflammatory process involving the tunica intima of the vascular endothelial wall, usually associated with and considered a complication of peripheral IV therapy.
- Thrombophlebitis implies formation of fibrin clot, can involve superficial vasculature or deep tissues.

PATHOPHYSIOLOGY

- Sensitization of vascular endothelium causes release of vasoactive substances that cause vasoconstriction, increase vascular permeability, activate coagulation systems, and promote leukocyte chemotaxis.
- Extravasation of proteins and plasma leads to swelling and edema. • Thrombotic formation obstructs blood flow and may cause palpable thickening or vascular cord, which may progress to irreversible vascular sclerosis.
- Leukocyte pyrogens may cause systemic inflammation and fever. Exudates may be present at venipuncture site, especially with bacterial colonization.

SYSTEMS AFFECTED

- Skin—local inflammation/infection.
- Cardiovascular—altered vascular permeability and blood flow. • Hemic/Lymphatic/Immune—bacteria, inflammatory mediators and emboli can cause systemic inflammatory response and organ dysfunction.
- Respiratory—deep venous thrombophlebitis may cause pulmonary embolism.

INCIDENCE/PREVALENCE

- 20–80% of hospitalized patients receiving peripheral IV therapy. • Superficial thrombophlebitis most common, 10–12% may progress to deep venous thrombosis.

SIGNALMENT

- Dog and cat. • No known specific age, breed, or gender predisposition in veterinary medicine. • Neonatal and geriatric patients may be predisposed due to poor immune function.

SIGNS

- At least two of the following indicators of local inflammation—erythema, pain, heat, swelling, and vessel hardness. • Drainage or exudates may be present with concurrent lymphedema, infection or abscess. • Fever may be present with associated systemic inflammation or infection.

CAUSES

- Mechanical injury—IV catheter size/stiffness/integrity/duration, traumatic placement, previous venipuncture, high fluid infusion rates. • Chemical injury—IV catheter material, drugs, fluids of extreme osmolality or pH, parenteral nutrition, other vesicant solutions. • Bacterial

colonization—improper aseptic technique during placement, poor catheter care after placement, sepsis or immunosuppression. Common sources of bacteria are break points in the infusion system, skin microbes, and circulating organisms. • Obstructed blood flow—large-bore catheter, vasoconstriction, hypotension, thrombus formation.

RISK FACTORS

- Duration of catheterization—higher incidence with catheters in place for longer than 72 hours.
- Types of infusate—caustic, hyperosmolar, immunogenic and/or large-volume bolus.
- Virchow's triad—hypercoagulable state, blood flow abnormalities, and vessel wall damage predispose to thrombosis.
- Patient characteristics—obesity, immobility, poor vein quality, immunodeficiency, thrombophilia, polycythemia or hemoconcentration, chronic cardiac or renal disease, pregnancy.
- Disease characteristics—malignancy, infection, trauma, respiratory or circulatory failure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cutaneous hypersensitivity, vasculitis, or other immune-mediated reaction.
- Subcutaneous tissue or interstitial infection or inflammation. • Previous unrelated injury or infection over vessel or IV catheter site.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC changes consistent with degree of systemic inflammatory response and platelet consumption.
- Biochemistry and urinalysis changes may be applicable with organ damage secondary to embolism (e.g., hepatic, renal, portal, caval, cerebral, cardiac, pulmonary).

OTHER LABORATORY TESTS

Coagulation—may see alterations in PT, PTT, D-dimer, antithrombin, Protein C, thromboelastography.

IMAGING

- Angiography/phlebography—gold standard for diagnosis of embolism, but invasive; requires contrast and may increase patient risk factors.
- CT or MRI—diagnosis of deep tissue embolism when suspected based on organ damage or dysfunction.
- B-mode ultrasonography, duplex ultrasonography or plethysmography—newer, less invasive methods of assessing venous patency, character, and blood flow, but limited availability.

DIAGNOSTIC PROCEDURES

- Doppler—inexpensive test of venous patency and blood flow.
- Culture intravenous cannula and site drainage (if present)—blood cultures may also be indicated with signs of systemic inflammation.

PATHOLOGIC FINDINGS

- Gross findings—vascular narrowing and thickening, focal or locally extensive with surrounding tissue swelling and discoloration. Thrombi may be present.
- Histopathology—swelling of endothelial cells, leukocytic infiltration of vascular wall with fibrin deposition and thrombus formation.

TREATMENT

APPROPRIATE HEALTH CARE

- Remove IV catheter(s) from affected sites as soon as possible. Initiate appropriate antibiotic, topical therapy, and wound care.
- Monitor for anaphylactic and other reactions when infusing blood products or any new medications. Pain during injection or at the insertion site is often first indicator of phlebitis, infiltration or extravasation.
- Avoid infusing hyperosmolar medications or solutions with pH less than 5 or greater than 9 through peripheral cannulas. With central venous access, always assess for blood return before starting the infusion.
- If caustic infiltration suspected, terminate infusion and leave cannula in place temporarily to aspirate any fluid remaining in the catheter and for instillation of specific antidote into affected tissue when applicable.
- Intermittent warm moist compress or hydrotherapy; some extravasated substances may require cold therapy.
- Photobiomodulation (low-level light therapy or LLLT) can be used directly over affected areas to reduce inflammation, activate stem cells, and promote blood flow and tissue repair.
- To avoid stagnant blood flow and thromboembolism, ensure adequate blood volume resuscitation and promote mobility; consider physical therapy and/or compression therapy.

NURSING CARE

- IV catheter placement—use strict aseptic technique and sterile dressing. With gauze dressing, check site every 48 hours to minimize manipulation during bandage change; transparent semi-permeable dressings are preferable to allow more frequent evaluation of catheter sites. Topical antimicrobial ointments or gels do not reduce the incidence of catheter-related infections, can promote development of antibiotic-resistant organisms, and are not recommended. Avoid lower extremities, joints and nerves when choosing catheter sites. Use smaller bore, longer catheters when possible; polyurethane is preferable to Teflon.
- IV catheter maintenance—IV cannulas should be checked for patency, line integrity and associated swelling every 1–2 hours with continuous infusions. Incidence increases significantly with peripheral catheters left in longer than 72 hours, but does not change from 72 to 96 hours. Change peripheral

PHLEBITIS

(CONTINUED)

catheters every 3–4 days, or within 24 hours if placed under emergency situation. Routine replacement of central venous catheters is not recommended.

ACTIVITY

- Moderate regular activity is recommended to reduce risk of thrombosis.
- Perform regular physical therapy, focused on the affected limb, especially in non-ambulatory patients.

DIET

- Nutritional support appropriate to treatment of underlying illness(es).
- Consider glycemic control if sepsis or risk of sepsis.

CLIENT EDUCATION

- Advise clients of IV catheter risks and complications, especially in patients with predisposing factors.
- Clients should be trained in and continue physical therapy and basic nursing care at home.

SURGICAL CONSIDERATIONS

- Infected catheter sites and/or extensive tissue damage may require surgical debridement and delayed closure.
- Surgical ligation or stripping of the corded vessels may be indicated to avoid deep vein thrombosis.

MEDICATIONS

DRUG(S) OF CHOICE

- Antibiotics (if infection suspected)—use empirical therapy, based on location (e.g., cephalaxin 20 mg/kg PO or IV q8h for skin) and potential contaminants if no culture and sensitivity available.
- NSAIDs—e.g., meloxicam 0.1–0.2 mg/kg PO or SC can significantly improve morbidity and patient comfort.
- Heparin—consider low molecular weight heparin therapy to prevent embolism. Use of heparin (100 U/mL) intravenous catheter flushes may reduce incidence and prolong IV catheter use.
- Topical therapy—heparinoid substances, such as polysulfate of mucopolysaccharide (e.g., Hirudoid) have anticoagulant action, inhibit thrombus formation, stimulate fibrinolysis and can activate local blood flow. Heparinoids may be more effective for treatment of pre-existing phlebitis than for prevention. Notoginseng cream, derived from the root of the ginseng plant, has been shown to be effective in reducing pain, erythema, edema and fibrous cord formation. Nitroglycerine patches, creams or gels (sprays not effective) promote local vasodilation within 10 minutes, last 3–6 hours and are effective for prevention as well as for treating first stages of phlebitis.
- Topical NSAIDs, such as piroxicam or

diclofenac gel, can help alleviate clinical signs and speed resolution.

CONTRAINDICATIONS

- Caustic, irritating, or immunogenic topicals or infusions.
- Use of NSAIDs with concurrent anti-inflammatory or immunosuppressive dose corticosteroid therapy.

PRECAUTIONS

- Avoid use of systemic NSAIDs if renal, hepatic or gastrointestinal dysfunction.
- Corticosteroids, unless used as an appropriate pre-treatment for chemotherapy, are associated with delayed wound healing and may predispose to infection.

POSSIBLE INTERACTIONS

- Systemic NSAIDs with significant inhibition of thromboxane (e.g., salicylate) used in combination with heparin may predispose to coagulopathy.
- Concurrent vasopressor therapy may predispose to thrombophlebitis; use of a topical vasodilator is recommended.

ALTERNATIVE DRUG(S)

- Topical dermatitis creams, such as silver-sulfadiazene may help reduce irritation and prevent infection.
- With excessive moisture or transdermal fluid leakage, keeping the skin dry using medicated powder (e.g., Gold Bond) may be helpful. Do not use on broken skin.

FOLLOW-UP

PATIENT MONITORING

- Persistent or progressive redness, swelling, pain, or heat—adjust antibiotic therapy based on most current culture and sensitivity results.
- Hardness, skin pallor, black discoloration, or eschar formation occur with tissue necrosis.

PREVENTION/AVOIDANCE

- Avoid use of phlebotic veins for IV therapy or blood collection until completely healed.
- Consider using submicron IV catheter filters, which may reduce incidence by removing particulates, endotoxin, and other soluble mediators of morbidity.

POSSIBLE COMPLICATIONS

- Tissue necrosis
- Neuritis or loss of function
- Lymphangitis
- Septicemia
- Extension to deep venous system

EXPECTED COURSE AND PROGNOSIS

- Most cases mild and self-limiting after 1–3 days with removal of catheter. Prognosis good but vascular patency commonly compromised.
- Severe local lesions can take 3–4 weeks to resolve and may result in loss of

function or permanent tissue damage.

- Prognosis guarded when associated with pulmonary thromboembolism and/or sepsis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Pulmonary thromboembolism
- Infection/cellulitis/sepsis

AGE-RELATED FACTORS

- Neonatal and geriatric patients may be predisposed to infection.
- Geriatric patients may have delayed wound healing.

PREGNANCY/FERTILITY/BREEDING

- Pregnancy may predispose to thromboembolism.
- Incidence of fetal complications with phlebitis is unknown.

PHOSPHOFRUCTOKINASE DEFICIENCY

BASICS

OVERVIEW

- Phosphofructokinase is the most important rate-controlling enzyme in glycolysis, and RBCs and intensely exercising skeletal muscles depend heavily on anaerobic glycolysis for energy. • Affected dogs have compensated hemolytic anemia and generally mild myopathy caused by markedly reduced total phosphofructokinase activity in both tissues. • Anemia develops because of insufficient generation of ATP to maintain normal RBC shape, ionic composition, and deformability and because RBCs from affected dogs are alkaline fragile and lyse when blood pH is slightly high.

SIGNALMENT

- English springer spaniel, American cocker spaniel, mixed breed, whippet, and wachtelhund dogs. • Transmitted as an autosomal recessive trait. • Affected homozygous animals generally not recognized as abnormal before 1 year of age.

SIGNS

- Some animals exhibit mild clinical signs that go unrecognized for years; others regularly exhibit episodes of severe illness. • Depression or weakness concomitant with episodes of red to brown pigmenturia; hemoglobinuria less likely to be recognized in female dogs, because of the sex difference in urination pattern.
- Mild lethargy with slight fever during mild hemolytic episodes. • Marked lethargy, weakness, pale or icteric mucous membranes, mild hepatosplenomegaly, muscle wasting, and fever as high as 41°C (106°F) possible during severe hemolytic crises. • Intravascular hemolysis can be caused by hyperventilation-induced alkalemia associated with exercise or excitement. • Signs of muscle dysfunction—usually limited to exercise intolerance and slightly diminished muscle mass, but muscle cramping and severe progressive myopathy can occur. • Two affected whippets had progressive cardiac disease in addition to muscle cramping after exercise.
- Heterozygous carrier animals appear clinically normal.

CAUSES & RISK FACTORS

Deficiency of the muscle-type subunit of phosphofructokinase—markedly reduced total activity in RBCs and skeletal muscle.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of hemolytic anemia—immune-mediated hemolytic anemia,

hemotropic mycoplasmosis, babesiosis, Heinz body hemolytic anemia, microangiopathic hemolytic anemia, and pyruvate kinase deficiency. • Affected dogs—negative Coombs' test, no parasites or Heinz bodies in stained blood films, seronegative for *Babesia* spp., and no evidence of DIC or heartworm disease. • Differentiated from pyruvate kinase deficiency by specific enzyme assays or DNA test.

CBC/BIOCHEMISTRY/URINALYSIS

- Persistent compensated hemolytic anemia.
- MCV usually 80–90 fL. • Reticulocyte counts generally 10–30%. • HCT values generally 30–40%; during hemolytic crises may decrease to ≤ 15%. • Bilirubinuria—often markedly high in male dogs.
- Hemoglobinuria in association with episodes of intravascular hemolysis.
- Serum—slightly high potassium, magnesium, calcium, urea, AST, total protein, and globulin; slightly to moderately high LDH, ALP, iron, and bilirubin; markedly high bilirubin in association with a hemolytic crisis; markedly high urea and creatinine if renal failure develops secondary to hemoglobin nephrosis or shock.

OTHER LABORATORY TESTS

- Measure RBC phosphofructokinase activity—easily identify affected animals older than 3 months; heterozygous carrier dogs have approximately one-half normal activity.
- Perform DNA test by PCR technology—clearly differentiate normal and carrier animals of any age. Wachtelhund dogs have a genetic mutation that is different from the defect in the other dog breeds.

TREATMENT

- Bone marrow transplantation is the only cure. • In patients with severe intravascular hemolysis, IV fluid therapy minimizes the chance of acute renal failure. • Blood transfusions usually not needed but should be given if anemia becomes life-threatening.

MEDICATIONS

DRUG(S)

For fever that often accompanies intravascular hemolysis and potentiates hemolytic crisis—aspirin (10 mg/kg PO q12h) or dipyrone (0.055 mL of 50% solution/kg SC q8h).

FOLLOW-UP

- Infrequently, affected dogs may die during a hemolytic crisis because of anemia or renal failure. • Affected animals can have a normal lifespan if properly managed. • Owners should avoid placing affected dogs in stressful situations or subjecting them to strenuous exercise, excitement, or high environmental temperatures.

MISCELLANEOUS

ABBREVIATIONS

- ALP = alkaline phosphatase • AST = aspartate aminotransferase • ATP = adenosine triphosphate • DIC = disseminated intravascular coagulation
- HCT = hematocrit • LDH = lactate dehydrogenase • MCV = mean cell volume
- PCR = polymerase chain reaction • RBC = red blood cell

Consulting Editor Alan H. Rebar

PHYSALOPTEROSIS

BASICS

OVERVIEW

- *Physaloptera* spp. occur in dogs and cats; adults attach to the stomach mucosa; there is no larval migration outside the gastrointestinal tract.
- Infection can be asymptomatic or cause gastritis, vomiting.
- Typically few worms are present; single worm or all-female infections are common.
- Transmitted by ingestion of infective larvae in intermediate hosts (e.g., coprophagous grubs, beetles, cockroaches, crickets) or in paratenic hosts (e.g., birds, rodents, frogs, snakes, lizards).

SIGNALMENT

Dogs and cats; any breed, age, or sex. Infected animals often undergo extensive work-ups for suspected inflammatory bowel disease/ulcers, only to discover the nematodes at the time of endoscopy.

SIGNS

- Vomiting, often chronic and intermittent; occasionally find worms in vomitus.
- Weight loss can occur, especially with chronic infection.
- Signs can occur without egg production during pre-patent period, single worm, or female-only infections.
- Possible melena.

CAUSES & RISK FACTORS

- Outdoor exposure; access to insect intermediate hosts or small vertebrate transport hosts.
- Access to habitat occupied by wildlife species (raccoon, fox, coyote, bobcat, cougar, badger, skunk) infected with *Physaloptera*.

P

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other infectious causes of vomiting including parasite, viral, or bacterial infections.

- *Spirocerca*, the esophageal worm, produces similar smaller eggs ($11\text{--}15 \times 30\text{--}37 \mu\text{m}$).
- *Ollulanus*, a trichostrongylid nematode, can cause chronic vomiting; seen mainly in colony and feral cats; larvae and adults (<1 mm long) but no eggs present in vomitus or feces.
- Roundworms (ascarids) in puppies and kittens; worms can be present in feces and vomitus; larger than *Physaloptera*; characterized by three lips and cervical alae.
- Other non-infectious causes of vomiting including dietary indiscretion, foreign objects in the stomach, noxious substances accidentally ingested, gastrointestinal neoplasia, metabolic diseases.

CBC/BIOCHEMISTRY/URINALYSIS

Mild anemia and eosinophilia can occur.

OTHER LABORATORY TESTS

N/A

IMAGING

Abdominal radiography, including contrast studies, to eliminate other causes of vomiting.

DIAGNOSTIC PROCEDURES

- Endoscopy (gastroscopy) to visualize and remove worms, usually attached to stomach or duodenal mucosa; careful, thorough exam necessary to detect all worms; typically few are present and they can be hidden by mucus, ingesta, stomach rugae; pinpoint hemorrhages from prior attachment sites can be seen.
- *Physaloptera* spp. are small (2.5–5 cm long), stout, white or pink, with an anterior cuticular collar; male and female *P. praeputialis* have a posterior prepuce-like cuticular sheath.
- Direct smear, wet mount, or fecal flotation to detect eggs in vomitus or feces; eggs are dense and can be difficult to detect by fecal flotation using low specific gravity solutions; use flotation solution with s.g. > 1.25 .
- Eggs are small ($42\text{--}58 \times 29\text{--}42 \mu\text{m}$), thick-shelled, larvated, ovoid to ellipsoidal, and colorless.

TREATMENT

- Outpatient treatment; anthelmintic with or without endoscopic removal of worms.

- Anthelmintic use is extra-label and anecdotal.

MEDICATIONS

DRUG(S)

- With no migration beyond the stomach wall, use adulticide anthelmintic released in stomach.
- Fenbendazole (dogs), 50 mg/kg PO q24h for 3–5 days; repeat if signs persist.
- Pyrantel pamoate (dogs/cats), 5 mg/kg twice at 3-week interval or 15–20 mg/kg once; repeat if signs persist.
- Ivermectin (cats), 0.2 mg/kg PO or SC once.
- Medication to reduce gastritis—histamine H₂-antagonists (e.g., famotidine 0.5 mg/kg PO q24h); sucralfate 0.25–1 g PO q8–12h in the dog; 0.25 g PO q8–12h in the cat.

FOLLOW-UP

PATIENT MONITORING

Recheck 1–2 weeks post-treatment and re-treat with anthelmintic if eggs still present on fecal exam and/or if vomiting persists.

PREVENTION/AVOIDANCE

- Prompt removal and disposal of feces to prevent infection of arthropod intermediate hosts.
- Keep pets from roaming freely outdoors; prevent hunting and scavenging.

EXPECTED COURSE AND PROGNOSIS

Clinical signs and/or shedding of eggs in feces should resolve within 2 weeks of treatment.

BASICS

OVERVIEW

- *Yersinia pestis*—Gram-negative, bipolar staining rod; reservoir: wild rodents (sylvatic), ground squirrels, prairie dogs, rabbits, bobcats, coyotes. • Occurs worldwide; movement of animals may result in occurrence in non-endemic areas.
- United States—reported cases from western states/Hawaii
- Common: May–October.
- Infected fleas transmit bacterium in bite but cats commonly infected by ingestion of infected rodents, not by bite of fleas.
- Bacteria migrate from skin lymphatics to regional LN; survive phagocytosis/multiply in LN; phagocytic cells rupture.
- Infection—fever and painful lymphadenopathy (bubo); intense local inflammation results in bubonic plague; intermittent bacteremia; LN rupture; may become septicemic with or without LN involvement.
- Cats—highly susceptible; severe fatal disease.
- Dogs—naturally resistant to infection.
- *Y. pestis* is potential bioterrorist agent (beware of clusters of pneumonia cases).

SIGNALMENT

Cat and rarely dog

SIGNS

- Dogs—may exhibit mild febrile signs/depression
- Cats—unique among carnivores in exhibiting bubonic/pneumonic/septicemic forms of plague.

Bubonic (Cats)

- Most common form
- Incubation period 2–7 days after flea bite or after eating infected rodent
- Duration of illness variable
- Bubo—head and neck; marked lymphadenopathy (hemorrhagic/necrotic/edematous); if patient survives long enough, LN abscess, rupture, drain through fistula tracts to skin
- Fever: 39.5–40.5°C (103–105°F)
- Depression
- Vomiting/diarrhea
- Dehydration
- Enlarged tonsils
- Anorexia
- Ocular discharge
- Weight loss
- Ataxia
- Coma
- Oral ulcers

Septicemic (Cats)

- Rare
- Septicemia without lymphadenopathy or abscess formation
- Other signs same as bubonic.

Pneumonic (Cats)

Severe disease; greatest risk for zoonotic spread to in-contact humans.

CAUSES & RISK FACTORS

- Hunter cats—greater exposure to wild rodents/fleas
- Travel to endemic areas
- Environment—homes/pets with heavy flea infestation; homes with large nearby rodent populations (e.g., garbage food source or wood pile)
- Plague becoming more common as homes encroach on wildlife habitats in plague-endemic areas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Acute disease state manifested by lymphadenopathy, malaise, oral ulceration, and fatal outcome in animals of endemic regions: Infection (feline calicivirus, feline coronavirus, feline immunodeficiency virus, feline leukemia virus, cryptococcosis, histoplasmosis, toxoplasmosis, tularemia, leishmaniasis); neoplasia (lymphoid/myelogenous leukemia; lymphoma in cats, multiple myeloma); drug eruption/skin hypersensitivity; epidermolysis bullosa; pemphigus; systemic lupus erythematosus; oropharyngeal foreign body/plant awn, trauma/injury, gingivitis, stomatitis; osteomyelitis, sequestrum, bone abscess.

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis: left shift/marked toxic changes
- Thrombocytopenia—with DIC
- High liver enzyme activity and hyperbilirubinemia

OTHER LABORATORY TESTS

- Serology—Communicable Disease Center/state health department
- Prolonged clotting times—with DIC.

DIAGNOSTIC PROCEDURES

- Culture by reference lab is definitive; samples from antemortem clinical material (abscess, LN, peripheral blood) **before treatment is given** or from post-mortem tissue (LN, abscess, liver, spleen); seeing large numbers of Gram-negative coccobacilli with bipolar staining on touch preps prior to culture, constitutes presumptive positive diagnosis
- Fluorescent antibody test—presumptive identify infected animals; samples same as for culture
- Molecular testing/PCR of blood/tissues

PATHOLOGIC FINDINGS

- Acutely ill cats—few lesions; enlarged LN (bubo) on head and neck; enlarged liver and spleen.
- LN—destruction of normal architecture; hemorrhagic necrosis; extracellular bacteria.

TREATMENT

- Inpatient
- High mortality if not treated early
- Treat aggressively with intravenous fluids to counteract septicemia
- Treat DIC, if indicated
- Treat patient for fleas.

MEDICATIONS

DRUG(S)

- Treat all suspect cases empirically until confirmed by lab
- Systemic antimicrobials—use in all patients except those with lung

involvement (such patients should be euthanized—high zoonotic potential)

- Tetracyclines—oxytetracyclines, tetracycline, chlortetracycline; 25 mg/kg PO q8h for 10 days; parenteral, 7.5 mg/kg q12h
- Doxycycline (5 mg/kg PO q12h)—effectiveness not established but probably effective
- Chloramphenicol 30–50 mg/kg PO q8h
- Gentamicin (2–3 mg/kg PO or SC q8h); trimethoprim-sulfamethoxazole, and kanamycin—use if the other listed drugs cannot be used
- Coordination with public health officials is necessary if threat of bioterrorism established (bioengineered strains of *Y. pestis* may be drug resistant).

FOLLOW-UP

PATIENT MONITORING

DIC—common later in infection, if disease not treated early.

PREVENTION/AVOIDANCE

- Limit travel with pet to avoid endemic areas
- Endemic areas—keep pet on a leash to control contact to wild rodents/fleas; spray/dust pet and home for flea control
- Neuter cats—limit hunting behavior/rodent exposure
- Eliminate rodents/habitats near houses/outbuildings (wood piles/garbage piles); store food in rodent-proof containers.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—poor if not treated early
- Pneumonic plague has greatest risk of death.

MISCELLANEOUS

ZOONOTIC POTENTIAL

High

CDC Recommendations

- Avoid contact with infectious materials from patient/fleas.
- Any material used in examination of patients—disinfect/autoclave/incinerate.
- Wear mask/gloves when handling patients.
- Use respirator/protective eye equipment during necropsies.
- Monitor staff health for 2 weeks after exposure; discuss post-exposure prophylaxis/fever watch with healthcare provider.

ABBREVIATIONS

- DIC = disseminated intravascular coagulation
- LN = lymph node

PLASMACYTOMA, MUCOCUTANEOUS

BASICS

OVERVIEW

- Tumor of plasma cell origin.
- Typically benign and local therapy can be curative.
- Rarely (< 1%) part of multiple myeloma process.
- Gastrointestinal extramedullary plasmacytoma (GI EMP) may be more aggressive.

SIGNALMENT

- Dog, rarely cat
- Cocker spaniel, West Highland white terrier, boxer, German shepherd, Airedale
- Median age 9–10 years

SIGNS

- 86% are cutaneous, 9% affect mucous membranes, 4% colorectal, 1% non-cutaneous/non-oral.
- Solitary, smooth, raised pink nodules, typically 1–2 cm in diameter.
- Bleeding, hematochezia, tenesmus, rectal prolapse if colorectal form.
- Vague, nonspecific signs if gastrointestinal EMP.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other round cell tumor types including lymphoma, mast cell tumor, histiocytoma, transmissible venereal tumor.
- Poorly differentiated carcinoma.
- Amelanotic melanoma.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal for EMP

OTHER LABORATORY TESTS

Bone marrow aspirate cytology and serum electrophoresis may be indicated for GI EMP.

IMAGING

- Colonoscopy recommended for colorectal EMP.

- Thoracic radiographs and abdominal ultrasound may be indicated for GI EMP.

DIAGNOSTIC PROCEDURES

- Cytologic examination of fine-needle aspirate reveals moderate to marked cellularity with round to polyhedral individual tumor cells with discrete margins, abundant royal blue cytoplasm, paranuclear clear zone, eccentric round nucleus, and clumped chromatin. Multinuclearity is common.
- Histologic evaluation identify—tumors to be densely cellular with single or multiple variably sized nuclei with many mitoses present, and amyloid deposition may be present. Histologically classified into mature, hyaline, cleaved, asynchronous, monomorphic blastic, and polymorphous blastic cell types. However, no prognostic significance has been associated with this classification.
- Immunohistochemistry may be necessary to distinguish from other neoplasms.

TREATMENT

- Conservative surgery for the majority of EMP types
- Radiation therapy if nonresectable

MEDICATIONS

DRUG(S)

Melphalan and prednisone may be indicated in GI EMP.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Reevaluation every 3 months to monitor for local tumor control and metastases.

EXPECTED COURSE AND PROGNOSIS

- Excellent in most patients.
- Long-term survival expected for GI EMP treated with surgery ± chemotherapy.
- Reported 15-month median survival time for colorectal form with surgery alone.
- 5% local recurrence rate with conservative surgery for the majority of EMP.
- Metastasis reported in 2% of patients with EMP.
- 2% of patients will develop *de novo* EMP.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Multiple myeloma
- Lymphoma—dogs
- Cats—may note systemic amyloidosis

SEE ALSO

PLEURAL EFFUSION

BASICS

DEFINITION

Abnormal accumulation of fluid within the pleural cavity

PATHOPHYSIOLOGY

- More than normal production or less than normal resorption of fluid.
- Alterations in hydrostatic and oncotic pressures or vascular permeability and lymphatic function may contribute to fluid accumulation.

SYSTEMS AFFECTED

- Cardiovascular
- Respiratory

SIGNALMENT

Species

Dog and cat

Breed Predilections

Varies with underlying cause

Mean Age and Range

Varies with underlying cause

Predominant Sex

Varies with underlying cause

SIGNS

General Comments

Depend on the fluid volume, rapidity of fluid accumulation, and the underlying cause.

Historical Findings

- Dyspnea
- Tachypnea
- Orthopnea
- Open-mouth breathing
- Cyanosis
- Exercise intolerance
- Lethargy
- Inappetence
- Cough

Physical Examination Findings

- Dyspnea—respirations often shallow and rapid
- Muffled or inaudible heart and lung sounds ventrally
- Preservation of breath sounds dorsally
- Dullness ventrally on thoracic percussion

CAUSES

High Hydrostatic Pressure

- CHF
- Overhydration.
- Intrathoracic neoplasia.

Low Oncotic Pressure

Hypoalbuminemia—occurs in protein-losing enteropathy, protein-losing nephropathy, and liver disease.

Vascular or Lymphatic Abnormality

- Infectious—bacterial, viral, or fungal.
- Neoplasia (e.g., mediastinal lymphoma, thymoma, mesothelioma, primary lung tumor, and metastatic disease).
- Chylothorax (e.g., from lymphangiectasia, CHF, cranial vena caval obstruction

[sometimes associated with transvenous pacemaker implantation], neoplasia, fungal infections, heartworms, diaphragmatic hernia, lung lobe torsion, trauma).

- Diaphragmatic hernia.
- Hemothorax (e.g., from trauma, neoplasia, coagulopathy, *Angiostrongylus vasorum*).
- Lung lobe torsion.
- Pulmonary thromboembolism.
- Pancreatitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Historical or physical evidence of external trauma—consider hemothorax or diaphragmatic hernia.
- Fever suggests an inflammatory, infectious, or neoplastic cause.
- Murmurs, gallops, or arrhythmias combined with jugular venous distension or pulsation suggest an underlying cardiac cause.
- Concurrent ascites suggests FIP, CHF (mainly dogs), severe hypoalbuminemia, diaphragmatic hernia, disseminated neoplasia, or pancreatitis.
- In cats, decreased compressibility of the cranial thorax suggests a cranial mediastinal mass.
- Concurrent ocular changes (e.g., chorioretinitis and uveitis) suggest FIP or fungal disease.

CBC/BIOCHEMISTRY/URINALYSIS

- Hemogram results may be abnormal in patients with pyothorax, FIP, neoplasia, or lung lobe torsion.
- Severe hypoalbuminemia (generally $< 1 \text{ g/dL}$ to cause effusion) suggests protein-losing enteropathy, protein-losing nephropathy, or liver disease.
- Hyperglobulinemia (polyclonal) suggests FIP.

OTHER LABORATORY TESTS

- Fluid analysis should include physical characteristics (i.e., color, clarity, odor, clots), pH, glucose, total protein, total nucleated cell count, and cytologic examination; Table 1 provides characteristics of various pleural fluid types and their disease associations.
- In cats the LDH concentration in transudates is $< 200 \text{ IU/L}$ and in exudates it is $> 200 \text{ IU/L}$.
- Pleural fluid pH < 6.9 suggests pyothorax in cats.
- Glucose concentration in pleural fluid usually parallels levels in serum. In cats, pyothorax and malignancy lower pleural fluid glucose concentration relative to serum glucose concentration; thus, pleural fluid with a normal pH and low glucose concentration suggests malignancy in cats.
- Serologic tests for feline leukemia virus (if patient has mediastinal lymphoma), feline immunodeficiency virus (if patient has

pyothorax), and coronavirus (if FIP is suspected) are available.

- Cardiac disease suspected—consider a heartworm test in dogs and cats and a thyroid evaluation in cats.
- Infection suspected—do aerobic and anaerobic bacterial culture and sensitivity tests and consider special stains (e.g., gram and acid-fast stains) of the fluid.
- FIP suspected—consider protein electrophoresis of the fluid; γ -globulin level $> 32\%$ of total protein strongly suggests a diagnosis of FIP.
- Chyle suspected—do an ether clearance test or Sudan stain of the pleural fluid, and triglyceride and cholesterol evaluations of the fluid and serum.

IMAGING

Radiographic Findings

- Used to confirm pleural effusion; should not be performed until after thoracocentesis in dyspneic patients with evidence of pleural effusion on physical examination.
- Evidence of pleural effusion includes separation of lung borders away from the thoracic wall and sternum by fluid density in the pleural space, fluid-filled interlobar fissure lines, loss or blurring of the cardiac and diaphragmatic borders, blunting of the lung margins at the costophrenic angles (ventrodorsal view), and widening of the mediastinum (ventrodorsal view).
- Rounding of the caudal lung lobe borders (lateral view)—most common in patients with fibrosing pleuritis caused by chylothorax, pyothorax, or FIP.
- Unilateral effusion—most common in patients with chylothorax and pyothorax; hemothorax, pulmonary neoplasia, diaphragmatic hernia, and lung lobe torsion.
- Evaluate post-thoracocentesis radiographs carefully for cardiomegaly, intrapulmonary lesions, mediastinal masses, diaphragmatic hernia, lung lobe torsion, and evidence of trauma (e.g., rib fractures).
- Can diagnose a diaphragmatic hernia with positive-contrast peritoneography.
- Can evaluate the thoracic duct by positive contrast lymphangiography.

Echocardiographic Findings

- Ultrasonographic evaluation of the thorax is recommended whenever cardiac disease, diaphragmatic hernia, or cranial mediastinal mass is suspected.
- Echocardiography is easiest to perform before thoracocentesis, provided the patient is stable.

DIAGNOSTIC PROCEDURES

- Thoracocentesis—allows characterization of the fluid type and determination of potential underlying cause.
- Exploratory thoracotomy or thoracoscopy—to obtain biopsy specimens of lung, lymph nodes, or pleura, if indicated.

PLEURAL EFFUSION

(CONTINUED)

Table 1

Characterization of pleural fluid.						
	<i>Transudate</i>	<i>Modified Transudate</i>	<i>Non-septic Exudate</i>	<i>Septic Exudate</i>	<i>Chyle</i>	<i>Hemorrhage</i>
Color	Colorless to pale yellow	Yellow or pink	Yellow or pink	Yellow to red-brown	Milky white	Red
Turbidity	Clear	Clear to cloudy	Clear to cloudy; fibrin	Cloudy to opaque; fibrin	Opaque	Opaque
Protein (g/dL)	< 1.5	2.5–5.0	3.0–8.0	3.0–7.0	2.5–6.0	3.0
Nucleated cells/ μ L	< 1,000	1,000–7,000 (LSA up to 100,000)	5,000–20,000 (LSA up to 100,000)	5,000–300,000	1,000–20,000	Similar to peripheral blood
Cytology	Mostly mesothelial cells and macrophages	Mostly macrophages and mesothelial cells; few nondegenerate PMNs; neoplastic cells in some cases	Mostly nondegenerate PMNs and macrophages; neoplastic cells in some cases	Mostly degenerate PMNs; also macrophages; bacteria	Small lymphocytes, PMNs, and macrophages	Mostly RBCs; with erytrophagocytosis
Disease associations	Hypoalbuminemia (protein-losing nephropathy, protein-losing enteropathy, or liver disease); early CHF	CHF; neoplasia; diaphragmatic hernia; pancreatitis	FIP; neoplasia; diaphragmatic hernia; lung lobe torsion	Pyothorax	Lymphangiectasia, CHF, cranial vena cava obstruction, neoplasia, fungal, dirofilariasis, diaphragmatic hernia, lung lobe torsion, trauma	Trauma, coagulopathy, neoplasia, lung lobe torsion

Modified from Sherding RG. Diseases of the pleural cavity. In: Sherding RG, ed. The Cat: Diseases and Clinical Management, 2nd ed. New York: Churchill Livingstone, 1994, p. 1061.

TREATMENT

- First, thoracocentesis to relieve respiratory distress; if the patient is stable after thoracocentesis, outpatient treatment may be possible for some diseases. Most patients are hospitalized because they require intensive management such as indwelling chest tubes (e.g., patients with pyothorax) or thoracic surgery.
- Preventing fluid reaccumulation requires treatment based on a definitive diagnosis.
- Surgery is indicated for management of some neoplasias, diaphragmatic hernia repair, lymphangiectasia (i.e., thoracic duct ligation), foreign body removal, and lung lobe torsion (i.e., lung lobectomy).
- Pleuroperitoneal shunts may relieve clinical signs in animals with intractable pleural effusion.
- Vascular access ports attached to intrathoracic Jackson-Pratt drains can be tried for chronic effusions that are not responsive to the therapy of the underlying disorder.

MEDICATIONS

DRUG(S) OF CHOICE

- Treatment varies with specific disease.
- Diuretics generally reserved for patients with diseases causing fluid retention and volume overload (e.g., CHF).

PRECAUTIONS

- Avoid drugs that depress respiration or decrease blood pressure.
- Inappropriate use of diuretics predisposes the patient to dehydration and electrolyte disturbances without eliminating the effusion.

FOLLOW-UP

PATIENT MONITORING

Radiographic evaluation is key to assessment of treatment in most patients.

POSSIBLE COMPLICATIONS

- Death due to respiratory compromise.
- Reexpansion pulmonary edema may develop after pleural effusion is manually removed.

EXPECTED COURSE AND PROGNOSIS

Vary with underlying cause, but usually guarded to poor. In a study of 81 cases of pleural effusion in dogs, 25% recovered completely and 33% died during or were euthanized immediately after completing diagnostic evaluation.

MISCELLANEOUS

SYNOMYS

Client Education Handout available online

PNEUMOCYSTOSIS

BASICS

OVERVIEW

- *Pneumocystis carinii (jirovecii)*—saprophyte of low virulence, infects virtually all mammals worldwide.
- Primary habitat is the lung
- Classified as an atypical fungal organism, based on analysis of nucleic acids
- Subclinical infections in cats and dogs. Clinical infections in dogs are linked with immunodeficiency. FIV and FeLV does not predispose cats.

SIGNALMENT

- Young dogs.
- Not reported in cats.
- Miniature dachshunds and Cavalier King Charles spaniels predisposed due to congenital immunodeficiency.

SIGNS

- Respiratory difficulty and weight loss progressing over weeks to months
- Dyspnea without fever
- Exercise intolerance
- Coughing
- Vomiting, and diarrhea
- Cachexia

CAUSES & RISK FACTORS

- *Pneumocystis carinii*. • Primary role of spread is by airborne droplet transmission between hosts. Neonates may be infected through aspiration of contaminated amniotic fluid
- Immunodeficiency or pre-existing pulmonary disease predisposes.
- Higher prevalence in dogs infected with canine distemper.
- Severe immunosuppression—deficiency of IgA, IgG, and IgM in dachshunds. CKCS—immunoglobulin deficiency and decreased lymphocyte function.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inflammatory (chronic pulmonary fibrosis, eosinophilic bronchopneumopathy, inhalational irritants).
- Infectious agents (systemic mycosis, toxoplasmosis, parasitic [including *Dirofilaria immitis*], bacterial pneumonia, viral).
- Cardiovascular (congestive heart failure, thromboemboli).
- Foreign body.
- Neoplasia.
- Noncardiogenic pulmonary edema.

CBC/BIOCHEMISTRY/URINALYSIS

- Changes usually nonspecific.
- Leukocytosis with neutrophilia and a left shift.
- Eosinophilia and monocytosis.
- Erythrocytosis—secondary to chronic hypoxia.
- Thrombocytopenia (CKCS) or thrombocytosis (dachshunds).
- Hypoglobulinemia.

OTHER LABORATORY TESTS

- Arterial blood gas—hypoxemia; hypocapnia; alkalosis and increased alveolar-arterial oxygen tension difference.

- Immunoglobulin fraction quantification—hypogammaglobulinemia.
- Indirect or direct fluorescent antibody test effective in specifically detecting organisms in sputum, washes, and pulmonary tissues.
- PCR of bronchoalveolar fluid and tissues.

IMAGING

Thoracic Radiography

- Changes not specific for *P. carinii*.
- Diffuse milary-interstitial to alveolar pattern with peribronchial opacification..
- Middle lung lobes more severely affected than the cranioventral lung lobes.
- Cavitary lesions and spontaneous pneumothorax may develop.
- Right-sided cardiomegaly, tracheal deviation, and pulmonary arterial enlargement. Cor pulmonale may develop as a result of increased pulmonary vascular resistance.

DIAGNOSTIC PROCEDURES

- Definitive diagnosis made by direct visualization of *P. carinii* in respiratory fluids, sputum, or biopsy specimens.
- Transtracheal aspiration, bronchoalveolar lavage, transbronchoscopic and endobronchial brushing shown to be reliable methods for obtaining samples.
- Cytology not as reliable or as definitive as histopathology. Biopsy for histopathology is invasive and has potential complications (hemorrhage, pneumothorax).
- Immunohistochemical kits available—positive result is specific and highly diagnostic; may be used on cytologic, formalin-fixed, and paraffin-embedded material; note: host species-specific antigenic variation has been demonstrated and may cause false-negative results.

PATHOLOGIC FINDINGS

- Lungs—firm, consolidated, and pale brown or gray; fluid not expressed from cut surfaces; do not collapse when the chest cavity is opened; small amounts of pleural fluid may be noted.
- Alveolar spaces—may be filled with amorphous, foamy, eosinophilic material with a honeycombed appearance; trophozoites and cyst stages may be identified.
- Pulmonary and mediastinal lymphadenopathy.
- Right-sided cardiomegaly.
- H&E only weakly stains internal structures of organism. Methenamine silver, Toluidine blue, Gram and Periodic acid-Schiff will stain cyst walls.

TREATMENT

- Inpatient—supportive care for patients with pneumonia. Oxygen administration, nebulization and coupage, bronchodilators, and intravenous fluids as required.
- Decrease exposure to other pathogens, discontinue any immunosuppressant agents.
- Anti-inflammatory doses of glucocorticoids improves pulmonary function and survival in humans.
- Cage rest or restricted exercise.

MEDICATIONS

DRUG(S)

- Trimethoprim sulphonamides 15 mg/kg q8h or 30 mg/kg q12h for 3 weeks—preferred therapy (in humans IV shown to be more effective than PO).
- Pentamidine isethionate 4 mg/kg IM q24h for 3 weeks (not as effective as trimethoprim sulphonamides but less toxic).
- Drug combinations—clindamycin and primaquine, dapsone and trimethoprim.
- Potential new drug options—caspofungin (no veterinary cases reported) and trimetrexate.
- Treatment may be started 24–48h before specimen collection without masking diagnosis.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Give folic acid supplementation if side effects of trimethoprim sulphonamides are observed or if long-term therapy required.
- Complications to pentamidine isethionate include renal and hepatic dysfunction, hypoglycemia, hypotension, hypocalcemia, urticarial, and hematologic disorders.

FOLLOW-UP

PATIENT MONITORING

- Pentamidine isethionate—check BUN and glucose daily
- Monitor clinical signs, vitals, radiographs. May need extended (months) course of treatment.

P

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Ubiquitous in environment with humans and animals being exposed to same sources.
- Potential risk if immunocompromised person is in close contact with clinically ill pet.

ABBREVIATIONS

- AIDS = acquired immunodeficiency syndrome
- CKCS = Cavalier King Charles spaniel
- HIV = human immunodeficiency virus

PNEUMONIA, ASPIRATION

BASICS

OVERVIEW

• Inflammation of the lungs caused by inhalation of oral ingestants, regurgitated material, and vomitus with subsequent pulmonary dysfunction; develops when laryngeal reflexes function improperly or are overwhelmed. • Pulmonary dysfunction—caused by (1) direct obstruction of small airways and indirect obstruction from bronchospasm and production of mucus and exudate; (2) aspiration of gastric acid—damages respiratory epithelium; can cause bronchospasm and ALI/ARDS; (3) bacterial pneumonia—bacteria in aspirated material can initiate an immediate infection; or later infections occur secondary to lung damage.

SIGNALMENT

Dogs; less commonly cats

SIGNS

• Paroxysmal, acute, or chronic. • Cough, tachypnea, nasal discharge, or exercise intolerance. • Respiratory distress or cyanosis when severe. • Depending on underlying cause—regurgitation; vomiting; dysphagia; altered consciousness; stertor or stridor.

CAUSES & RISK FACTORS

• Pharyngeal abnormalities—local paralysis; generalized neuromuscular disease; cricopharyngeal motor dysfunction; anatomic malformations. • Esophageal abnormalities—megaeosophagus; reflux esophagitis; esophageal dysmotility; esophageal obstruction; bronchoesophageal fistula. • Laryngeal paralysis, webbing, or obstruction; post-laryngeal surgery. • Altered consciousness—sedation, anesthesia; post-ictus; forebrain disease; metabolic disturbance. • Iatrogenic—force feeding; tube feeding, mineral oil administration.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Bacterial pneumonia • Lung abscess

CBC/BIOCHEMISTRY/URINALYSIS

Neutrophilic leukocytosis, left-shift, although WBCs may be normal.

OTHER LABORATORY TESTS

• Arterial blood gas analysis—hypoxemia; PaCO₂ generally low. • Consider tests for predisposing problems—acetylcholine receptor antibodies, resting cortisol or ACTH stimulation, creatine kinase.

IMAGING

• Thoracic radiography—bronchoalveolar pattern usually most severe in the gravity-dependent lobes (right cranial and

middle, left cranial); can take up to 24 hours for pattern to develop after aspiration; scrutinize for evidence of esophageal or mediastinal disease. • Videofluoroscopic swallowing study—provides evidence of swallowing or esophageal dysfunction that can predispose to aspiration. Caution: could result in aspiration of contrast medium.

DIAGNOSTIC PROCEDURES

- Tracheal wash—for bacterial culture and sensitivity testing before administering antibiotics; infection often caused by multiple organisms with unpredictable susceptibility.
- Bronchoscopy—rarely indicated.
- Laryngeal function examination—always perform if patient anesthetized for other purposes; otherwise, after resolution of pneumonia if supportive clinical signs.

TREATMENT

- Oxygen and cage rest—respiratory distress.
- Ventilatory support—if not oxygen responsive. • Intravenous fluids—avoid overhydration, which can exacerbate secondary edema. • Oral intake—withhold until primary problem identified and managed. • Do not allow patient to remain laterally recumbent on one side for more than 2 hours. • Mild exercise and saline nebulization with coupage can facilitate airway clearance. • Airway suction—only if performed immediately following aspiration (such as during recovery from anesthesia).
- Airway lavage—contraindicated.

MEDICATIONS

DRUG(S)

- Antibiotic therapy—if signs of sepsis or severe compromise, ampicillin with sulbactam (20 mg/kg IV q8h) plus a fluoroquinolone IV. Adjust antibiotic selection based on results of airway cytology, C/S, and clinical response; continue for 10 days after resolution of clinical and radiographic signs. • Beta agonist bronchodilators—sometimes cause dramatic improvement but have the potential to worsen ventilation:perfusion mismatch; most often helpful in acute aspiration or with auscultable wheezes. • Short-acting corticosteroids—consider for up to 48 hours to combat inflammation associated with life-threatening aspiration.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Diuretics—generally contraindicated; drying of airways reduces mucociliary clearance. • Corticosteroids—contraindicated beyond initial stabilization; predispose patient to infection. • Fluoroquinolones and

chloramphenicol—can prolong clearance of theophylline-derivative bronchodilators; decrease theophylline dosage by 30–50% or prolong dosing interval.

FOLLOW-UP

PATIENT MONITORING

- Radiographs—evaluate every 2–7 days initially to determine appropriateness of treatment; then every 1–2 weeks. • If signs do not resolve or suddenly worsen—possible recurrence of aspiration or a secondary infection; repeat diagnostic evaluation, including tracheal wash or bronchoscopy.

PREVENTION/AVOIDANCE

- Predisposed patients undergoing anesthesia—cisapride (slow infusion, 1 mL/kg over 30 min) 1–2 hours pre-induction may decrease esophageal reflux. • Suction esophagus prior to extubation. • Antacids could decrease acid related lung injury in predisposed patients; may also increase risk of infection.

POSSIBLE COMPLICATIONS

- Secondary infection common.
- ALI/ARDS. • Abscessation or granuloma formation rare.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—depends on severity of signs and ability to correct underlying disease. • Severe aspiration—can be fatal. • Recurrence—likely if underlying cause not addressed.

MISCELLANEOUS

SEE ALSO

- Acute Respiratory Distress Syndrome
- Megaeosphagus • Pneumonia, Bacterial

ABBREVIATIONS

- ALI/ARDS = acute lung injury/acute respiratory distress syndrome • C/S = culture and sensitivity • WBC = white blood cell

PNEUMONIA, BACTERIAL

BASICS

DEFINITION

Acquired inflammatory response to virulent bacteria in lung parenchyma characterized by exudation of cells and fluid into conducting airways and alveolar spaces.

PATHOPHYSIOLOGY

- Bacteria—enter the lower respiratory tract primarily by inhalation or aspiration; less commonly by the hematogenous route. Infection incites an overt inflammatory reaction.
- Tracheobronchial tree and carina—normally not sterile.
- Oropharyngeal bacteria—frequently aspirated; may be present for an unknown time period in the normal tracheobronchial tree and lung; can cause or complicate respiratory infection; presence complicates interpretation of airway and lung cultures.
- Respiratory infection—development depends on the complex interplay of many factors: inoculation site, number of organisms and their virulence, and age and resistance of the host.
- Bacteria produce extracellular proteins called invasins that impair host defenses and assist in the spread of bacteria.
- Viral infections—alter bacterial colonization patterns; increase bacterial adherence to respiratory epithelium; reduce mucociliary clearance and phagocytosis; thus allow resident bacteria to invade the lower respiratory tract.
- Foreign body—inoculates bacteria into a focal lung region and leads to obstructive pneumonia.
- Exudative phase—*Inflammatory hyperemia*; extravasation of high-protein fluid into interstitial and alveolar spaces.
- Leukocytic migration phase—leukocytes infiltrate the airways and alveoli; consolidation, ischemia, tissue necrosis, and atelectasis owing to bronchial occlusion, obstructive bronchiolitis, and impaired collateral ventilation.

SYSTEMS AFFECTED

Respiratory—primary or secondary infection

GENETICS

Heritable rhinitis/bronchopneumonia syndrome of Irish wolfhounds, unknown pathogenesis.

INCIDENCE/PREVALENCE

Common in both young and old dogs, less common in cats.

GEOGRAPHIC DISTRIBUTION

Widespread

SIGNALMENT

Species

Dog and cat

Breed Predilections

Dogs—sporting breeds, hounds, working breeds, and mixed breeds > 12 kg

Mean Age and Range

Dogs—range, 1 month–15 years; many cases in dogs < 1 year old

Predominant Sex

Dogs—60% males

SIGNS

Historical Findings

- Cough
- Labored breathing
- Exercise intolerance
- Anorexia and weight loss
- Lethargy
- Nasal discharge

Physical Examination Findings

- Cough
- Fever
- Difficult or rapid breathing
- Abnormal breath sounds on auscultation—increased intensity or bronchial breath sounds, crackles, and wheezes
- Weight loss
- Nasal discharge
- Lethargy
- Dehydration

CAUSES

Dogs

- Most common primary respiratory pathogens—*Bordetella bronchiseptica* and *Mycoplasma* spp.
- Most common gram-positive bacteria—*Staphylococcus*, *Streptococcus*, and *Enterococcus* spp.
- Most common gram-negative bacteria—*Escherichia coli*, *Klebsiella* spp., *Pseudomonas* spp., *Pasturella* spp.
- Anaerobic bacteria—found in pulmonary abscesses and various types of pneumonia (particularly with aspiration or foreign bodies); reported in ~ 20% of cases.

Cats

- Bacterial pathogens—poorly documented; *B. bronchiseptica*, *Pasteurella* spp., and *Moraxella* spp. most frequently reported.
- *Mycoplasma* spp. may be a primary pathogen in the lower respiratory tract.
- Carrier state—may exist; periods of shedding *B. bronchiseptica* after stress; infected queens may not shed organism prepartum but begin shedding post-partum, serving as a source of infection for kittens.

RISK FACTORS

- Preexisting viral infection.
- Regurgitation, dysphagia, or vomiting.
- Functional or anatomic defects—laryngeal paralysis, megaesophagus, cleft palate, primary ciliary dyskinesia.
- Reduced level of consciousness—stupor, coma, and anesthesia.
- Bronchial foreign body.
- Bronchiectasis.
- Immunosuppressive therapy—chemotherapy, glucocorticoids, immunosuppressives.
- Severe metabolic disorders—uremia, diabetes mellitus, hyperadrenocorticism.
- Sepsis.
- Age—very young more susceptible to fatal infections.
- Immunization status.
- Environment—housing, sanitation, ventilation.
- Phagocyte dysfunction—FeLV and diabetes mellitus.
- Complement deficiency—rare.
- Selective IgA deficiency—rare.
- Combined T-cell and B-cell dysfunction—rare.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Viral pneumonia—canine distemper virus, adenovirus, influenza virus, herpesvirus
- Protozoal pneumonia—toxoplasmosis
- Parasitic pneumonia—capillariasis, filarioidiasis
- Fungal pneumonia—histoplasmosis, blastomycosis, coccidioidomycosis, and cryptococcosis
- Eosinophilic pneumonia • Feline bronchial disease (asthma)
- Pulmonary abscess
- Pleural infection—pyothorax
- Bronchial foreign body

CBC/BIOCHEMISTRY/URINALYSIS

Inflammatory leukogram—neutrophilic leukocytosis with or without a left shift; absence does not rule out the diagnosis.

OTHER LABORATORY TESTS

- Arterial blood gas analysis—values correlate well with the degree of physiologic disruption; sensitive monitor of progress during treatment; $\text{PaO}_2 < 80 \text{ mmHg}$ on room air = mild or moderate hypoxemia; $\text{PaO}_2 < 60 \text{ mmHg}$ on room air = severe hypoxemia.
- Consider serology for canine influenza virus.
- Molecular diagnostics also available for viral and bacterial presence.

IMAGING

Thoracic Radiography

- Variable—diffuse, bronchointerstitial pattern to partial or complete alveolar infiltrates to consolidation.
- Most common—alveolar pattern characterized by increased pulmonary densities (margins indistinct; air bronchograms or lobar consolidation).
- More variable lung patterns in cats such as multifocal, patchy interstitial and alveolar changes and/or a diffuse nodular pattern.

P

DIAGNOSTIC PROCEDURES

- Microbiologic (aerobic, anaerobic bacterial, and mycoplasmal culture) and cytologic examinations for definitive diagnosis.
- Samples—transtracheal or endotracheal washing, bronchoscopy, bronchoalveolar lavage (with or without bronchoscope), or fine-needle lung aspiration.
- Degenerate neutrophils with septic inflammation (intracellular bacteria) predominating.
- Recent antibiotic administration—non-septic inflammation likely.
- Bacteria—not always obvious microscopically; always culture specimens, even if no bacteria are seen on cytology.

PATHOLOGIC FINDINGS

- Irregular consolidation in cranoventral regions.
- Consolidated lung—varies from dark red to gray-pink to more gray, depending on age of patient and nature of the process.
- Palpable firmness of the tissue.
- Nidus of inflammation—bronchiolar-alveolar junction.

PNEUMONIA, BACTERIAL

(CONTINUED)

- Early—bronchioles and adjacent alveoli filled with neutrophils and an admixture of cell debris, fibrin, and macrophages; necrotic to hyperplastic epithelium.
- Later—neutrophilic, fibrinous, hemorrhagic, or necrotizing inflammation, depending on virulence of bacteria and host response.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—recommended with multisystemic signs (e.g., anorexia, high fever, weight loss, and lethargy).

NURSING CARE

- Maintain normal systemic hydration—important to aid mucociliary clearance and secretion mobilization; use a balanced multielectrolyte solution.
- Saline nebulization—results in more rapid resolution if used with physical therapy and systemic antibacterials.
- Physical therapy—chest wall coupage, tracheal manipulation to stimulate mild cough and postural drainage; may enhance clearance of secretions; always do immediately after nebulization; avoid allowing the patient to lie in one position for a prolonged time.
- Oxygen therapy—as warranted for patients with hypoxemia, signs of respiratory distress.

ACTIVITY

Restrict during treatment (inpatient or outpatient), except as part of physical therapy after aerosolization.

DIET

- P**
- Ensure normal intake with food high in protein and energy density.
 - Enteral or parenteral nutritional support—indicated in severely ill patients.
 - Use caution in feeding animals with megaesophagus, laryngeal dysfunction or surgery, pharyngeal disease, or recumbent patients.

CLIENT EDUCATION

Warn client that high morbidity and mortality are associated with severe hypoxemia and sepsis.

SURGICAL CONSIDERATIONS

Surgery (lung lobectomy)—can be required with pulmonary abscessation or broncho-pulmonary foreign body with secondary pneumonia; may be indicated if patient is unresponsive to conventional treatment and disease is limited to one or two lobes.

MEDICATIONS

DRUG(S) OF CHOICE

Antimicrobials

- Antimicrobials are best selected based on results of culture and susceptibility testing from tracheal wash or other pulmonary

specimens.

- Empiric antimicrobial therapy is justified when there is significant risk in obtaining adequate samples or if the time required to culture causes a life-threatening delay in treatment.
- Reasonable initial antimicrobial choices pending culture results include amoxicillin-clavulanic acid (15 mg/kg PO q12h) or cephalaxin (22–30 mg/kg PO q12h) with enrofloxacin (dogs, 5–10 mg/kg q12h or 10–20 mg/kg q24h; cats, maximum 5 mg/kg q24h), or trimethoprim-sulfonamide (15 mg/kg PO q12h).
- Gram-positive cocci—ampicillin (22 mg/kg PO q12h), ampicillin-sulbactam; amoxicillin; amoxicillin-clavulanic acid; azithromycin; chloramphenicol, erythromycin; gentamicin; trimethoprim-sulfonamide; first-generation cephalosporins.
- Gram-negative rods—enrofloxacin, chloramphenicol; gentamicin; trimethoprim-sulfonamide; amikacin; marbofloxacin; carboxypenicillins.
- *Bordetella*—doxycycline (5 mg/kg PO q12h); chloramphenicol; enrofloxacin; azithromycin.
- *Mycoplasma*—doxycycline, enrofloxacin, marbofloxacin, chloramphenicol.
- Anaerobes—amoxicillin-clavulanic acid; chloramphenicol; metronidazole; clindamycin; ticarcillin-clavulanic acid.
- Antimicrobial nebulization for *Bordetella*—gentamicin nebulization 5 mg/kg q24h for 5–7 days, typically adjunctive with systemic antimicrobials.
- Continue treatment for at least 10 days beyond clinical resolution and/or 1–2 weeks following radiographic resolution.

CONTRAINdications

- Anticholinergics and antihistamines—may thicken secretions and inhibit mucokinesis and exudate removal from airways.
- Antitussives—potent, centrally acting agents inhibit mucokinesis and exudate removal from airways, can potentiate pulmonary infection and inflammation.

POSSIBLE INTERACTIONS

Avoid use of theophylline and fluoroquinolones concurrently.

ALTERNATIVE DRUG(S)

- Expectorants—recommended by some clinicians; no objective evidence that they increase mucokinesis or mobilization of secretions.
- Bronchodilators—recommended by some clinicians to alleviate bronchospasm.

FOLLOW-UP

PATIENT MONITORING

- Monitor respiratory rate and effort.
- Complete blood count will normalize.
- Arterial blood gases—most sensitive monitor of progress, pulse oximetry can be helpful.
- Frequent thoracic auscultation.
- Thoracic radiographs—improve more slowly than the clinical appearance.

PREVENTION/AVOIDANCE

- Vaccination—against upper respiratory viruses; against *B. bronchiseptica* if a dog is boarded or exposed to large numbers of other animals.
- Catteries—environmental strategies to lower population density and improve hygiene help control outbreaks of bordetellosis.

POSSIBLE COMPLICATIONS

Sepsis can develop.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—good with aggressive antibacterial and supportive therapy; more guarded in young animals, patients with immunodeficiency, and patients that are debilitated or have severe underlying disease.
- Prolonged infection—potential for chronic bronchitis or bronchiectasis in any patient.
- Mortality—associated with severe hypoxemia (low arterial oxygen concentration) and sepsis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Frequently develops secondary to underlying functional or anatomic abnormalities—cleft palate; tracheal hypoplasia; primary ciliary dyskinesia; laryngeal paralysis; megaesophagus or other esophageal dysmotility disorder.
- Bronchiectasis—both predisposing factor and potential complication.

AGE-RELATED FACTORS

- Young puppies and kittens—may have a poorer prognosis.
- Underlying functional and anatomic problems and immunodeficiencies—suspect in young patients.

PREGNANCY/FERTILITY/BREEDING

Bitches or queens infected with *B. bronchiseptica*—may transmit infection to neonates.

ABBREVIATION

- FeLV = feline leukemia virus

PNEUMONIA, EOSINOPHILIC

BASICS

DEFINITION

The fully developed inflammatory response to antigens in lung parenchyma characterized by exudation of eosinophils and fluid into lung interstitium, conducting airways, and alveolar spaces.

PATOPHYSIOLOGY

- Immunologic basis—supporting evidence generally accepted; mechanisms involved not yet clarified. • Eosinophilic infiltration and a predominance of CD4+ T cells in bronchoalveolar lavage fluid support the role of a dominant TH2 immune response in the lower airways. • Evolution of disease—likely determined by characteristics of antigens, host response, and regulation of that response.
- Antigens enter the lower respiratory tract by inhalation or hematogenous routes.
- Chronic exposure to antigens—elicits a humoral and cellular immune response.
- Allergic or hypersensitivity pulmonary disorders—associated with an abnormal humoral antibody response and a cell-mediated immunoregulatory defect.
- Immunoglobulin classes involved—IgE, IgG, and others. • High numbers of activated macrophages and T-lymphocytes and depressed suppressor T-cell activity—alter cell-mediated immunity. • Collagenolytic enzyme activity—increased. • Generally referred to as eosinophilic bronchopneumopathy although at least three disease patterns appear to exist: eosinophilic pneumonitis, eosinophilic bronchitis, and pulmonary eosinophilic granulomatosis.
- Severely affected dogs appear to develop marked granulomatous disease. • Heartworm disease with pneumonitis—microfilaria may become entrapped in the pulmonary circulation and trigger an immune response.
- Mortality—associated with severe hypoxemia (e.g., low arterial oxygen concentration) and (rarely) severe hemoptysis.

SYSTEMS AFFECTED

- Respiratory—lower respiratory tract primarily but nasal cavity can also be involved. • Cardiovascular—can develop cor pulmonale.

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Widespread

SIGNALMENT

Species

Dog

Breed Predilections

Siberian husky, possibly

Mean Age and Range

All ages but more often young adults (4–6 years of age)

Predominant Sex

None

SIGNS

General Comments

Extremely variable, depending on the severity

Historical Findings

- Cough—unresponsive to antibacterial therapy
- Labored breathing
- Exercise intolerance.
- Anorexia
- Lethargy
- Weight loss
- Nasal discharge
- Fever (uncommon)

Physical Examination Findings

- Harsh, moist cough.
- Tachypnea or respiratory distress.
- Abnormal breath sounds on auscultation—increased-intensity breath sounds; crackles; wheezes; decreased sounds can occur.
- Weight loss.
- Yellow-green or mucopurulent nasal discharge.
- Fever (uncommon).

CAUSES

- Purported aeroallergens—spores or hyphae from fungi and actinomycetes; pollen; insect antigens; dust or storage mites, unidentified triggers of the immune response.
- Parasitic antigens—heartworm microfilaria, respiratory parasites.

RISK FACTORS

- Living in a heartworm-endemic area without receiving preventive medication.
- Dusty or moldy environment.
- Air pollution.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Parasitic pneumonia—capillariasis; paragonimiasis; dirofilariasis.
- Fungal pneumonia—histoplasmosis; blastomycosis; coccidioidomycosis; cryptococcosis.
- For eosinophilic pneumonitis—bacterial pneumonia; viral pneumonia (e.g., canine distemper virus and canine adenovirus); rickettsial pneumonia (e.g., ehrlichiosis and Rocky Mountain spotted fever); protozoal pneumonia (e.g., toxoplasmosis); congestive heart failure; bartonellosis.
- For eosinophilic bronchitis—infectious tracheobronchitis; chronic bronchitis.
- For pulmonary eosinophilic granulomatosis—neoplasia (including lymphomatoid granulomatosis); pulmonary abscess; bronchial foreign body.

CBC/BIOCHEMISTRY/URINALYSIS

- Inflammatory leukogram—neutrophilic leukocytosis with or without a left-shift, eosinophilia, basophilia, or monocytosis.
- Absence of eosinophilia does not exclude diagnosis.
- Hyperglobulinemia—suggests chronic antigenic stimulus; rule out occult dirofilariasis.

OTHER LABORATORY TESTS

Arterial Blood Gas Analysis

- Values correlate well with the degree of physiologic disruption; sensitive monitor of patient's progress during treatment.
- Hypoxemia—mild or moderate, $\text{PaO}_2 < 80 \text{ mmHg}$ on room air; severe, $\text{PaO}_2 < 60 \text{ mmHg}$ on room air.

Other

- Heartworm microfilaria and antigen tests—positive results suggest dirofilariasis or eosinophilic pneumonitis associated with microfilaria trapped in the lung. Multiple tests can be required to rule out disease.
- Fecal flotation and Baermann sedimentation.
- Protein electrophoresis— β -globulin spike (hyperbeta-globulinemia) often found with occult dirofilariasis.

IMAGING

- Radiographic findings depend on extent and severity of disease.
- Thoracic radiographs—help document the severity of pulmonary artery disease; reveal interstitial pneumonitis in dogs with dirofilariasis.
- Eosinophilic pneumonitis—linear or miliary interstitial pattern that resembles changes seen with early pulmonary edema or fungal pneumonia; alveolar pattern characterized by increased pulmonary densities with indistinct margins in severely affected patients; tortuous, large pulmonary arteries and right-sided cardiomegaly in patients with dirofilariasis.
- Eosinophilic bronchitis—bronchial pattern with thickened bronchi extending into the periphery of the lung (tram/railroad track and donut signs); bronchiectasis in chronic cases.
- Eosinophilic granuloma—multiple nodular lesions of variable sizes in different lung lobes; patchy, focal alveolar densities; tracheo-bronchial lymphadenopathy possible.

P

DIAGNOSTIC PROCEDURES

- Transtracheal or endotracheal wash appropriate for sample collection.
- Bronchoscopy; yellow-green mucus, polypoid mucosal proliferation, partial airway collapse. Occlusive eosinophilic plaques or granulomas sometimes visible within airways.
- Bronchoalveolar lavage—with or without bronchoscope.
- Bacterial and mycoplasmal culture of bronchoalveolar lavage fluid is recommended to rule-out bacterial infection. Occasionally, concurrent bacterial infection can be identified in dogs with eosinophilic lung disease.
- Fine-needle lung aspiration and examination.
- Cytologic examination of aspirates, washings, or brushings—definitive diagnosis: eosinophilic inflammation predominates; may note other types of inflammatory cells; carefully examine specimens for antigenic sources (e.g., parasites, fungi, or neoplasia).
- Consider intradermal skin or serologic allergen testing—rarely may identify allergens.
- Fecal examinations—routine flotation, direct

PNEUMONIA, EOSINOPHILIC

(CONTINUED)

smear, sediment examination, and Baermann technique to rule out parasitic pneumonia; negative test can occur due to intermittent shedding and empirical therapy warranted in some cases.

PATHOLOGIC FINDINGS

- Gross—diffuse, patchy, or nodular firm lesions; usually pale or mottled.
- Histopathologic—eosinophilic, lymphocytic, and macrophagic infiltration of alveolar walls and alveolar spaces; as disease progresses, interstitial infiltrative process becomes fibrotic with obliteration of alveolar spaces, and granulomas can be dispersed within the interstitial fibrosis. Upper respiratory tract epithelium can also be involved with eosinophilic infiltration.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—recommended with multisystemic signs (e.g., anorexia, weight loss, or lethargy).

NURSING CARE

- Dehydration—hinders mucociliary clearance and secretion mobilization; maintain normal systemic hydration with a balanced multielectrolyte solution.
- Supplemental oxygen—for respiratory distress.

ACTIVITY

Restricted during treatment (inpatient or outpatient).

DIET

Ensure normal intake.

P

CLIENT EDUCATION

Warn client that morbidity and mortality are associated with severe hypoxemia.

SURGICAL CONSIDERATIONS

Lung lobectomy can be required with large granulomas.

MEDICATIONS

DRUG(S) OF CHOICE

- Corticosteroids—prednisolone or prednisone at 2 mg/kg/day until clinical signs begin to resolve (typically 2–3 weeks); then taper slowly (over months). Maintenance dosages of prednisone are often required long-term (0.125–0.5 mg/kg q48h or every 3 or 4 days for 4–6 months or longer).
- Following adequate control of disease and/or due to side effects of systemic glucocorticoids, inhaled corticosteroids (e.g.,

fluticasone propionate) can be used in conjunction with a spacing chamber and facemask. • Antibiotic therapy indicated only if active infection documented on airway culture. Prophylactic therapy could lead to development of antimicrobial resistance.

- Heartworm adulticidal therapy—for heartworm-positive patient; initiate after the patient has been stabilized with corticosteroids and rest. • Itraconazole or ketoconazole—use antifungal drugs only if the fungal infection is confirmed by cytologic examination or culture. • Hypo sensitization—allergy shots based on results of intradermal skin or serologic testing can be attempted but is not the treatment of choice in most patients. Most dogs will still require steroid therapy.

CONTRAINdications

N/A

PRECAUTIONS

N/A

ALTERNATIVE DRUG(S)

- Other immunosuppressive drugs (e.g., cyclosporine)—can use when corticosteroids are contraindicated or have been ineffective, although inhaled steroids are preferred. No trial results are available to date.
- Bronchodilators—can be helpful, particularly if wheezes are auscultated or labored respiratory effort is observed; see Bronchitis, Chronic.

FOLLOW-UP

PATIENT MONITORING

- Complete blood count will show resolution of peripheral eosinophilia or neutrophilia.
- Arterial blood gases—most sensitive monitor of progress. Can remain abnormal even with successful management of disease.
- Auscultate patient thoroughly several times daily. • Thoracic radiographs—improve more slowly than the clinical appearance.

PREVENTION/AVOIDANCE

- Routine heartworm-prevention medication.
- Consider changing patient's environment if an Aeroallergen is suspected.

POSSIBLE COMPLICATIONS

Pulmonary embolization—dogs treated with adulticidal therapy for dirofilariasis.

EXPECTED COURSE AND PROGNOSIS

- Prognosis good for mild-to-moderate cases; many patients require long-term treatment with steroids. • If allergen can be identified and eliminated—suspect improved prognosis.

- Heartworm infection—prognosis depends on severity of pulmonary hypertension, cor pulmonale, and embolization. • Eosinophilic granulomatosis—prognosis guarded; often disease is progressive.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Dirofilariasis • Bronchopulmonary fungal infection

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Corticosteroids and other immunosuppressive drugs are contraindicated in pregnant animals.

SYNOMYMS

- Allergic alveolitis • Allergic bronchitis
- Bronchitic pulmonary eosinophilia
- Eosinophilic bronchitis or bronchopneumopathy • Eosinophilic pneumonia/pneumonitis • Eosinophilic pulmonary granulomatosis • Extrinsic allergic alveolitis • Hypersensitivity pneumonitis
- Occult heartworm pneumonia • Parasitic pulmonary eosinophilia • Pulmonary infiltrates with eosinophilia (PIE)

SEE ALSO

- Cough • Dyspnea and Respiratory Distress
- Heartworm Disease—Dogs
- Lymphomatoid Granulomatosis • Panting and Tachypnea • Respiratory Parasites

PNEUMONIA, FUNGAL

BASICS

DEFINITION

Inflammation of the pulmonary interstitial, lymphatic, and peribronchial tissues caused by deep mycotic infection.

PATHOPHYSIOLOGY

- Mycelial fungal elements—inhaled from contaminated soil or plant debris; organisms then colonize the lungs.
- Dimorphic fungi such as *Blastomyces dermatitidis*, *Histoplasma capsulatum*, *Coccidioides immitis*—yeast phase at body temperature. Invasive fungal infections with *Aspergillus* spp. follow inhalation of airborne spores with growth as mycelia within tissue.
- Systemic dissemination of yeast from the lungs common in dogs and cats.
- Pulmonary interstitial and alveolar involvement—can cause hypoxia.
- Airway involvement—causes cough.
- Cell-mediated immune response leads to pyogranulomatous inflammation.
- Pulmonary complications include interstitial and/or bronchial pneumonia, pleural effusion, mediastinal granuloma formation, ARDS, and pulmonary thromboembolism.

SYSTEMS AFFECTED

- Depend on the specific fungal disease.
- Blastomycosis**—respiratory involvement in ~85% of cases; diffuse interstitial, alveolar, or bronchial pneumonia most common; solitary mass lesions can be seen, especially in cats; tracheobronchial lymphadenopathy can contribute to cough; nasal infection rare. Multisystemic involvement of skin, lymph nodes, eyes, bone, reproductive tract, and CNS often seen.
- Histoplasmosis**—diffuse interstitial pneumonia common, especially in cats; perihilar or mediastinal lymphadenopathy contributes to cough. Multisystemic involvement of gastrointestinal tract, liver, lymph nodes, spleen, bone marrow, eyes, bone, and CNS often seen.
- Coccidioidomycosis**—diffuse interstitial or bronchial pneumonia common in dogs but less common in cats; perihilar or mediastinal lymphadenopathy common. Multisystemic involvement of bone, skin, eyes, lymph nodes, and CNS often seen.
- Cryptococcosis**—nasal cavity involvement most common in cats, neurologic system in dogs. Skin and other organs also affected.
- Systemic aspergillosis—*Aspergillus terreus***: pneumonia, renal and bone involvement common.

GENETICS

Breed susceptibilities may be related to defects in cell-mediated immunity.

INCIDENCE/PREVALENCE

Depends on geographic distribution.

GEOGRAPHIC DISTRIBUTION

- Blastomycosis**—endemic in US Southeast and Midwest along the Mississippi, Ohio, Missouri, and Tennessee rivers and southern Great Lakes; also in southern Mid-Atlantic States, Pacific Northwest, and southern Canada from east coast to prairie regions of southern Saskatchewan and Manitoba.
- Histoplasmosis**—similar to but more widely distributed than blastomycosis; pockets of disease in Texas, Oklahoma, and California.
- Coccidioidomycosis**—US Southwest from Texas to California. Northern Mexico and parts of South America.
- Cryptococcosis** and aspergillosis—worldwide.

SIGNALMENT

Species

Dog and less commonly cat (except cryptococcosis)

Breed Predilection

- Systemic mycosis**—large-breed, hunting or field trial dogs; Doberman pinschers and rottweilers appear predisposed to disseminated disease.
- Systemic aspergillosis**—German shepherds over-represented. **Cryptococcosis**—cocker spaniels over-represented.

Mean Age and Range

- Young animals (< 4 years) predisposed.
- Any age can be affected.

Predominant Sex

Males affected two to four times more often than females.

SIGNS

General Comments

Multisystemic illness depends on organ systems involved.

Historical Findings

- Chronic weight loss and inappetence.
- Oculonasal discharge.
- Coughing—can be prominent but seen inconsistently even with marked pulmonary disease.
- Tachypnea or exercise intolerance common.
- Labored breathing—more common in cats; sign of severe disease in both dogs and cats.
- Acute blindness or blepharospasm—if eyes are affected.
- Papules and cutaneous nodules—common but often missed until draining tracts appear.
- Lameness—if bones affected or if osteomyelitis develops.
- Seizures, ataxia, behavior change—if CNS affected.

Physical Examination Findings

- Emaciation—in chronically affected patients.
- Fever—about 50% of patients.
- Harsh, loud breath sounds, crackles in cats, cough on tracheal palpation.
- Dyspnea—at rest with severe disease.
- Lymphadenopathy—common in dogs with dimorphic fungal infections.
- Blastomycosis (dogs)**—cutaneous and subcutaneous nodules with draining tracts; chorioretinitis; granulomatous retinal detachment common.
- Coccidioidomycosis (dogs)**—lameness and pain from osteomyelitis, pericardial disease;

cats—skin lesions.

- Histoplasmosis (dogs)**—emaciation and bloody diarrhea; cats—skin lesions.
- Cryptococcosis**—nasal cavity and soft tissue infection common in cats; chorioretinitis in dogs and cats.

CAUSES

- Primary route of infection: *Blastomyces dermatitidis*—lungs, *Histoplasma capsulatum*—lungs and possibly gastrointestinal tract, *Coccidioides immitis*—lungs.
- Cryptococcus neoformans* and *gattii*—nasal cavity, with direct extension into the eyes or CNS, lungs less important.
- Aspergillus* spp.—nasal cavity and lungs.

RISK FACTORS

- Blastomycosis**, histoplasmosis, and cryptococcosis—environmental exposure to soils rich in organic matter; blastomycosis and cryptococcosis—exposure to bird droppings or other fecal matter; blastomycosis—living near water.
- Coccidioidomycosis**—environmental exposure to sandy, alkaline soil after periods of rainfall; outdoor activities (hunting and field trials).
- FeLV** does not appear to be a risk factor and **FIV** may be minor risk factor.
- Prednisone**—may worsen the disease.
- Antineoplastic chemotherapy**.
- Lymphoreticular neoplasia**.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Metastatic neoplasia
- Eosinophilic lung disease
- Lymphomatoid granulomatosis
- Lymphoreticular and histiocytic neoplasia
- Idiopathic pyogranulomatous disease
- FIP or other vasculitic disease
- Parasitic pneumonia
- Bacterial pneumonia
- Chronic bronchial disease
- Pulmonary edema
- Pulmonary thromboembolism

P

CBC/BIOCHEMISTRY/URINALYSIS

- Moderate leukocytosis with or without a left-shift.
- Lymphopenia common.
- Leukopenia, thrombocytopenia, non-regenerative anemia—with histoplasmosis.
- Hyperglobulinemia and hypoalbuminemia common.
- Hypercalcemia—occasionally.
- Liver enzyme activities—more likely to be increased with histoplasmosis.
- Urinalysis usually normal; proteinuria—occasionally seen.
- Organisms—can be seen in urine (rarely, except for *Aspergillus*) if kidneys or lower urinary tract are affected.

OTHER LABORATORY TESTS

- Antigen can be detected in serum or urine by enzyme immunoassay for diagnosis of *Blastomyces* or *Histoplasma*—sensitivity and specificity high. Cross-reaction occurs between *Blastomyces* and *Histoplasma*. Antigen testing for *Coccidioides* is insensitive.
- Serologic (antibody) testing for blastomycosis and histoplasmosis—false-

PNEUMONIA, FUNGAL

(CONTINUED)

positive and false-negative results common. Positive titer for *Coccidioides* using heat-precipitated AGID consistent with infection with relevant clinical history and signs. • Latex agglutination test—for capsular antigen; highly reliable for cryptococcosis. • Cytologic or histologic identification of the organism—definitive diagnosis. • Culture—not usually necessary; can be difficult to isolate and risky due to zoonosis.

IMAGING

- Thoracic radiography—diffuse nodular interstitial and peribronchial infiltrates; nodular densities can coalesce to granulomatous masses with indistinct edges; tracheobronchial lymphadenopathy common; large focal granulomas more likely in cats.
- Appendicular or axial skeleton radiography—osteolysis with periosteal proliferation; soft tissue swelling.
- Abdominal ultrasonography—granulomas or large lymph nodes. • Ocular ultrasonography—retrobulbar mass, posterior uveitis.

DIAGNOSTIC PROCEDURES

- Impression smear or aspirate of a skin nodule—most likely to yield organisms.
- Fine-needle lung aspirate—possibly more diagnostic than tracheal aspirate or bronchoalveolar lavage specimen. • Lymph node aspirate or biopsy. • CSF tap—with cryptococcosis. • Bone marrow or liver/splenic aspirate—with histoplasmosis.
- Biopsy—may be needed.

PATHOLOGIC FINDINGS

- Pyogranulomatous inflammation.
- Organisms—usually seen with blastomycosis, histoplasmosis, cryptococcosis, and aspergillosis; difficult to find with coccidioidomycosis.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—if patient is stable. • Inpatient evaluation and treatment—dehydration, anorexia, and severe hypoxia.

NURSING CARE

Administration of fluids, oxygen, and antibiotics as needed.

DIET

- Feed high-quality protein, calorically dense food. • Histoplasmosis accompanied by marked gastrointestinal involvement—feed highly digestible food.

CLIENT EDUCATION

- Complete response to treatment in <70% of dogs and a smaller percentage of cats.
- Treatment is expensive and will be long term (> 2 months). • Clean environmental areas of highly organic matter or feces.

SURGICAL CONSIDERATIONS

Focal granulomas or glaucomatous; painful eyes can require removal.

MEDICATIONS

DRUG(S) OF CHOICE

- Itraconazole 5–10 mg/kg PO daily; must be given with food. Liquid suspension more bioavailable in cats (dose 1–1.5 mg/kg/day PO). • Fluconazole 10 mg/kg PO q12h; drug of choice for cryptococcosis and patients with CNS or urinary tract involvement. Usually requires longer treatment. • Lipid-complex amphotericin B 1–2 mg/kg IV q48h for 12 treatments; nephrotoxicity low; diuresis not required. • Posaconazole 5 mg/kg PO q24h with food may be more effective for aspergillosis.

CONTRAINDICATIONS

Corticosteroids are relatively contraindicated but may be required to reduce inflammation during initial treatment in severely dyspneic patients.

PRECAUTIONS

- Azole drugs—do not use with severe liver disease. • Amphotericin B—do not use in azotemic or dehydrated patients; stop use if BUN > 50 mg/dL or creatinine > 3 mg/dL.
- Itraconazole and the other azole drugs—anorexia; increase in liver enzymes; cutaneous vasculitis.

POSSIBLE INTERACTIONS

Antacids and anticonvulsants—can lower blood concentration of itraconazole.

ALTERNATIVE DRUG(S)

- Ketoconazole 10–30 mg/kg PO q12h; can be effective; higher incidence of side effects; longer treatment is necessary; relapse common. • Amphotericin B 0.5 mg/kg (dogs) or 0.25 mg/kg (cats) IV three times/week to a total dose of 8 mg/kg if used alone or 4 mg/kg if used with an azole drug; administer in 200–500 mL of D₅W after saline diuresis; best used with itraconazole or ketoconazole for severely affected patients. • Amphotericin B—alternative; 0.5–0.8 mg/kg 2–3 times per week; to reduce nephrotoxicity, can give subcutaneously diluted in 0.45% saline/2.5% dextrose solution (400 mL for cats, 500 mL for dogs < 20 kg, 1,000 mL for dogs > 20 kg). • Voriconazole 3–4 mg/kg PO q12h for invasive aspergillosis. • Terbinafine 30–40 mg/kg PO q12h can be added to azole treatment regimens in resistant infections.

FOLLOW-UP

PATIENT MONITORING

- Liver enzymes—evaluated monthly during azole therapy • BUN and creatinine—

measure before each dose of amphotericin B.

- Thoracic radiographs—reevaluate before discontinuing treatment. • Urine antigen testing for *Blastomyces/Histoplasma*—use to monitor therapy.

PREVENTION/AVOIDANCE

Reduce possible exposure.

POSSIBLE COMPLICATIONS

- Blindness is usually permanent. • Renal failure from amphotericin B.

EXPECTED COURSE AND PROGNOSIS

- Blastomycosis—requires a minimum of 2 months of treatment, 60–70% of dogs cured by itraconazole. Dogs with dyspnea or hypoxemia have poorer prognosis. • Others—continue until 1 month past remission.
- Systemic aspergillosis—poor prognosis.
- Relapse—can occur up to 1 year after treatment.

MISCELLANEOUS

AGE-RELATED FACTORS

Young animals predisposed

ZOONOTIC POTENTIAL

Infections in people—primarily from a common environmental source; no direct transmission from animals to humans, except by penetrating wounds contaminated by the organism; needle stick injury.

PREGNANCY/FERTILITY/BREEDING

- Fungal abortion possible. • Azole antifungals—teratogenic; do not use in pregnant animals.

SEE ALSO

- Aspergillosis • Blastomycosis
- Coccidioidomycosis • Cryptococcosis
- Histoplasmosis

ABBREVIATIONS

- AGID = agar gel immunodiffusion • ARDS = acute respiratory distress syndrome • CNS = central nervous system • CSF = cerebrospinal fluid • FeLV = feline leukemia virus • FIP = feline infectious peritonitis • FIV = feline immunodeficiency virus

PNEUMONIA, INTERSTITIAL

BASICS

DEFINITION

A form of pneumonia in which the inflammatory process occurs in alveolar walls and interstitial space.

PATHOPHYSIOLOGY

- Results from either aerogenous injury to the alveolar epithelium (type I or II pneumocytes) or hematogenous injury to the alveolar capillaries; may be triggered by infectious agents.
- Alveolar wall damage often occurs secondary to inflammation and antigen-antibody complex deposition.
- Progression from acute to chronic interstitial pneumonia can occur leading to alveolar fibrosis ± interstitial mononuclear cell accumulation and persistent type II pneumocyte hyperplasia.

SYSTEMS AFFECTED

- Respiratory.
- Cardiovascular (if cor pulmonale develops).

GENETICS

- IPF is breed associated (West Highland white terriers/terrier breeds); a definitive genetic defect is not known.

INCIDENCE/PREVALENCE

Incompletely understood

GEOGRAPHIC DISTRIBUTION

- Infectious organisms: *Aelurostrongylus abstrusus*—Europe, United States, Australia
- *Angiostrongylus vasorum*—Europe, Africa, South America, North America.
- *Leishmania chagasi*—South and Central America.
- H3N2—China, Chicago (USA).
- Pneumocystis and toxoplasmosis—worldwide.

SIGNALMENT

- Canine distemper virus—dogs 3–6 months of age. Greyhounds, Siberian huskies, Weimaraners, Samoyeds, and Alaskan malamutes overrepresented.
- Endogenous lipid pneumonia (EnLP)—older cats of either sex.
- Pulmonary interstitial lung disease—middle- to old-aged West Highland white terrier, ± cairn terriers and bull terriers.
- Feline idiopathic pulmonary fibrosis-like disease—middle-aged to older cats.
- *Pneumocystis jirovecii*—miniature dachshunds <1 year of age at risk, Cavalier King Charles Spaniels.
- Toxoplasmosis—middle-aged male cats.

SIGNS

General Comments

Depends on severity of disease.

Historical Findings

Tachypnea, coughing, respiratory difficulty, exercise intolerance.

Physical Examination Findings

- Open-mouth breathing, end-inspiratory and early expiratory crackles, orthopnea,

cyanosis, ± hemoptysis.

- Animals with paraquat toxicity often display vomiting, oliguria, diarrhea, and oropharyngeal ulcers (± hyperexcitability and neurologic signs in the early phase).
- Retinitis, uveitis, neurologic signs, and/or gastrointestinal signs can be seen with toxoplasmosis.

CAUSES & RISK FACTORS

Congenital

BOOP secondary to primary ciliary dyskinesia.

Metabolic

Uremic pneumonitis ± BOOP, hepatic disease, or pancreatitis in cats.

Neoplastic

Bronchiectasis or BOOP, pulmonary carcinoma associated with pulmonary fibrosis in cats.

Idiopathic

Pulmonary interstitial fibrosis and DIP, some cases of EnLP, BOOP, primary pulmonary alveolar proteinosis.

Inflammatory

EnLP most common in cats with bronchitis, bronchiectasis or necrotizing bronchiolitis.

Infectious

- Dogs—canine distemper virus, canine adenovirus-2, H3N2 or H3N8 influenza virus, *Leishmania chagasi*, *Pneumocystis jirovecii*, *Angiostrongylus vasorum*, *Toxoplasma*.
- Cats—*Aelurostrongylus abstrusus*, *Toxoplasma*, FIV, influenza virus (anthropozotic transmission described).

Toxic

Inhalation of dusts, gases, or vapors, thiacetarsemide, aspiration of petroleum-based products in cats, secondary PAP, paraquat toxicity, silicosis, asbestosis.

Vascular

Thromboembolism, circulating larval migrants

RISK FACTORS

- Immunosuppression, inadequate vaccination or preventative, and exposure to other animals can predispose to viral or parasitic pulmonary disease.
- Inhalation of toxic material or gases may predispose to pulmonary fibrosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Airway disease
- Bronchopneumonia
- Heartworm disease
- Embolic pneumonia
- Granulomatous pneumonia
- Neoplasia
- Cardiac disease

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilia, eosinophilia, lymphocytosis, hyperglobulinemia possible; polycythemia if chronically hypoxic.
- Thrombocytopenia with *Angiostrongylus vasorum*.
- Neutropenia or high liver enzymes and hyperbilirubinemia

possible with *Toxoplasma*.

- High liver enzymes and hyperbilirubinemia (dogs only)
- possible with hepatotoxicity due to thiacetarsemide therapy ± paraquat toxicity.
- Severe azotemia and isosthenuria with uremic pneumonitis.

OTHER LABORATORY TESTS

- Arterial blood gas measurement and calculation of alveolar-arterial (A-a) gradient to assess degree of respiratory impairment; $\text{PaO}_2 < 80 \text{ mmHg}$ indicates hypoxemia, A-a gradient > 15 is abnormal.
- Serologic and other tests for infectious causes.
- Fecal Baermann examination for *Aelurostrongylus abstrusus* or *Angiostrongylus vasorum*.
- Toxicologic analysis of the urine or serum to diagnose paraquat toxicity in live animals.
- Coagulation testing with *Angiostrongylus*.
- Immunodiagnostic testing for exposure to *Leishmania*.

IMAGING

Thoracic Radiographic Findings

- A focal or diffuse, mild to severe interstitial to bronchial to alveolar pattern can be present, dilated bronchi with bronchiectasis or BOOP.
- Right heart ± PA enlargement and hepatosplenomegaly if secondary pulmonary hypertension.
- Pleural effusion occasionally seen.

Computed Tomography

CT characteristics include ground-glass opacification, peribronchovascular thickening, and parenchymal banding.

DIAGNOSTIC PROCEDURES

- Electrocardiography—arrhythmias can occur with severe hypoxia or systemic disease.
- Open lung biopsy required for definitive diagnostic test.
- Endotracheal or transtracheal wash, bronchoscopy with bronchoalveolar lavage, and/or fine-needle aspirate of lungs might be useful (e.g., may visualize trophozoite or cysts of *Pneumocystis jirovecii* or *Toxoplasma* or see L1 larvae with *Aelurostrongylus abstrusus* or *Angiostrongylus vasorum*); cultures can reveal secondary bacterial infections. With pulmonary alveolar proteinosis, an opaque white material is retrieved from airway wash.
- Echocardiogram can document pulmonary hypertension.

PATHOLOGIC FINDINGS

- *Aelurostrongylus abstrusus*—greenish nodules in lungs, eggs and larvae in the alveolar spaces with foreign body type reaction (surrounded by mononuclear cells and giant cells), submucosal gland hypertrophy, and smooth muscle hypertrophy in airway and vessel walls.
- *Angiostrongylus vasorum*—thrombosing arteritis and fibrotic peribronchitis, parasites in arterioles.
- BOOP—polypoid plugs of loose, fibrous tissue fill bronchioles and alveoli, foamy macrophages within alveoli, variable inflammatory infiltrate with type II pneumocyte reactivity.
- Interstitial lung

PNEUMONIA, INTERSTITIAL

(CONTINUED)

disease in the West Highland white terrier—diffuse, mature pulmonary fibrosis (most common in caudal lung lobes), multifocal areas of accentuated subpleural and peribronchiolar fibrosis, thickening of the alveolar septum due to excess collagen in the extracellular matrix. • IPF-like disease in the cat lacks inflammation and may be associated with pulmonary carcinoma. Typical changes include multifocal distribution of interstitial fibrosis with foci of fibroblast/myofibroblasts, alveolar epithelial metaplasia, and interstitial smooth muscle metaplasia/hyperplasia.

- *Leishmania chagasi* is characterized by chronic and diffuse interstitial pneumonitis and thickened inter-alveolar septae in some cases.
- Lipid pneumonias—macroscopic lesions can include subpleural, parenchymal, or perivascular white, firm nodules. Mixed pattern of inflammation with accumulation of lipid-laden macrophages, cholesterol clefts, and multinucleated giant cells.
- Paraquat toxicity—lungs are heavy, edematous, and hemorrhagic. Emphysematous bullae and pneumomediastinum are commonly present.
- PAP—alveolar spaces are distended with a PAS staining eosinophilic proteinaceous material. Intra-alveolar cholesterol clefts and mucus-laden macrophages with mild mixed-inflammatory infiltrates are common.
- Uremic pneumonitis—pulmonary edema and calcification of smooth muscle and/or alveolar walls.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient care and monitoring for animals with evidence of respiratory distress.

NURSING CARE

- Oxygen therapy.
- Minimize exposure to house dust, vapors, chemical fumes, or tobacco smoke.
- Humidification of inspired air.
- PAP—therapeutic bronchoalveolar lavage.
- Antimicrobial therapy—as indicated by results of culture and susceptibility.

ACTIVITY

- Exercise restriction as needed.
- Harness preferred to collar.

DIET

Weight loss if obese.

CLIENT EDUCATION

Palliative care employed.

SURGICAL CONSIDERATIONS

Definitive diagnosis of interstitial lung disease requires histopathology; it is best preceded by CT to determine an appropriate site for biopsy.

MEDICATIONS

DRUG(S) OF CHOICE

- Inhaled corticosteroids (e.g., fluticasone, 1 puff q12h) using a spacing chamber and facemask.
- Bronchodilators can be helpful in reducing respiratory effort: extended-release theophylline (dog, 10 mg/kg PO q12h; cat, 15–19 mg/kg q24h in the evening), terbutaline sulfate (dog or cat, 0.01 mg/kg SC, IM, or IV q8–12h). Inhaled bronchodilators can also be used.
- Aeluropromys abstrusus*—fenbendazole 50 mg/kg PO q24h for 14 days (off label), ivermectin (400 µg/kg, SC, twice at a 3-week interval), or spot-on selamectin 45 mg (once).
- Angiostrongylus vasorum*—levamisole, 20–40 mg/kg PO q48h for 5 treatments ± aspirin ± corticosteroids. Alternative therapies include fenbendazole, mebendazole, and ivermectin.
- BOOP—corticosteroid use has been reported.
- Idiopathic pulmonary fibrosis—no effective therapy.
- Anti-inflammatory steroid therapy with prednisolone (0.5–1 mg/kg PO q24–48h often used) and bronchodilators, antitussives, or antibiotics if indicated. Pirfenidone not yet investigated.
- Leishmania chagasi*—meglumine antimonate 100 mg/kg IV or SC q24h for 3–4 weeks or sodium stibogluconate 30–50 mg/kg IV or SC q24h for 3–4 weeks.
- Paraquat toxicity—vomition and activated charcoal therapy is indicated if recent ingestion is known. Supportive care, diuresis using furosemide (most effective in the first 3 days following ingestion), ± immunosuppressive dexamethasone, cyclophosphamide, nicotinamide, superoxide dismutase, and vitamin A.

CONTRAINDICATIONS/PRECAUTIONS

Immunosuppressive therapy can exacerbate secondary infections.

FOLLOW-UP

PATIENT MONITORING

- Have owners observe clinical response to therapy, monitor respiratory rate and effort.
- Repeat physical examination/chest auscultation, chest radiographs, lab test, and arterial blood gas analysis as indicated.

PREVENTION/AVOIDANCE

- Avoid proximity to toxic fumes or paraquat.
- Vaccinate and deworm animals.
- Appropriate insect and rodent control.
- Avoid ingestion by pets of frogs, lizards, rodents, and birds.

POSSIBLE COMPLICATIONS

- Secondary pulmonary infections possible.
- Pulmonary hypertension can develop.

EXPECTED COURSE AND PROGNOSIS

- Guarded to poor with interstitial pneumonia caused by infectious agents or uremic pneumonitis.
- Poor long-term prognosis with idiopathic pulmonary fibrosis (mean survival time is 17 months in dogs and 5.5 months in cats).
- Paraquat toxicity—commonly fatal in dogs.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Pulmonary carcinoma—associated with IPF in cats.

AGE-RELATED FACTORS

Young, free-roaming animals are more likely to succumb to infectious diseases.

ZOONOTIC POTENTIAL

Toxoplasmosis, if animal is shedding oocysts.

PREGNANCY/FERTILITY/BREEDING

Transplacental infection with *Toxoplasma* and canine distemper virus is possible.

SEE ALSO

- Bronchiectasis
- Canine Distemper
- Canine Infectious Respiratory Disease
- Feline Immunodeficiency Virus Infection
- Leishmaniasis
- Primary Ciliary Dyskinesia
- Toxoplasmosis

ABBREVIATIONS

- BOOP = bronchiolitis obliterans with organizing pneumonia
- CT = computed tomography
- DIP = desquamative interstitial pneumonitis
- EnLP = endogenous lipid pneumonia
- FIV = feline immunodeficiency virus

PNEUMOTHORAX

BASICS

DEFINITION

- Air accumulation in the pleural space; categorized as traumatic or spontaneous.
- Closed pneumothorax—no defects in the thoracic wall.
- Open pneumothorax—defect in the thoracic wall resulting in communication of the pleural space with the atmosphere.
- Tension pneumothorax—where pleural pressure in a closed pneumothorax exceeds atmospheric pressure; created by unidirectional transfer of air into the pleural space.

PATHOPHYSIOLOGY

- The pleural space is normally a potential space between visceral and parietal pleura containing a thin layer of fluid that contributes to “tethering” of the lungs to the thoracic wall. Air accumulation in the pleural space causes the lungs to collapse away from the thoracic wall.
- Closed pneumothorax—air leakage from the pulmonary parenchyma, large airway, or esophagus.
- Tension pneumothorax—typically due to a pleural or pulmonary flap-like defect that opens on inspiration to allow leakage of air into the pleural space and closes during expiration. Development of high intrathoracic pressure can reduce venous return to the heart.
- Open pneumothorax—may or may not have associated pulmonary pathology; pleural pressure equals atmospheric pressure, leading to lung collapse.
- Spontaneous pneumothorax associated with underlying pulmonary disease that ruptures, allowing air leakage.
- Pneumothorax is usually bilateral disease due to mediastinal fenestrations.

SYSTEMS AFFECTED

- Respiratory • Cardiovascular

INCIDENCE/PREVALENCE

Traumatic pneumothorax occurs in > 40% of cases with chest trauma and 11–18% of dogs and cats presented for vehicular trauma. Pneumothorax has been reported in ~ 25% of cases with intrathoracic grass awns and 70% of dogs with thoracic bite wounds.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Spontaneous pneumothorax—more common in large, deep-chested dogs. Siberian huskies may be overrepresented.

SIGNS

Historical Findings

- Traumatic—recent trauma, thoracocentesis, jugular venipuncture, lung aspirate, thoracotomy, mechanical ventilation, neck surgery. Recent anesthesia and intubation raises the possibility of tracheal trauma or

pulmonary barotrauma.

- Spontaneous—may or may not have previous history of pulmonary disease; usually acute, but can have a slowly progressive onset.

Physical Examination Findings

- Respiratory distress (tachypnea, increased respiratory effort, +/- orthopnea).
- Shallow, rapid abdominal breathing common.
- Decreased to absent breath sounds dorsally (difficult to appreciate with severe distress).
- Cyanosis.
- Tachycardia.

Traumatic Pneumothorax

- Signs of trauma (blunt or penetrating thoracic wall injury) or hypovolemic shock (pale mucous membranes, prolonged capillary refill time, altered mentation, poor pulse quality, tachycardia, decreased extremity compared to core temperature).
- Subcutaneous emphysema in some cases with pneumomediastinum and/or tracheal trauma.

CAUSES

- Traumatic: blunt trauma, penetrating thoracic or cervical injuries, post-thoracocentesis or thoracotomy, esophageal perforation, endotracheal tube—associated tracheal trauma, mechanical ventilation, pulmonary aspirate.
- Spontaneous: bullous emphysema (most common in dogs), pulmonary bullae or bleb.
- Migrating pulmonary foreign body, pulmonary neoplasia, pulmonary abscess, feline asthma, bronchopneumonia, mycotic pulmonary granuloma, parasitic pulmonary disease (*Paragonimus*, *Dirofilaria immitis*—pulmonary bullae rupture), congenital pulmonary cyst, congenital lobar emphysema, secondary to lung lobe torsion.
- Extension of pneumomediastinum.

RISK FACTORS

- Trauma
- Thoracocentesis
- Thoracotomy
- Overinflation of endotracheal cuff
- Excessive airway pressure during ventilation
- Pulmonary disease/pathology
- Migrating grass awns

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pleural effusion
- Diaphragmatic hernia
- Pulmonary parenchymal disease (i.e., pulmonary contusions, pneumonia)

CBC/BIOCHEMISTRY/URINALYSIS

Neutrophilia with a left-shift if pulmonary infection or inflammation.

OTHER LABORATORY TESTS

- Arterial blood gases—hypoxemia; hypocapnia or hypercapnia can occur.
- Fecal sedimentation or zinc sulfate centrifugation-flotation for *Paragonimus*.

IMAGING

Thoracic Radiography

- Delay until patient is stable; may not be able to get more than one view.
- Air in pleural space, pulmonary vascular pattern does not extend to the chest wall, cardiac silhouette elevated off the sternum.
- Pulmonary pathology can be obscured by lung lobe collapse; often need to repeat radiographs following thoracocentesis.
- Traumatic pneumothorax—evaluate for other traumatic injury such as contusions, rib fractures, diaphragmatic hernia, hemothorax, foreign bodies.
- Spontaneous pneumothorax—evaluate for any sign of parenchymal pathology.
- Right lateral horizontal beam results in the highest rate of detection and severity gradation while VD/DV views have the lowest rate.

Thoracic Ultrasound

- Pneumothorax evidenced by loss of the “glide sign.”
- Sensitivity of 78% and specificity of 93% compared to thoracic radiographs in identification of traumatic pneumothorax in dogs.

Thoracic Computed Tomography

- Used preoperatively to improve localization of pulmonary pathology in cases with spontaneous pneumothorax.
- CT can fail to detect pulmonary bullae prior to surgical exploration; larger pulmonary bullae more readily identified than smaller bullae.

DIAGNOSTIC PROCEDURES

- Thoracocentesis—confirms diagnosis; remove maximal amount of air from pleural space.
- Bronchoscopy—consider if evidence of tracheal or large airway trauma.

P

PATHOLOGIC FINDINGS

- Will vary depending on underlying disease.
- Gross evaluation—may be able to visualize pulmonary blebs, pulmonary or airway tears, pulmonary parenchymal disease or masses.
- Histopathology—blebs are most commonly found at the apex and are contained entirely within the pleura; bullae are lined by pleura, fibrous pulmonary tissue, and emphysematous lung.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient care until air accumulation has stopped or has stabilized.
- Animals in respiratory distress must have thoracocentesis and a maximal amount of air removed.
- Thoracocentesis can be performed with an intravenous catheter attached to an extension set and stopcock or via a butterfly needle.
- ALWAYS provide oxygen therapy until patient is stabilized.
- If large open chest wound—cover as cleanly as possible with airtight bandage (use of sterile lubricant/ointment around periphery of wound). Must

PNEUMOTHORAX

(CONTINUED)

be accompanied by chest tube placement; will require surgical closure once animal is stable.

- Tube thoracostomy—use if unable to stabilize with thoracocentesis or repeated thoracocentesis required for continued pneumothorax; chest tube placement (under local or general anesthesia)—skin entrance site aseptically prepared in dorsal caudal quadrant of lateral thorax; skin incision similar in size to the tube is made over rib space 11–12 or 12–13; skin is then pulled cranially by an assistant so that the incision now lies over rib spaces 7–8 or 8–9. Chest tube is passed into pleural space, aiming cranoventrally; skin can then be released and a subcutaneous tunnel is formed. Purse string suture around insertion site and secure tube with finger trap suture pattern; thoracic radiographs should be performed after chest tube placement to ensure proper positioning.
- If pneumothorax is rapidly accumulating—use continuous chest tube suction via one-, two- or three-bottle drainage system with an underwater seal. If pneumothorax is not severe or is resolving—use intermittent tube aspiration. • In emergency situation of life-threatening tension pneumothorax—consider emergency thoracotomy to convert problem to an open pneumothorax; animal can then be intubated and ventilated with positive pressure until stabilized.
- Open traumatic pneumothorax—surgery as soon as patient is stable.
- Closed traumatic pneumothorax—rarely requires surgical intervention.
- Spontaneous pneumothorax—early surgical intervention recommended in dogs; exploratory thoracotomy often performed via median sternotomy if location of lesion is unknown. Pleural access port placed for medical management.

NURSING CARE

• Intravenous fluids required in most cases of trauma.

- Appropriate pain control.
- Chest tube maintenance—ensure all connections are airtight (cable ties are excellent for securing connections); ensure that tube is attached to animal at two points to reduce chance of inadvertent tube removal. Clean tube site and change dressing once daily. Do not allow animal to chew at chest tube.

ACTIVITY

Strict rest for at least a week following resolution of pneumothorax in an effort to minimize the chance of recurrence.

CLIENT EDUCATION

- Traumatic pneumothorax—discuss possibility of a chest tube and need for hospitalization; some animals require surgery.
- Spontaneous pneumothorax—recommend early surgical intervention in most canine cases. Discuss possibility of underlying pulmonary disease that can make resolution challenging and recurrence possible. Warn owner that even with thoracotomy, the source

of the pneumothorax may not be found and recurrent disease is possible.

SURGICAL CONSIDERATIONS

- Do not use positive-pressure ventilation for closed pneumothorax. Place chest tube prior to ventilation or await thoracotomy prior to ventilation.
- Thoracoscopy—may allow visualization of local lesion; allows instillation of substances for pleurodesis.
- Thoracotomy—if lesion is not evident, can fill thorax with saline and look for bubbles as sign of a leak. Greater than one lesion is not uncommon. Partial or full lung lobectomy for localized lesions. Traumatic lacerations can be sutured. In some cases the location of the leak may not be evident at surgery. Thoracostomy tube should be placed at time of surgery in all patients.
- Pleurodesis with mechanical abrasion of the pleura or instillation of an inflammatory substance, such as talc, into the pleural space (success rate is believed to be poor).
- Autologous blood-patch treatment for persistent pneumothorax is a simple and relatively safe procedure that can be considered in patients that have failed conservative or surgical management.

MEDICATIONS

DRUG(S)

Judicious use of pain control.

PRECAUTIONS

Beware excess respiratory depression with opiates.

FOLLOW-UP

PATIENT MONITORING

- Respiratory rate—increased rate suggests recurrence of pneumothorax.
- Serial thoracic radiographs to quantitate accumulation of air.
- Pulse oximetry if breathing room air can help determine oxygenation status. Arterial blood gases give the best evaluation of oxygenation status if lung disease is present.
- Central venous (jugular) blood gases can be used to evaluate ventilation status via PvCO₂.
- Rate of air production from chest tube—on continuous drainage with a three-bottle suction system need to count bubbles/minute produced in middle chamber; if intermittent aspiration, can quantitate with syringe.

PREVENTION/AVOIDANCE

Keep pets confined—less likely to be injured.

POSSIBLE COMPLICATIONS

- Death from hypoxemia and cardiovascular compromise.
- Incorrect placement of chest tube or trauma associated with thoracocentesis—lung lobe laceration, cardiac puncture, diaphragmatic laceration, liver

trauma.

- Pleural infection from thoracocentesis or chest drain.

EXPECTED COURSE AND PROGNOSIS

- Traumatic pneumothorax—if thoracic trauma is not severe, the prognosis is good with thoracocentesis ± chest drain placement. With severe thoracic trauma, patient can deteriorate despite all efforts to stabilize it—usually because of severe pulmonary contusions.
- Spontaneous pneumothorax—prognosis depends on underlying cause. If a single, focal lesion can be surgically resected, prognosis is good. If unable to locate lesion or diffuse or neoplastic pulmonary disease is present—prognosis is poor.

MISCELLANEOUS

SYNOMYMS

Punctured lung

SEE ALSO

- Dyspnea and Respiratory Distress • Panting and Tachypnea

PODODERMATITIS

BASICS

DEFINITION

An inflammatory, multifaceted complex of diseases that involves the feet of dogs and cats.

PATOPHYSIOLOGY

- Depends on the underlying cause including infection, allergy, auto-immune dermatoses, endocrine or metabolic disease, neoplasia, and environmental disease.
- Psychogenic dermatosis (rare cause).

SYSTEMS AFFECTED

Skin/Exocrine

INCIDENCE/PREVALENCE

- Dogs—common
- Cats—uncommon

SIGNALMENT

Species

Dogs and cats

Breed Predilections

- Dogs: short-coated breeds—most commonly affected; English bulldog, Great Dane, basset hound, mastiff, bull terrier, boxer, dachshund, Dalmatian, German shorthaired pointer, and Weimaraner.
- Dogs: long-coated breeds—German shepherd dog, Labrador retriever, golden retriever, Irish setter, and Pekingese.
- Cats—none.

Mean Age and Range

- Any age.
- Young dogs—hypersensitivity, demodicosis, infection, follicular cysts, auto-immune dermatoses.
- Old dogs—also neoplasia or systemic diseases.

Predominant Sex

- Dogs—male
- Cats—none

SIGNS

General Comments

History and physical findings vary considerably depending on the underlying cause.

Historical Findings

- Environment and general husbandry—indoor vs. outdoor, working dog vs. pet, unsanitary conditions, other pets affected, trauma, contact irritants, hookworms.
- Age of onset.
- Seasonality—atopic dermatitis, allergic contact dermatitis, or irritant contact dermatitis.
- Lesions elsewhere on the body.
- Lesions confined to just the feet; note which feet are affected and what parts of the feet are affected (entire foot, one area, or one toe).
- Response to previous therapy—antibiotics, antifungals, and corticosteroids.
- Diet, travel history, and other medical problems.

Physical Examination Findings

Infectious (Dogs)

- Erythema and edema, nodules, inflammatory plaques (fungal “kerions”), ulcers, fistulae, hemorrhagic bullae, or serosanguineous or seropurulent discharge.
- Feet—may be grossly swollen; may have

pitting edema of the metacarpal and metatarsal areas.

- Skin—may be alopecic and moist from constant licking; patient may have some degree of pain, pruritus, and paronychia.
- Regional lymph nodes may be enlarged.

Infectious (Cats)

- Painful paronychia, involving one or more claws.
- Higher incidence of nodular, often ulcerated lesions, compared to dog.
- Footpads and periungual areas—commonly involved.
- Interdigital spaces—seldom affected.
- Scaly and crusted lesions—occasionally seen.

Allergic (Dogs)

- Erythema and alopecia (dorsal or ventral or both) secondary to pruritus; dorsal surfaces may be more severely affected than ventral surfaces.
- Interdigital erythema.
- Salivary staining.
- Allergic contact dermatitis—an uncommon cause; dermatitis of the ventral interdigital surfaces is usually worse.

Allergic (Cats)

- Single or multiple, exudative or ulcerated, pruritic plaques of the digits, periungual, and interdigital spaces.
- Eosinophilic granuloma complex lesions.

Immune-Mediated (Dogs)

- Crusts and ulcerations—most common lesions; occasional vesicles or bullae.
- All feet may be affected, especially the nailbeds and footpads.
- Hyperkeratotic and erosive dermatitis of the footpad margins—common finding in pemphigus foliaceus.

Immune-Mediated (Cats)

- Lesions—generally involve the footpad, including hyperkeratosis and ulceration.
- Lameness and paronychia with ungual fold exudate.

Endocrine/Metabolic (Dogs)

- Lesions—usually consistent with secondary infection.
- Hepatocutaneous syndrome (superficial necrolytic dermatitis)—rare condition; skin disease precedes the onset of signs of internal disease; hyperkeratosis (with adherent crusts), fissures, and ulceration of the footpads.

Endocrine/Metabolic (Cats)

- Cutaneous xanthomatosis—seen with diabetes mellitus; whitish nodules resembling candle wax.

Neoplastic

- Dogs—nodules, variably ulcerated, scale, erythema, depigmentation of the footpads; may have only one digit involved (nailbed carcinoma, ungual keratoacanthoma); multiple feet involvement with nailbed squamous cell carcinoma, epitheliotrophic lymphoma; pruritus variable.
- Cats—nodules; variably ulcerated and painful; localized destruction variable, depends on tumor type; foot pad tumors may develop *de novo* or be metastatic carcinoma.

Environmental (Dogs and Cats)

- Depends on underlying cause.
- Lesions—involve one digit or foot (foreign body, trauma) or multiple digits (irritant

contact dermatitis, thallium toxicity, housing on rough surface or in moist environment).

- Chronic interdigital inflammation, ulceration, pyogranulomatous abscesses, draining tracts, or swelling, with or without pruritus.

Miscellaneous

- Hyperkeratosis of the footpads (dogs)—associated with several diseases (e.g., zinc-responsive dermatosis, generic dog food dermatosis), and idiopathic digital hyperkeratosis.
- Interdigital follicular cysts—interdigital nodules, fistulae and draining tracts dorsally; most often only the front feet; affects the lateral interdigital space; history of recurrence and poor to no response to antibiotics, with an area of alopecic, thickened skin with comedones ventrally.
- Nodules without draining tracts (dogs)—associated with sterile pyogranuloma in several breeds and nodular dermatofibrosis of German shepherd dogs and golden retrievers.
- Hypomelanosis of the footpads (cats)—associated with vitiligo.
- Hypermelanosis of the footpads (cats)—associated with lentigo simplex.
- Acral mutilation and analgesia—seen in pointers (English and German shorthaired) and spaniels (English springer and French)—cause unknown; often runts of the litter; no known treatment; dogs are usually euthanized within days to months of diagnosis.

CAUSES

Infectious (Dogs)

- Bacterial—*Staphylococcus pseudintermedius*, *Pseudomonas* spp., *Proteus* spp., *Mycobacterium* spp., *Nocardia* spp., *Actinomyces* spp.
- Fungal—dermatophytes, intermediate mycoses (sporotrichosis, mycetoma), deep mycoses (blastomycosis, cryptococcosis).
- Parasitic—*Demodex canis*, *Pelodera strongyloides*, hookworms.
- Protozoal—leishmaniasis.

Infectious (Cats)

- Bacterial—same as dog; *Pasteurella* spp.
- Fungal—same as dog, excluding blastomycosis.
- Parasitic—*Neotrombicula autumnalis*, *Notoedres cati*, *Demodex* spp.
- Protozoal—*Anatrichosoma cutaneum*.

Allergic

- Dogs—atopy; food hypersensitivity; allergic contact dermatitis.
- Cats—atopy; rare for flea allergic dermatitis, food hypersensitivity, or contact dermatitis to involve paws (except lesions of eosinophilic granuloma complex).

Immune-Mediated

- Dogs—pemphigus foliaceus; systemic lupus erythematosus; erythema multiforme; cold agglutinin disease; pemphigus vulgaris; bullous pemphigoid; epidermolysis bullosa acquisita, symmetrical lupoid onychodystrophy.
- Cats—pemphigus foliaceus; systemic lupus erythematosus; erythema multiforme; vasculitis; cold agglutinin disease; plasma cell pododermatitis.

P

PODODERMATITIS

(CONTINUED)

Endocrine/Metabolic

- Dogs—hypothyroidism; hyperadrenocorticism; hepatocutaneous syndrome (superficial necrolytic dermatitis).
- Cats—hyperthyroidism; hyperadrenocorticism; cutaneous xanthomatosis (secondary to diabetes mellitus); endocrine pododermatitis rare.

Neoplastic

- Higher incidence in cats than in dogs.
- Dogs—squamous cell carcinoma; epitheliotrophic lymphoma, melanoma; mast cell tumor; keratoacanthoma; inverted papilloma; eccrine adenocarcinoma.
- Cats—papilloma; spinocellular epithelioma; trichoepithelioma; fibrosarcoma; malignant fibrous histiocytoma; metastatic primary adenocarcinoma of the lung; other metastatic carcinoma.

Environmental

- Dogs—irritant contact dermatitis; trauma; concrete and gravel dog runs; excessive exercise; clipper burn; foreign bodies (grass awns, bristle-like hairs of short-coated dogs); thallium toxicity.
- Cats—irritant contact dermatitis; foreign bodies; thallium toxicity.

Miscellaneous

- Dogs—sterile interdigital granuloma; interdigital follicular cyst; see “Physical Examination Findings.”
- Cats—see “Physical Examination Findings.”

RISK FACTORS

- Lifestyle and general husbandry conditions—fluence development.
- Excess exercise, abrasive or moist housing, poor grooming, and/or lack of preventive medical care may predispose an animal or exacerbate condition.
- Body size, foot conformation, and breed influence the development of interdigital follicular cysts.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

See “Signs” and “Causes”

CBC/BIOCHEMISTRY/URINALYSIS

- Depends on the underlying cause
- Rarely significant

OTHER LABORATORY TESTS

- Depends on the underlying cause
- Endocrine tests, serology, or immune studies

IMAGING

Depends on the underlying cause

DIAGNOSTIC PROCEDURES

- Skin scrapings or hair plucks—demodicosis.
- Fungal culture—dermatophytosis.
- Exudate or pustule smear—bacterial or yeast infection.
- Culture and sensitivity from exudates and/or biopsy tissues.
- Dogs—biopsies indicated if skin scrapings are negative and lesions (nodules, draining tracts)

are seen; samples from the ventral surface with draining tracts may reveal follicular cysts and pyogranulomatous inflammation leading to the dorsal surface.

- Cats—biopsies may be indicated in all cases; pedal dermatosis is relatively rare.
- Restricted-ingredient food trial—food hypersensitivity.
- Intradermal testing—atopy.
- Endocrine assays—hypothyroidism, hyperadrenocorticism, diabetes mellitus.

PATHOLOGIC FINDINGS

Depends on the underlying cause

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient, unless surgery is indicated.

NURSING CARE

Foot soaking, hot packing, and/or bandaging may be necessary, depending on cause.

ACTIVITY

Depends on severity of the lesions and on the underlying cause.

DIET

Restricted-ingredient food trial if indicated.

CLIENT EDUCATION

- Depends on underlying cause and severity of condition.
- Discuss husbandry and preventive medical practices.
- Allergic, immune-mediated, or endocrine etiologies can be managed but not cured.

SURGICAL CONSIDERATIONS

- Melanoma and squamous cell carcinoma—very poor prognosis; early diagnosis necessitates amputation of the digit(s) or paw.
- Infectious—may benefit from surgical debridement of devitalized tissue before medical therapy.
- Recurrent draining tracts caused by interdigital follicular cysts may be cleared with laser ablation.

MEDICATIONS DRUG(S) OF CHOICE

- Depend on the underlying cause and secondary infections; see related chapters for dosages of appropriate medications
- Antibiotics based on culture and sensitivity; 4–6 weeks minimum
- Antifungal medications
- Anti-inflammatory or immunosuppressive dosage of corticosteroids
- Immunomodulatory medications
- Chemotherapeutic agents
- Hormone-replacement therapy
- Zinc supplementation
- Intravenous amino acids

PRECAUTIONS

Depend on the treatment protocol selected for the underlying cause; see specific drugs and their precautions.

POSSIBLE INTERACTIONS

Depends on the underlying cause and treatment protocol selected.

FOLLOW-UP

PATIENT MONITORING

Depends on the underlying cause and treatment protocol selected.

PREVENTION/AVOIDANCE

- Environmental cause—good husbandry and preventive medical care.
- Allergic cause—avoidance (food) or immunotherapy (atopy), if possible.

POSSIBLE COMPLICATIONS

Depends on the underlying cause and treatment protocol selected.

EXPECTED COURSE AND PROGNOSIS

- Success of therapy depends on finding the underlying cause; often the cause is unknown; even when the cause is known, management can be frustrating owing to relapses or lack of affordable therapeutics.
- Often the disease can only be managed and not cured.
- Referral to dermatologist often appropriate.
- Surgical intervention is sometimes necessary.

MISCELLANEOUS

AGE-RELATED FACTORS

Depends on the underlying cause.

ZOONOTIC POTENTIAL

Depends on the underlying cause; uncommon.

PREGNANCY/FERTILITY/BREEDING

Avoid systemically administered corticosteroids, antifungals, chemotherapeutic agents, azathioprine, and certain antimicrobials (e.g., enrofloxacin) in pregnant animals.

POISONING (INTOXICATION) THERAPY

BASICS

DEFINITION

- Acutely ill patients are often diagnosed as poisoned when no other diagnosis is obvious.
- Direct initial efforts toward stabilizing the patient. Remember ABCs (airway, breathing, circulation).
- Make the diagnosis after determining preexisting conditions and controlling clinical signs.
- Goals of treatment—provide emergency intervention; prevent further exposure; prevent additional absorption; apply specific antidotes; hasten elimination; provide supportive measures; offer client education.
- Suspected intoxication—suspected toxic materials and specimens may be valuable from a medical-legal aspect; maintain a proper chain of physical evidence; keep excellent medical records.
- Valuable time can be saved by applying the appropriate treatment for a suspected or known intoxicant.

Initial Instructions to Client

- Transport patient to a veterinarian as soon as possible.
- Delayed transport—keep patient warm; avoid any other stress.
- Warn onlookers about the condition of the patient and danger to themselves.
- May need to muzzle the patient.
- Transport urine (if available), uncontaminated vomitus and suspected toxic materials and their containers to the veterinary facility.
- Use clean plastic containers or clean glass jars for the specimens.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Definitive diagnosis—difficult; animals come in contact with a vast array of toxicants. ASPCA Animal Poison Control Center; Pet Poison Helpline; local poison control center; state diagnostic laboratory. Provide great value for cases of suspected intoxication, especially when labels or containers are available.
- When suspected compound and clinical signs do not concur—treat the signs; disregard the label.
