- Confirmation of diagnosis—chemical analysis (often after the fact); accurate diagnosis and detailed records may help with future patients affected by the same toxicant and are invaluable in medico-legal proceedings.

TREATMENT

SUPPORTIVE

- Control body temperature.
- Maintain respiratory and cardiovascular function.
- Control acid-base balance.
- Alleviate pain.
- Control CNS disorders—see specific chapters.

EMERGENCY

- Establish a patent airway.
- Artificial respiration.
- Cardiac massage—external or internal.
- Apply defibrillation techniques.
- After stabilization—may proceed with more specific therapeutic measures.

PREVENT ABSORPTION

- Major treatment factor.
- Remove patient from the affected environment, especially with inhaled toxins.
- Protect caregivers as well from inhaled toxins.
- Other available measures—washing or bathing; judicious use of emetics; gastric lavage; adsorbents and cathartics.

Washing Skin or Bathing

- External toxicants.
- Wash patient's skin or bathe to remove the noxious agent.
- CAUTION: avoid contamination of the people handling the patient.

Emetics

- Of little value beyond 1–2 hours after ingestion of most toxicants; material will have passed into the duodenum.
- Do not induce in unconscious or severely depressed patients or after ingestion of strong acids, alkalis, petroleum distillates, tranquilizers, or other antiemetics.
- Apomorphine—most effective and reliable for use in dogs; availability at any given time unknown; 0.03–0.04 mg/kg IV or IM; emesis occurs in 4–6 minutes; control adverse clinical signs caused by apomorphine with an appropriate intravenous narcotic antagonist (e.g., naloxone at 0.01–0.04 mg/kg).
- 3% Hydrogen peroxide—emetic of choice for home use; 2.2 mL/kg PO, do not exceed 45 mL in dogs; ineffective in cats, not always effective in dogs.
- Ipecac—little efficacy and no longer recommended; never use when activated charcoal is part of the therapeutic regimen.
- Xylazine—most successful in cats (0.44–1 mg/kg IM or SQ). Can be reversed with an alpha₂-adrenergic antagonist such as atipamezole or yohimbine.
- Salt or salt solution is NOT recommended. Salt can be toxic.

Activated Charcoal

- Does not detoxify but prevents absorption if properly used.
- Highly absorptive of many toxicants—organophosphate insecticides; other insecticides; rodenticides; mercuric chloride; strychnine; other alkaloids (e.g., morphine and atropine); barbiturates; ethylene glycol.
- Ineffective against alcohols, chlorate, cyanide, heavy metals, petroleum distillates, sodium chloride, and xylitol.
- Administered after emetic—increases efficacy of toxicant elimination.
- Use easily cleansed area when administering.
- Dosage 1–5 g/kg body weight; generally a single dose administration but some situations require multidose administration (1–2 g/kg PO q4–6h for 24 hours).
- Generally administered with a cathartic such as sorbitol or sodium sulfate; only the first dose should contain a cathartic.
- Hypernatremia has been reported after administration of activated charcoal, especially when a cathartic (sorbitol) is used in a dehydrated patient.

Gastric Lavage

- Effective means of emptying the stomach, but must be used in the first 1–2 hours.
- An appropriate size, cuffed endotracheal tube must be in place prior to starting the lavage procedure.
- Orogastic (stomach) tube size—use the largest possible; a good rule: use the same size as the cuffed endotracheal tube (1 mm = 3 Fr).
- Volume of water or lavage solution for each washing—5–10 mL/kg body weight.
- Infusion cycle—repeated more than 5–10 times.
- After the last cycle and prior to the removal of the orogastric tube, activated charcoal with a cathartic should be instilled.
- Precautions: (1) use low pressure to prevent forcing the toxicant into the duodenum; (2) reduce the infused volume in obviously weakened stomachs (e.g., in a patient that has ingested a caustic or corrosive toxicant); (3) do not force the stomach tube through either the esophagus or the stomach wall.

P

Oils

- Mineral or vegetable oil—valuable for lipid-soluble toxicants.
- Mineral oil (liquid petrolatum)—inert; less likely to be absorbed.
- Use as a cathartic.

Enemas

- Colonic lavage or high enema—may hasten the elimination of toxicants from the gastrointestinal tract.
- Warm water with Castile soap—excellent solution.
- Commercially available preparations that act as osmotic agents are available.

Poisoning (Intoxication) Therapy

(Continued)

- Take care to avoid the induction of dehydration and electrolyte imbalances with overzealous treatment.
- Do not use hexachlorophene soaps or phosphate-based enemas in cats.

ENHANCE ELIMINATION

- Absorbed toxicants—generally excreted by the kidneys; may be excreted by other routes (e.g., bile, feces, lungs, and other body secretions).
- Renal excretion—may be manipulated in many animals.
- Urinary excretion—may be enhanced by the use of diuretics or by altering the pH of the urine.

Diuretics

- Enhance urinary excretion of some toxicants—requires maintenance of adequate renal function.
- If minimum urine flow cannot be established—must use peritoneal dialysis (normal urine output is 1–2 mL/kg/hour).
- Agents of choice—furosemide (2 mg/kg IV q6–8h, if no response increase dose to 4–6 mg/kg IV q6–8h) or mannitol (1–2 g/kg IV slowly over 20–30 minutes q6h).

Manipulating Urine pH

- Classic pharmacologic technique
- Acidic compounds remain ionized in alkaline urine; alkaline compounds remain ionized in acidic urine.
- Intravenous 0.9% sodium chloride—rapid, urinary acidifying agent.
- Intravenous sodium bicarbonate may be used as an alkalinizing agent.
- Ammonium chloride (200 mg/kg PO divided 4 times a day) and ethylenediamine dihydrochloride (1–2 tablets q8h for the average-sized dog)—long-term urinary acidification.

Peritoneal Dialysis

- Indicated for patients with oliguria or anuria.
- Indicated for simple removal of absorbed toxicants in patient with normal renal function.

- pH of the solution—may be altered to maintain the ionized state of the offending compound.

FLUID THERAPY

Consider volume replacement with crystalloids and colloids if necessary.

Lipid Emulsion Therapy (ILE or IFE)

- Promising use as antidote for toxicosis from many fat soluble drugs.
- Useful for complications associated with local anesthetic medications. Successfully resuscitated human patients with cardiac collapse related to local anesthetics in particular, but also clomipramine and verapamil.
- Has been used successfully in veterinary medicine to treat toxicity from baclofen, beta antagonists, calcium channel antagonists, ivermectin, moxidectin, and other fat-soluble medications.
- Exact mechanism of action remains unknown, but may act as a lipid sink.
- Potential adverse effects include hyperlipidemia, hepatosplenomegaly, jaundice, seizures, hemolytic anemia, prolonged clotting time, thrombocytopenia, and fat embolism.
- Dosage extrapolated from humans using the 20% commercially available fat emulsion product. Standard Protocol: 1.5 mL/kg IV over 5–15 minutes followed by 0.25 mL/kg/minute CRI over 1–2 hours. Repeat in several hours if signs return and serum in not lipemic. See Appendix V on Antidotes and Other Useful Drugs.

MEDICATIONS

Specific antidotes or procedures are available for the more common toxicants; see specific chapter and Appendix V.

FOLLOW-UP

Specific monitoring depends on the toxicant and the patient's signs and laboratory abnormalities.

MISCELLANEOUS

ABBREVIATIONS

- CNS = central nervous system
- ILE = intravenous lipid emulsion
- IFE = intravenous fat emulsion

POLIOENCEPHALOMYELITIS—CATS

BASICS

OVERVIEW

- Subacute to chronic nonsuppurative encephalomyelitis with a predominance of pathologic changes in the gray matter, mainly affecting the medulla oblongata and the spinal cord.
- This disease is considered rare with a prevalence of less than 1% in cats presented with spinal cord diseases.

SIGNALMENT

- There is no breed or sex predilection.
- Cats of any age can be affected.
- The disease is sporadic but has been observed worldwide, especially in northern Europe.

SIGNS

- Ataxia, paresis, and decreased postural reactions of pelvic or all four limbs.
- Lower motor neuron signs may be also possible (muscle atrophy and decreased to absent segmental spinal reflexes).
- Intracranial signs (seizures, cerebellar signs, and cranial nerve deficits) are uncommon.
- The progression is subacute to chronic (over weeks to months) but may also stabilize.

CAUSES & RISK FACTORS

The underlying cause remains still unknown but pathologic findings are highly suggestive of a viral agent.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- FIP
- Toxoplasmosis
- Fungal infection
- Bacterial infection

CBC/BIOCHEMISTRY/URINALYSIS

- Laboratory changes not well characterized
- Nonspecific changes (e.g., leukopenia and non-regenerative anemia) rare

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- The presumptive diagnosis is based on history, clinical signs, and possibly CSF changes (mononuclear pleocytosis with or without moderate increased total protein levels).
- The final diagnosis is based on histopathology (disseminated inflammatory lesions in the brain and spinal cord and, as the disease progresses, there is extensive neuronal loss and astrogliosis with little inflammation).

TREATMENT

No curative treatment has been found.

MEDICATIONS

DRUG(S)

- No drug therapy used in reported cases.
- Because lesions are nonsuppurative, steroid therapy may palliate clinical signs, at least temporarily.
- Supportive treatment with antiepileptic medication to control seizures if indicated.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

Prognosis can be good if the neurologic signs are mild and nonprogressive.

MISCELLANEOUS

ABBREVIATIONS

- CNS = central nervous system
- CSF = cerebrospinal fluid
- FIP = feline infectious peritonitis

POLYARTHRITIS, IMMUNE-MEDIATED

BASICS

DEFINITION

An immune-mediated inflammatory disease of joints resulting in progressive destruction of articular tissues and subsequent pain and lameness. The disease may be erosive in nature (including rheumatoid arthritis, idiopathic, erosive polyarthropathy of greyhounds or feline chronic progressive polyarthropathy) or nonerosive (including idiopathic polyarthritides, SLE, polyarthritides associated with chronic disease, polyarthritides-polymyositis syndrome, polymyositis syndrome, polyarthritides-meningitis syndrome, polyarthritides nodosa, familial renal amyloidosis in Chinese shar-pei dogs, lymphocytic-plasmacytic synovitis, juvenile-onset polyarthritides of Akitas).

PATHOPHYSIOLOGY

- Pathogenesis—inciting cause unknown as extrapolated from human arthritis research; likely perpetuated by cell-mediated immunity; predominance of CD4+ helper T-lymphocytes and immune complex depositions found in synovium of affected joints; leukocytes, leukocyte enzymes, cell-mediated immunity, immune complexes, and auto-allergic reactions are directed against cartilage components; leads to an inflammatory response and complement activation.
- SLE—nuclear material from various cells becomes antigenic, leading to formation of auto-antibodies (antinuclear antibody).
- IEP—associated with an abnormal antigenic response to host immunoglobulin, similar to human rheumatoid arthritis.
- EPG and FCPP—offending antigens unknown.

SYSTEMS AFFECTED

Musculoskeletal—diarthrodial joints

GENETICS

Not known to be hereditary

INCIDENCE/PREVALENCE

- Overall, uncommon
- Idiopathic—most common in dogs
- Chronic infection related form may be misdiagnosed as idiopathic
- Other forms uncommon

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Idiopathic nonerosive—large- (more common) and small-breed dogs; uncommon in cats; German shepherd, Doberman pinscher, retriever, spaniel, pointer, toy poodle, Lhasa apso, Yorkshire terrier, and Chihuahua overrepresented.
- Idiopathic erosive—small or toy breeds.
- SLE—tendency to affect large-breed dogs; collie, German shepherd, poodle, terrier, beagle, and Shetland sheepdog.
- Secondary to

administration of sulfa drugs—increased sensitivity in Doberman pinscher.

- Polyarthritis-meningitis syndrome—reported in Weimaraner, German shorthaired pointer, boxer, Bernese mountain dog, beagle, rottweiler, and Japanese Akita.
- Amyloidosis and synovitis—prominent features of a syndrome affecting young Shar-Pei dogs.
- Greyhound specific version.
- Juvenile onset polyarthritides reported in Akitas.
- Lymphocytic-plasmacytic synovitis in German shepherds and other large-breed dogs.

Mean Age and Range

Dogs—young to middle-aged. Cats—FCPP: onset at 1.5–4.5 years of age.

Predominant Sex

FCPP—male cats only

SIGNS

General Comments

Non-erosive and erosive forms of immune-mediated inflammatory disease initially appear similar.

Historical Findings

- Dogs and cats—acute or insidious onset; single- or multiple-limb (more common in most syndromes) lameness.
- Lameness—may shift from leg to leg.
- Usually no history of trauma.
- May also note vomiting, diarrhea, anorexia, pyrexia, polyuria, or polydypsia.
- May also note signs associated with systemic disease or infections (pyometra, prostatitis, or discospondylitis), or neoplastic disease.
- Often cyclic—may appear to respond to antibiotic therapy, but may be undergoing spontaneous remission.
- Disease may develop when patient is being treated with antibiotics.

Physical Examination Findings

- Stiffness of gait, lameness, decreased range of motion, crepitus, and joint swelling and pain in one or more joints.
- Joint instability, subluxation, and luxation—depend on duration of disease.
- Lameness—mild weight-bearing to more severe non-weight-bearing.
- Diarthrodial joints—all may be affected; small distal joints more common.
- Chronic localized focus of infection (pyometra, prostatitis).

CAUSES

- Unknown for most.
- Immunologic mechanism likely.
- Chronic—associated with antigenic stimulation along with concurrent meningitis, gastrointestinal disease, neoplasia, urinary tract infection, periodontitis, bacterial endocarditis, heartworm disease, pyometra, chronic otitis media or externa, fungal infections, and chronic *Actinomyces* or *Salmonella* infections.
- May occur secondary to a hypersensitivity reaction involving the deposition of drug antibody complexes in the blood vessels of the synovium; suspected antibiotics include sulfas, cephalosporins, lincomycin, erythromycin, and penicillins.
- FeLV and FeSFV—linked to FCPP.

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious arthritis
- Joint trauma
- Polymyositis
- Osteoarthritis—primary or secondary

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Hemogram—may show leukocytosis, neutrophilia, and hyperfibrinogenemia.
- Hematologic abnormalities (e.g., thrombocytopenia and hemolytic anemia)—rare.

OTHER LABORATORY TESTS

- Positive lupus erythematosus preparation or positive antinuclear antibody test—dogs with SLE (both false-positive and false-negative results are common).
- Rheumatoid factor—positive in only about 25% of IEP patients.
- Coombs' test and antinuclear antibody titer—normal.
- Serum titers (*Borrelia*, *Ehrlichia*, and *Rickettsia*)—should be normal.
- Serologic evidence of FeSFV—found in all FCPP patients.
- Serologic evidence of FeLV exposure—found in 50% or fewer of cats with FCPP.

IMAGING

- Earliest finding is periarticular soft tissue swelling.
- Severe disease—joint capsular distention; osteophytosis; soft tissue thickening; narrowed joint spaces; subchondral sclerosis; decreased trabecular bone density; bony ankylosis in severely affected joints.
- Cyst-like lucencies—occasionally seen in subchondral bone in erosive forms.
- Chronic disease—subluxation, luxation, and obvious joint deformity.

DIAGNOSTIC PROCEDURES

- Arthrocentesis and synovial fluid analysis—essential for diagnosis.
- Synovial fluid—typically appears cloudy with normal viscosity; large increase in non-degenerate neutrophils (20,000–200,000 cells/mL); submit for bacterial culture and sensitivity.
- Synovial biopsy—may help diagnosis.
- Look for a source of chronic infection.

PATHOLOGIC FINDINGS

- Joint capsule—may be thickened; synovial effusion.
- Synovial hypertrophy and hyperplasia—associated with a mononuclear cell infiltrate.
- Neutrophils—seen in the synovial tissues owing to chemotaxis.
- Erosion of articular cartilage—particularly near the periphery at synovial attachments (erosive forms).
- Eburnation and sclerosis of subchondral bone with full-thickness cartilage loss—chronic disease.
- Granulation tissue (pannus)—may invade the margins of articular cartilage, and arise from the marrow

(CONTINUED)

POLYARTHRITIS, IMMUNE-MEDIATED

cavity to destroy cartilage at central regions of the joint. • Enthesiophytes—at joint capsular attachments and adjacent to the joint.

- Histopathology of the synovial membrane—typically reveals villous synovial hyperplasia, hypertrophy, and lymphoplasmacytic inflammatory infiltrate.
- Synovial fluid—cloudy; increased volume.

**TREATMENT****APPROPRIATE HEALTH CARE**

Usually outpatient

NURSING CARE

- Physical therapy—range-of-motion exercises and swimming; may be indicated for severe disease.
- Bandages and/or splints—to prevent further breakdown of the joint; may be indicated for severe disease with compromised ambulation.

ACTIVITY

Limited to minimize aggravation of clinical signs

DIET

Weight reduction—to decrease stress placed on affected joints

CLIENT EDUCATION

Warn client of poor prognosis for cure and complete resolution if a primary cause is not found.

SURGICAL CONSIDERATIONS

Remove source of infection where applicable (e.g., pyometra); no other therapy needed in these cases.

- Healing rates—may be long and protracted; range of recovery levels.
- Surgery—generally not a good treatment option.
- Arthroplasty—total hip replacement, femoral head ostectomy; may consider if the hip is the primary clinical problem.
- Arthrodesis—in selective cases of joint pain and joint instability; carpus; generally yields the best results and is a good salvage option; shoulder, elbow, stifle, or hock: less predictable results.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Eliminate underlying causes if possible—chronic disease; offending antibiotic.
- Typical therapy—initial trial of glucocorticoids; if poor response, then combination chemotherapy (glucocorticoids and cytotoxic drugs). • Complete remission—usually achieved in 2–16 weeks; determined by resolution of clinical signs and confirmation of normal synovial fluid analysis.
- Recurrence rate—30–50% once therapy is discontinued.
- Prednisone

1.5–2 mg/kg PO q12h for 10–14 days as initial treatment; synovial fluid cell counts <4,000 cells/mL and mononuclear cells predominate: If positive response is achieved, slowly taper by reducing doses every 3–4 weeks to 1 mg/kg PO q48h; clinical signs persist or abnormal synovial fluid analysis: add cytotoxic agents; no clinical signs after 2–3 months of alternate-day therapy: discontinue. • Combination of glucocorticoids and cytotoxic drug—recommend for synergistic effect; may try cyclophosphamide or a thiopurine (azathioprine or 6-mercaptopurine).

- Cyclophosphamide—patient <10 kg: 2.5 mg/kg; patient 10–50 kg: 2 mg/kg; patient >50 kg: 1.75 mg/kg; agent given PO q24h for 4 consecutive days of each week; given concurrently with prednisone (as described above; some clinicians reduce the total steroid dose by half).
- Azathioprine or 6-mercaptopurine 2 mg/kg PO q24h for 14–21 days, then q48h; given concurrently with prednisone as for cyclophosphamide, but on alternating days.
- Leflunomide—may be used synergistically with azathioprine, prednisone, and cyclophosphamide (4 mg/kg q24h for dogs). After several days, adjust dose to plasma trough levels of 20 µg/mL.
- Discontinue cytotoxic drugs 1–3 months after remission is achieved.
- Maintaining remission—alternate-day glucocorticoid therapy (prednisone 1 mg/kg PO) is generally successful; clinical signs or synovial neutrophilia recur: long-term cytotoxic drug therapy may be necessary; clinical signs do not recur after 2–3 months: may stop the glucocorticoid; clinical signs recur after glucocorticoid is stopped: continue treatment.
- Aurothiomalate (chrysotherapy) 1 mg/kg IM weekly; successfully alleviates symptoms in some reports.

FCPP

- Treatment may slow progression.
- Prednisone (2 mg/kg PO q12h) and cyclophosphamide (2.5 mg/kg PO)—typically as described above.

EPG

- Treatment is unrewarding.
- Antibiotics, NSAIDs, glucocorticoids, cytotoxic drugs, and polysulfated glycosaminoglycan (Adequan)—fail to induce remission.

CONTRAINDICATIONS

- Do not use cytotoxic drugs with chronic infections or bone marrow suppression (cats with FCPP).
- Avoid using glucocorticoids with NSAIDs such as aspirin, carprofen, etodolac, and deracoxib, as gastric ulceration may result.
- Chrysotherapy—do not use with renal disease owing to nephrotoxicity.

PRECAUTIONS

- Glucocorticoids—long-term use may lead to iatrogenic Cushing's disease.
- Cytotoxic drugs—frequently induce bone marrow

suppression; monitor CBC weekly (see Polyarthritis, Immune Mediated).

- Leflunomide may cause intestinal necrosis with overdosing.

POSSIBLE INTERACTIONS

None known

**FOLLOW-UP****PATIENT MONITORING**

- Treatment is often frustrating and requires frequent reevaluation.
- Clinical deterioration—requires a change in drug selection or dosage, or surgical intervention.
- Important to try to induce remission; allowing the disease to smolder uncontrolled will increase risk of secondary degenerative joint disease.

EXPECTED COURSE AND PROGNOSIS

- Recurrence—seen with moderate frequency
- Erosive forms—progression likely; cure is not expected; remission is the goal.
- SLE and FCPP—progression common; guarded prognosis
- Other forms—good prognosis

**MISCELLANEOUS****ABBREVIATIONS**

- FCPP = feline chronic progressive polyarthritis
- FeLV = feline leukemia virus
- FeSFV = feline syncytium-forming virus
- SLE = systemic lupus erythematosus
- EPG = erosive polyarthritis of greyhounds
- IEP = idiopathic erosive polyarthritis
- NSAID = nonsteroidal anti-inflammatory drug

P

POLYCYSTIC KIDNEY DISEASE

BASICS

OVERVIEW

Disorder in which large portions of normally differentiated renal parenchyma are displaced by multiple cysts; renal cysts develop in preexisting nephrons and collecting ducts; both kidneys are invariably affected. In most cases the disease is inherited.

SIGNALMENT

- Persian and Persian-related breeds (e.g., Exotic Shorthair, Himalayan, Scottish fold) are affected more commonly than other breeds.
- Dog breeds affected include cairn terriers and beagles.

SIGNS

- Cysts often remain clinically silent until their increasing size and number contribute to renal failure or abdominal enlargement; thus patients typically are clinically normal during initial stages of cyst formation.
- May detect bosselated (lumpy) kidneys by abdominal palpation.
- Most renal cysts are not painful when palpated, but acute secondary infection of cysts may be associated with rapid distension of the renal capsule and pain.

CAUSES & RISK FACTORS

- Autosomal-dominant inheritance in Persian cats. A nucleotide transversion (cytosine to adenine) causing a premature stop codon has been strongly associated with the phenotype.
- The stimuli for renal cyst formation remains obscure; genetic, endogenous, and environmental factors appear to influence the process.
- Cystogenic chemicals include diphenylthiazole, nordihydroguaiaretic acid, diphenylamine, trichlorophenoxyacetic acid, and long-acting corticosteroids.

P

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other multicystic diseases of the kidneys.
- Glomerulocystic disease of collies.
- Renal cystadenocarcinoma associated with nodular fibrosis in German shepherd dogs.
- Renal cysts associated with chronic renal failure or renal dysplasia.
- Non-cystic causes of renomegaly.
- Renal neoplasia.
- Hydronephrosis.
- Perirenal pseudocysts.
- Feline infectious peritonitis.
- Mycotic or bacterial nephritis.

CBC/BIOCHEMISTRY/URINALYSIS

- Results usually unremarkable unless patient has renal insufficiency.
- Hematuria is rare.

OTHER LABORATORY TESTS

- Genetic tests are available to identify the autosomal dominant-polycystic kidney

disease (AD-PKD) type 1 mutation in cats. This test is especially useful to screen kittens less than 3–4 months old when ultrasonography may be less sensitive. The test is also useful to confirm inherited AD-PKD type 1 in breeding cats, once renal cysts are detected ultrasonographically. Other mutations may also cause inherited kidney cysts.

- Cyst fluid can be clear, cloudy, or hemorrhagic, and the fluid from different cysts in the same kidney can differ.
- Bacterial culture of cyst fluid helps in diagnosing concomitant infection.
- Hypertension is uncommon without renal failure.

IMAGING

Radiography

Survey radiography and intravenous contrast urography are insensitive methods of confirming cystic disease.

Ultrasonography

- Reveals anechoic cavitating lesions characterized by sharply marginated smooth walls and distal enhancement, which are diagnostic.
- Cysts have been detected in cats as young as 7 weeks; screening cats younger than 6 months is associated with higher false-negative test result rate.
- Used to detect cysts in other organs (e.g., liver, pancreas), which helps to differentiate AD-PKD from other inherited or acquired multicystic disorders of the kidneys.

DIAGNOSTIC PROCEDURES

Evaluation of fine-needle aspirates of the kidney may allow differentiation of cystic disease from other diseases that cause renomegaly.

TREATMENT

- Usually not immediately life-threatening, but bacterial nephritis and cyst involvement warrant immediate measures to prevent sepsis and mortality. In our experience, bacterial infection of cysts is rare.
- Spontaneous resolution of cysts has not been documented in dogs and cats; most cysts increase in size and number, often compressing adjacent normal functioning renal parenchyma.
- Elimination of renal cysts and associated renal parenchymal lesions is not yet feasible; treatment is often limited to minimizing the pathophysiologic consequences of renal cyst formation (i.e., chronic kidney disease [CKD], renal infection, hematuria, and pain).
- Removing fluid (cystocentesis, fenestration) from large renal cysts may minimize pain and compression of adjacent normal renal parenchyma. However, this procedure is impractical for kidneys with multiple large

- Some patients may require treatment for concomitant CKD.
- Consider nephrectomy only if infected cysts are associated with uncontrollable sepsis.

- Disease eradication by selective breeding of unaffected cats may be impossible because almost 40% of Persians are affected. Selective breeding may reduce genetic diversity, increasing the frequency of other unwanted inherited traits.

MEDICATIONS

DRUG(S)

- Bacterial infection of cysts has been observed in cats but is rare. Unless infection is accompanied by pyelonephritis, bacteria may not be observed in urine. Consider parenchymal infection when renal cysts are associated with renal pain and fever, even in absence of bacteriuria.
- Treatment of infected cysts requires special consideration. The acidic nature of cyst fluid and its containment by an epithelial barrier might reduce bactericidal concentrations of commonly used acidic antibiotics (e.g., cephalosporins and penicillins) within cystic lumens. Alkaline, lipid-soluble antibiotics (e.g., trimethoprim-sulfonamide combinations, fluoroquinolones, chloramphenicol, tetracycline, and clindamycin), which penetrate epithelial barriers and become ionized and trapped in cyst lumens, have been recommended.

FOLLOW-UP

- Monitor patients every 2–6 months for associated disease (e.g., CKD, renal infection, and pain).
- In the absence of sepsis, the short-term prognosis appears to be favorable without treatment.

MISCELLANEOUS

ABBREVIATIONS

AD-PKD = autosomal dominant-polycystic kidney disease

Suggested Reading

Bonazzi M, Volta A, Gnudi G, et al. Comparison between ultrasound and genetic testing for early diagnosis of polycystic kidney disease in Persian and Exotic Shorthair cats. J Feline Med Surg 2009;11:430–434.

Authors Jody P. Lulich and Carl A. Osborne

Consulting Editor Carl A. Osborne

BASICS

DEFINITION

An increase in PCV, hemoglobin concentration, and RBC count above the reference intervals because of a relative, transient, or absolute increase in the number of circulating RBCs.

PATHOPHYSIOLOGY

- Number of circulating RBCs affected by changes in plasma volume, rate of RBC destruction or loss, splenic contraction, EPO secretion, and rate of bone marrow production.
- Erythropoiesis also affected by hormones from the adrenal cortex, thyroid gland, ovary, testis, and anterior pituitary gland; normal PCV maintained by an endocrine loop.
- Polycythemia is classified as relative, transient, or absolute.
- Relative—develops when a decrease in plasma volume, usually caused by dehydration, produces a relative increase in circulating RBCs.
- Transient—caused by splenic contraction, which injects concentrated RBCs into the circulation; because splenic contraction is a momentary response to epinephrine; this type is usually not a major diagnostic consideration.
- Absolute—characterized by an absolute increase in the circulating RBC mass as a result of an increase in bone marrow production; either primary or secondary to an increase in the production of EPO.
- Primary absolute (polycythemia rubra vera)—a myeloproliferative disorder characterized by the uncontrolled but orderly production of excessive numbers of mature RBCs.
- Secondary absolute—caused by a physiologically appropriate release of EPO resulting from chronic hypoxemia or by an inappropriate and excessive production of EPO or an EPO-like substance in an animal with normal SaO₂.

SYSTEMS AFFECTED

- Cardiovascular, respiratory, nervous, renal/urologic—hyperviscosity and poor perfusion and oxygenation of tissues, which are related directly to the high PCV, especially values > 60–70%.

GEOGRAPHIC DISTRIBUTION

- Reference intervals for PCV, hemoglobin, and RBC count vary with geographic location and breed.
- Animals living at altitudes > 6,000 feet have higher values than those at sea level.

SIGNALMENT

Species

Dogs and cats

Breed Predilections

- Brachycephalic breeds have higher PCV values than do normocephalic breeds.
- Large, excitable breeds are prone to splenic contraction.
- Greyhounds typically have

high PCV values; normal range is 50–65%.

Mean Age and Range

Primary and absolute polycythemia—cats 6–7; dogs 7 years or older.

Predominant Sex

Cats males, dogs females

SIGNS

General Comments

Vary with the degree of polycythemia

Historical Findings

- Transient—excitement or vigorous exercise.
- Absolute—lethargy, anorexia, epistaxis, seizures, hyperemia of mucous membranes.

Physical Examination Findings

- Relative—dehydration caused by vomiting, diarrhea, or lack of water intake and oliguria.
- Absolute—lethargy, low exercise tolerance, behavioral change, brick red or cyanotic mucous membranes, sneezing, bilateral epistaxis, large size and tortuosity of retinal and sublingual vessels, and cardiopulmonary impairment.
- Primary absolute—variable degrees of splenomegaly, hepatomegaly, thrombosis, and hemorrhage; occasional seizure.
- Secondary absolute caused by tissue hypoxia—clinical signs of hypoxemia caused by chronic pulmonary disease, cardiac disease or anomaly with right-to-left shunting, or hemoglobinopathy.
- Secondary absolute caused by inappropriate EPO secretion—signs associated with neoplasia, space-occupying renal lesion, or endocrine disorder.

CAUSES

- Relative (common)—hemoconcentration/dehydration.
- Transient—excitement, anxiety, seizures, and restraint.
- Primary absolute—rare myeloproliferative disorder.
- Secondary absolute caused by tissue hypoxia—chronic pulmonary disease, cardiac disease or anomaly with right-to-left shunting, high altitude, brachycephalic breed conformation, methemoglobinemia, and impairment of renal blood supply.
- Secondary absolute caused by inappropriate EPO secretion (rare)—renal cyst or tumor, hydronephrosis, hyperadrenocorticism, hyperthyroidism, pheochromocytoma, nasal fibrosarcoma, hepatic neoplasia, extradural schwannoma, cecal leiomyosarcoma, hyperandrogenism, therapeutic administration of recombinant EPO.

RISK FACTORS

None

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Moderately high PCV and total plasma protein with concurrent dehydration—suggest relative polycythemia.
- Secondary absolute—caused by diseases that produce chronic hypoxemia or by space-occupying

lesions of the kidney, endocrine disorders, neoplasms that produce EPO or an EPO-like substance independent of hypoxia, history of EPO administration.

• Polycythemia vera—diagnosed by elimination of other causes.

CBC/BIOCHEMISTRY/URINALYSIS

Assessment begins with CBC and total plasma protein measurement. Concurrent anemia, hypoproteinemia, dehydration, and dilutional effects of fluid therapy can affect interpretation of PCV and total plasma protein values; additional tests selected as indicated and noted in following table (Inc = Increase, Dec = Decrease):

OTHER LABORATORY TESTS

- SaO₂ and EPO determinations—diagnose absolute polycythemia.
- Hormone assays—assessment of endocrine dysfunction; EPO samples can be sent to a human testing laboratory; control sample from a normal animal (not a blood donor) should also be submitted.
- Extensive overlap in EPO values exists between normal and affected animals; in some animals with secondary absolute polycythemia, low or normal EPO values have been reported. Laboratories at the University of Pennsylvania and Tennessee have established reference intervals for EPO in dogs and cats.

IMAGING

Radiography and ultrasonography to detect cardiopulmonary disease and space-occupying lesions of the kidneys or other neoplasms.

DIAGNOSTIC PROCEDURES

Pulse oximetry to determine oxygen saturation of the blood.

PATHOLOGIC FINDINGS

- Polycythemia vera—generalized vascular congestion, arterial thrombosis, variable splenomegaly, and diffusely red bone marrow with reduced fat gross findings.
- Microscopic findings include a hyperplastic marrow with a normal or reduced myeloid/erythroid ration and reduced iron content.

TREATMENT

APPROPRIATE HEALTH CARE

- Relative—rehydration with IV fluids appropriate for the primary cause; assessment of renal function, gastrointestinal system, acid-base status, and electrolyte balance important to the selection of the fluid.
- Absolute—phlebotomy recommended (20 mL/kg over 1 to several days) to reduce the RBC mass to a PCV of 55%; blood volume should be replaced concurrently with isotonic fluids to prevent hypotension, cardiovascular collapse, and thrombosis.
- Secondary caused by inappropriate EPO production—phlebotomy combined with identification and removal of the EPO source.
- Secondary caused by hypoxemia—

POLYCYTHEMIA

(CONTINUED)

Table 1

Mechanism	Relative	Absolute		
	Dehydration	Primary Myeloproliferative	Secondary Hypoxemia	Secondary Excess EPO
PCV	Inc	Marked Inc > 60%	Marked Inc > 60%	Marked Inc > 60%
TPP	Inc	N	N	N
SaO ₂		N > 90%	Dec << 90%	N > 90%
EPO		N/Dec	Inc	Inc
Bone marrow		Erythroid Hyperplasia	Erythroid Hyperplasia	Erythroid Hyperplasia
Other	Prerenal Azotemia	Inc WBC Inc Platelets		

phlebotomy and hydroxyurea. The high PCV is an appropriate compensatory response; thus phlebotomy may be dangerous; if indicated, remove blood at a slower rate (5 mL/kg); a higher PCV (60–65%) may be necessary to sustain life until the cause of hypoxemia can be corrected. • Polycythemia vera—phlebotomy (20 mL/kg) and hydroxyurea; frequency of bleeding and dosage adjusted to maintain a PCV of 55% in dogs and 45% in cats.

NURSING CARE

Oxygen therapy may be indicated for patients with cyanosis, low arterial oxygen saturation, severe cardiopulmonary disease, or weakness following phlebotomy.

ACTIVITY

Excessive exercise should be avoided during phlebotomy.

DIET

Normal diet with free-choice water.

P

CLIENT EDUCATION

- Patients need to be observed for change in activity such as weakness, difficult breathing, bleeding episodes, or evidence of systemic infections.
- If chemotherapy drugs are dispensed, personal safety handling and administration of these drugs should be discussed. These drugs can cause changes in skin pigmentation and sloughing of toenails.

SURGICAL CONSIDERATIONS

If surgery is necessary, monitoring oxygen saturation with pulse oximetry is necessary to avoid hypoxemia.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Polycythemia vera—hydroxyurea (40–50 mg/kg PO divided twice daily, dogs; 30 mg/kg q24h, cats).
- Polycythemia secondary to hypoxemia—hydroxyurea (40–50 mg/kg PO q48h).

CONTRAINDICATIONS

Phlebotomy may be contraindicated in patients with hypoxemia.

PRECAUTIONS

- Removal of blood at a rapid rate can cause hypotension and cardiovascular collapse.
- Adverse effects of hydroxyurea include marrow hypoplasia with thrombocytopenia, anemia, and neutropenia, alopecia, changes in skin pigmentation, and sloughing of toenails.
- Methemoglobinemia and hemolytic anemia are reported in cats treated with hydroxyurea.

ALTERNATIVE DRUG(S)

Polycythemia vera—chlorambucil (0.2 mg/kg PO q24h, dogs and cats) or busulfan (2–4 mg/m² PO q24h, dogs).

**FOLLOW-UP****PATIENT MONITORING**

- PCV, total plasma protein, urine output, and body weight 2–3 times daily in severely dehydrated animals until normal hydration is maintained.
- Patients being treated for polycythemia vera by chemotherapy—monitor weekly for changes in PCV, leukocytes, and platelets during the initial treatment; then monthly for adjustment of chemotherapy and periodic phlebotomy.
- Periodic assessment of marrow iron store or serum iron levels is indicated to detect iron deficiency.

POSSIBLE COMPLICATIONS

- Hyperviscosity in patients with absolute polycythemia, especially polycythemia vera, may lead to thrombosis, infarction, or hemorrhage.
- Chemotherapy may cause bone marrow suppression.
- Patients with absolute polycythemias can develop iron deficiency as a result of phlebotomy and active erythropoiesis.

EXPECTED COURSE AND PROGNOSIS

- Relative polycythemia: identification and correction of the primary cause with appropriate fluid therapy result in recovery with a fair to good prognosis depending on primary cause.
- Secondary absolute polycythemia due to hypoxemia: clinical course and prognosis are determined by the severity of the lesion causing hypoxemia. Improvement of cardiac

function or inflammatory lung disease and a reduction in PCV with improved oxygen saturation improves quality of life. Prognosis would remain guarded.

- Secondary absolute polycythemia due to inappropriate EPO secretion: if the tissue source of excessive EPO secretion can be identified (tumor, renal cyst, endocrine disease) and removed or corrected, the polycythemia will resolve with a good to fair prognosis depending on cause.
- Primary absolute polycythemia: this myeloproliferative disorder does respond to treatment but requires monitoring for changes in CBC values and clinical evidence of hemorrhage, thrombosis, or decreased activity. Prognosis is guarded.

**MISCELLANEOUS****PREGNANCY/FERTILITY/BREEDING**

Hydroxyurea may arrest or inhibit spermatogenesis.

SYNOMYS

Erythrocytosis

POLYCYTHEMIA VERA

BASICS

OVERVIEW

Myeloproliferative disorder of the chronic myelogenous leukemia spectrum (CML), resulting in high blood viscosity secondary to an increased RBC mass.

SIGNALMENT

- Dog and cat
- Primarily old animals

SIGNS

- Gradual in onset; may be incidental diagnosis
- Depression
- Anorexia
- Weakness
- Polydipsia and polyuria
- Erythema of skin and mucous membranes
- Dilated and tortuous retinal blood vessels
- Uveitis
- Acute blindness
- Splenomegaly and hepatomegaly uncommon

CAUSES & RISK FACTORS

A *JAK2* mutation has been implicated in the disease pathogenesis.

DIAGNOSIS

Diagnostic tests should exclude all other conditions that may lead to increased packed cell volume (PCV) and red blood cell mass.

DIFFERENTIAL DIAGNOSIS

- Severe dehydration
- Renal neoplasia
- Chronic pyelonephritis
- Hyperadrenocorticism
- Androgen stimulation
- Chronic pulmonary disease
- Cardiac disease with right-to-left shunts

CBC/BIOCHEMISTRY/URINALYSIS

- High PCV
- Absolute increase in RBC mass

- Prerenal azotemia possible
- Leukocytosis in 50% of dogs

OTHER LABORATORY TESTS

- PaO₂—normal.
- Serum erythropoietin concentrations are usually low to zero and often overlap with those reported for other causes of polycythemia.
- Cytologic examination of bone marrow and core biopsy, in parallel with peripheral blood count analysis.

IMAGING

- Radiography—assess kidneys and cardiopulmonary system.
- Abdominal ultrasonography—assess kidneys and adrenal glands.
- Echocardiography—evaluate for right-to-left cardiac shunts.

DIAGNOSTIC PROCEDURES

- Bone marrow biopsy
- Electrocardiography—assess heart disease
- Retinal examination/ophthalmologic consult
- Blood pressure measurement

TREATMENT

- Phlebotomy and concurrent replacement with intravenous isotonic fluids—to provide relief of signs during clinical crisis.
- Hydroxyurea—may temporarily decrease the RBCs and provide disease control.
- Consult a veterinary medical oncologist for most current recommendations and disease management.

MEDICATIONS

DRUG(S)

Hydroxyurea—40–50 mg/kg PO divided twice daily; titrate to response and toxicity (dog and cat).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

Periodic reexaminations with serial CBCs, retinal examinations, and serum biochemical profiles to monitor disease control and hydroxyurea side effects on bone marrow and other organs.

POLYNEUROPATHIES (PERIPHERAL NEUROPATHIES)

BASICS

DEFINITION

Diseases affecting peripheral motor, sensory, autonomic, and/or cranial nerves, in any combination.

PATHOPHYSIOLOGY

- Inherited or acquired (degenerative, idiopathic, metabolic/endocrine, neoplastic, paraneoplastic, immune-mediated inflammatory, infectious, drugs/toxic).
- Primary pathologic process—(1) *axonal neuropathies*, caused by either destruction or degeneration of neuronal cell bodies in dorsal root ganglia, ventral horn cells, or autonomic ganglia (neuronopathies) or axonal degeneration with secondary demyelination (axonopathies), or (2) *demyelinating neuropathies* with primary demyelination due to disease of the Schwann cells or myelin sheath.

SYSTEMS AFFECTED

- Nervous—peripheral nervous system (occasionally also affecting CNS); possible involvement of the cranial nerves.
- Other organ systems may be involved in the primary disease process.

GENETICS

- Most inherited—autosomal recessive disorders.
- Spinal muscular atrophy in Brittany spaniels, laryngeal paralysis in Bouvier des Flandres—autosomal dominant.

INCIDENCE/PREVALENCE

- Inherited—rare.
- Peripheral nerve involvement in metabolic and neoplastic diseases—incidence unknown.
- Inflammatory—uncommon; CHP most frequent.

GEOGRAPHIC DISTRIBUTION

- CHP—North and Central America, parts of South America.
- Distal denervating disease—dogs in UK; not reported elsewhere.
- Dysautonomia—mostly dogs (occasionally cats) in Missouri, Oklahoma, and Kansas; cats in Scandinavia and UK.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Inherited

Spinal Muscular Atrophy

- Brittany spaniel, Swedish Lapland dog, English pointer, German shepherd, Doberman, rottweiler, Griffon Briquet, Saluki, Maine Coon cats
- Progressive neuronopathy—cairn terrier

Axonopathies

- Giant axonal neuropathy—German shepherd
- Progressive axonopathy—Boxer
- Laryngeal paralysis—Bouvier des Flandres
- Laryngeal paralysis/polyneuropathy complex—Dalmatian, rottweiler, Pyrenean

mountains dog • Distal sensorimotor polyneuropathy—rottweiler, Alaskan Malamute, Great Dane, Leonberger dog, Bouvier des Flandres • Progressive central and peripheral sensorimotor axonopathy—golden retriever • Central-peripheral distal axonopathy—Birman cat • Axonal neuropathy—Snowshoe cat • Primary hyperoxaluria—domestic shorthair cats

Demyelination

- Hypertrophic neuropathy—Tibetan mastiff
- Congenital hypomyelination neuropathy—golden retriever • Demyelinating polyneuropathy—miniature schnauzers
- Recurrent demyelinating-remyelinating polyneuropathy—Bengal cat

Lysosomal Storage Diseases

- Globoid cell leukodystrophy—West Highland white terrier, cairn terrier, domestic shorthair cats • Alpha-L-fucosidosis—English Springer spaniel • Mannosidosis—Persian and domestic shorthair cats • G_{M1} gangliosidosis type II—Siamese and Korat cats • Sphingomyelinosis (Niemann-Pick disease type A)—Siamese and Balinese cats
- Glycogenosis type IV—Norwegian forest cat

Sensory Neuropathy

- Longhaired dachshund, English pointer, German shorthaired pointer, English springer spaniels, French spaniels, Jack Russell terrier, border collies • Ganglionic radiculitis—Siberian husky

Acquired

- CHP—higher incidence in coonhounds
- Clinical diabetic polyneuropathy—more common in cat than dog • Insulinomas—German shepherd, boxer, Irish setter, standard poodle, collie

Mean Age and Range

Inherited

- Often begin at < 6 months of age.
- Feline hyperchylomicronemia—1–8 months.
- Feline hyperoxaluria—5–9 months.
- Rottweiler, Bouvier, Leonberger distal polyneuropathies—> 1 year.
- Giant axonal neuropathy in German shepherd—14–16 months.
- Intermediate and chronic forms of spinal muscular atrophy in heterozygote Brittany spaniel—6–12 months.

Acquired

- Secondary to neoplasia and insulinoma-associated hypoglycemia—middle-aged to older animals.
- Neospora caninum* polyradiculoneuritis—usually dogs < 6 months of age.
- Ganglionic radiculitis—> 1 year.

SIGNS

Historical Findings

Inherited

- Most—progressive LMN tetraparesis; generalized weakness, muscle tremors and atrophy, plantigrade/palmigrade stance; stridor/voice change if laryngeal paralysis.
- Sensory neuropathies—self-mutilation (nociceptive deficits), mild to severe ataxia.

- Lysosomal storage diseases—slowly progressive CNS involvement (head tremors, ataxia, dysmetria, seizures, blindness, dementia) occur in conjunction with the LMN signs.
- Sphingomyelinosis in cats—often present only with progressive motor and sensory neuropathy.
- Giant axonal neuropathy of German shepherds—rapidly progressive generalized weakness (< 3 weeks). **Acquired**

- Rapid or slow progression.
- Rapidly progressive course—initial stiff, stilted gait, leading to generalized LMN paresis or paralysis (CHP, distal denervating disease).
- Slowly progressive course—generalized weakness and muscle atrophy; in distal polyneuropathies (diabetic neuropathy especially in cats), plantigrade/palmigrade stance.
- Dysautonomia—primarily acute onset (< 48 hours) of depression, anorexia, regurgitation, vomiting, paralytic ileus, xerostomia, KCS, third eyelid protrusion, urinary incontinence.
- Metabolic—owner reports non-neurologic clinical signs associated with weakness.
- Paraneoplastic—primary tumor may be clinically silent at time of presentation or revealed on thoracic radiographs or abdominal ultrasound.

Physical Examination Findings

- Motor and sensorimotor—tetraparesis to tetraplegia, hyporeflexia to areflexia, hypotonia to atonia, and muscle atrophy classic; muscle tremors common.
- Sensory—proprioceptive deficits, hypoesthesia to anesthesia, without muscle atrophy or hyporeflexia (except in boxers); sensory ataxia.
- Paraesthesia—feline diabetic neuropathy, sensory neuropathies.
- Hypothyroidism—may be associated with generalized polyneuropathy, laryngeal and/or facial nerve paralysis, megaesophagus, and vestibular signs.
- Lysosomal storage diseases—hepatosplenomegaly common.
- Paraneoplastic—may find evidence of neoplasia.
- Dysautonomia—dry nose, KCS, bradycardia, anal areflexia.
- Primary hyperchylomicronemia (cats)—lipid granulomata, which can be palpated under the skin and abdomen.
- Primary hyperoxaluria (cats)—enlarged, painful kidneys on palpation.
- Cranial nerve abnormalities (including dysphonia/aphonia)—variable.

CAUSES

Acquired

- Immune-mediated—primary or secondary; may be seen with SLE, glomerulonephritis, polyarthritis.
- Metabolic/endocrine—diabetes mellitus (cats), hypothyroidism, hyperadrenocorticism.
- Neoplastic/Paraneoplastic—insulinoma, carcinomas, malignant melanoma, mast cell tumor, osteosarcoma, multiple myeloma, lymphosarcoma.
- Infectious—*N. caninum*, FeLV, FIV.
- Chemotherapy drugs—vincristine, vinblastine, cisplatin.
- Toxic—

(CONTINUED)

POLYNEUROPATHIES (PERIPHERAL NEUROPATHIES)

thallium, organophosphates, salinomycin (cats), lasalocid (dogs). • Idiopathic.

RISK FACTORS

Development of specific diseases (metabolic, immune, neoplastic) or exposure to specific drugs/toxins or causal factors (raccoon saliva).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute—botulism; tick paralysis; fulminant myasthenia gravis; acute multifocal myelopathies. • Chronic—polymyopathy; chronic multifocal myelopathies.

CBC/Biochemistry/Urinalysis

- Standard laboratory tests—often normal; may indicate underlying metabolic or neoplastic disease. • High serum creatine kinase—indicates an accompanying myopathy or diagnosis of polymyopathy.

OTHER LABORATORY TESTS

- Antinuclear antibody, Coombs' test—if immune disease suspected. • Low total T₄, low free T₄, and high endogenous TSH—hypothyroidism. • Amended insulin: glucose ratio > 30—supports the diagnosis of insulinoma. • Serology—assists in the diagnosis of *N. caninum*, FIV, FeLV infection.
- Diminished lysosomal enzyme activity in leukocytes, cultured fibroblasts—lysosomal storage diseases. • Pharmacologic testing (pilocarpine ophthalmic drops, bethanechol challenge)—dysautonomia. • High serum cholesterol and triglycerides, low lipoprotein lipase—hyperchylomicronemia. • Oxalate and/or l-glyceric acid in urine—primary hyperoxaluria. • Monoclonal gammopathy—multiple myeloma.

IMAGING

Thoracic and abdominal radiographs—search for a neoplastic cause; megaesophagus, ileus, bladder atony, constipation, and delayed gastric emptying in dysautonomia.

DIAGNOSTIC PROCEDURES

- Electrophysiology (EMG, motor and sensory nerve conduction studies ventral and dorsal nerve root studies)—cornerstone for diagnosis. • Lumbar CSF analysis—valuable in diagnosing nerve root involvement.
- Muscle biopsy—confirms denervation.
- Peripheral nerve biopsy (distal)—further characterizes disease process.

PATHOLOGIC FINDINGS

Lesion distribution along peripheral nerves (proximal, distal, widespread) and degree of axonal degeneration, demyelination, and/or neuronal cell body degeneration depends on the specific condition present.

TREATMENT

APPROPRIATE HEALTH CARE

- Usually outpatient. • Inpatient—observe dogs with CHP closely for respiratory failure in early progressive phase of disease.

NURSING CARE

- Dysautonomia—may require IV fluid therapy and/or parenteral feeding. • Physical therapy.

DIET

- Generally no special management, unless megaesophagus or dysphagia occurs.
- Hyperchylomicronemia—low-fat diet alone can resolve the polyneuropathy in 2–3 months. • Paralysis—ensure patient can reach food and water. • Regurgitation and/or vomiting—temporarily halt oral intake; consider gastrostomy tube. • Diabetes mellitus—monitor food intake; in cats, feed a low-carbohydrate, high-protein diet; diabetic neuropathy often reversible with treatment.

CLIENT EDUCATION

- Treatment of primary cause may not lead to reversal of signs; in some cases, deterioration will continue. • Canine axonal degeneration—progressive deterioration.

MEDICATIONS

DRUG(S) OF CHOICE

- Inherited—most untreatable. • Acquired—treat primary cause with the hope that the secondary polyneuropathy improves or resolves; not always successful. • Chronic relapsing demyelinating neuropathy—most likely of immune origin; may improve with long-term immunosuppressive therapy (prednisone, azathioprine, cyclophosphamide); response of individual patient variable.
- SLE-related—treat as for chronic relapsing polyneuropathy. • Neoplasia—treat primary neoplasia. • *Neospora*-associated polyradiculoneuritis—clindamycin combined with pyrimethamine. • Dysautonomia—treat symptomatically with IV fluids, artificial tears, metoclopramide, bethanechol (cats, 0.5–2.5 mg SC q12h or 2.5–10 mg PO q6–8h; dogs, 0.5–15 mg SC q12h or 2.5–30 mg PO q6–8h), and pilocarpine eye drops.

CONTRAINdicATIONS

- Corticosteroids—contraindicated in *Neospora*-associated polyradiculoneuritis, hyperadrenocorticism, and CHP.

FOLLOW-UP

PATIENT MONITORING

Repeat neurologic examinations.

PREVENTION/AVOIDANCE

- Avoid breeding patients with *Neospora* (placental transfer of the organism from the bitch). • Avoid contact with raccoons.
- Avoid future vaccinations if suspected associated with vaccines.

POSSIBLE COMPLICATIONS

Continued neurologic deterioration leading to inability to ambulate, severe muscle atrophy, pressure sores, urinary tract infection, muscle fibrosis, aspiration pneumonia.

EXPECTED COURSE AND PROGNOSIS

- Demyelinating conditions—more rapid improvement than axonal neuropathies (majority), which can take months for partial or complete recovery, if at all. • Inherited—most have a poor prognosis (except hyperchylomicronemia in cats). • Acute polyradiculoneuritis (CHP)—good long-term prognosis; may take weeks to months to recover. • Metabolic—fair-to-good prognosis with successful treatment of primary metabolic abnormality; insulinomas have high recurrence rate. • Other acquired—most show continued deterioration despite treatment.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Immunosuppressive agents—contraindicated.

ABBREVIATIONS

- CHP = coonhound paralysis • CNS = central nervous system • CSF = cerebrospinal fluid • EMG = electromyography • FeLV = feline leukemia virus • FIV = feline immunodeficiency virus • LMN = lower motor neuron • SLE = systemic lupus erythematosus • T4 = thyroxine • TSH = thyroid stimulating hormone

POLYPHAGIA

BASICS

OVERVIEW

Increased food intake

PATHOPHYSIOLOGY

- Failure to assimilate or loss of nutrients (e.g., maldigestion/malabsorption syndromes such as exocrine pancreatic insufficiency).
- Inability to use nutrients (e.g., diabetes mellitus, poor-quality diets, gastrointestinal parasites).
- Hypoglycemia (e.g., insulinoma, insulin overdose).
- Increased metabolic rate or demand (e.g., hyperthyroidism, cold environments, pregnancy, lactation).
- Psychologic or learned behaviors (e.g., palatable diets, competition, drugs such as anticonvulsants or glucocorticoids).

SYSTEMS AFFECTED

- Cardiovascular—obesity can worsen clinical cardiac disease.
- Central nervous system—tumors of the brain, especially of the hypothalamus, can cause polyphagia.
- Integument—obese animals, especially cats, are susceptible to dermatitis.
- Musculoskeletal—overweight patients are susceptible to arthritis and other orthopedic problems.
- Respiratory—obesity exacerbates dyspnea in patients with respiratory disease.

SIGNALMENT

Dogs and cats

P SIGNS

Historical Findings

- Eating more frequently and/or a greater quantity than normal.
- Excessive food-seeking and food-stealing behaviors possible.
- Weight loss may occur with certain disease states (e.g., exocrine pancreatic insufficiency, diabetes mellitus, hyperthyroidism).
- PU/PD occurs in some patients (diabetes mellitus, hyperthyroidism, hyperadrenocorticism).

Physical Examination Findings

Patients may have excessive body fat, but those with an underlying medical problem (e.g., exocrine pancreatic insufficiency, diabetes mellitus, hyperthyroidism) may be thin.

CAUSES & RISK FACTORS

Physiologic

- Pregnancy
- Lactation
- Growth
- Response to a cold environment
- Increased exercise

Pathologic

- Diabetes mellitus

- Hyperthyroidism—cats
- Hyperadrenocorticism—dogs
- Exocrine pancreatic insufficiency
- Gastrointestinal parasites
- Insulinoma
- Insulin overdose
- Lymphangiectasia
- Growth hormone–secreting pituitary tumor
- Megaesophagus
- Lymphocytic plasmacytic enteritis—cats—uncommon
- Neoplasms of the brain—rare
- Gastrointestinal neoplasms—rare

Iatrogenic

- Corticosteroids
- Progestins
- Benzodiazepines
- Anticonvulsants
- Palatable food/overfeeding
- Poor diet
- Competition for food

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

PU/PD (excessive trips to food/water area)—differentiate by observation.

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilia, monocytosis, lymphopenia, and eosinopenia with hyperadrenocorticism, and in patients receiving corticosteroids.
- Hyperglycemia with diabetes mellitus, growth hormone–secreting pituitary tumors (cats, insulin-resistant diabetes mellitus), and hyperadrenocorticism (mild).
- Hypercholesterolemia with recent food intake, hyperadrenocorticism, and diabetes mellitus, and in patients receiving corticosteroids.
- High ALP and ALT activity with hyperadrenocorticism (dogs), hyperthyroidism (cats), and diabetes mellitus, and in patients receiving corticosteroids.
- Hypoproteinemia with protein-losing enteropathies (e.g., lymphangiectasia, inflammatory bowel disease).
- Hypoglycemia in patients with insulinoma or insulin overdose.
- Low urine specific gravity with diabetes mellitus, diabetes insipidus, hyperthyroidism, and hyperadrenocorticism, and in patients receiving corticosteroids.
- Glucosuria, possibly ketonuria, with diabetes mellitus.

OTHER LABORATORY TESTS

- Fecal examination to rule out gastrointestinal parasites.
- Serum trypsin-like immunoreactivity to diagnose exocrine pancreatic insufficiency.
- Total serum T_4 to rule out hyperthyroidism (cats); T_3 suppression testing if hyperthyroidism is suspected but serum total T_4 is normal.

- Low-dose dexamethasone suppression or ACTH stimulation test to diagnose hyperadrenocorticism; plasma ACTH level or high-dose dexamethasone suppression testing to differentiate pituitary-dependent hyperadrenocorticism from adrenal tumor if hyperadrenocorticism is confirmed with the low-dose dexamethasone suppression test or ACTH stimulation test.
- Serum insulin levels in hypoglycemic patients to rule out insulinoma.

IMAGING

- Abdominal radiology may demonstrate hepatomegaly associated with hyperadrenocorticism, diabetes mellitus, and corticosteroid administration.
- Abdominal ultrasonography may demonstrate an adrenal mass or bilateral adrenomegaly (hyperadrenocorticism), hepatomegaly (hyperadrenocorticism, diabetes mellitus, and corticosteroid administration), bowel wall thickening or bowel wall layering disruption (inflammatory bowel disease, lymphoma, lymphangiectasia), and pancreatic masses (insulinoma).
- Magnetic resonance imaging could be used to visualize a neoplasm of the hypothalamus.

DIAGNOSTIC PROCEDURES

Endoscopy with biopsy of the upper gastrointestinal tract to rule out gastrointestinal diseases.

TREATMENT

- Usually outpatient medical management.
- Polyphagia without weight gain or with weight loss is more likely due to a medical problem; evaluate the animal prior to food restriction or manipulation.
 - Once pathologic causes of polyphagia have been excluded, limit the amount of food available, feed a reduced-calorie diet, and/or increase exercise if obesity or weight gain is present.
 - Owners must measure food to accurately assess intake.
 - Some dogs may benefit by the addition of low-calorie bulky foods such as canned green beans.
 - Feeding smaller meals two to three times daily may be beneficial for some patients, provided the total food provided remains the same as required by life stage and activity to promote weight loss or prevent weight gain.
 - Removing the pet during human meal preparation and consumption to reduce begging behavior and the pet obtaining additional food.
 - Slowing down the rate of eating may be beneficial in some dogs, using food-dispensing toys that require manipulation to obtain daily ration.

(CONTINUED)

POLYPHAGIA

- If social issues within the home influence intake these must be addressed:
 - Feed all dogs in separate locations, preferably without visual contact.
 - Have multiple feeding stations available in a multiple-cat home.
- The average animal's daily caloric need can be estimated by the formula $30 \times \text{weight (kg)} + 70$.
- Chew toys can be used as a substitute for food.

**MEDICATIONS****DRUG(S)**

- See specific diseases for detailed therapy.
- Drug-induced—attempt to taper or discontinue drug.
- If a compulsive eating disorder is suspected in dogs, clomipramine (1–3 mg/kg PO q12h) or fluoxetine 1–2 mg/kg q24h may be used or in cats clomipramine 0.25–1.0 mg/kg q24h or fluoxetine 0.5–1.0 mg/kg q24h.
- Dirlotapide is a selective microsomal triglyceride transfer protein inhibitor that blocks the assembly and release of lipoprotein chylomicrons into the bloodstream, thus triggering peptide YY release and a decreased

appetite. This could be used in obese dogs at a dose of 0.01–0.02 mL/kg PO q24h (see package insert for dose adjustment protocol).

**FOLLOW-UP****PATIENT MONITORING**

- Monitor body weight in patients with non-pathologic causes of polyphagia.
- Assess compliance with feeding regime and food measurement to decrease intake and promote weight loss.

POSSIBLE COMPLICATIONS

- Obesity in non-pathologic polyphagia.
- Owner responds to begging behavior and caloric intake is not decreased.
- Weight loss/emaciation in pathologic causes of polyphagia.
- Worsening of respiratory or cardiovascular disease processes in obese patient.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Obesity

PREGNANCY/FERTILITY/BREEDING

A normal physiologic response to pregnancy.

SYNONYMS

- Eating disorder
- Hyperphagia

SEE ALSO

- Compulsive Disorders—Cats
- Compulsive Disorders—Dogs

POLYPOID CYSTITIS

BASICS

OVERVIEW

Polyloid cystitis is a chronic inflammatory condition of the urinary bladder characterized by villous or polyloid protrusions from the mucosa. Polyloid projections are diffusely located over the bladder surface and may be present in the urethra. If they become eroded and ulcerated, varying degrees of hematuria and dysuria occur. The gross appearance of polyps cannot be distinguished from that of bladder neoplasms such as transitional cell carcinomas. Polyloid cystitis in dogs appears to be associated with chronic irritation of the mucosa from either infectious or non-infectious inflammation.

SIGNALMENT

- Dogs with chronic urinary tract infections or urolithiasis.
- No cases reported in cats.

SIGNS

- Initially, may be asymptomatic.
- Hematuria is the most common sign.
- Gross hematuria often occurs at the end of the micturition stream.
- Pollakiuria and dysuria may also be present and are associated with irritation of the polyps.
- Urethral obstruction could occur if a sufficient number of bladder polyps are located in the trigone area of the bladder. Polyps originating or in the urethra may also cause partial or total obstruction.
- Ureteral obstruction may occur if polyps surround the ureteral orifice.
- Urinary tract infection may be present concurrently, which can predispose to upper UTI.

P

CAUSES & RISK FACTORS

- Causes of polyloid cystitis in dogs have not been well documented, but this disorder is commonly associated with UTI or urolithiasis.
- Chronic infection and inflammation secondary to indwelling transurethral urinary catheters have been related to cases of polyloid cystitis in humans.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Polyloid cystitis should be ruled-out in cases of hematuria, pollakiuria, dysuria, and recurrent UTI.
- Bladder neoplasms (such as TCC), UTI, and urolithiasis are the most common rule-outs.

CBC/BIOCHEMISTRY/URINALYSIS

- Serum biochemistry profiles should be normal in most cases of polyloid cystitis unless azotemia occurs as a result of obstruction to urine outflow and/or concurrent pyelonephritis.
- Urinalysis will reveal hematuria, pyuria, and transitional epithelial cells.

OTHER LABORATORY TESTS

- Urine should be cultured by sterile catheterization or at the time of cystoscopy, but not by cystocentesis until TCC has been ruled-out. This will prevent potential abdominal spread of TCC along the needle track.
- Representative polyps removed via cystoscopy or cystotomy should be placed in formalin for light microscopic examination.
- An adequate sample of bladder tissue should be placed in culture media suitable for growth of microbes. Treatment with antimicrobics should be discontinued to minimize inhibition of growth of pathogens in the bladder tissue.

IMAGING

- Survey radiographs may reveal a normal bladder, an irregular thickening of the surface contour of the bladder, and/or concurrent urolithiasis.
- Double-contrast cystography or positive-contrast cystography may reveal irregular polyloid masses in the bladder lumen and/or a thickened bladder wall. The most common location of involvement is the cranioventral bladder wall. Single large polyps with a narrow or broad base may be observed scattered throughout the contrast puddle. Uroliths will migrate to the most dependant portion of the contrast puddle.
- Ultrasonography may show polyps scattered along the mucosal surface of the bladder, especially in the cranioventral aspect.

DIAGNOSTIC PROCEDURES

- Cystoscopic or ultrasound-guided biopsy may be used to obtain representative portions of the polyps for light microscopic examination of stained sections of the lesions.
- More invasive, full-thickness biopsy of the wall of the bladder via cystotomy may be required to include the base of the polyps with an adequate margin of healthy tissue.

PATHOLOGIC FINDINGS

- Gross changes involving the mucosal surface of the urinary bladder include single or multiple small masses ranging from 1 to 10 mm in size. The masses may be nodular with a broad base or attached to the bladder wall by a thin stalk.
- Light microscopic changes include polyloid projections of hyperplastic epithelium that surround a core of proliferative connective tissue mixed with acute and chronic

inflammation (congestion, edema, and acute and chronic inflammatory cells). Findings characteristic of malignancy (e.g., disproportionate enlargement of nuclei in relation to the cytoplasm; increase in chromatin content causing hyperchromasia; structural changes such as aberrant chromatin patterns, lack of distinct cell boundaries, irregularity in cell outlines; enlargement and/or increase in number of nuclei; multinucleated cells with atypical nuclei; abnormal number of mitotic figures; cytoplasmic inclusions and vacuolization; invasion of basement membranes) are conspicuously absent. In some patients, changes typical of granulomatous inflammation predominate.

TREATMENT

- Elimination of bacteria that are a source of chronic irritation is a rational therapeutic goal.
- Non-surgical removal of urocystoliths (voiding urohydropropulsion, lithotripsy, dietary management) that are causing chronic irritation may result in elimination of inflammatory polyps.
- The polyps may also be removed either by cystoscopy or cystotomy.
- Partial cystectomy may be required to remove polyps affecting large portions of the bladder. The remaining portion of the urinary bladder may compensate by increasing its capacity to contain urine in 3–6 months.

MEDICATIONS

DRUG(S)

- Select an antibiotic based on culture of urine and polyp tissue. The patient should receive antibiotic therapy for a minimum of 4–6 weeks.
- Piroxicam and immunosuppressive drugs are of unproven value.

FOLLOW-UP

PATIENT MONITORING

- A urine culture should be performed 7–10 days after antimicrobial therapy is initiated, to confirm urine sterility. Follow-up urinalysis and urine cultures should also be performed by cystocentesis 7 days after antimicrobial therapy has ceased and 1 month post-therapy.

(CONTINUED)

- Ultrasonographic reevaluation of the urinary tract is recommended at 1, 3, and 6 months.

PREVENTION/AVOIDANCE

Control of predisposing factors such as UTI and urolithiasis.

POSSIBLE COMPLICATIONS

- Chronic UTIs
- Upper UTI
- Complete obstruction of ureters or urethra

EXPECTED COURSE AND PROGNOSIS

- The expected course is favorable and the prognosis good if the underlying cause is treated and eradicated.
- Rarely patients with polypoid cystitis develop TCC several years after initial diagnosis. It is unknown if some of these cases represent early carcinoma in situ.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Urinary tract infection
- Urolithiasis

AGE-RELATED FACTORS

No age-related factors have been reported

POLYURIA AND POLYDIPSIA

BASICS

DEFINITION

- PU—greater than normal urine production (dogs, > 45 mL/kg/day; cats, > 40 mL/kg/day).
- PD—greater than normal water consumption (dogs, > 90 mL/kg/day; cats, > 45 mL/kg/day).

PATHOPHYSIOLOGY

The volumes of urine produced and water consumed are controlled by interactions between the kidneys, pituitary gland, and hypothalamus. Plasma osmolality (normally determined primarily by serum sodium concentration) is the primary parameter monitored by this control system. Volume receptors within the cardiac atria and aortic arch also influence thirst and urine production. PU may occur when the quantity of functional antidiuretic hormone synthesized in the hypothalamus or released from the posterior pituitary is limited, or when the kidneys fail to respond normally to ADH. PD occurs when the thirst center in the anterior hypothalamus is stimulated. • In most patients, PD maintains hydration (as normal tonicity) as a compensatory response to PU. Patients' plasma becomes relatively hypertonic and activates thirst mechanisms. Occasionally PD is the primary process and PU is the compensatory response. In this case, the patient's plasma becomes relatively hypotonic because of excessive water intake, ADH secretion is reduced, resulting in PU.

SYSTEMS AFFECTED

- Urologic—full bladder
- Cardiovascular—circulating volume
- Endocrine/Metabolic—pituitary gland, hypothalamus play a role in compensation to PU or PD

SIGNALMENT

- Dog and cat. • Congenital diseases in many breeds (e.g., central diabetes insipidus, nephrogenic diabetes insipidus, portal-vascular anomalies, certain renal diseases).
- Hypoadrenocorticism, some causes of primary PD predominantly affect young dogs.
- Renal failure, hyperadrenocorticism, hyperthyroidism, neoplastic disorders affecting the pituitary and hypothalamus predominantly affect middle-aged and older dogs and cats.

CAUSES

- Primary PU due to impaired renal response to ADH—renal failure, HAC (dogs), hyperthyroidism (cats), pyelonephritis, leptospirosis, pyometra, hepatic failure, hypercalcemia, hypokalemia, renal medullary solute washout, dietary protein restriction, drugs, congenital NDI. • Primary PU caused by osmotic diuresis—diabetes mellitus, primary renal glucosuria, post-obstructive

diuresis, some diuretics (e.g., mannitol and furosemide), ingestion or administration of large quantities of solute (e.g., sodium chloride or glucose), and

hypersomatotropism. • Primary PU due to ADH deficiency—idiopathic, traumatic, neoplastic, or congenital CDI; some drugs (e.g., alcohol and phenytoin). • Primary PD—behavioral, pyrexia, pain, organic disease of the anterior hypothalamic thirst center of neoplastic, traumatic, or inflammatory origin.

RISK FACTORS

- Renal, liver and/or endocrine disease
- Administration of diuretics, corticosteroids, anticonvulsants
- Low-protein diets
- Low purine u/d?

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiating Similar Signs

• Differentiate PU from abnormal increase frequency of urination (pollakiuria). Pollakiuria: often associated with dysuria, stranguria, hematuria. Patients with PU void large quantities of urine; patients with pollakiuria frequently void small quantities of urine. Confirm PU/PD by measuring 24-hour water intake and urine output (3- to 5-day collection period preferred). • Alternatively, urinary specific gravity measurement may provide evidence of adequate urine concentrating ability (dogs, > 1.030; cats, > 1.035), ruling-out persistent PU/PD.

Differentiating Causes

- Renal failure, HAC, and DM (dogs). Renal failure, hyperthyroidism, DM: (cats). • If associated with progressive weight loss—consider renal failure, DM, hyperthyroidism, hepatic failure, pyometra, pyelonephritis, hypoadrenocorticism, malignancy-induced hypercalcemia. • If associated with decreased appetite—consider kidney disease, pyelonephritis, malignancy-induced hypercalcemia, hepatic disease, hypoadrenocorticism. • If associated with polyphagia—consider DM, hyperthyroidism, HAC, acromegaly. • If associated with bilateral alopecia or other cutaneous problems—consider HAC, endocrinologic disorders. • If associated with uremic breath and stomatitis—consider advanced kidney disease. • If associated with vomiting—consider kidney disease, hypoadrenocorticism, pyelonephritis, hepatic failure, hypercalcemia, hypokalemia, hyperthyroidism, DM. • If associated with malaise and/or weakness—kidney disease, hypoadrenocorticism, pyometra, hypercalcemia, DM, hepatic disease, hypokalemia, HAC. • If associated with

palpable thyroid nodule—consider hyperthyroidism. • If associated with hypertensive retinopathy—consider renal failure, hyperthyroidism, DM, HAC. • If associated with recent estrus (previous 2 months) in a middle-aged intact female—consider pyometra. • If associated with abdominal distention—consider hepatic failure, HAC, pyometra, nephrotic syndrome. • If associated with lymphadenopathy, anal sac mass or other neoplastic process—consider hypercalcemia of malignancy. • If associated with behavioral or neurologic disorder—consider hepatic failure, primary PD, CDI. • If associated with marked PD (patients almost continuously seek and consume water)—consider primary PD, CDI, NDI. • If patient is on medication, consider drug induced (steroids, diuretics, anticonvulsants) PU/PD. • If patient is consuming a urolith prevention/dissolution or high salt diet, consider diet-induced PU/PD. • **Key point:** PU/PD may be the first sign of disease with many conditions.

CBC/BIOCHEMISTRY/URINALYSIS

- Urinalysis is useful to confirm PU, discriminate water diuresis from solute diuresis, and identify UTI. • Serum sodium concentration or osmolality may help differentiate primary PU from primary PD. Measuring serum osmolality is preferred; calculated serum osmolality is not an acceptable alternative. • Relative hypernatremia or high serum osmolarity suggests primary PU (values typically at or exceed the high end of normal range).
- Hyponatremia or low serum osmolarity suggests primary PD (values typically at or below normal range), except in animals with hypoadrenocorticism, which have hyponatremia and primary PU. • Azotemia is typical of renal causes for PU/PD, but may also indicate dehydration resulting from inadequate compensatory PD.
- Unexpectedly low BUN concentrations suggest hepatic failure. • With high hepatic enzymes, consider HAC (especially when value for ALP exceeds ALT), hyperthyroidism, hepatic failure, pyometra, DM. Administration of some drugs that promote PU/PD (e.g., anticonvulsants and corticosteroids) also may elevate hepatic enzymes. • Persistent hyperglycemia is consistent with DM. • Hyperkalemia, particularly if associated with hyponatremia, suggests hypoadrenocorticism or therapy with potassium-sparing diuretics. • Hypercalcemia induces PU only when it results from increased ionized calcium (not protein-bound calcium) concentration. • Hypercalcemia and hypokalemia can cause, or occur in association with, other diseases that cause PU/PD. • Hypoalbuminemia supports renal or hepatic causes of PU/PD. • Neutrophilia is

(CONTINUED)

consistent with pyelonephritis, pyometra, HAC, corticosteroid administration. • USG values 1.001- 1.003 suggest primary PD, CDI, congenital NDI. • Glucosuria supports a diagnosis of DM or renal glucosuria. • Pyuria, white blood cell casts, and/or bacteriuria should prompt consideration of pyelonephritis.

OTHER LABORATORY TESTS

- ACTH stimulation or dexamethasone suppression tests rule out HAC in middle-aged to older dogs. • Thyroxine concentration to rule out hyperthyroidism in middle-aged to old cats. • Bile acids (fasting and postprandial) to rule out portosystemic shunt or hepatic failure. • Urine culture—chronic pyelonephritis cannot be conclusively ruled-out by absence of pyuria or bacteriuria.
- Cytologic examination of lymph node aspirate may provide evidence of lymphoma, which induces PU by hypercalcemic nephrotoxicity or direct infiltration of renal tissues. • Paired *Leptospira* titer to rule out leptospirosis. • ADH response test to rule-out CDI. • Water deprivation testing (to assess ability to make and respond to ADH) is controversial due to humane considerations; use selectively.

IMAGING

Abdominal survey radiography, ultrasonography: may provide evidence of renal (e.g., primary renal diseases, urinary obstruction), hepatic (e.g., microhepatica, portal vascular anomalies, hepatic infiltrate), adrenal (e.g., adrenal mass or bilateral adrenal hypertrophy suggesting HAC), or uterine (e.g., pyometra) disorders that can contribute to PU/PD.

DIAGNOSTIC PROCEDURES

Modified Water Deprivation with ADH Response Test (see Appendix II)

- Differentiates CDI from primary PD and NDI. Rule out other causes for PU/PD before performing this test. Controversial, some suggest omitting water deprivation and proceeding directly to ADH administration to rule in CDI. Administration of ADH to patients with primary PD may be dangerous.
- Useful for patients with marked PU/PD and hyposthenuria. • Contraindicated in dehydrated and azotemic patients, but ADH response testing may be performed safely in these patients. • Patients that concentrate urine adequately in response to water deprivation have adequate ADH production and renal response to ADH. If other causes have been ruled out, primary PD is presumed to be present. • Failure to concentrate urine adequately in response to properly designed

water deprivation tests, but further concentrate their urine in response to administration of exogenous ADH = CDI.

- Failure to concentrate urine adequately in response to water deprivation and also failure to further concentrate urine in response to administration of exogenous ADH = NDI.

TREATMENT

• Serious medical consequences are rare if patient has free access to water and is able to drink. Until the mechanism of PU is understood, discourage owners from limiting access to water. Direct treatment at the underlying cause. • Provide PU patients with free access to water unless they are vomiting. If vomiting, give replacement maintenance fluids parenterally after appropriate samples have been collected for initial diagnostics. Provide fluids parenterally when other conditions limit oral intake or dehydration persists despite PD. • Base fluid selection on knowledge of the underlying cause for fluid loss. In most patients, lactated Ringer's solution is acceptable. • When dehydration has resulted from withholding water, or when urine is hyposthenuric, providing oral water or parenteral administration of dextrose 5% in water may be preferred to lactated Ringer's solution. • Primary PD—treat by gradually limiting water intake to a normal daily volume. May be necessary to reduce water intake over days–weeks to avoid undesirable behavior such as barking, urine consumption, or other bizarre behavior. Monitor patient closely to avoid iatrogenic dehydration. Salt (1 g/30 kg q12h) or sodium bicarbonate (0.6 g/30 kg q12h) may be given orally to help reestablish renal medullary solute gradient. Consider behavior modification if water restriction alone is unsuccessful.

CLIENT EDUCATION

Do not withhold water from patients with PU because potentially dangerous dehydration may result.

MEDICATIONS

DRUG(S) OF CHOICE

Varies with underlying cause

CONTRAINDICATIONS

Do not administer ADH (or any of its synthetic analogs, such as DDAVP) to patients with primary PD because of the risk of inducing water intoxication.

PRECAUTIONS

Until renal and hepatic failure have been excluded as potential causes for PU/PD, use caution in administering any drug eliminated via these pathways.

FOLLOW-UP

PATIENT MONITORING

- Hydration status—clinical assessment of hydration, serial evaluation of body weight.
- Fluid intake and urine output provide a useful baseline for assessing adequacy of hydration therapy.

POSSIBLE COMPLICATIONS

Dehydration, hypovolemic shock, hypernatremia

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Bacterial UTI. • Urinary incontinence may develop in dogs with concurrent urethral sphincter dysfunction, presumably because of increased bladder filling associated with PD.

PORTOSYSTEMIC SHUNTING, ACQUIRED

BASICS

OVERVIEW

- Acquired portosystemic shunts (APSS): develop subsequent to portal hypertension (PH).
- Prehepatic PH: abdominal portion of portal vein causes.
- Intrahepatic PH: presinusoidal, sinusoidal, postsinusoidal causes.
- Posthepatic PH: rostral to hepatic vein causes (includes cardiac, pericardial, major veins).

SIGNALMENT

- Most common—dogs with chronic necroinflammatory liver disease.
- Less common—dogs with ductal plate malformations (congenital hepatic fibrosis phenotype), non-cirrhotic portal hypertension, recovery from panlobular necrosis, dogs with PSVA intolerant to ligation (portal atresia).
- Cats—ductal plate malformations (DPM), congenital hepatic fibrosis [CHF] phenotype), severe CCHS (rare), or PSVA intolerant to ligation (portal atresia).
- Extrahepatic bile duct obstruction (EHBD) > 6 weeks.
- Certain disorders—have age or breed incidence (see Ductal Plate Malformations (Congenital Hepatic Fibrosis); Cirrhosis and Fibrosis of the Liver; Chronic Hepatitis).
- Breeds: DPM more common in Persians and Himalayan cat, and Boxer dogs.

SIGNS

- P**
- Clinical signs represent sequelae of impaired hepatic perfusion; or reduced hepatic function in chronic liver disease.
 - Episodic HE—major sign, may include neurobehavioral abnormalities, blindness, PU/PD, anorexia, lethargy, vomiting; neurologic signs may localize to cerebrum, brainstem, or suggest transverse myelopathy; signs often improve with fluid therapy (e.g., dextrose and potassium supplements), broad-spectrum antibiotics, lactulose, and dietary protein restriction (see Hepatic Encephalopathy).
 - Ascites—common but variable; may fluctuate.

- Hypertensive splanchnic vasculopathy—causes gastroduodenal bleeding/ulceration; may progress to perforation and septic peritonitis, life-endangering blood loss if coexistent coagulopathy; can provoke severe HE due to potent encephalogenic effect of enteric blood; causes anorexia, vomiting, diarrhea, abdominal pain, anemia, and sometimes iron deficiency.
- Urogenital—obstructive uropathy due to ammonium biurate urolithiasis: gross or microscopic hematuria; pollakiuria; dysuria.

CAUSES & RISK FACTORS

- Multiple tortuous vessels—represent vasculature interconnecting portal splanchnic and systemic venous circulations.
- Lack of valves in the portal vein—allows blood to follow “a path of least resistance.”
- Portal hypertension—results from many disease processes: importantly, diffuse hepatic fibrosis with or without cirrhosis; chronic unresolved EHBD (> 6 weeks); other causes, include portal venous thromboembolism (TE), idiopathic portal hypertension, non-cirrhotic PH (obliteration of tertiary portal venules), and hepatic sinusoidal occlusion syndrome (zone 3, level of hepatic venules, veins, or vena cava); less common, disorders impair abdominal portal venous (splanchnic segment): TE, stricture, strangulation, rare portal vein atresia (congenital malformation) and congenital or acquired hepatic AV malformation (arterialized portal circulation); see Hypertension, Portal).
- Episodic HE coincidental with meal ingestion (high protein), enteric hemorrhage (bleeding tendencies, portal vasculopathy), azotemia, alkalemia, electrolyte disturbances, blood transfusion or hemolysis, infections, and administration of certain drugs.
- Hyperammonemia and impaired metabolism of uric acid to water-soluble allantoic causes ammonium urate urolithiasis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- CNS signs—*infectious* disorders (e.g., FIP, canine distemper, toxoplasmosis, FeLV- or FIV-related infections); toxicities (e.g., lead,

mushrooms, drugs, acute hepatic failure); hydrocephalus; idiopathic epilepsy; metabolic disorders (e.g., severe hypoglycemia, hypo- or hyperkalemia, hypocalcemia, severe hypophosphatemia).

- Gastrointestinal signs—bowel obstruction; dietary indiscretion; foreign body ingestion; inflammatory bowel disease.
- Urinary tract signs—bacterial urinary tract infection; urolithiasis.
- PU/PD—disorders of urine concentration (e.g., diabetes insipidus, abnormal adrenal function, hypercalcemia, primary polydipsia, congenital or acquired renal disease).
- Causes of abdominal effusion—cardiopulmonary disorders causing right-sided heart failure; pericardial disease; primary inflammatory hepatopathies; infiltrative hepatic disease (e.g., neoplasia, amyloid); non-hepatic abdominal disorders associated with effusions (e.g., splenic torsion, visceral neoplasia, carcinomatosis); or peritonitis: chemical (e.g., bile, urine, chyle) or sepsis.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—microcytosis (reflects PSS or iron deficiency); mild nonregenerative anemia common; poikilocytes (cats); target cells (dogs).
- Biochemistry—low BUN, low to low normal creatinine, glucose, albumin, and cholesterol are common; variable liver enzyme activity (ALP usually high in young animals [bone isoenzyme]) and bilirubin variable; findings depend on underlying cause.
- Urinalysis—variable urine concentration; ammonium biurate crystalluria, hematuria, pyuria, and proteinuria reflect urolithiasis (mechanical trauma, inflammation or infection).

OTHER LABORATORY TESTS

- TSBA—sensitive indicator of PSS; variable pre-meal and markedly increased postprandial values (> 100 µmol/L) = “shunting pattern.”
- Blood ammonia values—sensitive but inconsistent indicator of HE; samples cannot be frozen or mailed for later analysis (ammonia lability); ammonium biurate crystalluria infers high blood ammonia (evaluate 3 urine specimens, 4–8 h after eating); ammonia tolerance testing—(ammonium chloride solution) most reliable test for ammonia intolerance; **caution:** may induce HE.

(CONTINUED)

PORTOSYSTEMIC SHUNTING, ACQUIRED

- Coagulation tests—prolonged PT, APTT, and PIVKA reflect severity of liver dysfunction, synthetic failure, DIC, or vitamin K₁ adequacy; PIVKA useful in deciding need for supplemental vitamin K₁ treatment. Low protein C activity reflects PSS (PSVA, APSS).
- Abdominal effusion—usually pure or modified transudate; high serum:effusion albumin ratio (> 1.1) substantiates provocative role of PH in effusion formation.

IMAGING

Abdominal Radiography

- Liver size depends on underlying cause; microhepatia: common in dogs with chronic liver disease or PSVA variant causing ascites (portal atresia) and DPM in dogs, DPM causes variable liver size in cats; severe polycystic liver may cause hepatomegaly.
- Abdominal effusion.
- Ammonium biurate calculi—radiolucent unless radiodense mineral shell (infection).

Radiographic Portovenography

Demonstrates multiple APSS; not recommended due to risks of iatrogenic complications, see alternatives below.

Abdominal Ultrasonography

- Liver size depends on underlying cause.
- May disclose disease related parenchymal or biliary system changes.
- APSS—identify with color-flow Doppler; confirms hepatofugal portal flow; tortuous APSS usually adjacent to kidneys or spleen.
- Abdominal effusion—common.
- Uroliths: renal pelvis, urinary bladder; rare in ureters.
- Intrahepatic AV communication—pulsating arterialized vascular structure within enlarged liver lobe, abdominal effusion and APSS; see Arteriovenous Malformation of Liver.
- Color-flow Doppler may detect portal thrombi.

Colorectal (CRS) or Splenoporttal (SPS) Scintigraphy

- Sensitive noninvasive test confirms PSS.
- Cannot differentiate PSVA from APSS.
- CRS: Administer technetium-99m pertechnetate rectally; gamma camera imaging determines rate of isotope appearance in liver and heart; calculate shunt fraction from time/activity plots (normal ≤ 15%); not quantitative.

- SPS: isotope splenic injection via US guidance under heavy sedation or anesthesia; may not provide superior information vs. CRS.

Multisector CT

Non-invasive imaging method of choice; details vascular anatomy and visceral abnormalities, rapid data collection; requires short-term anesthesia, and IV contrast injection.

DIAGNOSTIC PROCEDURES

Fine-needle Aspiration Cytology

- Hepatic aspiration—22-gauge needle aspirates cannot differentiate disorders causing PSS.
- Liver biopsy—open surgical wedge biopsy or laparoscopic sampling (cup biopsy forceps); obtain tissue from several liver lobes; Tru-Cut samples may not provide adequate tissue for definitive diagnosis.

PATHOLOGIC FINDINGS

- Gross—small, irregularly contoured liver with chronic liver disease (cirrhosis, fibrosis).
- Normal to large size in early venous outflow obstruction (Budd-Chiari, sinusoidal obstruction syndrome).
- Large liver lobe (remainder of liver normal to small) with intrahepatic AV malformation.
- Normal to small—DPM (CHF phenotype), non-cirrhotic PH, portal TE.
- Small liver if congenital portal atresia.
- Normal to large liver in cats with polycystic liver disease: may only have microscopic cystic structures inapparent on US; characterized microscopically as DPM.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—severe signs of HE; critical care

NURSING CARE

See Hepatic Encephalopathy

DIET

- Nutritional support—essential to maintain body condition for optimal management of HE; balanced, restricted-protein diet important; but diet should be optimized for that patient's tolerance—(see Hepatic Encephalopathy).

- Protein allocation titrated to response in combination with treatments ameliorating HE (see Hepatic Encephalopathy); use commercial diets formulated for liver disease or moderate renal insufficiency as diet baseline.

- Dogs: baseline diet provides 2.2–2.5 g protein/kg body weight when fed to meet energy requirements; titrate protein using 0.5 g/kg allocation additions (dairy protein or soy sources), q5–7 days until optimum level established: dairy and soy protein are best sources.

- Cats being pure carnivores require meat-derived protein.

- Parenteral nutrition—see Hepatic Encephalopathy.

CLIENT EDUCATION

- Depends on underlying cause.
- Educate client about signs of HE and potential for ammonium biurate obstructive uropathy in males; male dogs may require pre-scrotal urethrostomy.
- Educate client how to adjust diuretics (as-needed basis) to mobilize abdominal effusion.
- Educate client how to adjust oral medications and enemas (as-needed basis) to ameliorate HE (see Hepatic Encephalopathy).

MEDICATIONS

DRUG(S)

- Enteric hemorrhage—associated with hypertensive splanchnic vasculopathy (diapedesis and gastroduodenal ulceration) and coagulopathy; some clinicians use prophylactic acid blockers or gastroprotectants to reduce risk; treat symptomatic animal with H₂blocker or HCl pump inhibitor (omeprazole) and sucrlate; may require blood components or DDAVP (see Coagulopathy of Liver Disease).

- *Abdominal effusion*—sequentially measure weight, girth, body condition; initially exercise restrict (improves renal perfusion, sodium and water elimination), dietary sodium restriction.

- *Conventional diuretics*—combine furosemide and spironolactone; furosemide (0.5–2 mg/kg PO q12–24h) and

PORTOSYSTEMIC SHUNTING, ACQUIRED

(CONTINUED)

- spironolactone (0.5–2 mg/kg PO q12h, use a single doubled dose for loading one time); dose titrations based on response q4 days; adjust using incremental 25–50% dose increase. Spironolactone: potassium sparing; less potent than furosemide. Furosemide: potassium wasting, diuresis induces RAAS response. Serum:effusion albumin ratio (> 1.1) may predict response to diuretics.
- *Losartan and telmisartan*—angiotensin receptor blockers (ARB), selectively antagonizing angiotensin-1 receptor, bypassing intermediary activation within RAAS cascade—may improve water and sodium elimination (see Portal Hypertension; Hepatic Fibrosis and Cirrhosis).
 - *Vasopressin V₂ antagonists* (aquaretics) may assist with management of diuretic resistant ascites. Tolvaptan: see Portal Hypertension.
 - *Diuretic-resistant ascites*—see Portal Hypertension.
 - Avoid dehydration as this can lead to HE.
 - Avoid hypokalemia as this can provoke HE.

PRECAUTIONS

- Remain aware of altered drug metabolism related to reduced first-pass extraction (portosystemic shunting), altered hepatic metabolism/biotransformation, and reduced protein binding (if hypoalbuminemic).
- Remain vigilant for diuretic-induced dehydration and electrolyte dysregulation that may provoke HE.

POSSIBLE INTERACTIONS

Avoid metoclopramide if using spironolactone (blocks effect); avoid NSAIDs; these may inhibit furosemide-induced diuresis, potentiates renal injury, may cause sodium accumulation.

P

FOLLOW-UP

PATIENT MONITORING

- Reevaluate patient's at-home demeanor and appetite as a reflection of HE.
- Monitor clinical signs, appetite, body condition, weight, abdominal girth, CBC, serum biochemistry, and urine for ammonium

biurate crystalluria; TSBA not useful for sequential evaluation as these are consistently increased due to PSS and ursodeoxycholic acid (drug measured in assay) administration.

- Adjust medical management to reduce episodic HE, ammonium biurate crystalluria (potential for urolith formation), and abdominal effusion.
- Inspect patient carefully for evidence of clinical bleeding; determine need for intermittent chronic vitamin K₁ administration (parenteral route).

PREVENTION/AVOIDANCE

- Early treatment of acquired liver disease and EHBDO minimizes fibrosis/ remodeling.
- Cautious PSVA attenuation.

POSSIBLE COMPLICATIONS

- Treat underlying disorder(s).
- Enteric hemorrhage associated with hypertensive vasculopathy; may require acute intensive care: to manage hypovolemia, coagulopathy, and ensuing HE; may require surgical resection of involved gut (rare).
- Dehydration, contraction alkalosis, azotemia—complications of diuretics.
- Death—from liver failure, HE complications, lethal enteric hemorrhage, or sepsis.

EXPECTED COURSE AND PROGNOSIS

- Varies with underlying cause.
- Management of chronic liver disease or hepatic fibrosis seemingly extends life.
- Animals with non-cirrhotic PH and DPM (CHF phenotype) may live > 8 years if managed successfully during symptomatic illness.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Ammonium urate urolithiasis
- Ascites
- Coagulopathy
- Hepatic encephalopathy

PORTOSYSTEMIC VASCULAR ANOMALY, CONGENITAL

BASICS

DEFINITION

- Congenital PSVA—are venous malformations connecting the portal and systemic circulations permit portal blood to circumvent the liver (hepatofugal circulation, away from the liver).
- May be extrahepatic (more common in small breed dogs and cats) or intrahepatic (more common in large-breed dogs).
- Most are single vessels.
- Many small-breed dogs with PSVA also have vascular abnormalities involving tiny branches of the intrahepatic microvasculature (see Hepatoportal Microvascular Dysplasia).
- Acquired portosystemic shunts (APSS)—develop subsequent to portal hypertension (PH) and result if the patient is intolerant to shunt attenuation (surgical); see Portosystemic Shunting, Acquired.
- Genetically transmitted in high-risk small breeds; complex polygenic trait.

PATHOPHYSIOLOGY

- Clinical signs—caused by hepatofugal circulation; prohibits hepatic cleansing of enteric toxins and food derived nitrogenous toxins substances from portal blood.
- Microhepatia—deprivation of enteric hepatotrophic factors causes hepatic atrophy.
- Episodic HE—associated with high-protein food, gastrointestinal bleeding, dehydration, azotemia, alkalosis, electrolyte disturbances, blood transfusion, hemolysis, infections, constipation, catabolism, and certain drugs.
- Ammonium biurate crystalluria/ urolithiasis—caused by hyperammonemia and impaired transformation of uric acid to water-soluble allantoin; may be presenting problem.
- Clinical signs reflect the magnitude of shunting through anomalous vasculature.

SYSTEMS AFFECTED

- Nervous—episodic HE in many but not all.
- Gastrointestinal—intermittent inappetence; vomiting; diarrhea; pica; ptalism (cats).
- Urogenital—“plump” kidneys; ammonium urate urolithiasis; 50% of male dogs cryptorchid (one report).
- Asymptomatic—up to 20% of dogs.

GENETICS

- Breeds affected—e.g., most small-breed dogs: esp., Yorkshire terrier, cairn terrier, Maltese, Tibetan spaniel, miniature schnauzer, Norfolk terrier, pugs, Shih Tzu, Havanese, Papillon; large breeds: Irish wolfhound; Labrador retriever, Old English sheepdog.
- Autosomal dominant polygenic complex trait causes PSVA/MVD trait in small breeds; MVD most common phenotype.

INCIDENCE/PREVALENCE

0.2–0.6% of large referral clinic population

GEOGRAPHIC DISTRIBUTION

Reported worldwide

SIGNALMENT

Species

Dog and cat; more common in dog

Breed Predilections

- Higher risk—purebred and mixed small “terrier” dogs; cats—DSH, fewer pure breeds
- See “Generics” (above)

Mean Age and Range

- Usually identified in juveniles; some dogs as old as 13 years at initial diagnosis
- Asymptomatic animals present older; miniature schnauzers; portoazygous shunts
- Serendipitous discovery: if asymptomatic

Predominant Sex

N/A

SIGNS

Historical Findings

- Stunted growth—common.
- Signs often initiate with weaning of puppy or kitten to commercial growth foods.
- Gastrointestinal signs—inappetence; vomiting; diarrhea; pica.
- Cats initially thought to have upper respiratory infection (display ptalism).
- Episodic HE—most dramatic predominate signs, transiently improve with fluids, broad-spectrum antibiotics, and lactulose.
- CNS signs—weakness; pacing; ataxia; disorientation; head pressing; amaurotic blindness; behavioral change: aggression (cats), vocalization, hallucination; seizure; coma.
- Urinary signs—PU/PD; ammonium biurate crystalluria: pollakiuria, dysuria; hematuria; urethral (rarely ureteral) urolith obstruction.
- Asymptomatic—up to 20% of dogs.
- Affected bitches may produce litters.

Physical Examination Findings

- Normal appearance; stunted stature; microhepatia; HE; copper-colored irises in non-blue-eyed cats (note: Persian, Russian blue, some others normally have copper-colored iris; iris color does not change with PSVA ligation).
- Neurologic signs (see above).
- Ascites; rare, implies congenital portal atresia with APSS or erroneous diagnosis.

CAUSES

- Congenital malformations.
- APSS in congenital PSVA—develop subsequent to portal atresia (cats > dogs) or surgically induced PH (from shunt attenuation).

RISK FACTORS

PSVA—purebred dogs, especially small terrier-type breeds; Irish wolfhound have slow ductus venosus closure, early puppy screening in this breed may erroneously identify apparently “affected” dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

- CNS signs—*infectious disorders* (e.g., FIP, canine distemper, toxoplasmosis, FeLV- or FIV-related infections); *toxicities* (e.g., lead, mushrooms, recreational drugs); hydrocephalus; idiopathic epilepsy; *metabolic disorders* (e.g., severe hypoglycemia, hypokalemia or hyperkalemia, hypocalemia).
- Gastrointestinal signs—bowel obstruction; dietary indiscretion; foreign body ingestion; inflammatory bowel disease.
- Urinary tract signs—bacterial urinary tract infection; urolithiasis.
- PU/PD—*disorders of urine concentration* (e.g., diabetes insipidus, abnormal adrenal function, hypercalcemia, primary polydipsia); associated with high GFR in PSVA.
- Primary liver disease—distinguished by diagnostic imaging and liver biopsy.
- Abnormal liver function (high TSBA) suggests PSVA, without clinical signs or clinicopathologic features or macroscopic shunt—most likely hepatoportal MVD.
- APSS—many differentials; see Portosystemic Shunting, Acquired.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—microcytosis; mild nonregenerative anemia; poikilocytosis (cats); target cells (dogs).
- Biochemistry—low BUN, creatinine, and cholesterol common but inconsistent; hypoglycemia—least common, liver enzyme activity variable (ALP high in young patients [bone isoenzyme]); bilirubin normal, hypoalbuminemia inconsistent and mild.
- Urinalysis—dilute urine (PU/PD); ammonium biurate crystalluria, hematuria, pyuria, and proteinuria: mechanical inflammation and infection secondary to metabolic calculi.

OTHER LABORATORY TESTS

- TSBA—sensitive indicator of PSS; random fasting values may be within reference intervals; 2 h postprandial values usually markedly high (> 100 µmol/L); always use paired samples around meal ingestion, no need to fast.
- Blood ammonia—sensitive indicator of HE and shunting but less reliable than TSBA in practice (analytic/methodologic issues [samples cannot be frozen or mailed for analysis]); ammonia tolerance testing—oral or rectal NHCl₄ administration demonstrates ammonia intolerance. **Note:** may cause transient HE.
- Coagulation tests—prolonged clotting times compared to healthy dogs but not clinically significant; not associated with bleeding.
- Protein C—low values help differentiate PSVA from MVD; protein C < 70% in PSVA, usually > 70% in MVD; reflects shunting magnitude. Protein C may be normal in asymptomatic PSVA dogs; used to estimate improved portal flow postoperatively. TSBA often remains

PORTOSYSTEMIC VASCULAR ANOMALY, CONGENITAL

(CONTINUED)

abnormal due to concurrent MVD. Not similarly used in cats. • Abdominal effusion—as post-surgical complication reflects iatrogenic portal hypertension; cytologic/physicochemical analysis: pure or modified transudate

IMAGING

Abdominal Radiography

- Microhepatia—dogs > cats.
- Renomegaly—coordinates with high GFR.
- Abdominal effusion—may be transient after surgical ligation; if precedes surgery coordinates with APSS and suggests portal atresia, AV malformation, non-cirrhotic PH, ductal plate malformation (congenital hepatic fibrosis phenotype).
- Ammonium urate urolithiasis—radiolucent unless combined with radiodense mineral shell.

Radiographic Portovenography

- Mesenteric portography—old gold standard confirming PSVA; defines portal circulation.
- Verifies shunt location—extrahepatic suggested by caudal extent of PSVA caudal to vertebra T₁₃; intrahepatic if caudal extent of PSVA cranial to vertebra T₁₃.

Abdominal Ultrasonography (US)

- Subjective assessment; may be difficult to identify some PSVA (e.g., portoazygous, splenophrenic); microhepatia; hypovascular liver, may confirm shunting vessel.
- Color-flow Doppler—assists shunt localization; interrogate vena cava cranial to phrenicoadominal vein for turbulence (where PSVA enters).
- Intrahepatic shunts—easily imaged.
- Other features: renomegaly, uroliths common (cystic, renal pelvis, rarely ureteral).
- Microbubble study—used to confirm shunting; splenic injection of heparinized blood with microbubbles with hepatic US observation for hepatopetal delivery.

Colorectal (CRS) or Splenoportal (SPS) Scintigraphy

- Technetium-^{99m} pertechnetate; gamma camera imaging documents isotope appearance in heart before liver; shunt fraction (time activity plot) is not quantitatively reliable; shunt fraction $\leq 15\%$ = normal; PSVA usually $> 60\%$.
- CRS: sensitive noninvasive test—confirms shunting; cannot differentiate PSVA from APSS or intra- from extrahepatic PSVA.
- SPS: involves splenic isotope injection; may miss caudal PSVA malformations.

Multisector CT

- New imaging gold standard demonstrates arterial and portal circulations and PSVA.
- Noninvasive: requires IV iodinated contrast and short-term general anesthesia (20 min.).

DIAGNOSTIC PROCEDURES

- Fine-needle aspiration cytology—cannot differentiate PSVA; binucleate small hepatocytes common.
- Liver biopsy—open surgical wedge or laparoscopic cup samples

necessary, biopsy of several liver lobes (avoid caudate lobe: best perfused lobe receives circulation from first portal vein branch; fewest lesions); needle core samples may be inadequate for definitive diagnosis of portal hypoperfusion.

PATHOLOGIC FINDINGS

- Gross—small, smooth-surfaced liver; PSVA may be difficult to verify at autopsy; young animals with portal atresia may have APSS.
- Portal hypoplasia: invalid microscopic diagnosis; lesion best termed “portal hypoperfusion” as portal thrombi, portal vein ligation, surgically created PSS—have histologic features identical to PSVA.
- Microscopic—small non-perfused or absent portal venules; multiple portal arteriole cross-sections; juvenile portal triads (tiny, too many), lobular atrophy, variable scattered lipogranulomas (coalesced foamy macrophages contain hemosiderin-iron); thick prominent throttling musculature of hepatic venules; unusual longitudinal hepatic venule profiles; engorged lymphatics; some dogs with severe zone 3 lipid vacuolation, lipogranulomas, and nonsuppurative inflammation shrouding hepatic venules, appear intolerant to complete PSVA ligation.
- **Note:** MVD has histologic features identical to PSVA but lack macroscopic shunt. MVD diagnosis requires clinical information (lack of signs, absence of clinicopathologic features typical of PSVA), and scintigraphy or vascular imaging (usually not justified).

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—severe signs of HE; medical intervention prior to liver biopsy and ligation.

NURSING CARE

See Hepatic Encephalopathy

DIET

- Nutritional support—essential to maintain body condition as muscle functions as a site of temporary ammonia detoxification.
- Balanced protein-restricted diet—use commercial canine liver diet for dogs and feline liver diet for cats as baseline diet. To this diet, additional protein allocations are titrated based on patient response) in combination with treatments ameliorating HE.
- Dogs—as tolerated, add 0.5 g protein/kg body weight using dairy quality protein (e.g., cottage cheese, cheddar cheese, yogurt): observe over 5–7 day intervals to adjust (see Hepatic Encephalopathy).
- Asymptomatic or minimally symptomatic animals can survive well with dietary and medical interventions.
- Explain therapeutic options: medical vs. surgical.
- Surgical ligation—has potential to cure; expect improvement in all symptomatic dogs that tolerate some degree of shunt attenuation.
- Postoperative clinical signs—may persist requiring chronic nutritional and medical management; some dogs can have medical and dietary interventions withdrawn.
- Clinical improvement after surgical ligation despite persistent high TSBA values.
- Surgical/anesthetic risks—5–25% mortality; depending on surgeon, type of PSVA, hepatic microscopic lesions, supportive critical care.
- Monitoring protein C—documents change in hepatic portal perfusion; values increase and may normalize if successful surgery; re-test 2–6 months after surgery.
- If surgery not pursued or ligation not tolerated: remain vigilant for ammonium biurate obstructive uropathies (all levels of urinary system); urethral obstruction (males) may require permanent urethrostomy.

dogs that tolerate some degree of shunt attenuation.

• Postoperative clinical signs—may persist requiring chronic nutritional and medical management; some dogs can have medical and dietary interventions withdrawn.

• Clinical improvement after surgical ligation despite persistent high TSBA values.

• Surgical/anesthetic risks—5–25% mortality; depending on surgeon, type of PSVA, hepatic microscopic lesions, supportive critical care.

• Monitoring protein C—documents change in hepatic portal perfusion; values increase and may normalize if successful surgery; re-test 2–6 months after surgery.

• If surgery not pursued or ligation not tolerated: remain vigilant for ammonium biurate obstructive uropathies (all levels of urinary system); urethral obstruction (males) may require permanent urethrostomy.

SURGICAL CONSIDERATIONS

- HE—should be mitigated with medical management before anesthesia and surgery.
- ICU monitoring—recommended postoperatively for 72–96 h.
- Surgical PSVA ligation—optimal goal is total ligation; may not be tolerated leading to APSS (esp. ameroid or cellophane banding).
- Partial ligation: improves patient health.
- Degree of tolerated PSVA closure judged at surgery: physiologic responses to temporary shunt occlusion (change in portal/systemic blood pressure, splanchnic circulation, pulse rate); but intraoperative assessments can be inaccurate.
- Ameroid constrictor—reduces immediate surgical risks of ligation; **caution:** may later result in APSS in some patients.
- Intrahepatic PSVA—most difficult to ligate; coil embolectomy is alternative procedure, may require multiple procedures, expensive.
- Intraoperative portography advised for all patients—verifies correct vascular ligation.
- Postoperative complications—acute severe PH; portal venous thrombi; mesenteric ischemia; endotoxemia; seizures; sepsis; acute pancreatitis; enteric hemorrhage.
- Intra- and postoperative hypothermia—risk for very small patients; prolongs recovery.
- Emergency surgery—rarely required for ligature removal; ameroid constrictors difficult to remove if complications develop.
- Abdominal effusion—transient after shunt ligation; alone, does not indicate intolerable PH if resolves within 7 days; serious PH indicated by signs of mesenteric ischemia (bloody diarrhea, abdominal pain, failure to recover from surgery/anesthesia, unexplained tachycardia, hyper- or hypothermia); monitor girth and body weight postoperatively.
- Hetastarch can increase bleeding risks.
- Blood component therapy containing ACD may provoke hypocalcemia and coagulopathy (hypercalcemia) in patients < 5 kg.
- Intractable seizures in $< 5\%$ dogs post-ligation; cause unclear, treatment for cerebral edema and sedation required; no rigorous clinical evidence that prophylactic

(CONTINUED)

PORTOSYSTEMIC VASCULAR ANOMALY, CONGENITAL

KBr or Keppra is beneficial; CRI propofol unreliable; flumazenil (5–10 µg/kg IV bolus) anecdotally suggested but is unreliable for resolution of neurologic signs.

MEDICATIONS

DRUG(S)

See Hepatic Encephalopathy

PRECAUTIONS

Remain aware of altered drug metabolism related to reduced first-pass extraction (portosystemic shunting), altered hepatic metabolism/biotransformation.

FOLLOW-UP

PATIENT MONITORING

- Reevaluate—patient's at-home behavior; body condition, weight, girth circumference (postoperatively); CBC (resolution of microcytosis), biochemistry (resolution of low cholesterol, BUN, creatinine), urinalysis (resolution of ammonium biurate crystalluria). • TSBA (small-breed dogs)—persistent high values do not substantiate surgical failure because of common coexistent MVD.

POSSIBLE COMPLICATIONS

See "Surgical Considerations"

PREVENTION/AVOIDANCE

Multiple portosystemic shunts—should be detected by US; if identified indicate need for liver biopsy but contraindicates pursuit of shunt ligation; implicates portal atresia or another underlying disorder causing PH; PSVA is not associated with PH and APSS.

EXPECTED COURSE AND PROGNOSIS

- Cannot predict individual response to surgery. • Dogs—ligation improves signs in ~80% symptomatic patients. • Cats—many develop APSS with ligation. • Post-surgery—continue HE management (especially diet) until reevaluation and observation confirm improvement. • Some patients—require indefinite nutritional and medical support after surgical ligation. • Partial ligation—may result in full shunt attenuation (granulation response to ligature). • Ameroid constrictor—may result in full ligation within a few days (twisting after placement, thrombi); may cause APSS. • Increased risk for poor surgical outcome—in small dogs with zone 3 lipogranulomas/lipid vacuolation shrouding hepatic venule; and cats. • Despite initial good response, recrudescence shunting may develop 3 years post-ligation. • Asymptomatic non-ligated PSVA dogs can have a full life expectancy with medical management.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Ammonium urate urolithiasis • Copper-colored iris (cats) • Cryptorchidism (dogs) • Hepatic encephalopathy

AGE-RELATED FACTORS

- PSVA—surgical outcome may be good in young and old patients, especially those with minimal signs of HE. • Dogs with PSVA identified at older ages are usually asymptomatic for HE and may have easily attenuated shunts (portoazygous).

PREGNANCY/FERTILITY/BREEDING

- Asymptomatic bitches can carry litters to term. • Asymptomatic dogs have been used

for stud. • Breeding PSVA dogs not advised (genetic).

SYNONYM

Portacaval shunt

SEE ALSO

- Hepatic Encephalopathy • Hepatoportal Microvascular Dysplasia • Juvenile Fibrosing Liver Disease • Portosystemic Shunting, Acquired

ABBREVIATIONS

- APSS = acquired portosystemic shunt
- CRS = colorectal scintigraphy • HE = hepatic encephalopathy • MVD = microvascular dysplasia • PSVA = portosystemic vascular anomaly • SPS = splenoportal scintigraphy • TSBA = total serum bile acids • US = ultrasound

P

Poxvirus Infection—Cats

BASICS

OVERVIEW

- Member of the genus Orthopoxvirus, family Poxviridae.
- Enveloped DNA virus, resistant to drying (viable for years) but readily inactivated by most disinfectants.
- Geographically limited to Eurasia.
- Relatively common.
- Serologic evidence of infection may approach 10% in cats in western Europe.

SIGNALMENT

- Cats—domestic and exotic
- No age, sex, or breed predisposition

SIGNS

- Skin lesions—multiple, circular; dominant feature; usually develop on head, neck, or forelimbs.
- Primary lesions—crusted papules, plaques, nodules, crateriform ulcers, or areas of cellulitis or abscesses.
- Secondary lesions—erythematous nodules that ulcerate and crust; often widespread; develop after 1–3 weeks.
- Oral lesions—erosions, ulcers either concurrently or alone (20% of cases).
- Pruritus variable.
- Systemic—20% of cases; anorexia; lethargy; pyrexia; vomiting; diarrhea; oculonasal discharge; conjunctivitis; pneumonia.

CAUSES & RISK FACTORS

- Reservoir host—wild rodents (voles, mice, gerbils, ground squirrels).
- Infection thought to be acquired during hunting and being wounded by infected rodents; most common in young adults and active hunters, often from rural environment.
- Lesions—often develop at the site of a bite wound (presumably inflicted by the prey animal carrying the virus).
- Most cases occur between August and October, when small wild mammals are at maximum population and most active.
- Severe cutaneous and systemic signs with poor prognosis are frequently associated with immunosuppression (iatrogenic or co-infection with FeLV or FIV).
- Cat-to-cat transmission—rare; causes only subclinical infection.

P

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bacterial and fungal infections
- Eosinophilic granuloma complex

- Neoplasia—particularly mast cell tumor; lymphoma
- Miliary dermatitis

CBC/BIOCHEMISTRY/URINALYSIS

Non-contributory

OTHER LABORATORY TESTS

Serologic testing—demonstrate rising titers; hemagglutination inhibition, virus neutralizing, complement fixation, or ELISA; titers may remain high for months or years.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Virus isolation from scab material—definitive diagnosis; 90% positive.
- Electron microscopy of extracts of scab, biopsy, or exudate—rapid presumptive diagnosis; 70% positive.
- Skin biopsy—characteristic histologic changes of epidermal hyperplasia and hypertrophy; multilocular vesicle and ulceration; large eosinophilic intracytoplasmic inclusion bodies; immunofluorescence tests.
- PCR.

TREATMENT

- No specific treatment.
- Clean and treat ulcerated areas to prevent secondary infection.
- Supportive (antibiotics, fluids) when necessary.
- Elizabethan collar—to prevent self-induced damage.

MEDICATIONS

DRUG(S)

Antibiotics—prevent secondary infections.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Immunosuppressive agents (e.g., glucocorticoids and megestrol acetate)—absolutely contraindicated because they can induce fatal systemic disease.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Natural reservoir host is possibly small rodents; cats infected incidentally.
- Vaccines—none available; vaccinia virus may be considered for valuable zoo

collections, but its effects in non-domestic cats have not been investigated.

EXPECTED COURSE AND PROGNOSIS

- Most cats recover spontaneously in 1–2 months.
- Healing may be delayed by secondary bacterial skin infection.
- Prognosis is poor with severe respiratory or pulmonary involvement.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Rare human poxvirus infections have been linked to contact with infected cats with skin lesions; use basic hygiene precautions (disposable gloves) when handling infected cats.
- Infection is usually mild and transient in healthy humans, but severe and even lethal infections can occur in immunocompromised individuals.
- May cause painful skin lesion and severe systemic illness, particularly in the very young or elderly, people with a pre-existing skin condition, and the immunodeficient.
- With discontinuation of vaccination against smallpox (with its cross-reactive immune effect) may expect increase in human poxvirus infections.

ABBREVIATIONS

- ELISA = enzyme-linked immunosorbent assay
- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus
- PCR = polymerase chain reaction

Consulting Editor Stephen C. Barr

PREMATURE LABOR

BASICS

OVERVIEW

Inappropriate myometrial activity preterm, which can lead to abortion.

SIGNALMENT

Gravid female dog or cat, no age or breed predilection.

SIGNS

- Early: no signs, fetal resorption evident ultrasonographically.
- Late: vulvar discharge: hemorrhagic or lochial.
- History of unexplained loss of pregnancy.

CAUSES & RISK FACTORS

- Unknown; genetics can play a role; luteolysis can result; luteal insufficiency suspected but not documented.
- Myometrial activity inappropriate for stage of pregnancy precedes luteolysis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Term gestation, onset of normal labor.
- Pathologic loss of pregnancy (trauma, toxin, developmental disorder, or infectious causes).

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal (typical anemia of pregnancy can be present).
- Blood loss anemia, inflammatory leukogram can occur.

OTHER LABORATORY TESTS

Serum progesterone will be < 2 ng/mL when abortion occurs.

IMAGING

- Ultrasonographic evaluation of fetal heart rate (stress evidenced by rates consistently < 170).
- Change in the normal morphologic appearance of uterus and fetuses when death occurs (See Web Figures 1, 2).

DIAGNOSTIC PROCEDURES

- Tocodynamometry is diagnostic: finding $> 0\text{--}2$ contractions/hour is not normal for preterm (earlier than eighth week) gestation.
- Quantitative (chemiluminescence, fluorescence enzyme immunoassay)

progesterone assay is important to detect levels < 2.0 ng/mL. Rapid in-hospital semi-quantitative assays are least accurate between 2 and 5 ng/mL.

TREATMENT

- In humans, bed and pelvic rest and antibiotics do not contribute to a positive outcome, although frequently prescribed.
- Tocolytic agents are administered (beta-agonists, calcium channel blockers, magnesium sulfate, prostaglandin synthetase inhibitors).

MEDICATIONS

DRUG(S)

- Tocolytics (terbutaline 0.03 mg/kg PO q6–12h PRN); the dose is titrated based on uterine monitoring.
- \pm Progestagen compounds: progesterone in oil dosed at 2 mg/kg IM q72h; altrenogest (Regu-Mate, Hoechst-Roussel), a synthetic progestagen manufactured for use in the mare, is dosed at 0.088 mg/kg PO q24h; oral progesterone (Prometrium® capsules) dosed at 10 mg/kg q24h with monitoring of serum progesterone q24–48h for dosage adjustments. Clients should be informed of potential side effects with exogenous progesterone, and should only be used if the serum progesterone is < 2 ng/mL.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Prolonged gestation if terbutaline or progestagen compounds are not withdrawn 24–48 hours before due date calculated from first progesterone rise, luteinizing hormone peak, or Day 1 cytologic diestrus (see Breeding, Timing) if natural whelping is planned. If elective cesarean section is planned, medications can be continued until day of surgery.
- Poor lactation if progestagen compounds are used (inhibits normal prolactin elevation resulting from declining progesterone level).
- Masculinization of female fetuses if progestagen compounds are used.
- Forced retention of a pathologic pregnancy if idiopathic premature labor is misdiagnosed.

FOLLOW-UP

- Serial abdominal ultrasound
- Serial tocodynamometry
- Fetal heart rate monitoring with Doppler or dual B- and M-mode ultrasonography

MISCELLANEOUS

Usually a diagnosis by exclusion of all other causes of late-term abortion (*Brucella canis*, metritis, placatitis, trauma, metabolic disease, coagulopathy, inborn error of metabolism, genetic defects) prompting midterm tocodynamometry at the next pregnancy.

PRIMARY CILIARY DYSKINESIA

BASICS

OVERVIEW

- Congenital (autosomal recessive) disorder of ciliary dysfunction in the respiratory tract, auditory tubes, ventricles of the brain, spinal canal, oviducts, efferent ducts of the testes, and sperm flagellum. • In normal animals ciliary beating is coordinated—characteristically dyskinetic or absent in affected dogs.
- Hydrocephalus and/or situs inversus (Kartagener syndrome) can be concurrent.
- Dogs with chronic respiratory disease and situs inversus likely have primary ciliary dyskinesia and do not warrant extensive workup.

SIGNALMENT

- Generally young dogs (< 8 weeks) but some are asymptomatic until older (1/2–10 years).
- Reported predominately in purebred dogs, higher incidence in Bichon frise, Old English sheepdog, but mixed-breed dogs and cats can be affected.

SIGNS

Historical Findings

- Chronic sneezing, nasal discharge, coughing, exercise intolerance, and respiratory distress. Dramatic initial response to antibiotics, but relapse after treatment is stopped. • Family history—large litters can have > 1 affected dog. • Infertility in males.

Physical Examination Findings

- Bilateral mucopurulent nasal discharge.
- Productive cough. • Tachypnea, dyspnea, and cyanosis during exacerbation of infection.
- Diffuse increase in lung sounds of variable intensity. • Heart sounds can be inaudible with severe bronchopneumonia, can be loudest on the right side with situs inversus.

CAUSES & RISK FACTORS

Genetics—recessive mutation identified in the Old English sheepdog, inbreeding.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congenital (neutrophil dysfunction, immunoglobulin deficiency) or acquired disease (canine distemper) producing chronic rhinosinusitis and bronchopneumonia.
- Recurrent aspiration pneumonia. • Chronic bacterial pneumonia. • Bronchoesophageal fistula. • Exposure to cigarette smoke—can delay mucociliary clearance. • *Mycoplasma* spp. or *Bordetella* infection—can cause acquired ciliary defects.

CBC/BIOCHEMISTRY/URINALYSIS

- Mature neutrophilic leukocytosis—left-shift and toxic neutrophils with severe bronchopneumonia.

- Hyperglobulinemia—older dogs.
- Polycythemia—with chronic hypoxemia.

OTHER LABORATORY TESTS

- Blood gas analysis can reveal hypoxemia with normocapnia or hypocapnia.
- Bronchoalveolar lavage typically yields mucoid to mucopurulent material characterized cytologically as a purulent exudate with one or more bacterial species isolated on culture. *Mycoplasma* culture should be requested. • Normal sperm motility in an intact male rules out ciliary dyskinesia.

IMAGING

Radiography

- Changes consistent with chronic bronchopneumonia. • Situs inversus.
- Bronchiectasis. • Thickened or sclerotic tympanic bullae.

Tracheal Scintigraphy (Mucociliary Clearance)

- First exclude infections or chronic exposure to cigarette smoke. • Affected animals show no movement of radiopharmaceutical from the carina.

DIAGNOSTIC PROCEDURES

Electron Microscopy

- Ultrastructural lesions in the cilia of nasal or bronchial mucosa identified in most patients, including central microtubular disarrangement and loss of dynein arms. • Specific lesions must be found in > 20% of cilia. • Acquired ultrastructural lesions involving < 20% of cilia common with chronic respiratory tract infection. • Dogs with primary ciliary dyskinesia but no ultrastructural ciliary lesions have been described and require in vitro analysis of ciliary beat frequency and synchrony for diagnosis.

PATHOLOGIC FINDINGS

Upper Respiratory Tract

Chronic bacterial rhinitis with mucoid to mucopurulent exudate, and mucosal inflammation, mucous gland hyperplasia, and occasionally hypoplastic nasal turbinates, atresia of the frontal sinuses, frontal sinusitis, and rhinoliths.

Lower Respiratory Tract

Mucoid to mucopurulent material within airways with bronchitis, bronchiectasis, atelectasis, and subpleural emphysema.

Miscellaneous

- Hydrocephalus. • Situs inversus of thoracic viscera or abdominal viscera or both (situs inversus totalis). • Impaction of one or both middle ears with a sterile gelatinous material.

TREATMENT

- Routine exercise enhances mucus clearance by increasing respiration and inducing coughing. • Supplemental oxygen therapy

during episodes of severe bronchopneumonia.

- Airway therapy with saline nebulization and coupage useful for clearing secretions.

MEDICATIONS

DRUG(S)

- Antibiotics based on bacterial culture and sensitivity testing; duration varies with severity of infection. • Continuous antibiotic therapy not advised due to colonization with resistant bacteria.

CONTRAINdications/POSSIBLE INTERACTIONS

Cough suppressants trap secretions and exacerbate airway inflammation.

Anesthesia

- Patients have impaired gas exchange and increased risk of complications. • Minimize respiratory depression and recovery time.

FOLLOW-UP

POSSIBLE COMPLICATIONS

- Pneumothorax—subpleural cysts, bronchiectatic cysts, interstitial cysts, and emphysematous bullae can develop from prolonged infection or inflammation causing air entrapment and rupture. • Pulmonary arterial hypertension, cor pulmonale, and right-sided heart failure can result from chronic hypoxemia. • Systemic reactive amyloidosis secondary to persistent bacterial bronchopneumonia.

EXPECTED COURSE AND PROGNOSIS

- Clinical course of disease and longevity of patients highly variable. • Some dogs will become subclinical with age. • Appropriate antibiotic treatment and pulmonary physical therapy can result in prolonged survival.

PROLAPSED GLAND OF THE THIRD EYELID (CHERRY EYE)

BASICS

OVERVIEW

- Gland of the third eyelid—normally anchored by a fibrous attachment to the periorbita beneath the third eyelid.
- Weak attachment—several breeds of dogs and cats; predisposes animals to unilateral or bilateral prolapse.

SIGNALMENT

- Dog and cat.
- Dog—usually in young dogs (aged 6 months to 2 years); common breeds: cocker spaniel, bulldog, beagle, bloodhound, Lhasa apso, mastiff, Shih Tzu, other brachycephalic breeds.
- Cat—rare; occurs in Burmese and Persians.

SIGNS

- Oval, hyperemic mass protruding from behind the leading edge of the third eyelid.
- May be unilateral or bilateral.
- May see accompanying epiphora, hyperemic conjunctiva, or blepharospasm.
- Additional swelling and hyperemia caused by environmental irritation and desiccation of the exposed gland.

CAUSES & RISK FACTORS

- Congenital weakness of the attachment of the gland of the third eyelid.
- Inheritance unknown, but considered complex and multigenic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Scrolled or everted cartilage of the third eyelid—seen in Wiemaraners, Great Danes, German shorthaired pointers, and other breeds in which the T-shaped cartilage of the third eyelid is rolled away from the surface of

the eye instead of conforming to the surface of the cornea.

- Neoplasia of the third eyelid—usually seen in older animals; may see squamous cell carcinoma, lymphoma, or fibrosarcoma; may be origin of adenoma or adenocarcinoma; small incisional biopsy is indicated in older patients (> 7–9 years) to differentiate.
- Orbital fat prolapse—may dissect anteriorly between the conjunctiva and globe; occasionally occurs in the medial canthus and simulates a prolapsed gland of the third eyelid.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Surgical replacement of the gland (imbrication technique)—see “Suggested Reading.”
- Excision of the gland—avoid; gland produces up to 50% of the aqueous tear film; puts patient at substantial risk for developing KCS as the dog ages.
- Elizabethan collar—recommended to prevent self-trauma.

MEDICATIONS

DRUG(S)

Topical anti-inflammatory medications, such as corticosteroids (if no corneal ulceration) or nonsteroidal anti-inflammatory medications—may be used before and after surgery to lessen swelling.

CONTRAINdications/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Recurrence—5–20%, depending on the breed, with large-breed dogs such as mastiffs having the highest recurrence rates; re-replacement of the gland is encouraged.
- If unilateral, warn client that the other gland may also prolapse and that no preventive procedure or medication exists.

MISCELLANEOUS

SYNONYM

Cherry eye

ABBREVIATION

KCS = keratoconjunctivitis sicca

Consulting Editor Paul E. Miller

P

PROPTOSIS

BASICS

OVERVIEW

- Forward displacement of the globe, with the eyelids trapped behind the globe's equator.
- Frequently acute and due to bite wounds, head trauma. • Vision threatening.
- Immediate repositioning of the globe critical if eye is salvageable.

SIGNALMENT

- More common in the brachycephalic breeds due to a relatively shallow orbit and large palpebral fissure. • May occur in any species or breed if the traumatic force is severe enough.

SIGNS

Possible Accompanying Signs

- Subconjunctival or intraocular hemorrhage.
- Abnormalities in pupil size—dilated or constricted. • Intraocular inflammation (uveitis).
- Globe deviation/strabismus/rupture.
- Corneal ulceration/desiccation.
- Periorbital bite wounds. • Fractures of the bony orbit or skull. • Systemic injuries.
- Trauma to the contralateral eye.

CAUSES & RISK FACTORS

- Trauma—primary cause; relatively minor force (restraint) in brachycephalic breeds; usually severe force in dolichocephalic and mesocephalic breeds. • Space-occupying retrobulbar lesion—secondary cause: rare.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Buphthalmia—globe enlargement; rarely acute. • Exophthalmia—forward displacement of the globe due to a retrobulbar space occupying lesion; may be acute, rarely peracute.

CBC/BIOCHEMISTRY/URINALYSIS

Normal, unless trauma-related abnormalities present.

IMAGING

Skull CT or radiographs—may show fractures due to trauma. Further diagnostic workup indicated if suspect other systemic injuries.

TREATMENT

- Prevent further trauma,—lubricate the cornea, E-collar. • Stabilize patient and do a thorough systemic physical examination before surgery.

Repositioning the Globe

- As soon as safely possible. • Performed under sedation and local anesthesia or, if the

patient is stable, under general anesthesia.

- Lateral canthotomy—may ease tension on the eyelids and allow easier globe repositioning; not always necessary. • Engage the eyelid margins with eyelid forceps (e.g. Von Graefe or Allis forceps) or strabismus/muscle hooks, then pull the eyelids forward and away from the globe while protecting and gently pushing the globe back into the orbit (a lubricated scalpel blade handle can serve this function). • Place two or three temporary tarsorrhaphy mattress sutures (sutures emerge from the eyelid margin in line with the meibomian gland openings) with stents; suture the lateral canthotomy wound.
- Fluorescein—stain the cornea prior to replacing the globe. • If the optic nerve and/or more than two extraocular muscles are severed, if the globe is ruptured, infected, or desiccated, enucleation may be the best option.

MEDICATIONS

DRUG(S)

- Systemic and topical broad-spectrum antibiotics—until sutures are removed.
- Systemic corticosteroids—usually used at least initially; may be continued with marked periorbital and retrobulbar swelling. • Topical corticosteroids—to treat uveitis or hyphema, if cornea is not ulcerated. • Topical atropine—for intraocular inflammation or hemorrhage; relieve ciliary spasm and lower the risk of synechiae.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Topical corticosteroids—do not use with ulcerations. • Systemic corticosteroids—do not use with peri- or retrobulbar infection.

FOLLOW-UP

PATIENT MONITORING

Suture removal—usually done sequentially, rather than all at once, starting 10–14 days after repositioning. Integrity of the globe and vision are reassessed 10–14 days after surgery.

PREVENTION/AVOIDANCE

Bilateral medial and/or lateral canthoplasty to shorten the palpebral fissure and prevent future proptosis in brachycephalic breeds should be discussed with the client.

POSSIBLE COMPLICATIONS

- Blindness. • Most patients retain a dorsolateral strabismus and slight forward displacement of the medial side of the globe due to rupture of the inferior oblique and

medial rectus muscles. This may improve with time due to tissue fibrosis and contraction.

- Decreased tear production—perform Schirmer tear tests after suture removal.
- Corneal denervation causing neurotrophic keratitis with chronic ulceration and decreased corneal sensitivity. • Exposure keratitis due to forward displacement of globe, decreased tear production, facial nerve palsy and/or corneal denervation (decreased blink reflex). • Phthisis bulbi.

EXPECTED COURSE AND PROGNOSIS

- Most affected eyes can be salvaged; majority will be blind (especially if proptosis was caused by significant trauma: more common in dolichocephalic than brachycephalic breeds). • Extensive tissue damage, avulsion of more than two extraocular muscles, facial and/or orbital fractures, and corneal or scleral rupture—grave prognosis for vision and globe salvage for cosmesis. • Normal retinal vessels and optic nerve, normal IOP, and a short time from occurrence to repair—relatively favorable prognosis for maintaining vision.
- Positive menace response, dazzle and/or pupillary light reflexes—good prognosis for maintaining vision (always observe the indirect pupillary light reflex in the healthy eye originating from the injured eye!). • Pupil size at the time of the injury—not necessarily an accurate prognostic indicator; mydriasis may be the result of trauma to the optic nerve (if permanent, results in blindness) or damage to the oculomotor nerve (does not affect vision). Miosis can be caused by uveitis (if the uveitis is severe enough, pupillary constriction occurs even with retinal or optic nerve damage).

PROSTATE DISEASE IN THE BREEDING MALE DOG

BASICS

OVERVIEW

- Prostate is the only accessory sex gland in the dog; easily palpated per rectum as a bilobed oval gland with a median septum.
- 5- α reductase in prostatic epithelial cells metabolizes serum testosterone to DHT; DHT stimulates growth of the prostate gland.

Benign Prostatic Hyperplasia

- Normal hormonally dependent diffuse glandular, stromal hyperplasia and hypertrophy of the prostate. • Cystic hyperplasia may occur later in the disease process. • Pathogenesis unknown; contributing factors include age-associated alteration in the intraprostatic estrogen:androgen ratio, which potentiates the hyperplastic response, and DHT-permissive growth of the prostate.
- Clinical effects minimal or absent in most dogs. • Renders the prostate more susceptible to ascending infection and subsequent development of bacterial prostatitis.

Prostatitis/Prostatic Abscess

- Inflammation/infection of the prostate; abscess of the prostate. • Associated with acute or chronic bacterial infection. • Abscess formation usually secondary to chronic bacterial prostatitis. • May be associated with BPH or retention cysts. • Prostate gland and urinary tract are normally sterile. • Bacterial colonization typically via urinary tract pathogens; hematogenous spread possible.
- Common isolates include *E. coli*, *Proteus vulgaris*, *Streptococci* spp., *Staphylococci* spp.; concurrent bacterial urinary tract infection is not always noted with chronic bacterial prostatitis. • *Brucella canis* may be associated with acute or chronic prostatitis (see Brucellosis). • Fungal prostatitis (*Blastomyces* and *Cryptococcus*).

Prostatic Cysts

- Either within the prostatic parenchyma due to coalescing glandular/cystic hyperplasia and ductular occlusion (retention cysts), or outside the prostate (paraprostatic cysts). • Estrogen exposure induces stratified squamous change to prostatic epithelium; subsequent ductular occlusion contributes to cyst formation (see Sertoli Cell Tumor). • Paraprostatic cysts are attached to the prostate, are lined by secretory epithelium, and variable in size; larger cysts may be transabdominally palpable; almost always sterile.

Prostatic Neoplasia

- Prostatic ACA is most common; other tumor types include fibrosarcoma, leiomyosarcoma, and SCC. • Prostatic TCC arises from prostatic urethra and invades the prostate gland. • BPH is not a risk factor for prostatic neoplasia. • Tumor development is

not androgen dependent; castration is not protective. • Tumors typically detected after metastatic spread as clinical signs occur late and early screening is unavailable. • ACA bone metastasis is common, typically to LS spine or pelvis; intraprostatic fibrosing reaction with some areas of ossification and hyperplasia is typical.

SIGNALMENT

INCIDENCE/PREVALENCE

- BPH: incidence high; 50% of intact dogs exhibit histologic evidence by 5 years of age, > 95% by 9 years of age. • Prostatitis/prostatic abscess: considered common; about 40% of dogs with prostatic cysts have evidence of bacterial infection. • Prostatic cysts: prevalence around 14%, 42% of these had evidence of bacterial infection.
- Neoplasia: low; prevalence range 0.2–0.6% in general population, and 5–7% of dogs with prostatic disease.

Mean Age and Range

- BPH: microscopic onset by 5 years of age.
- Prostatitis/prostatic abscess: any age; more common in the adult (> 6 years). • Prostatic cysts: more common after 8 years of age.
- Neoplasia: mean age 10 years.

SIGNS

General Comments

- Dogs with prostatic disease display overlapping clinical signs:
- Asymptomatic
- Dyschezia, tenesmus, constipation, ribbon-like stool
- Sanguinous urethral/preputial discharge
- Dysuria, hematuria, stranguria
- Hemospermia

Benign Prostatic Hyperplasia

- If mild, generally asymptomatic
- Hematuria and hemospermia are most common signs

Prostatitis—Acute

- Systemic illness (vomiting, fever, inappetance)
- Pyuria
- Stiff-legged gait

Prostatitis—Chronic

- Recurrent/chronic urinary tract infection
- Stiff gait
- Infertility

Prostatic Cyst

- See BPH, above
- If infected see signs associated with prostatitis

Prostatic Neoplasia

- Emaciation
- Dyschezia
- Rear limb locomotory disturbance
- LS pain

Physical Examination Findings

Benign Prostatic Hyperplasia

Large, symmetrically enlarged, nonpainful prostate

Prostatitis—Acute

- Fever
- Dehydration
- Signs of sepsis
- Caudal abdominal pain
- Normal to enlarged, asymmetrical, painful prostate

Prostatitis—Chronic

- Symmetrical, nonpainful, firm, normal size prostate.
- May have fluctuant areas (focal cysts) on palpation.

Prostatic Cyst

- Symmetrical, enlarged prostate with fluctuant areas; large cysts may preclude rectal palpation, enlarged prostate may be transabdominally palpable.
- External signs of feminization if cyst (retention cysts) formation is due to estrogen exposure (e.g., Sertoli cell tumor).

Prostatic Neoplasia

- Large, asymmetrical, irregular painful prostate.
- Rectal, abdominal, LS pain.
- Palpable abdominal mass.
- Lymphadenopathy (sublumbar).

CAUSES & RISK FACTORS

BPH

Age and sexual status

Prostatitis

- BPH and/or prostatic cysts
- Breeding dogs may have higher risk for *Brucella canis*

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Hematuria

- Urinary tract infection
- Thrombocytopenia
- Penile trauma
- Urinary tract neoplasia (TCC)

Tenesmus

Disease of the colon or rectum

Hind Limb Gait/Locomotory Disturbance

- Arthritis
- Degenerative disc disease
- Neuromuscular disease
- Cauda equina syndrome

CBC/BIOCHEMISTRY/URINALYSIS

Benign Prostatic Hyperplasia

Typically normal with the exception of hematuria

Prostatitis—Acute

- Leukocytosis and neutrophilia (+/- immaturity and signs of toxicity)
- Hypoalbuminemia
- Pyuria
- Bacteriuria
- Hematuria

Prostatitis—Chronic

- CBC typically normal; occasionally leukocytosis
- Pyuria
- Bacteriuria
- Hematuria

Prostatic Cyst

- Anemia (if cyst formation due to hyperestrogenism)
- Biochemistry and urinalysis typically normal

Prostatic Neoplasia

- Leukocytosis and neutrophilia
- Elevated alkaline phosphatase
- Pyuria
- Hematuria
- Atypical cells may be noted in urine sediment

OTHER LABORATORY TESTS

- Prostate culture: culture third ejaculate fraction or fine-needle aspirate of prostate; positive growth supports bacterial prostatitis.
- Paired Seminal Fluid and Urethral culture:

PROSTATE DISEASE IN THE BREEDING MALE DOG

(CONTINUED)

prostatitis is confirmed when seminal fluid bacterial growth (in CFU) is ≥ 100 times the corresponding urethral/urine growth.

- Semen evaluation: may be normal or hemospermic with BPH; neutrophils, phagocytized bacteria, variable degree of reduced sperm motility and teratospermia, with bacterial prostatitis. • Prostate specific markers: not of clinical use in the dog.

IMAGING

- Abdominal ultrasound: preferred method for imaging; detects size, and tissue homogeneity; identifies focal parenchymal abnormalities, such as cysts or abscesses; loss of tissue homogeneity (prostatitis or neoplasia); regional lymph nodes and paraprostatic structures (paraprostatic cysts).
- Abdominal radiography: bony metastases; degree of prostatomegaly not correlated with any specific prostatic disease. • Lack of prostatic mineralization in intact dogs with prostatomegaly has a negative predictive value of 96% for neoplasia. • Retrograde cystourethrogram: evaluates urethral compression or identifies contrast leakage.

DIAGNOSTIC PROCEDURES

- Prostatic wash: culture and cytologic evaluation of prostatic fluid. • Ultrasound-guided fine-needle aspirate: cytologic evaluation may distinguish between BPH, prostatitis and neoplasia; aspiration of active infections may seed the periprostatic and subcutaneous tissues; aspiration of cysts rarely provides clinical resolution. • Ultrasound-guided transabdominal biopsy: provides definitive diagnosis for BPH, prostatitis, prostatic neoplasia.

P

TREATMENT

- Temporary indwelling urethral catheter placement may benefit animals with severe pain or urethral obstruction. • Analgesia.
- Stool softeners and low residue diets to ease defecation.

BENIGN PROSTATIC HYPERPLASIA

- Treat symptomatic dogs. • Castration is curative. • Finasteride is the medical treatment of choice in breeding animals; decreases prostatic weight and diameter; prostate returns to pretreatment size 8 weeks after stopping therapy; typically used to reduce clinical signs permitting frozen semen stores to be generated; castrate when desired doses of semen are stored.

PROSTATITIS—ACUTE

Antibiotics based on culture and sensitivity; blood-prostate barrier is not intact with acute prostatitis; administer for a minimum of 3 weeks; document negative prostatic fluid culture prior to, and 1–2 weeks after, stopping antibiotic treatment.

PROSTATITIS—CHRONIC

- Antibiotics based on culture and sensitivity, and ability to penetrate the blood-prostate barrier (enrofloxacin, trimethoprim, chloramphenicol, erythromycin, doxycycline).
- Administer for a minimum of 6 weeks; repeat urine and prostatic fluid culture at 1 week, and prior to discontinuing, to document no growth. • If positive culture is obtained, continue appropriate antibiotic administration 4 weeks after the first negative culture; repeat culture at 1 week and 1 month post-therapy to evaluate for return of infection. • Castration recommended for refractory cases.

PROSTATIC CYST

- Castration treatment of choice.
- Finasteride may be useful if associated with BPH. • Remove source of estrogen if squamous metaplasia. • Large solitary cysts: surgical marsupialization and castration advised. • Paraprostatic cysts: may be surgically excised. • Aspiration and drainage of cysts: not associated with resolution; fluid should be cultured.

PROSTATIC NEOPLASIA

- Metastasis—typical at time of diagnosis.
- Differentiation between adenocarcinoma and transitional cell carcinoma will determine appropriate chemotherapeutic agents (see Adenocarcinoma, Prostate, and Transitional Cell Carcinoma). • Urine should be cultured to evaluate for UTI. • A piroxicam trial should always be offered with or without chemotherapy.

CLIENT EDUCATION

- Regular *Brucella canis* testing for breeding animals. • Proactive semen freezing at young age prior to onset prostatic disease/BPH.

MEDICATIONS

DRUG(S)

- Finasteride (0.1 mg/kg PO q24h to a maximum of 5 mg PO q24h): 5 α reductase inhibitor; inhibits intraprostatic conversion of testosterone to DHT without altering serum testosterone; causes decreased semen volume but no change in semen quality; suitable for use in breeding male dogs. • Antimicrobials: drug used, and duration, will vary with culture results and disease process; e.g., enrofloxacin (2.5–5 mg/kg PO q12h) for 3–6 weeks.

PRECAUTIONS

- Estrogens and progestagens decrease prostatic mass via negative feedback on serum testosterone concentrations; however, toxic side effects are common and their use is not recommended. • NSAIDs may be associated with hepatic and/or renal dysfunction, GI ulcerations; patients should be monitored for

adverse reactions. • Trimethoprim-sulpha use may be associated with KCS, and hepatic necrosis.

ALTERNATIVE DRUG(S)

GnRH agonist—deslorelin (Suprelorin) not approved for this use in the US; not recommended for dogs intended for breeding; dramatically suppresses hypothalamic-pituitary-gonadal axis and testosterone production.

FOLLOW-UP

PATIENT MONITORING

- Repeat prostatic fluid cultures to document antimicrobial efficacy as described above.
- Semen evaluation should be performed 70 days after resolution of illness in any dog being used for breeding. • Repeat abdominal ultrasound to evaluate the prostatic response to treatment. • Dogs testing positive for brucellosis should not be used for breeding.

EXPECTED COURSE AND PROGNOSIS

- BPH generally responsive to finasteride.
- Chronic prostatitis more refractory to medical management; castration may be indicated. • Poor prognosis for prostatic neoplasia.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Sertoli cell tumor • Infertility • Recurrent urinary tract infection

ABBREVIATIONS

- ACA = adenocarcinoma • BPH = benign prostatic hypertrophy • CFU = colony forming units • DHT = dihydrotestosterone • GI = gastrointestinal • KCS = keratoconjunctivitis sicca • LS = lumbosacral • NSAID = nonsteroidal anti-inflammatory drug • SCC = squamous cell carcinoma • TCC = transitional cell carcinoma • UTI = urinary tract infection

Author Sophie A. Grundy

Consulting Editor Sara K. Lyle

PROSTATIC CYSTS

BASICS

OVERVIEW

- Prostatic cysts in the dog include those associated with diffuse epithelial cystic change from androgen-dependent benign prostatic hypertrophy, retention cysts within the prostatic parenchyma that are cavitating, fluid-filled lesions with a distinct capsule, and paraprostatic cysts that are cavitating, fluid-filled lesions with a distinct capsule located outside of the prostatic parenchyma. Prostatic cysts may range in diameter from a few mm to more than 20 cm.
- Paraprostatic cysts usually arise craniolateral to the prostate, displacing the bladder cranially and ventrally, or caudal to the prostate in the pelvis. Prostatic cysts may represent dilated embryonal remnants of the wolffian ducts.
- Pathogenesis is unknown, but the occurrence of retention cysts in dogs with estrogen-secreting Sertoli cell tumors causes speculation that these cysts are dilations of prostatic acini secondary to estrogen-induced squamous metaplasia.

SIGNALMENT

- Male intact dogs. Rare occurrence in castrated dogs
- Age range—2–12 years, mean age 8 years
- Large dogs are more commonly affected than small dogs

SIGNS

- Asymptomatic
- Lethargy and anorexia
- Abdominal distention
- Tenesmus if the cyst compresses the rectum
- Dysuria if the cyst compresses the urethra
- Sanguineous urethral discharge in the presence of BPH

CAUSES & RISK FACTORS

- Benign prostatic hypertrophy
- Androgenic hormones
- Estrogenic hormones

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- BPH—distinguished by ultrasound.
- Prostatic abscess—distinguished by ultrasound and semen culture.

- Distended urinary bladder—distinguished by cystocentesis, imaging.
- Caudal abdominal mass of undetermined origin—distinguished by imaging.

CBC/BIOCHEMISTRY/URINALYSIS

No abnormalities

OTHER LABORATORY TESTS

- Examination of prostatic fluid collected by ejaculation or prostatic massage confirms absence of infection.
- Culture and cytology of cyst fluid collected by ultrasound-guided fine-needle aspiration or by aspiration at surgical exploration reveals sterile clear or sanguineous fluid consistent with prostatic fluid.

IMAGING

Retrograde contrast urethrocystography followed by prostatic ultrasonography confirms presence, location, echo-texture, and size of prostatic cysts, and differentiates retention cysts from paraprostatic cysts.

DIAGNOSTIC PROCEDURES

Collection of prostatic fluid by ejaculation followed by prostatic imaging is recommended prior to fine-needle aspiration of cystic fluid to rule-out bacterial infection.

PATHOLOGIC FINDINGS

Epithelial cysts within the prostatic parenchyma occur with parenchymal hypertrophy and hyperplasia; squamous metaplasia of the ducts and alveoli may be present. Retention cysts and paraprostatic cysts are lined by a single layer of prostatic epithelium or fibrous connective tissue and contain clear to sanguineous fluid with fibrin.

TREATMENT

- Intraprostatic cysts (epithelial, retention) respond to prostatic involution, which may be induced by castration or by the 5 alpha-reductase inhibitor finasteride. Large cysts may be drained percutaneously with ultrasound guidance prior to initiation of finasteride therapy.
- Large retention cysts and paraprostatic cysts should be partially or completely surgically resected, depending on adherence to surrounding structures, or marsupialized and drained for 1–2 months.
- Simple drainage of the cyst(s) is not recommended, as persistence of the capsule may result in recurrence.

MEDICATIONS

DRUG(S)

Prostatic parenchyma and diffuse epithelial cysts involute following treatment with the 5 alpha-reductase inhibitor finasteride (0.1–1 mg/kg PO q24h for 2–4 months). Finasteride prevents conversion of testosterone to dihydrotestosterone, causing prostatic involution without adversely affecting libido or spermatogenesis. BPH recurs following cessation of finasteride therapy. Paraprostatic cysts do not respond to finasteride treatment.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Imaging assessment of cyst size at 4-week intervals following treatment.
- Standard postoperative monitoring of marsupialized stoma, if any.

MISCELLANEOUS

ABBREVIATION

- BPH = benign prostatic hypertrophy

PROSTATITIS AND PROSTATIC ABSCESS

BASICS

DEFINITION

Acute Prostatitis

Infection of the canine prostate with bacteria, mycoplasmas, and/or fungi with systemic signs of fever, anorexia, lethargy, pain, and inflammatory exudate in prostatic fluid.

Abscessation is variable, occurring in 15 of 25 dogs with prostatitis in one study. Abscesses occasionally rupture into the peritoneal cavity, causing sepsis, shock, and death.

Chronic Prostatitis

Subclinical (recent or long-term) infection of the canine prostate in absence of prostatic abscessation and polysystemic signs. Affected animals are asymptomatic except for inflammatory exudate in the prostatic fluid, which causes infertility. Chronic prostatitis may occur after or independently of acute prostatitis.

PATHOPHYSIOLOGY

• Predisposing pathology is gross and/or microscopic benign prostatic hypertrophy, which occurs under the influence of dihydrotestosterone in more than 80% of intact male dogs > 5 years of age. • BPH is characterized by large, irregularly shaped, well-vascularized prostatic alveoli and branching infoldings of epithelium with microcysts containing sanguineous prostatic fluid; if infected, these can become abscesses. • Infection of the hypertrophied canine prostate develops most commonly from ascent of normal urethral flora—rarely from blood-borne bacteria and/or from penetrating wounds introducing bacteria or fungi to the scrotum. The prostate of intact male dogs constantly secretes prostatic fluid, which is deposited into the prostatic urethra and then flows both into the urinary bladder and out the tip of the penile urethra. With prostatitis, prostatic fluid containing blood, inflammatory exudate, and bacteria or fungi is deposited into the urinary bladder and discharged intermittently from the tip of the penis.

SYSTEMS AFFECTED

- Gastrointestinal—tenesmus if the enlarged prostate compresses the rectum. • Hemic/Lymphatic/Immune—mature or immature neutrophilia in acute prostatitis.
- Polysystemic—septic shock if prostatic abscesses rupture, tachycardia, poor tissue perfusion, elevated temperature, and focal or generalized peritonitis. • Urinary—dysuria if the enlarged prostate compresses the urethra; deposition of prostatic fluid with inflammatory exudate into the urinary bladder. • Reproductive—pain at copulation

and reduction in libido; infertility from infected prostatic fluid in the ejaculate.

INCIDENCE/PREVALENCE

High in intact male dogs more than 5 years of age. Infection is reported in 40% of dogs with prostatic disease.

SIGNALMENT

Species

Dog

Breed Predilections

All breeds and mixed breeds

Mean Age and Range

Middle-aged; mean age range, 7–11 years

Predominant Sex

Intact male dogs; may occur secondary to prostatic neoplasia in castrated dogs.

SIGNS

Acute Prostatitis

- Lethargy/depression • Anorexia • Tenesmus
- Dysuria • Pyrexia • Pain at prostatic or caudal abdominal palpation • Sanguineous urethral discharge • Stiff hindlimb gait
- Septic shock (rare)

Chronic Prostatitis

- Asymptomatic • Tenesmus • Dysuria
- Sanguineous urethral discharge

CAUSES

- Infection of the hypertrophied prostate with ascending urethral flora, including *Escherichia coli*, *Staphylococcus* spp., *Streptococcus* spp., *Proteus mirabilis*, *Klebsiella* spp., *Enterobacter* spp., *Hemophilus* spp., *Pseudomonas* spp., *Pasteurella* spp., anaerobic bacteria, and *Mycoplasma* (most common). • Infection of the hypertrophied prostate with systemic bacterial infection, including *Brucella canis*.
- Systemic or local puncture wound infection with *Blastomyces dermatitidis*.

RISK FACTORS

- Increasing age • Presence of functional testes in affected dogs • BPH and, less commonly, prostatic neoplasia • Historical androgen or estrogen administration
- Impaired host defense mechanisms

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- BPH without infection, distinguished by semen culture • Prostatic cysts, distinguished by ultrasound and semen culture • Prostatic neoplasia, distinguished by ultrasound and tissue biopsy • Abdominal mass or abscess, distinguished by abdominal imaging

CBC/BIOCHEMISTRY/URINALYSIS

- CBC abnormalities in acute prostatitis and abscessation include immature neutrophilia and toxic neutrophils; immature neutropenia

may occur with sepsis. Most dogs with chronic prostatitis have a normal CBC.

- Serum chemistry abnormalities are variable with acute prostatitis. Most dogs with chronic prostatitis have normal serum chemistries.
- Urinalysis abnormalities include hematuria, purulent exudate, and causative microbes; these abnormalities arise, not from primary UTI, but from deposition of infected prostatic fluid into the urinary bladder.

OTHER LABORATORY TESTS

- Gross examination, cytology, and culture of whole semen or the prostatic fluid (third) fraction of semen or fluid collected at prostatic massage yields inflammatory exudate with aerobic bacteria, anaerobic bacteria, *Mycoplasma*, or fungi. Normal prostatic fluid should contain fewer than 100,000 colony-forming bacterial units per mL, and fewer than 5 leukocytes per high power field following fluid centrifugation.
- Although infection with *Brucella canis* is uncommon, because of the zoonotic potential of this infection, *B. canis* serology is recommended in all dogs with suspected prostatitis, with follow-up culture of semen for *B. canis* if serology is positive.

IMAGING

Survey radiography of the caudal abdomen, retrograde urethrocytography, and prostatic ultrasonography are indicated to evaluate prostatic size, echo-texture, and detection of cavitating prostatic lesions. The prostate is enlarged if its greatest craniocaudal diameter measured on a line parallel to the line connecting the sacral promontory to the anterior aspect of the pubis on a lateral radiograph exceeds 70% of the length of the distance between the sacral promontory and the anterior aspect of the pubis.

DIAGNOSTIC PROCEDURES

- Collection and evaluation of prostatic fluid in seminal plasma and collection of prostatic fluid by prostatic massage in dogs reluctant to ejaculate.
- Ultrasound-directed percutaneous fine-needle aspirate of the prostate.

PATHOLOGIC FINDINGS

- Gross pathology of the infected prostate includes enlargement, variable loss of symmetry of the dorsal median raphe, and variable presence of fluid-filled abscesses within or on the surface of the gland. Enlargement may be focal, multifocal, or diffuse.
- Bacterial or fungal infection causes suppurative (bacterial) or granulomatous (fungal) inflammation of the gland. Inflammatory lesions may be focal, multifocal, or diffuse. Abscesses contain accumulations of purulent fluid exudate.
- Biopsy of the infected prostate is not recommended because biopsy may result in the spread of infection to adjacent tissues.

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

- Acute prostatitis, prostatic abscess, and rupture of prostatic abscesses into the peritoneal cavity are potentially life-threatening emergencies that can lead to septic shock and death. Hospitalize affected patients and collect diagnostic samples (blood, urine, semen, imaging) immediately.
- Chronic prostatitis patients may be seen as outpatients for diagnostic procedures and started on specific therapy when laboratory results are available.

NURSING CARE

- Dogs with acute prostatitis or prostatic abscess should receive antimicrobial drugs intravenously. • If abscess rupture and peritonitis is suspected, administer intravenous fluid therapy for septic shock.

ACTIVITY

Breeding should be avoided until bacteria have been cleared from the prostatic fluid.

CLIENT EDUCATION

- Castration is recommended for dogs with acute prostatitis and/or prostatic abscess, as castration induces permanent prostatic involution. • If maintenance of breeding potential is necessary, long-term or intermittent treatment with finasteride is recommended to induce prostatic involution; routine rechecks at 2- to 3-month intervals for semen culture, semen cytology, and prostatic imaging are recommended. BPH recurs over time in intact male dogs after treatment with finasteride is discontinued, and BPH increases risk of recurrence of prostatitis.

SURGICAL CONSIDERATIONS

- Surgical management of prostatic abscesses should be deferred until after initiation of antimicrobial therapy and prostatic involution; involution is associated with resolution of abscesses, often making surgery unnecessary. • Castration is recommended for induction of prostatic involution in non-breeding dogs with prostatitis; castration should be deferred until after identification and treatment (for at least 1 week) of the causative bacterial/fungal agent; alternatively, medical involution of the prostate may be induced with finasteride. • Placement of Penrose drains, marsupialization, partial prostatectomy, and use of an ultrasonic surgical aspirator have been advocated for treatment of prostatic abscesses in dogs; however, these procedures have been associated with a high percentage of short- and long-term adverse sequelae, including recurrence of abscesses. Surgical drainage with subsequent packing of the cavity with omentum has been associated with the fewest adverse sequelae among surgical treatments.

PROSTATITIS AND PROSTATIC ABSCESS

MEDICATIONS

DRUG(S)

Eradicating Infection

- Choice of antimicrobial agent is based on culture and susceptibility findings in the prostatic fluid, antibiotic lipid solubility (which enhances its ability to diffuse into prostatic tissue in therapeutic concentrations), and assessment of acute or chronic status of the infection. • Antibiotics of choice in chronic prostatitis are those known to diffuse into normal prostatic tissue in therapeutic concentrations including chloramphenicol, erythromycin, fluoroquinolones, and trimethoprim. In acute prostatitis, the blood-prostate barrier is assumed to be disrupted, and almost any antibiotic will penetrate the prostatic parenchyma in therapeutic concentrations. • Emergency antibiotic treatment of choice in dogs with acute prostatitis and/or abscess, administered after collection of prostatic fluid for culture, is amoxicillin/clavulanate (25 mg/kg PO q8h) with enrofloxacin (5 mg/kg PO q12h).

Inducing Prostatic Involution

- Treatment of choice for inducing permanent prostatic involution is castration. • Alternatively, the 5 alpha-reductase inhibitor finasteride (0.1–1 mg/kg PO q24h) for 2–4 months induces involution of the prostatic parenchyma and diffuse epithelial cysts and abscesses. • Finasteride prevents conversion of testosterone to DHT, thereby causing prostatic involution without adversely affecting libido or spermatogenesis. • BPH recurs following cessation of finasteride therapy.

CONTRAINdications

Estrogens and androgens cause squamous metaplasia of the prostate and BPH, respectively.

PRECAUTIONS

Long-term therapy with trimethoprim may lead to keratoconjunctivitis sicca and/or hypothyroidism.

FOLLOW-UP

PATIENT MONITORING

- Repeated evaluation of semen culture, cytology, and prostatic imaging. • Intervals between reevaluations vary with severity of signs, presence of an abscess, selection of castration or finasteride therapy for prostatic involution, and use of the dog in a breeding program. Intervals between evaluations range from 1 to 8 weeks, with recheck recommended prior to breeding. • Continue patient monitoring until the dog has been castrated.

PREVENTION/AVOIDANCE

Castration is recommended to induce prostatic involution, resolution of BPH, and prevention of recurrent infection.

POSSIBLE COMPLICATIONS

- Recurrence of infection if prostatic involution is not induced. • Surgical drainage of abscesses is associated with many complications, including urinary incontinence, recurrent abscessation, hypoproteinemia, scrotal edema, anemia, sepsis, and shock.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is good to excellent except in the case of rupture of prostatic abscesses into the peritoneal cavity, with resulting peritonitis.
- Castration prevents recurrence and improves prognosis. • Surgical management of prostatic abscesses is associated with complications and a poorer prognosis than medical/surgical induction of prostatic involution.

MISCELLANEOUS

ASSOCIATED CONDITIONS

When prostatic fluid is infected, blood, inflammatory exudate, and microbial organisms may reflux into the urinary bladder, which, if detected in a urine sample collected by cystocentesis, may be misinterpreted as primary UTI.

ZOONOTIC POTENTIAL

Rare. *Brucella canis* and *Blastomycoses dermatitidis* have been isolated from the urine of dogs with prostatic infection, but human infection from these sources has not been reported.

P

SEE ALSO

- Benign Prostatic Hyperplasia • Dysuria and Pollakiuria • Hematuria • Peritonitis

PROSTATOMEGLY

BASICS

DEFINITION

Abnormally large prostate gland determined by rectal or abdominal palpation or by abdominal radiography or prostatic ultrasonography. The enlargement can be symmetrical or asymmetrical, painful or non-painful. Normal prostate size varies with age, body size, castration status, and breed so assessment of enlargement is subjective.

PATOPHYSIOLOGY

Enlargement can result from epithelial cell hyperplasia or hypertrophy (e.g., benign prostatic hyperplasia), neoplasia of prostatic epithelium or stroma, cystic change within the prostatic parenchyma, or inflammatory cell infiltration (e.g., acute and chronic bacterial prostatitis and prostatic abscess).

SYSTEMS AFFECTED

- Urinary
- Reproductive

SIGNALMENT

- Dog
- Typically occurs in middle-aged to older males

SIGNS

- May be none
- Straining to defecate
- Ribbon-like stools
- Dysuria
- Urethral outflow obstruction

CAUSES

- Benign prostatic hyperplasia
- Squamous metaplasia
- Adenocarcinoma
- Transitional cell carcinoma
- Sarcoma
- Metastatic neoplasia
- Acute bacterial prostatitis
- Prostatic abscess
- Chronic bacterial prostatitis
- Prostatic cyst

RISK FACTORS

- Castration lowers the risk of benign prostatic hyperplasia and bacterial prostatitis.
- Risk of adenocarcinoma may be increased three-fold in castrated dogs.

- Primary or metastatic neoplasia—typically causes painful, non-symmetric enlargement of the prostate gland; weight loss, impaired appetite, rear limb weakness observed in some patients; suspect neoplasia in castrated dogs.

- Acute bacterial prostatitis—typically results in slight-to-moderate symmetric or non-symmetric enlargement of the prostate gland with prostatic pain. Fever, impaired appetite, rear limb weakness, and painful abdomen observed in some patients.
- Chronic bacterial prostatitis—signs similar to those seen in dogs with acute prostatitis or those related to recurrent lower urinary tract infection (e.g., dysuria and hematuria). Systemic signs less common than in acute bacterial prostatitis; bacterial prostatitis uncommon in castrated dogs.
- Prostatic abscess—may result in signs similar to those in patients with acute or chronic prostatitis; abscess rupture causes fever and caudal abdominal pain.
- Prostatic cysts—may be associated with palpable caudal abdominal mass, straining to urinate, or straining to defecate; patient may also be asymptomatic.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC normal in patients with benign prostatic hyperplasia.
- Leukocytosis in patients with acute and chronic (occasionally) bacterial prostatitis, prostatic abscess, and prostatic neoplasia (occasionally).
- High bilirubin and alkaline phosphatase in some patients with prostatic abscess.
- Urinalysis—may be normal.
- Hematuria in patients with benign prostatic hyperplasia.
- Pyuria, hematuria, proteinuria, and bacteriuria in patients with bacterial prostatitis.
- Pyuria, hematuria, proteinuria, and, occasionally, neoplastic cells in dogs with prostatic neoplasia.

OTHER LABORATORY TESTS

Serum prostatic esterase concentration may be high in dogs with benign prostatic hyperplasia.

IMAGING

Radiographic Findings

Prostatomegaly

Ultrasonographic Findings

- Abscess or cyst—hypoechoic or anechoic lesions with distal enhancement.
- Acute bacterial prostatitis—uniform prostatic echogenicity.
- Benign prostatic hyperplasia—uniform prostatic echogenicity; small fluid-filled cysts in some patients.
- Chronic bacterial prostatitis—focal or diffuse hyperechogenicity.

- Prostatic neoplasia—focal to multifocal areas of coalescing echogenicity and acoustic shadowing (if dystrophic mineralization occurs).

DIAGNOSTIC PROCEDURES

- Examination of prostatic fluid obtained by ejaculation or prostatic massage may reveal changes similar to those seen on urinalysis.
- Bacterial culture of prostatic fluid typically reveals $> 100,000$ CFU of bacteria/mL in dogs with bacterial prostatitis.
- Needle biopsy of the prostate with ultrasound guidance provides visualization of the area to be sampled and increases the likelihood of obtaining a diagnostic sample; take care to avoid iatrogenic rupture of a prostatic abscess.

TREATMENT

- Varies with the cause of prostatomegaly.
- Surgical castration—indicated in symptomatic dogs with benign prostatic hyperplasia and after acute infection resolves in dogs with bacterial prostatitis.
- Surgical drainage—indicated in dogs with prostatic abscess or large prostatic cysts.

MEDICATIONS

DRUG(S) OF CHOICE

Benign Prostatic Hyperplasia

- If castration is not acceptable, the following drugs may produce a temporary response:
 - Finasteride (0.1–0.5 mg/kg/day PO for up to 4 months)
 - Megestrol acetate (0.11 mg/kg PO daily for 3 weeks)
 - Medroxyprogesterone (3 mg/kg SC).

Bacterial Prostatitis

Choose antibiotics on the basis of antibacterial susceptibility testing of the isolated pathogen and ability of the antibiotic to diffuse into prostatic fluid in therapeutic concentrations. Good choices for the latter include trimethoprim-sulfa, chloramphenicol, and fluoroquinolones.

Prostatic Carcinoma

Chemotherapy has not been proven beneficial.

PRECAUTIONS

Long-term administration of megestrol acetate or medroxyprogesterone can cause diabetes mellitus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Benign prostatic hyperplasia—typically causes non-painful symmetrical enlargement of the prostate gland; not found in neutered dogs.

(CONTINUED)

PROSTATOMEGLY**FOLLOW-UP****PATIENT MONITORING**

- Abdominal radiographs or prostatic ultrasonography to assess efficacy of treatment in benign prostatic hyperplasia, prostatic carcinoma, or bacterial prostatitis.
- Urine and prostatic fluid culture to access efficacy of treatment in patients with bacterial prostatitis.

POSSIBLE COMPLICATIONS

- Urethral obstruction
- Rectal obstruction

**MISCELLANEOUS****SEE ALSO**

- Adenocarcinoma, Prostate
- Benign Prostatic Hyperplasia
- Prostatic Cysts
- Prostatitis and Prostatic Abscess

PROTEIN-LOSING ENTEROPATHY

BASICS

DEFINITION

- Any disease process that is characterized by excessive loss of protein into the gastrointestinal lumen.
- Diseases associated with PLE include primary gastrointestinal diseases such as inflammatory bowel disease, intestinal lymphoma, or intestinal lymphangiectasia and systemic disorders such as congestive heart failure.

PATOPHYSIOLOGY

- Under physiologic conditions, two-thirds of normal protein loss in dogs occurs through the small intestine.
- Plasma proteins that leak into the gastrointestinal lumen are rapidly digested into constituent amino acids that can then be reabsorbed and used for the synthesis of new proteins.
- This normal loss of plasma proteins can be accelerated by gastrointestinal mucosal disease or by increased leakage of lymph into the gastrointestinal lumen.
- Gastrointestinal protein loss is associated with loss of both albumin and globulin.
- In response to increased gastrointestinal protein loss, the liver increases albumin synthesis.
- However, the liver cannot increase albumin synthesis to more than twice the normal output.
- When protein loss exceeds protein synthesis, hypoproteinemia results.
- Severe hypoproteinemia causes decreased plasma oncotic pressure, which may be associated with hemodynamic changes and may lead to effusion into body cavities or, less commonly, peripheral edema.
- Dogs and cats with PLE are not always panhypoproteinemic, and can have low-normal serum globulin concentrations with hypoalbuminemia.

P

SYSTEMS AFFECTED

- Coagulation—patients with PLE also lose antithrombin and may be hypercoagulable.
- Gastrointestinal—primary gastrointestinal disease that may be associated with diarrhea, vomiting, or other clinical signs of GI disease.
- Hemodynamic—ascites or pleural effusion due to decreased oncotic pressure leading to abdominal discomfort or even dyspnea.
- Lymphatic—lymphangiectasia.
- Respiratory—dyspnea due to pleural effusion.
- Skin—subcutaneous edema.

GENETICS

A hereditary nature of PLE due to specific underlying causes is suspected, based on an increased prevalence of such conditions in specific dog breeds.

INCIDENCE/PREVALENCE

- The true incidence and prevalence are unknown.
- Many dogs with subacute or acute gastroenteritis have transient PLE.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Soft-coated Wheaten terrier, Basenji, Yorkshire terrier, and Norwegian Lundehund.

Mean Age and Range

Any age

SIGNS

General Comments

Clinical signs are variable

Historical Findings

- Diarrhea (chronic, continuous or intermittent, watery to semisolid), weight loss, and lethargy are most frequently reported. However, a significant number of dogs with PLE have normal stools.
- Vomiting is uncommon.
- Dogs can be presented for apparent weight gain or abdominal distension as the only clinical sign.

Physical Examination Findings

- Ascites, dependent edema, and dyspnea from pleural effusion may be detected with marked hypoproteinemia.
- Abdominal palpation may reveal thickened bowel loops, although most dogs with intestinal lymphangiectasia do not have thickened bowel loops.

CAUSES

Disorders of Lymphatics

- Intestinal lymphangiectasia
- Gastrointestinal lymphoma
- Granulomatous infiltration of the small bowel
- Congestive heart failure leading to lymphatic hypertension

Diseases Associated with Increased Mucosal Permeability or Mucosal Ulceration

- Viral gastroenteritis—parvovirus and others.
- Bacterial gastroenteritis—salmonellosis and others.
- Fungal gastroenteritis—histoplasmosis and others (note: serum globulin concentrations can be in the normal reference interval range with fungal disorders causing PLE in light of increased globulin production secondary to antigenic stimulation).
- Parasitic enteritis—hookworms, whipworms, and others.
- Inflammatory bowel disease—lymphocytic, lymphocytic-plasmacytic, or eosinophilic gastroenteritis.
- Adverse food reactions—food allergy, food intolerance, and others.
- Mechanical enteropathies—chronic intussusception, chronic foreign body, and others.
- Intestinal neoplasia—lymphoma, adenocarcinoma.
- Gastric or intestinal ulcers.

RISK FACTORS

- Gastrointestinal disease
- Lymphatic disease
- Heart disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypoalbuminemia due to PLE must be differentiated from other causes of

hypoalbuminemia.

- Hypoalbuminemia due to hepatic failure is most often associated with a normal or even increased serum globulin concentration. Hepatic enzyme activities may be increased, serum BUN, cholesterol, and even glucose may be decreased, and serum pre- and postprandial bile acids concentrations may also be increased.

- Hypoalbuminemia due to PLN: mild in patients with fever or hyperadrenocorticism, moderate to severe in patients with glomerulonephritis or amyloidosis; is commonly associated with a normal or even increased serum globulin concentration—ruled out by a normal urine protein:creatinine ratio.
- Hypoalbuminemia due to severe blood loss is associated with hypoglobulinemia—blood loss can be excluded by assessment of erythrocyte count on CBC and a thorough physical examination; in some cases a test for fecal occult blood may be necessary.
- Inadequate protein intake (i.e., starvation) is a rare cause of hypoalbuminemia.
- Hypoalbuminemia due to PLE is often associated with hypoglobulinemia—confirmed by an increased fecal α_1 -protease inhibitor concentration (must be assessed in naturally passed and freshly frozen fecal samples from 3 consecutive days).

CBC/BIOCHEMISTRY/URINALYSIS

- Hypoalbuminemia and frequently hypoglobulinemia (panhypoproteinemia).
- A normal or increased serum globulin concentration in some cases, when the underlying disease is associated with chronic antigenic stimulation (e.g., immunoproliferative enteropathy of the Basenji).
- Hypocalcemia—secondary to hypoalbuminemia.
- Hypocholesterolemia can be seen.
- Lymphopenia may be seen with lymphangiectasia.

OTHER LABORATORY TESTS

- Increased fecal α_1 -protease inhibitor concentration.
- Once PLE has been identified as the cause of the hypoalbuminemia, specific tests may be useful to determine the specific cause of PLE—multiple fecal examinations (smears and centrifugation flotations) to rule-out intestinal parasitism as a cause of PLE; serum cobalamin and folate concentrations to diagnose small intestinal dysbiosis or cobalamin deficiency.

IMAGING

- Thoracic radiographs may show evidence for cardiac or fungal disease.
- Abdominal radiographs may show evidence for a mechanical enteropathy or other causes of PLE.
- Abdominal ultrasound also may show evidence for a mechanical enteropathy or other causes of PLE.
- Abdominal ultrasound is helpful for evaluating the intestinal wall layering pattern associated with a variety of enteropathies. A hyperechoic linear or “tiger stripe” effect associated with distension of

(CONTINUED)

intestinal lacteals with lymph fluid can be seen in many dogs with lymphangiectasia and is characterized by hyperechoic lacteals extending from the lumen of the bowel to the submucosal layer. • Cardiac ultrasound may show evidence for cardiac disease.

DIAGNOSTIC PROCEDURES

- Broad-spectrum anthelmintic agent-to treat for potential parasitism with a variety of gastrointestinal endoparasites.
- Feeding trial of an elimination diet containing an intact protein source or hydrolyzed protein source—to rule out adverse reactions to food.
- Rectal mucosal scraping—to help rule out histoplasmosis in geographic regions where histoplasmosis is endemic.
- Gastroduodenoscopy and colonoscopy—to visualize the gastrointestinal mucosa and to collect endoscopic biopsies for histopathologic evaluation. Visualizing white “plaques” (e.g., chylomicron distended lacteals) along the mucosa suggests lymphangiectasia. Endoscopic biopsies should contain full-thickness mucosa to maximize the diagnostic yield of tissue specimens.
- Abdominal exploratory laparotomy may show dilated intestinal lymphatics and allows for full-thickness biopsies of intestines and lymph nodes.
- Fecal α_1 -protease inhibitor concentration to document excessive gastrointestinal protein loss. α_1 -protease inhibitor is a plasma protein with a similar molecular weight to albumin and is thus lost at a similar rate to albumin. Assays for the measurement of α_1 -protease inhibitor are species-specific for dogs and cats and are only available through the Gastrointestinal Laboratory at Texas A&M University. Samples from 3 consecutive defecations need to be collected in special pre-weighed fecal tubes that can be sourced from the GI Lab.

PATHOLOGIC FINDINGS

PLE is not associated with any specific gross or histopathologic lesions. Lesions identified are those of the specific cause of PLE.

TREATMENT

NURSING CARE

- In cases of severe hypoalbuminemia that are associated with clinical signs due to edema or effusion plasma transfusions or colloids (such as hetastarch or dextran) should be considered to increase plasma oncotic pressure.
- Abdominocentesis to remove ascites or pleurocentesis to remove pleural effusion in cases with compromise from severe effusion.

ACTIVITY

Normal

DIET

- May need to be modified depending on the underlying cause of PLE.
- If lymphangiectasia is diagnosed or highly suspected, a low-fat diet that contains < 25% fat in a ME basis should be used. An elemental diet can also be used in patients with severe disease.

suspected, a low-fat diet that contains < 25% fat in a ME basis should be used. An elemental diet can also be used in patients with severe disease.

CLIENT EDUCATION

Prepare clients for long-term therapy; spontaneous cures are rare.

SURGICAL CONSIDERATIONS

- Hypoalbuminemia increases postoperative morbidity because of slow wound healing.
- Some causes of PLE (e.g., intussusception, chronic foreign body, and some intestinal neoplasias), however, require surgical intervention.

MEDICATIONS

DRUG(S) OF CHOICE

- There is no pharmacologic therapy for PLE itself. Instead, the underlying cause of PLE must be addressed. See “Treatment” for these conditions.
- However, patients with PLE also lose antithrombin and can be hypercoagulable. Thus, patients should be treated with a platelet aggregation inhibitor:
 - In dogs or cats: clopidogrel bisulfate (3–5 mg/kg PO q24h in dogs; 18.75 mg/cat PO q24h, which equals one-fourth of a 75-mg tablet).
 - In dogs: low-dose aspirin (0.5 mg/kg q12h PO; use an 81-mg tablet of aspirin and put into the barrel of a 10-mL syringe, add 8.1 mL of water and shake until completely dissolved to make a 10-mg/mL solution; discard unused portion immediately).

CONTRAINdicATIONS

- Aspirin and clopidogrel should not be used concurrently.
- Clopidogrel should not be used with other NSAIDs, phenytoin, torsemide, or warfarin.

PRECAUTIONS

Bleeding may be enhanced in patients treated with platelet aggregation inhibitors that have to undergo surgery.

ALTERNATIVE DRUG(S)

- Diuretics such as furosemide (1 mg/kg PO q12h) in combination with spironolactone (1 mg/kg PO q12h) have been used by some clinicians to control edema, pleural effusion, and ascites. However, they do not work consistently in patients with PLE because of decreased plasma oncotic pressure and may be associated with side effects.
- There are anecdotal reports about the use of the long-acting somatostatin analogue octreotide in dogs with PLE, but no clinical trials have been completed to date.

PROTEIN-LOSING ENTEROPATHY

FOLLOW-UP

PATIENT MONITORING

Check body weight, serum albumin concentration, and evidence of recurrent clinical signs (i.e., pleural effusion, ascites, and/or edema). Frequency depends on the severity of the condition. Monitor serum cobalamin concentrations after initial 6-week induction phase of weekly administrations.

POSSIBLE COMPLICATIONS

- Respiratory difficulty from pleural effusion
- Severe protein-calorie malnutrition
- Intractable diarrhea

EXPECTED COURSE AND PROGNOSIS

- Prognosis is guarded and depends on the underlying cause. Smaller breed dogs carry a more favorable prognosis because nutritional support is easier to perform.
- The primary disease cannot be treated in many cases.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Soft-coated Wheaten terriers may have PLN in conjunction with PLE and should be evaluated accordingly.

ZOONOTIC POTENTIAL

Histoplasmosis, hookworms, and coccidia have zoonotic potential to humans.

ABBREVIATIONS

- GI = gastrointestinal
- NSAID = nonsteroidal anti-inflammatory drug
- PCV = packed cell volume
- PLE = protein-losing enteropathy
- PLN = protein-losing nephropathy

PROTEINURIA

BASICS

DEFINITION

- Urinary protein detected by dipstick analysis, urinary protein:creatinine ratio (UP:C ≥ 0.4 in cats or ≥ 0.5 in dogs), urinary albumin:creatinine ratio (UA:C probably $> 30 \text{ mg/g}$), or 24-hour urine protein content ($> 20 \text{ mg/kg}$). UP:C of 0.2–0.4 in cats and 0.2–0.5 in dogs is borderline.
- Microalbuminuria is the abnormal presence of low concentrations of albumin in the urine (1–30 mg/dL) below the limit of detection of standard urine dipsticks.

PATHOPHYSIOLOGY

- Prerenal: greater than normal delivery of low molecular weight plasma proteins to glomeruli.
- Renal, glomerular: excessive loss of larger molecular weight proteins (e.g., albumin) across the GBM secondary to altered permselectivity of glomeruli.
- Renal, tubular: reduced tubular reabsorption of proteins.
- Post-reenal: exudation of blood or plasma into lower urinary tract.

SYSTEMS AFFECTED

- Renal/Urologic—chronic glomerular proteinuria causes progressive tubular damage resulting in advanced chronic kidney disease (CKD).
- Cardiovascular—systemic hypertension is common with glomerular disease.
- Hemic/Lymphatic/Immune—severe glomerular proteinuria can lead to edema and/or hypercoagulability. Hypercoagulability is brought about by vascular stasis, hyperfibrinogenemia, platelet abnormalities, loss of antithrombic substances, and an increase in procoagulant factors. The pathogenesis of edema involves both inappropriate renal sodium retention and decreased plasma oncotic pressure.

GENETICS

Familial nephropathies associated with glomerular proteinuria have been described in several breeds of dogs; in only a few has the mode of inheritance been established: Samoyed (X-linked), English cocker spaniel (autosomal recessive), bull terrier (autosomal dominant), Dalmatian (autosomal dominant), Bernese mountain dog (suspect autosomal recessive), Brittany spaniel (autosomal recessive), Chinese Shar-Pei (suspect autosomal recessive). Doberman pinscher, bullmastiff, Newfoundland, rottweiler, Pembroke Welsh corgi, beagle, English foxhound, soft-coated Wheaten terrier, and others.

INCIDENCE/PREVALENCE

- In a study of urinalysis data from 500 dogs, the prevalence of proteinuria was approximately 19%.

- The prevalence of microalbuminuria was 25% in 3,041 dogs and 25% 1,243 cats. Prevalence increased with advancing age.

SIGNALMENT

Species

Dog and less commonly cat

Breed Predilections

Glomerular proteinuria may be the initial manifestation of several familial renal diseases (see "Genetics").

Mean Age and Range

Proteinuria can occur in animals of any age. Familial renal diseases tend to occur in younger animals; acquired glomerular proteinuria more likely in middle-aged or older animals.

Predominant Sex

Probably varies with different diseases.

SIGNS

- Vary with underlying cause and severity of proteinuria.
- Patients with glomerular proteinuria are frequently asymptomatic or have signs attributable to underlying diseases.

Historical Findings

- Many have weight loss and lethargy; animals with pulmonary thromboembolism may have acute dyspnea.
- Patients with LUT disorders may have dysuria, pollakiuria, inappropriate urination, and/or hematuria.

Physical Examination Findings

- May have edema or abdominal distention.
- May have oral ulceration (if uremic), edema or cavity effusion, or changes in pulse quality (if thromboembolic).

CAUSES

Prerenal Proteinuria

Overload proteinuria—tubular resorptive capacity exceeded by large amounts of low molecular weight plasma proteins in glomerular filtrate (e.g., excessive hemolysis or rhabdomyolysis, neoplastic production of paraproteins or Bence-Jones proteins).

Renal Proteinuria

- Functional proteinuria—strenuous exercise, fever, hypothermia, seizures, or venous congestion; poorly documented causes of proteinuria in dogs and cats.
- Glomerulonephritis (e.g., membranoproliferative, proliferative), glomerulonephropathy (e.g., membranous nephropathy), minimal change disease, hereditary nephritis, amyloidosis, focal segmental glomerulosclerosis, glomerulosclerosis.
- All glomerular diseases can be associated with severe proteinuria but those that are immune-complex mediated (particularly membranoproliferative and membranous) may be associated with higher magnitude proteinuria than those that are not immune-complex mediated.
- Tubular dysfunction resulting in failure of tubular protein reabsorption is associated with mild-to-moderate proteinuria.

Post-reenal Proteinuria

Hemorrhage or inflammation of the urogenital tract.

RISK FACTORS

- Chronic inflammatory (e.g., infectious and immune-mediated) and neoplastic diseases can lead to development of glomerulonephritis or amyloidosis. Examples include dirofilariasis, ehrlichiosis, borreliosis, babesiosis, chronic bacterial infections (e.g., endocarditis, pyoderma), pyometra, bartonellosis, FIV, mast cell tumor, lymphosarcoma, hyperadrenocorticism, and systemic lupus erythematosus.
- Systemic hypertension.
- Chronic hyperlipidemia (e.g., miniature schnauzer).
- Multiple myelomas can produce paraproteins resulting in Bence-Jones proteinuria.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiate prerenal, post-reenal, and renal tubular from glomerular causes.

CBC/BIOCHEMISTRY/URINALYSIS

- Urine dipstick and sulfosalicylic acid tests allow qualitative and semiquantitative assessment of urine protein content. Results of both are affected by urine concentration and must be interpreted in context of urine specific gravity. Low urine protein (trace or 1+) may be normal in a concentrated urine sample.
 - The dipstick lacks specificity (dog, 69%; cat, 31%) and sensitivity (dog, 54%; cat, 60%).
 - Contamination with quaternary ammonium compounds causes false-positive urine dipstick colorimetric (tetrabromphenol blue) test results. False-positive test results also occur when urine is highly alkaline (pH > 8–9) or when the dipstick is immersed in the urine for a prolonged time.
 - Low concentrations of Bence-Jones proteins or gamma globulins may not be detected by urine dipsticks.
 - SSA turbidometric test results are falsely increased by radiographic contrast media, penicillins, sulfisoxazole, or the urine preservative thymol.
 - SSA test results are falsely decreased by very alkaline urine and increased by uncentrifuged urine.
 - If proteinuria is detected by these methods, the urine sediment should be evaluated for hematuria, pyuria, and/or bacteriuria. Hematuria alone typically does not increase urine albumin content above the negligible range (i.e., > 1 mg/dL) or the UP:C above

(CONTINUED)

0.4 until there is a visible color change in the urine. In a study of the effects of inflammation on urine protein determination, 67% of dogs with varying degrees of pyuria had negligible urine albumin concentrations ($< 1 \text{ mg/dL}$) and 81% had normal UP:C (< 0.4).

- To determine if proteinuria is persistent repeat the urine protein screening test in proteinuric patients that initially have a normal urine sediment or have been treated for urinary tract inflammation or hemorrhage. If proteinuria is transient and the urine sediment is normal, consider functional proteinuria or false-positive test results.
- Although not all animals with glomerular disease are hypoalbuminemic, glomerular proteinuria should be suspected when proteinuria and hypoalbuminemia are concurrent. As disease progresses, clinicopathologic changes consistent with glomerular disease may develop.

OTHER LABORATORY TESTS

- Urine protein should be quantified in dogs and cats that have hypoalbuminemia and/or repeatedly positive urine dipstick or SSA tests in absence of LUT hemorrhage or inflammation. In theory, the UP:C, UA:C or 24-hour urine collections can be used for quantification. The UP:C is the preferred for quantification because more is known about use of this test and it is technically easier to perform than 24-hour urine collections.
- Microalbuminuria is detected in dogs using a point of care immunoassay or quantitation using an immunoassay. Microalbuminuria is an early predictor of proteinuria. If microalbuminuria is detected via one of these tests, the test should be repeated in 2–4 weeks. If repeatedly positive, and if the concentration is increasing, the patient may be at risk for glomerular disease.
- Appropriate diagnostic testing should be performed to thoroughly evaluate an animal for an underlying disease when persistent proteinuria is believed to be of glomerular origin.

IMAGING

Ultrasound and radiographs may reveal an underlying infectious, inflammatory, or neoplastic disease process or evidence of LUT disease. Ultrasound may provide information about structural changes suggesting primary renal disease (e.g., loss of corticomedullary distinction, hyperechogenicity, and irregular surface margin) or evidence in support of LUT disease.

DIAGNOSTIC PROCEDURES

- Blood pressure should be monitored in patients with persistent renal proteinuria.
- Renal biopsy is needed to specifically diagnose the glomerular disease when an underlying disease cannot be identified or proteinuria has persisted for several months following treatment of an underlying disease.

TREATMENT

APPROPRIATE HEALTH CARE

Most patients with proteinuria can be managed as outpatients. Inpatient care may be required during select diagnostic evaluation (renal biopsy) or when there are complications associated with uremia, thromboembolism or edema in patients with glomerular proteinuria.

NURSING CARE

Physical therapy and exercise may limit formation of edema in patients with glomerular proteinuria and hypoalbuminemia. For these patients, cage confinement should be avoided.

ACTIVITY

Activity should not be restricted in animals with proteinuria.

DIET

If glomerular disease is suspected, feed a diet formulated for kidney diseases.

CLIENT EDUCATION

It is important to determine the cause of persistent proteinuria, which may indicate the presence of kidney disease. Renal proteinuria is a risk factor for progressive kidney disease, thromboembolism, and edema. It is important that all medications are given and the animal is evaluated as prescribed by a veterinarian.

SURGICAL CONSIDERATIONS

Animals with severe hypoalbuminemia (i.e., $< 2 \text{ g/dL}$) present unique challenges to anesthesia. Consideration should be given to referral of these patients to a secondary or tertiary care facility if anesthesia and/or surgery are indicated.

MEDICATIONS

DRUG(S) OF CHOICE

An angiotensin-converting enzyme inhibitor should be given to dogs and cats with glomerular proteinuria. Animals that do not have a meaningful reduction in proteinuria (see "Patient Monitoring") when given a maximal dose of an ACEi can also be given an angiotensin receptor blocker (ARB). An ARB can also be given to those animals that have adverse effects from an ACEi. Use of aldosterone antagonists in management of proteinuria needs further investigation but may be indicated for patients that have increased aldosterone concentrations following treatment with an ACEi or ARB. Animals with concurrent hypertension often require addition of a calcium channel blocker (e.g., amlodipine) or another antihypertensive agent to control both hypertension and

proteinuria. Supplementation with n-3 polyunsaturated fatty acid (PUFA) should be considered in dogs, and possibly cats, with glomerular proteinuria when the diet being fed does not have a reduced n-6/n-3 PUFA ratio that approximates 5:1. Dogs with glomerular disease should also be given low-dose aspirin or clopidogrel as thromboprophylaxis.

CONTRAINDICATIONS

There are no known contraindications in animals with proteinuria.

PRECAUTIONS

Drugs highly bound to albumin may have an altered effect if hypoalbuminemia is present. The use of warfarin as an anticoagulant should be avoided. With hypoalbuminemia or azotemia, higher doses of furosemide may be required to mobilize edema effectively; however, they should be used with extreme caution.

POSSIBLE INTERACTIONS

There are no known important drug interactions in dogs with proteinuria other than the previously mentioned concern with highly protein-bound drugs.

ALTERNATIVE DRUGS

An ARB is an alternative to an ACEi.

FOLLOW-UP

PATIENT MONITORING

- The UP:C, urinalysis, systemic arterial blood pressure and serum albumin, creatinine and potassium concentrations should be monitored at least quarterly in all dogs and cats being treated for glomerular disease.
- Use the UP:C to assess progression of glomerular disease. Response to treatment should be evaluated for several months after resolution of any underlying disease. In general, a reduction of a UP:C to < 0.5 (dog) or < 0.2 (cat) without inappropriate worsening of renal function is considered a therapeutic success. However, this ideal target is often not achieved and a reduction in UP:C of 50% or greater is the recommended alternate target.
- Monitor serum creatinine concurrently. Reduced proteinuria or reduced albuminuria that is concurrent to a rising serum creatinine may reflect deteriorating renal function.
- Because UP:Cs may vary, two to five serial assessments may be needed to evaluate response to treatment or progression in patients with glomerular proteinuria. Alternatively, the UP:C can be measured in a sample that has been pooled by adding equal aliquots of 2 to 3 samples that have been collected and refrigerated over a 48-hour time period.
- When given an ACEi or an ARB, dogs with stage 1 or 2 CKD can have an increase in

PROTEINURIA

(CONTINUED)

serum creatinine of up to 30% without warranting a change in treatment. Worsening of renal function in dogs with stage 3 or 4 CKD should be avoided. During therapy the serum potassium concentration should not be allowed to exceed 6 mmol/L and the systolic blood pressure should not be < 120 mmHg.

PREVENTION/AVOIDANCE

Adult dogs and cats should have annual urinalyses including determination of urine protein. Repeat the tests in 2–4 weeks if proteinuria is detected. Patients with persistent proteinuria or microalbuminuria of glomerular origin should be evaluated more thoroughly for underlying causes of glomerular injury. Potential underlying causes should be eliminated or managed. If proteinuria persists, potential underlying causes have been managed appropriately or underlying causes were not identified, and the patient is in CKD stage 1, 2, or 3, the dog or cat should be evaluated via renal biopsy and managed appropriately.

POSSIBLE COMPLICATIONS

- Edema
- Thromboembolism
- Systemic hypertension
- Progressive kidney disease
- Poor wound healing

EXPECTED COURSE AND PROGNOSIS

- Vary with the cause of proteinuria.
 - Post-renal and prerenal proteinuria should resolve following resolution of inciting causes.
 - Most diseases associated with renal tubular proteinuria are progressive.
 - Although glomerular diseases are often progressive, the rate of progression varies and spontaneous remissions have been reported.
- Animals with persistent glomerular proteinuria may develop renal tubular damage

resulting in advanced CKD and eventual uremia and death. Some dogs die shortly after the initial detection of proteinuria, while others remain alive for years. Dogs with nephrotic syndrome and/or azotemia may have a shorter survival.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Heavy proteinuria can be associated with hypoalbuminemia, hypoglobulinemia (rare), hypercholesterolemia, low antithrombin III, thrombocytosis, hyperfibrinogenemia, edema, thromboembolism, and systemic hypertension.

AGE-RELATED FACTORS

Familial glomerular diseases should be considered in young animals with glomerular range proteinuria.

ZOONOTIC POTENTIAL

Proteinuria does not have a zoonotic potential. However, glomerular proteinuria can occur with a variety of infectious diseases, some of which could have a zoonotic potential.

PREGNANCY/FERTILITY/BREEDING

Some drugs used in the treatment of diseases associated with proteinuria may be contraindicated in pregnancy.

PROTOTHECOSIS

BASICS

OVERVIEW

- *Prototheca wickerhamii* and *P. zopfii*—single-celled achlorophylous blue-green algae (Chlorophyta) that can cause disease in warm-blooded animals.
- Humans and cats—usually localized infection of the skin or gastrointestinal tract.
- Dogs—usually colitis.

SYSTEMS AFFECTED

- Skin/Exocrine
- Gastrointestinal
- Nervous
- Ophthalmic

SIGNALMENT

- Dogs—young, female adult, medium- to large-breed dogs, boxer and collie are overrepresented.
- Cats—uncommon, usually cutaneous form.

SIGNS

Historical Findings

Dogs

- Intermittent and chronic large bowel diarrhea with fresh blood.
- Chronic weight loss.
- Acute onset blindness.
- Neurologic disease; deafness, seizures, ataxia.
- Cutaneous lesions.

Cats

Chronic cutaneous or mucous membrane ulceration with few systemic signs.

Physical Examination Findings

Dogs

- Gastrointestinal, ocular, or neurologic disease most common.
- Severe weight loss and debilitation.
- Hemorrhagic colitis, vomiting, anorexia.
- Blindness due to chorioretinitis and/or detached retinas.
- CNS—depression, ataxia, vestibular signs, seizures and/or paresis.
- Cutaneous—ulcers and crusts on the extremities and mucosal surfaces.

Cats

Large cutaneous nodules on the face or limbs.

CAUSES & RISK FACTORS

- Dogs—usually *P. zopfii*; *P. wickerhamii* infection may also occur.
- Cats—usually *P. wickerhamii*.
- Basis for the pathogenicity of *Prototheca* sp. unknown, likely traumatic inoculation.
- Organism—ecologic niche is raw and treated sewage; contaminants of water, soil, and food; occasionally isolated from fecal samples from healthy individuals.
- Dogs and humans—depressed cell-mediated immunity may predispose to gastrointestinal and disseminated infections with *P. zopfii*.
- Cats—no known predisposing factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Systemic—histoplasmosis, blastomycosis, cryptococcosis, pythiosis.
- Cutaneous—

systemic and subcutaneous mycoses; mycobacterioses, neoplasia, L-form bacterial infection, actinomycosis.

CBC/BIOCHEMISTRY/URINALYSIS

- Dogs—often normal; depends on organ system affected; organism occasionally seen in urine sediment.
- Cats—almost always normal.

OTHER LABORATORY TESTS

CSF tap—pleocytosis with mononuclear cells; increased protein; organisms.

DIAGNOSTIC PROCEDURES

Cytology

- Definitive diagnostic test; gram's iodine solution.
- Rectal or colonic mucosa, vitreous humor, CSF, cutaneous aspirations.
- Organisms—unicellular, non-pigmented, oval or round cell walls often appear folded; diagnostic characteristic is endospore formation with internal septation in two planes.

Culture

- Blood agar or Sabouraud's dextrose agar (without cycloheximide) at 25–37°C (77–97°F) white or creamy, smooth colonies within 48 hours.
- Specific identification by selective agars or biochemical tests in culture (susceptibility to clotrimazole, sugar and alcohol assimilation tests) or immunohistochemistry.

Polymerase Chain Reaction (PCR) Assays

PCR and DNA to determine species; specimens can be taken from biopsies, CSF or urine.

PATHOLOGIC FINDINGS

Dogs

- Small granulomatous foci or hemorrhagic ulcers—found in many organs, especially kidneys; identification of organisms is diagnosed.
- Nodular thickening of the gastrointestinal mucosa with ulceration.
- Nonspecific inflammatory foci surrounding organisms or pyogranulomas—poorly organized; mixed with other inflammatory cells.

Cats

Cutaneous masses—localized; extend deep into subcutaneous tissues; consist of granulomatous inflammation and mixed-cell inflammation; made up primarily by organisms.

TREATMENT

- Dogs—surgical excision and combination drug therapy.
- Cats—excision of localized cutaneous masses is primary therapeutic modality.

MEDICATIONS

DRUG(S)

- Amphotericin B—use for localized disease after surgical excision; 0.25–0.5 mg/kg IV three times weekly or until a total dose of 8 mg/kg; lipid formulation 1 mg/kg every other day until 12 mg/kg cumulative; concurrent administration of tetracycline or amikacin may provide synergistic effect; lipid formulations may be more efficacious and less toxic for cutaneous disease; reported effective for ocular disease.
- Ketoconazole, fluconazole, and itraconazole (5–10 mg/kg PO q12h)—may use with amphotericin B, or as sole agents for less life-threatening disease.
- Alternative treatments—clotrimazole (locally for *P. wickerhamii*); potassium iodide.
- Amphotericin B cream or clotrimazole enemas for colitis.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Difficult to eradicate with drug therapy.
- No definitive therapeutic protocol.
- Dogs—prognosis guarded to grave (median survival 4 months).
- Cats—prognosis fair to good for cutaneous disease if lesions completely excised.

MISCELLANEOUS

ZOONOTIC POTENTIAL

None

PRURITUS

BASICS

DEFINITION

- Pruritus—a sensation that triggers itch.
- Acute pruritus—a component of the innate immune response.
- Identification and treatment of the cause is required for long-term control and to reduce the need for long-term medical therapy.
- Chronic cases should be referred to a dermatologist.

PATHOPHYSIOLOGY

- Activation of neuronal cells by cytokine, neurotrophin and neuropeptide release from keratinocytes, mast cells, eosinophils and lymphocytes.
- Many factors modify the perception of pruritus peripherally and centrally.

SYSTEMS AFFECTED

- Skin/Exocrine
- Behavioral

SIGNALMENT

Variable depending on the underlying cause

SIGNS

- Scratching, licking, biting, rubbing, or chewing
- Self-trauma and cutaneous inflammation
- Alopecia without evident inflammation (cats)

CAUSES

- Parasitic—fleas, *Sarcoptes*, *Demodex*, *Otodectes*, *Notoedres*, *Cheyletiella*, *Trombicula*, lice, *Pelodera*, endoparasite migration.
- Allergic—parasite allergy, atopy, cutaneous adverse reaction to food, contact allergy, drug hypersensitivity, bacterial hypersensitivity, *Malassezia* hypersensitivity.
- Infectious—*Staphylococci* and *Malassezia*; rarely dermatophyte.
- Primary or secondary seborrhea.
- Calcinosis cutis.
- Cutaneous neoplasia.
- Immune-mediated dermatoses.
- Psychogenic.

P

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pruritus often causes alopecia.
- Demodicosis, dermatophytosis, bacterial pyoderma, immune-mediated dermatoses, seborrhea, some cutaneous neoplasms, and unusual diseases such as leishmaniasis may be pruritic.
- Severe pruritus is common with scabies; flea bite dermatitis or hypersensitivity, cutaneous adverse reaction to food, and *Malassezia* dermatitis can be highly pruritic.
- Uncomplicated atopy—initially steroid-responsive, possibly seasonal,

progressive pruritus of the face, feet, ears, forelimbs, axillae, and caudal body; inadequate management encourages tachyphylaxis; allergen-specific immunotherapy is the only treatment that permits control without chronic medical therapy; flea-allergic and food-hypersensitive animals may be predisposed to atopy.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Miscellaneous Procedures

- Identification and treatment of the underlying cause of pruritus is paramount; multiple concurrent causes possible.
- History and physical examination required for diagnostic workup.
- Skin scrapes—demodicosis, scabies.
- Epidermal cytology—bacterial or yeast infection.
- Dermatophyte culture—dermatophytosis.
- Skin biopsy useful if lesions associated with pruritus are unusual or appear to be primary.

Allergy Testing

- Positive test result does not diagnose allergy as the cause of pruritus; used to select allergens for immunotherapy; results must be carefully correlated with history and physical examination; combined intradermal and serum testing for allergen selection associated with most successful immunotherapy.
- Skin testing—gold standard; allows for identification of individual allergens by physiologically-appropriate mechanism; preferred over serum testing whenever possible.
- Serum tests—measure serum IgE; not a physiological test; repeatability and inter-laboratory consistency (as well as quality control) highly variable; acceptable only when referral for intradermal testing not possible.
- Immunotherapy—selection of allergens based on patient history and environmental exposure; administration produces immunotolerance and/or downregulation of reaction to native allergens; see chapter, Atopic Dermatitis.

Trial Courses of Treatment

- Useful diagnostic tool—empirical therapy for scabies or restricted-ingredient diet trial.
- Canine scabies—difficult to diagnose; skin scrapes are often negative.
- Cutaneous adverse reaction to food—restricted-ingredient food trial using a novel or hydrolyzed protein; commercial tests are available; multiple studies have documented neither demonstrated efficacy nor accuracy, and are not recommended; see chapter, Food Reactions, Dermatologic.

TREATMENT

- More than one disease can contribute to pruritis.
- Numerous palliative therapeutic options exist but identification and treatment or removal of the causative agent permits long-term control.
- Avoidance or reduction of long-term medical therapy should be pursued when possible.
- Chronic cases should be referred to a dermatologist for diagnosis and management.

Topical Therapy

- Topical therapy—helpful for most pruritic patients.
- Localized areas—sprays, lotions, and creams/ointments.
- Large regions/generalized symptoms—shampoos and conditioners/rinses.
- Colloidal oatmeal—common in all forms of topical therapy; short duration of effect.
- Topical corticosteroids—very useful to reduce need for systemic therapy; can cause localized and systemic side effects with overuse; preferred over systemic corticosteroids when effective; low-potency products useful for long-term management (Genesis spray: Virbac).

Systemic Therapy

- Therapy is complex and depends on the etiology—identification of the underlying cause is required for successful outcome; see specific chapters for treatment.
- Scabies—scabicidal therapy.
- Food hypersensitivity—diet trial.
- Atopy—allergen-specific immunotherapy based on testing.
- Flea bite/hypersensitivity dermatitis—adequate flea control.
- Secondary infections should be identified and treated; if the underlying cause is not properly addressed, infections will recur.

DRUG(S)

Chronic therapy without evaluation or management by a dermatologist not recommended.

Glucocorticosteroids

- Affect many biologic responses associated with pruritus; rapid onset of action and easily adjusted dose (oral administration) allow intermittent or pulse treatment; can be a safe adjunct therapy in some patients; best for acute relief.
- Acute relief—subcutaneous injection of dexamethasone (0.15–0.2 mg/kg); results in significant benefit for 2–5 days; rarely causes significant polyuria.
- Chronic control—oral prednisolone (or prednisone—dogs) (0.5 mg/kg tapering to twice-weekly maintenance). A prednisolone or prednisone dose of 0.15–0.2 mg/kg/Q48 hours and initiated the day after a

(CONTINUED)

PRURITUS

dexamethasone injection often provides adequate intermediate to long term relief with minimal side effects; dose is approximatively one half of the equivalent physiological replacement dose for glucocorticoids and typically well tolerated while waiting for allergen specific immunotherapy to become effective for atopic dermatitis.

Cyclosporine, modified

- Atopica (Novartis) 5 mg/kg/day—effective to control pruritus associated with chronic atopic dermatitis.
- Success rate is similar to that of glucocorticosteroids.
- Slow onset of activity (1–4 weeks).
- Many patients can be adequately controlled with less frequent dosing (every 2–4 days).
- Patient monitoring (CBC/serum chemistry) recommended.
- Serum/plasma drug concentration should be monitored in cats.

Oclacitinib

Janus Kinase (JAK) inhibitor (0.4–0.6 mg/kg q12h for 14 days then 0.4–0.6 mg/kg q24h); new category of drug.

Antihistamines

- Dogs: hydroxyzine (1–2 mg/kg PO q12h), chlorpheniramine (0.2–0.4 mg/kg PO q12h), diphenhydramine (2.2 mg/kg PO q12h), fexofenadine (2–5 mg/kg PO q12–24h), and clemastine (0.04–0.10 mg/kg PO q12h).
- Cats: chlorpheniramine (0.5 mg/kg PO q12h); efficacy estimated at 10–50%.

Fatty acids

Modulate formation of inflammatory mediators and improve the epidermal barrier function (eicosapentaenoic acid 66 mg/kg/day); ω -3 may be more effective than ω -6 (linoleic acid 130 mg/kg/day) fatty acids; may require 6–8 weeks of use for maximum effect.

Behavior-modifiers

- Dogs: amitriptyline (1–2 mg/kg q12h); doxepin 1–2 mg/kg PO q12h; potent antihistaminic effects; side effects similar to antihistamines.

- Fluoxetine (1 mg/kg q24h).
- Gabapentin—pain modifier; dogs, 10–30 mg/kg q6–12h; cats, 3–8 mg/kg q6–8h.

CONTRAINDICATIONS

Palliative medical therapy should be avoided in cases of pruritus caused by an infectious etiology; evaluate to determine the underlying cause; referral to a dermatologist is advisable.

PRECAUTIONS

- Client frustration is common; client education is extremely important.
- Cyclosporine—gastrointestinal upset; not recommended in patients with history of malignancy; papillomatosis; gingival hyperplasia; hirsutism.
- Oclacitinib—should not be used in dogs < 12 months of age; may increase susceptibility to infection, including demodicosis and exacerbate neoplastic conditions; humans should wash hands immediately after handling the tablets; long term effects and safety currently unknown; most appropriate for temporary relief of pruritus.

POSSIBLE INTERACTIONS

- Concurrent use of cyclosporine and ketoconazole requires a 50% dose reduction of each drug.
- Safety of concurrent use of oclacitinib and other medications unknown.

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

- Patient monitoring as well as client communication are imperative.
- Several different unrelated diseases may contribute to pruritus and the control of more than one disease may be necessary until the “itch threshold” is reduced; one or more may have a seasonal incidence.

- Patients receiving chronic medication should be evaluated regularly for potential side effects as well as for the occurrence of new contributing factors.

POSSIBLE COMPLICATIONS

- Due to the chronic nature of pruritus, client frustration is common.
- Skin scrapes and other tests that may have been negative or normal during the original workup should be repeated if symptoms return.
- Complications are also common with chronic corticosteroid use.

P

PSEUDOEPHEDRINE/PHENYLEPHRINE TOXICOSIS

BASICS

OVERVIEW

- Syndrome resulting from exposure to excessive levels of pseudoephedrine or phenylephrine.
- Present in a variety of concentrations in a variety of OTC cold and allergy products.

SIGNALMENT

Any species may be affected, but dogs are most commonly involved in accidental overdoses.

SIGNS

- Mydriasis, panting, hyperthermia, agitation/hyperactivity, tachycardia, hypertension are common. Other signs include vomiting, vocalization, tremors, disorientation, or lethargy.
- Head-bobbing, sinus arrhythmias, scleral hemorrhage, or seizure-like activity are possible. Acute collapse may follow.
- Signs of acute intoxication may persist 1–3 days, depending on dose ingested.
- Severe cases may progress to DIC, myoglobinuria/uria with secondary renal injury, or permanent CNS dysfunction.

CAUSES & RISK FACTORS

- Pseudoephedrine is a synthetic salt of ephedrine and is an indirect sympathomimetic amine.
- Phenylephrine is a synthetic sympathomimetic amine chemically related to ephedrine and pseudoephedrine. Phenylephrine has poor oral bioavailability and generally will have less severe cardiovascular effects than pseudoephedrine.
- Pseudoephedrine indirectly stimulates alpha and, to a lesser degree, beta-adrenergic receptors.
- Pseudoephedrine dosages > 1 mg/kg can result in agitation, hyperactivity, and panting.
- Phenylephrine dosages > 3–4 mg/kg may cause vomiting, lethargy or hyperactivity, hypertension, and tachycardia.
- Head-bobbing, DIC, or myoglobinuria indicate serious intoxication and a more guarded prognosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other CNS stimulants and sympathomimetics: amphetamines, cocaine, serotonergic antidepressants, phenylpropanolamine, methylxanthines, ephedra.

CBC/BIOCHEMISTRY/URINALYSIS

- No specific clinical pathology alterations are expected in most cases.
- In severe cases DIC, myoglobinemia, myoglobinuria, or azotemia may occur.

OTHER LABORATORY TESTS

Urine or serum from patients with pseudoephedrine toxicosis may give a positive test for amphetamine in over-the-counter drug test kits or human hospital drug screens.

TREATMENT

- Manage severe or life-threatening signs first.
- Control CNS stimulation, then manage CV stimulation, as blood pressure and heart rate may decrease significantly once CNS signs are managed.
- For seizures, use propofol, pentobarbital, or phenobarbital; consider gas anesthetic for refractory cases.
- For agitation, hyperactivity, or other CNS stimulation, use acepromazine or chlorpromazine.
- Cyproheptadine has been used with some success to manage dysphoria, vocalization, and hyperthermia.
- Propranolol (or other beta blocker) may be considered in patients with sustained tachycardia.
- External cooling measures may be required for hyperthermic patients.
- Intravenous fluid administration assists in stabilization of cardiovascular effects, support of kidney function, and excretion of pseudoephedrine and its metabolites.
- Monitor heart rate/rhythm, body temperature, and blood pressure. In severely affected patients, monitor renal function, coagulation parameters, hydration, and electrolytes.
- Gastrointestinal decontamination (induction of emesis, administration of activated charcoal) may be considered in patients that have ingested > 1 mg/kg of pseudoephedrine and are not displaying significant clinical signs.

MEDICATIONS

DRUG(S)

- Propofol 0.1–0.6 mg/kg/min IV.
- Pentobarbital 30 mg/kg IV to effect.
- Phenobarbital 3–4 mg/kg IV.
- Acepromazine 0.05–1.0 mg/kg IM or IV; start low and titrate up as needed.

- Chlorpromazine 0.5–1.0 mg/kg IV or IM; start low and titrate up as needed.
- Cyproheptadine 1.1 mg/kg PO or per rectum q6h (dogs); 2–4 mg PO or per rectum (cats).
- Propranolol 0.02–0.06 mg/kg IV q6–8h PRN.
- Emetics—3% hydrogen peroxide 2.2 mL/kg PO, maximum 45 mL, may repeat once if first dose unsuccessful; apomorphine crushed and diluted with sterile saline and instilled in conjunctival sac, rinse eye after emesis, or 0.03 mg/kg IV.
- Activated charcoal 1–3 g/kg suspended in 50–200 mL of water.

CONTRAINdications/POSSIBLE INTERACTIONS

The use of diazepam to control CNS stimulation should be avoided, as diazepam may induce a dysphoric effect in these patients and worsen the CNS excitation.

FOLLOW-UP

Renal insufficiency resulting from myoglobinuria may require long-term follow-up and care.

MISCELLANEOUS

Ma huang (ephedrine) and amphetamine exposures in animals are managed similarly to pseudoephedrine toxicosis.

ABBREVIATIONS

- CNS = central nervous system
- CV = cardiovascular
- DIC = disseminated intravascular coagulation

Consulting Editor Lynn R. Hovda

PSEUDORABIES VIRUS INFECTION

BASICS

OVERVIEW

- Uncommon but highly fatal disease of dogs and cats, usually occurring in animals that have contact with swine.
- Characterized by sudden death, often without characteristic signs or with signs that include hypersalivation, intense pruritus, and neurologic changes.
- Also known as Aujeszky's disease, mad itch, or infectious bulbar paralysis.

SIGNALMENT

- Domestic and exotic dogs and cats.
- Other domestic animals—swine, cattle, sheep, and goats.
- Primarily farm dogs and cats, with no breed or age predilection.

SIGNS

- Sudden death.
- Hypersalivation.
- Rapid and labored breathing.
- Fever.
- Vomiting.
- Neurologic—depression and lethargy, ataxia, convulsions, reluctance to move, recumbency, intense pruritus and self-mutilation, coma, and death.

CAUSES & RISK FACTORS

- Pseudorabies virus (*Herpesvirus suid*)—an alphaherpesvirus.
- Contact with swine.
- Eating contaminated, uncooked meat or offal from swine.
- Ingestion of infected rats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rabies—in the furious form, affected dog or cat will attack anything that moves; no pruritus or sudden death; immunofluorescent antibody test of brain positive.
- Canine distemper—no hypersalivation, sudden death, or personality change; respiratory and gastrointestinal signs common.
- Poisoning (organophosphate, lead, strichnine, inorganic arsenic)—no pruritus or personality change; history of exposure to toxin; signs consistent with toxicity.

CBC/BIOCHEMISTRY/URINALYSIS

No characteristic changes

OTHER LABORATORY TESTS

Serologic assays—reveal pseudorabies virus antibodies if an animal recovers.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Immunofluorescent antibody test—brain tissue.
- Viral isolation—affected tissues.
- Animal (rabbit) inoculation.

PATHOLOGIC FINDINGS

- Severe skin lesions—caused by self-mutilation from intense pruritus.
- Histopathologic examination—glial and ganglion cells of neurologic tissues reveal Cowdry type A intranuclear inclusion bodies.
- Non-suppurative meningoencephalitis in the medulla oblongata.

TREATMENT

- Dogs and cats—no known effective treatment.
- General supportive therapy and prevention of self-injury indicated.

MEDICATIONS

DRUG(S)

- None specific.
- Antitherapeutic antivirals—not evaluated for dogs and cats.
- Rapid course makes successful use of antiviral drugs unlikely.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None

FOLLOW-UP

PREVENTION/AVOIDANCE

- Avoid contact with infected swine, the reservoir host.
- Avoid ingestion of contaminated pork.
- Avoid ingestion of infected rats.
- Cat-to-cat and dog-to-dog transmission usually does not occur.

EXPECTED COURSE AND PROGNOSIS

- Classic (cats)—60% of cases; lasts 24–36 hours; almost invariably fatal.
- Atypical (cats)—40% of cases; lasts > 36 hours; almost invariably fatal.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Mild potential for human infection; take precautions when treating infected animals and handling infected tissues and fluids.

Author Fred W. Scott

Consulting Editor Stephen C. Barr

P

PTYALISM

BASICS

DEFINITION

- Excessive production and secretion of saliva.
- Pseudopytialism is the excessive release of saliva that has accumulated in the oral cavity due to the inability to swallow.

PATHOPHYSIOLOGY

- Saliva is constantly produced and secreted into the oral cavity from the salivary glands (parotid, sublingual, mandibular, zygomatic).
- Saliva production increases when salivary nuclei in the brainstem are stimulated.
- Higher centers in the CNS can also excite or inhibit the salivary nuclei. • Taste and tactile stimuli in the oral cavity increase saliva production. • Normal physiologic hypersalivation may occur with: anticipation of eating, hyperthermia and purring (cats).
- Saliva production may be increased with gastrointestinal or CNS disorders.

SYSTEMS AFFECTED

- Gastrointestinal • Hepatic
- Nervous/Neuromuscular • Renal/Urologic

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Breeds with a relatively higher incidence of congenital portosystemic shunts include: Yorkshire terrier, Maltese terrier, Australian cattle dog, miniature schnauzer, and Irish wolfhound. • Megesophagus is hereditary in wirehaired fox terrier and miniature schnauzer; familial predispositions have been reported in German shepherd, Newfoundland, Great Dane, Irish setter, Chinese Shar-Pei, greyhound, and retriever breeds, as well as in Siamese cats.
- Congenital hiatal hernia has been recognized in the Chinese Shar-Pei. • Giant breeds, such as Saint Bernard, Great Dane, and mastiff, typically exhibit excessive drooling due to lower lip conformation.

Mean Age and Range

- Congenital abnormalities (e.g., portosystemic shunt) are more likely to be diagnosed in younger animals. • Young animals may also be more likely to have ingested toxic or caustic agents or a foreign body.

SIGNS

Historical Findings

- Anorexia—seen most often in patients with oral lesions, gastrointestinal disease, and systemic disease. • Eating behavior changes—patients with oral disease or cranial nerve dysfunction may refuse to eat hard food, chew only on the unaffected side (if unilateral lesion), maintain an unusual head/neck position, or drop prehended food.

- Other behavioral changes—irritability, aggressiveness, and reclusiveness are common, especially in patients with a painful condition. • Dysphagia—may be seen with inability to swallow. • Nausea—may present as increased swallowing. • Regurgitation—in patients with esophageal disease.
- Vomiting—secondary to gastrointestinal or systemic disease. • Weight loss—as a consequence to many of the above findings.
- Pawing at the face or muzzle—patients with oral discomfort or pain. • Neurologic signs—patients that have been exposed to caustic drugs or toxins, those with hepatic encephalopathy, patients with seizure disorders or other intracranial disease.

Physical Examination Findings

- Periodontal disease. • Gingivitis/stomatitis caused by toxins, infection, immune-mediated disease or nutritional deficiency.
- Oral mass—neoplasia or granuloma.
- Glossitis caused by ulceration, mass or foreign body. • Lesions of the oropharynx may be due to inflammation, ulceration, mass, or foreign body. • Blood in the saliva suggests bleeding from the oral cavity, pharynx, or esophagus. • Halitosis is usually caused by oral disease, but may also be the result of esophageal and/or gastric disease.
- Facial pain may be seen with oral or pharyngeal disease. • Dysphagia may be caused by oral, pharyngeal, pharyngoesophageal, and esophageal causes, and can be precipitated by anatomic or structural causes or underlying neuropathic, myopathic, or junctionopathetic causes.
- Cranial nerve deficits—trigeminal nerve (CN V) lesions can cause drooling due to inability to close the mouth; facial nerve palsy (CN VII) can cause drooling from the affected side; glossopharyngeal (CN IX), vagus (CN X), and hypoglossal (CN XII) nerve lesions can cause a loss of the gag reflex or inability to swallow. • Cheilitis or acne—persistent drooling can lead to dermatologic lesions.

CAUSES

Conformational Disorder of the Lips

- Most common in giant-breed dogs

Oral and Pharyngeal Diseases

- Oral trauma. • Foreign body (e.g., stick, foxtail, or sewing needle). • Neoplasm.
- Abscess. • Gingivitis or stomatitis—secondary to periodontal disease, bacterial, viral (e.g., FeLV or FIV) or fungal infection, immune-mediated disease (e.g., lymphoplasmacytic stomatitis, pemphigus vulgaris), uremia, ingestion of a caustic agent, poisonous plants, effects of radiation therapy to the oral cavity or burns (e.g., biting on an electrical cord). • Neurologic or functional disorders affecting the swallowing center or oropharyngeal structural disease.

Salivary Gland Diseases

- Sialadenitis • Sialolithiasis • Sialadenosis (idiopathic enlargement) • Salivary mucocele

- Salivary gland fistula • Foreign body
- Neoplasm • Infarction • Immune-mediated disease (rare)

Esophageal or Gastrointestinal Disorders

- Esophageal foreign body • Esophageal neoplasm • Esophagitis • Gastroesophageal reflux • Infection (e.g., Spirocercosis, Pythiosis) • Hiatal hernia • Megesophagus
- Esophageal dysmotility • Gastric distension/volvulus • Gastric ulcer
- Gastroenteritis

Metabolic Disorders

- Hepatoencephalopathy (especially in cats)—caused by congenital or acquired portosystemic shunt or hepatic failure.
- Hyperthermia. • Uremia.

Neurologic Disorders

- Rabies—decreased swallowing causes increased drooling. • Pseudorabies in dogs.
- Botulism. • Tetanus. • Dysautonomia.
- Disorders that cause dysphagia. • Disorders that cause facial nerve palsy or a dropped jaw.
- Disorders that cause seizures—during a seizure, ptialism may occur because of autonomic discharge or reduced swallowing of saliva, and may be exacerbated by chomping of the jaws. • Nausea associated with vestibular disease. • Anxiety.

Drugs and Toxins

- Those that are caustic (e.g., household cleaning products and some common house plants). • Anesthesia may induce reflux esophagitis. Drugs used for premedication may induce nausea, vomiting or ptialism.
- Oral, otic or ophthalmic medications that are poorly palatable (especially in cats).
- Those that induce hypersalivation, including organophosphate compounds, cholinergic drugs, insecticides containing boric acid, pyrethrin and pyrethroid insecticides, ivermectin (dogs), fluids containing benzoic acid derivatives (cats), clozapine (a tricyclic dibenzodiazepine), caffeine, and illicit drugs such as amphetamines, cocaine, and opiates.
- Animal venom (e.g., black widow spider, Gila monster, and North American scorpion).
- Toad and newt secretions. • Plant consumption or prehension (e.g., poinsettia, Christmas trees, *Amanita* mushrooms) may cause increased salivation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differentiating causes of ptialism and pseudopytialism requires a thorough history, including vaccination status, current medications, possible toxin exposure, and duration of ptialism. • May be able to distinguish salivation associated with nausea (signs of depression, lip smacking, and retching) from dysphagia by observing the

(CONTINUED)

PTYALISM

patient. • Complete physical examination (with special attention to the oral cavity and neck) and neurologic examination are critical; wear examination gloves when rabies exposure is possible.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—often unremarkable; leukocytosis in patients with immune-mediated, inflammatory or infectious disease. • Stress leukogram—common in animals that have ingested a caustic agent or organophosphate.
- FeLV-infected cats may have leukopenia and nonregenerative anemia. • Serum creatine kinase (CK) activity should be evaluated in all dysphagic patients. • Possible microcytosis with portosystemic shunts. • Biochemical analysis—usually unremarkable except in patients with renal disease (azotemia, hyperphosphatemia), and hepatoencephalopathy (possibly elevated hepatic enzyme activities, decreased BUN, hypoalbuminemia, hypcholesterolemia, hyperbilirubinemia, and hypoglycemia).
- Marked ptalism can result in hypokalemia and acidosis from the loss of potassium and bicarbonate-rich saliva. • Urinalysis—often normal; decreased urine specific gravity with renal or hepatic disease. • Urate urolithiasis may be noted in patients with portosystemic shunts.

OTHER LABORATORY TESTS

- Fasting and postprandial bile acids and/or fasting ammonia when hepatoencephalopathy is suspected. • Serologic FeLV and FIV testing in cats with oral lesions. • Acetylcholine receptor antibody titer if focal myasthenia gravis is suspected to be cause of megaesophagus. • Serum cholinesterase level if organophosphate toxicosis is suspected.
- Post-mortem fluorescent antibody testing of brain tissue if rabies is suspected.

IMAGING

- Survey radiography of the oral cavity, neck, and thorax when foreign body, structural abnormality, or neoplasm is suspected.
- Abdominal radiographs ± abdominal ultrasound may help diagnose cause of vomiting; may also help diagnose hepatic or renal disease. • Ultrasonographic evaluation, portal venography, or portal scintigraphy may help diagnose a portosystemic shunt.
- Fluoroscopic evaluation of swallowing may be useful in dysphagic patients to evaluate esophageal function and motility; use caution during barium administration in animals that are dysphagic. • MRI or CT for suspected intracranial lesions. • CT of head may be more sensitive than radiographs, especially when foreign body or neoplasia is suspected.

DIAGNOSTIC PROCEDURES

- Biopsy and histopathology of mucocutaneous lesions—possibly including immunofluorescence testing when immune-mediated disease (e.g., pemphigus

vulgaris) is suspected. • Fine-needle aspiration of oral lesions and regional lymph nodes.

- Biopsy and histopathology of oral lesion, salivary gland, or mass. • Consider esophagoscopy or gastroscopy if lesions distal to the oral cavity are suspected; endoscopic removal of foreign bodies may be possible.

PATHOLOGIC FINDINGS

Varies as to the underlying condition.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Treat the underlying cause (refer to sections pertaining to specific conditions).
- Symptomatic treatment to reduce the flow of saliva—generally unnecessary, may be of little value to the patient, and may mask other signs of the underlying cause and thus delay diagnosis; only recommended when hypersalivation is prolonged and severe and, if possible, after the underlying condition has been diagnosed.

NURSING CARE

- Petroleum jelly can be applied to areas of the face constantly wet from saliva to help prevent moist dermatitis. • Astringent solutions applied for 10 minutes q8–12h can be used to treat areas of moist dermatitis.

DIET

- Enteral nutritional support (esophagostomy, gastrostomy tubes, etc.) may be needed in patients with ptalism and anorexia secondary to severe oral, gastrointestinal, or metabolic causes. • Reduced protein diets may be recommended for patients with hepatic encephalopathy or renal disease, but are not necessarily warranted in animals with portosystemic shunts that are not encephalopathic.

CLIENT EDUCATION

Client education will depend on the underlying disease process.

SURGICAL CONSIDERATIONS

Surgical procedures will vary depending on underlying cause; ligation of parotid salivary duct has been described.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Anticholinergic medications may be given symptomatically to reduce the flow of saliva; atropine (0.05 mg/kg SC PRN) or glycopyrrolate (0.01 mg/kg SC PRN).
- Antiemetics given in conjunction with opioid premedication have variable effects on nausea, vomiting, and ptalism (see chapter,

Vomiting, Acute, for list of antiemetics and dosages). • Crystallloid fluids may be given IV or SC to treat dehydration caused by prolonged or severe ptalism. • Phenobarbital (2 mg/kg PO q12h) has been effective in treating idiopathic hypersialosis.

- Anticonvulsant therapy is indicated for seizure activity.

**FOLLOW-UP****PATIENT MONITORING**

- Depends on the underlying cause (see “Causes”). • Continually monitor hydration, body weight, serum electrolytes, and nutritional status, especially in dysphagic or anorexic animals.

POSSIBLE COMPLICATIONS

- Metabolic acidosis • Dehydration
- Hypokalemia • Moist dermatitis
- Aspiration pneumonia

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

Rabies

SYNONYMS

- Drooling • Hypersalivation • Sialism
- Sialorrhea • Sialosis

PULMONARY CONTUSIONS

BASICS

OVERVIEW

- Hemorrhage in the lung parenchyma caused by tearing and crushing during direct thoracic trauma.
- Relatively small volumes of blood in the parenchyma markedly compromise lung function.
- Fluid resuscitation for treatment of shock can exacerbate lung dysfunction by producing edema.

SIGNALMENT

Dog and cat

SIGNS

- History of blunt trauma
- Tachypnea
- Abnormal respiratory effort
- Postural adaptations to respiratory distress
- Cyanotic or pale mucous membranes
- Auscultation of harsh bronchovesicular sounds or crackles
- Expectoration of blood or blood-tinged fluid
- Concurrent signs of shock can be present.
- Additional injuries secondary to blunt force trauma can also be noted.

CAUSES & RISK FACTORS

- Blunt trauma
- Motor vehicle accidents
- Falls from a height
- Abuse

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hemothorax—auscult dull lung sounds ventrally.
- Pneumothorax—auscult dull lung sounds dorsally.
- Diaphragmatic hernia—distinguished radiographically.
- Coagulopathy can result in pulmonary hemorrhage; identified by abnormal coagulation tests or platelet count.
- Acute onset of pulmonary hemorrhage—can be a feature of some neoplasms or pulmonary infarction associated with bacterial endocarditis or heartworm disease.
- Expectoration of bloody fluid (not frank hemorrhage) can occur in animals with ARDS or congestive heart failure.
- In animals without a known history of trauma, pneumonia, or edema (cardiogenic and noncardiogenic) are possible differentials.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—can reveal anemia or mature neutrophilia.
- Biochemistry profile—can demonstrate hypoproteinemia, indicating blood loss; can reveal damage to other organ systems.

IMAGING

Thoracic Radiography

- Usually a patchy alveolar pattern, often focal or asymmetrical but can be generalized.
- If there are concurrent rib fractures, contusions generally worse in the area of the fractures.
- Always perform thoracic radiographs in trauma patients after

stabilization to rule out hemothorax, pneumothorax, and diaphragmatic hernia.

DIAGNOSTIC PROCEDURES

- Coagulation tests for coagulopathy or disseminated intravascular coagulation.
- Pulse oximetry or arterial blood gas analysis—can confirm hypoxemia.
- Examination of tracheal wash cytology—can show excessive numbers of erythrocytes and macrophages; culture to detect bacterial infection.

TREATMENT

- Usually inpatient for stabilization.
- Support respiratory function, stabilize cardiovascular function.
- If concurrent pneumothorax suspected, thoracocentesis should be performed immediately.
- Assess and treat injuries to other organ systems.
- Restrict activity, minimize stress, and monitor carefully for deterioration of respiratory function.
- Respiratory support—oxygen supplementation for hypoxemia; intubation and positive-pressure ventilation if severe.
- Shock—fluids generally required; be conservative with fluid administration to avoid creation or exacerbation of pulmonary edema.
- Blood or plasma transfusion—consider if hemorrhage has resulted in anemia or if there is a coagulopathy.
- Nutritional support—as needed to maintain body condition and immune status.

MEDICATIONS

DRUG(S)

- Oxygen supplementation in animals with dyspnea or hypoxemia.
- Analgesics administered if warranted.
- Low-dose diuretics—furosemide (0.5–2 mg/kg IV, IM); use only when hemorrhage is accompanied by edema or suspected volume overload and respiratory distress is severe. Excessive diuresis can exacerbate shock.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Diuretics—no value in the early stages of pulmonary contusions and potentially harmful; decrease intravascular volume, which is contraindicated for shock.

FOLLOW-UP

PATIENT MONITORING

- Monitor respiratory rate and effort, mucous membrane color, heart rate and pulse quality, and lung sounds.
- Measure serial PCV and total solids and perform pulse oximetry and/or arterial blood gas analysis as needed

for the first 24 hours.

- Monitor ECG frequently to detect ventricular arrhythmias associated with hypoxemia or myocarditis
- Radiographs—repeated in 48–72 hours if clinically indicated, to ensure that the contusions are resolving.

PREVENTION/AVOIDANCE

Appropriate restriction of the animal to prevent trauma.

POSSIBLE COMPLICATIONS

- Bacterial pneumonia (uncommon)—owing to systemic immunosuppression from trauma, shock, and reduced pulmonary defenses.
- Development of a moist productive cough and failure to improve within 48 hours—suspect pneumonia.
- Patients with severe shock can develop ARDS (less common).

EXPECTED COURSE AND PROGNOSIS

- Respiratory function can deteriorate during the initial 12–24 hours after trauma and then should gradually improve.
- Clinical improvement within 48 hours with radiographic resolution likely in 7–10 days.
- If patient fails to improve clinically after 48 hours, evaluate for complications or concurrent disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Pneumothorax
- Fractured ribs
- Flail chest
- Ruptured trachea, bronchi, or esophagus
- Cardiac arrhythmias—ventricular
- Other possible complications of trauma

SEE ALSO

Pneumothorax

ABBREVIATIONS

- ARDS = acute respiratory distress syndrome
- ECG = electrocardiogram
- PCV = packed cell volume

Consulting Editor Lynelle R. Johnson

PULMONARY EDEMA, NONCARDIOGENIC

BASICS

DEFINITION

Accumulation of edema fluid in the pulmonary interstitium and alveoli, in the absence of heart disease.

PATHOPHYSIOLOGY

- Associated with increased pulmonary vascular permeability and leakage of fluid into the interstitium and alveoli; if severe, can be accompanied by an inflammatory response and accumulation of neutrophils and macrophages in the interstitium and alveoli.
- Several mechanisms contribute to changes in pulmonary vascular permeability.
- Stimulation of brainstem (medulla) vasomotor centers can lead to a reflex systemic release of catecholamines resulting in systemic vasoconstriction, temporary shunting of blood into the pulmonary circulation, transient pulmonary circulatory overload, and endothelial damage; probably occurs in patients with neurogenic edema, electric cord bites, and upper airway obstruction.
- In patients with upper airway obstruction, negative intrathoracic pressure from inspiratory attempts against an airway obstruction contributes to edema formation.
- Increased vascular permeability can be part of a generalized inflammatory response that develops in patients with SIRS, sepsis, or pancreatitis.
- The inciting insult can trigger a cascade inflammatory response that often worsens over 24 hours following the initial episode.
- Severity of clinical manifestation—varies, ranging from mild to severe; the most seriously affected patients can progress from normal to death in as little as a couple of hours after the incident.

SYSTEMS AFFECTED

- Respiratory.
- Cardiovascular—hypotension, tachycardia, and shock.
- Hemic/Lymphatic/Immune—if severe and causing respiratory failure, can be associated with DIC.
- Renal/Urologic—acute renal failure.

GENETICS

Unknown

INCIDENCE/PREVALENCE

Uncommon

SIGNALMENT

Species

Mainly dogs, occasionally cats. No breed or sex predilection except regarding airway obstruction.

Breed Predilections

None specific; brachycephalic dogs are more prone to airway obstruction, older large-breed dogs—laryngeal paralysis, small breed dogs—tracheal collapse.

Mean Age and Range

- Higher incidence in puppies < 1 year old—associated with strangulation, head trauma, and electric cord bites.
- Old—associated with laryngeal obstruction and neoplasia.

SIGNS

General Comments

Vary, depending on underlying cause and severity

Historical Findings

- Predisposing causes—airway obstruction; electric cord bite; seizures; head trauma; near drowning; smoke exposure; adverse drug effects.
- Acute onset of dyspnea.

Physical Examination Findings

- Mild to severe dyspnea.
- Increased respiratory rate and effort; open-mouthed breathing.
- Postural adaptations to respiratory distress (if severe).
- Unwillingness to lie down.
- Pale or cyanotic mucous membranes (severe).
- Harsh lung sounds (early, mild) or generalized crackles (late, severe) on auscultation.
- Expectoration of pink froth or bubbles; can have large volumes of bloody fluid flowing out through the endotracheal tube in severely affected intubated animals.
- Normal cardiac auscultation; can detect arrhythmias; tachycardia common.
- Oral ulceration or burns in cases of electrocution.
- Cranial nervous system abnormalities or other indications of previous seizure-like activity.
- Stridor over the upper airway in cases of brachycephalic syndrome, airway masses, foreign bodies, or abscesses.
- Smokey odor or burns indicative of smoke exposure.

CAUSES

- Upper airway obstruction—laryngeal paralysis; choke-chain injury; mass; abscess.
- Electric cord bite.
- Acute neurologic disease—head trauma; prolonged seizures.
- Smoke inhalation.
- Aspiration pneumonia.
- Systemic inflammatory response syndrome—sepsis; endotoxemia; pancreatitis.
- Anaphylaxis (cats).
- Near drowning.
- Adverse drug reactions including certain anesthetic drugs (ketamine), thiazides, or certain antineoplastics (vincristine, cisplatin in cats).
- Transfusion-related acute lung injury—not reported in veterinary medicine.

RISK FACTORS

- Hypoproteinemia
- Crystalloid fluid resuscitation

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cardiogenic pulmonary edema
- Pulmonary infection—bacterial, viral, or fungal pneumonia
- Pulmonary neoplasia
- Pulmonary hemorrhage (e.g., anticoagulant

rodenticide exposure)

- Pulmonary thromboembolism

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis common, leukopenia and thrombocytopenia possible—owing to neutrophil sequestration in the lung and platelet consumption.
- Biochemistries—usually normal; may note hypoalbuminemia owing to pulmonary protein loss; mild stress-related hyperglycemia.
- Urinalysis—usually normal.

OTHER LABORATORY TESTS

- Pulse oximetry and arterial blood gas analysis—usually demonstrates mild to severe hypoxemia and hypocapnia; results are not specific but indicate the severity of pulmonary dysfunction.
- Coagulation testing (severely affected patients)—mild to moderate prolongation of PT and PTT in animals with consumption and DIC. Severe coagulopathy could indicate hemorrhage as the cause for respiratory signs rather than noncardiogenic pulmonary edema.

IMAGING

- Thoracic radiographs—vital; can reveal prominent interstitial pattern with mild or early disease; alveolar infiltrates with moderate or severe disease; alveolar infiltrates commonly in dorsocaudal lung fields but can be seen in other lung fields, are sometimes asymmetrical and predominantly right-sided. Cardiac silhouette generally normal.
- Echocardiography—rule out cardiogenic pulmonary edema.

DIAGNOSTIC PROCEDURES

- Cytology of airway fluid—inflammatory with neutrophils and some alveolar macrophages. Fluid tends to have high protein values > 3 g/dL. Culture typically negative unless concurrent bacterial pneumonia.
- Edema fluid to plasma ratio (EF:PL) compares protein in the edema fluid to plasma protein. An increased ratio (> 0.65) is indicative of non-cardiogenic pulmonary edema.
- Pulse oximetry—non-invasive, continuous monitoring of arterial hemoglobin saturation with oxygen; provides information about the severity and progression of pulmonary dysfunction.
- Pulmonary artery wedge pressure—normal value confirms noncardiogenic origin; not commonly performed.
- NT Pro-BNP testing in cats and dogs can suggest underlying heart disease and thus support a diagnosis of cardiogenic edema.

PATHOLOGIC FINDINGS

- Gross—lungs usually heavy, red, or congested; fail to collapse; often exhibit a wet cut surface; can ooze foam from major airways.
- Histopathology—depends on severity of the insult; early, mild: may note eosinophilic amorphous material filling the alveoli or can be near normal because fluid removed in processing; severe: alveolar hyaline

PULMONARY EDEMA, NONCARDIOGENIC

(CONTINUED)

membranes, alveolitis, and interstitial inflammatory infiltrates with neutrophils and macrophages evident and accompanied by atelectasis, vascular congestion, and hemorrhage; lesions can be found within hours of a severe insult.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient versus outpatient—depends on the severity of respiratory dysfunction and the underlying cause of disease (e.g., dogs with upper airway obstruction or severe seizures generally require hospitalization).
- Make every effort to resolve and treat the underlying cause (e.g., relieve airway obstruction or treat seizures).
- Mild to moderate—patients generally improve on their own within 24–48 hours with complete resolution; offer support of pulmonary and cardiovascular function while the lung repairs.
- Severe—difficult to treat; usually requires PPV because of respiratory failure; many patients die despite intensive supportive care.

NURSING CARE

- Minimize stress.
- Oxygen therapy—vital in moderate to severe disease; administer via mask or hood, nasal catheter, or oxygen cage; inspired oxygen concentration depends on the severity of disease; most patients do well on 40–50% oxygen, but severe disease can require 80–100% to sustain life.
- Severe—can require PPV and PEEP.
- Fluid therapy with a balanced electrolyte—give as replacement solution with dehydration or shock; use cautious fluid administration.
- Plasma or synthetic colloids—consider with hypoproteinemia or low colloid osmotic pressure measurements; improve oncotic pressure, minimizing movement of fluid into the lungs.

P

ACTIVITY

Dogs with moderate to severe hypoxemia and respiratory distress—rest and minimal stress vital for minimizing oxygen requirements.

CLIENT EDUCATION

- Warn client that the condition can worsen before improving.
- Inform client that severe disease that progresses rapidly to fulminant pulmonary edema and respiratory failure is associated with a very poor prognosis.

SURGICAL CONSIDERATIONS

Relevant only for treating the underlying cause.

MEDICATIONS

DRUG(S) OF CHOICE

- Damaged endothelium in the pulmonary vasculature—no specific treatment available.

- Inflammatory response—generated by a variety of mediators and cascades; cannot be blocked by one specific anti-inflammatory drug to resolve edema.
- Diuretics—usually minimally effective; edema is caused by changes in permeability, not high hydrostatic pressure; can use furosemide cautiously in boluses of 0.5–2 mg/kg IV, IM or at 0.1–1 mg/kg/h IV in a continuous infusion. Additional beneficial effects may include decreases in bronchospasm and bronchodilation.
- Corticosteroids—used to reduce swelling in patients with upper airway obstruction; generally ineffective for pulmonary inflammatory response; may predispose patients to infectious complications (e.g., bacterial pneumonia); if used, recommend an anti-inflammatory dosage (e.g., dexamethasone sodium phosphate at 0.05–0.1 mg/kg IV).
- The use of beta-adrenergic agonists such as terbutaline may increase clearance of alveolar fluid.
- Sedatives can be used cautiously if patient's anxiety is contributing to respiratory distress or upper airway obstruction. The patient should be carefully monitored as sedation can decrease central respiratory drive leading to progression of respiratory failure.
- Additional therapy as indicated by underlying cause, such as anticonvulsants, analgesics for oral ulcerations.

PRECAUTIONS

- Diuretics (e.g., furosemide)—excessive use can cause dehydration and a marked decrease in intravascular volume with minimal resolution of edema; low intravascular volume can exacerbate cardiovascular collapse or shock.
- Corticosteroids—can predispose patients to infectious complications (e.g., bacterial pneumonia).

FOLLOW-UP

PATIENT MONITORING

- Observe respiratory rate and pattern and auscultate frequently (every 2–4 hours) for the first 24–48 hours, depending on severity of disease.
- Assess pulmonary function by pulse oximetry or arterial blood gas analysis (initially every 2–4 hours).
- Assess PCV and total solids and evaluate mucous membranes, pulse quality, heart rate, blood pressure, and urine output every 2–4 hours to monitor cardiovascular status and possible progression to shock.

PREVENTION/AVOIDANCE

- Avoid contact with electric wire.
- Correct and avoid airway obstruction.
- Treat seizures and high intracranial pressure.

POSSIBLE COMPLICATIONS

Usually none if patient recovers from the acute crisis.

EXPECTED COURSE AND PROGNOSIS

- Mild to moderate—resolution of signs in 24–72 hours; no specific treatment required except for oxygen and careful fluid supplementation.
- Severe—difficult to treat; can require PPV because of respiratory failure.
- Overall survival rates—80–90%.
- Long-term prognosis—excellent for recovered patients.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Acute respiratory distress syndrome

SYNOMYMS

- Acute alveolar failure

PULMONARY THROMBOEMBOLISM

BASICS

DEFINITION

Develops when a thrombus lodges in the pulmonary arterial tree and occludes blood flow to the portion of lung supplied by that artery.

PATHOPHYSIOLOGY

- Pulmonary thromboemboli associated with heartworm disease occur *in situ* in the pulmonary vessels; in most other instances, the origin of the thrombus is unclear.
- Potential sites of origin include the right atrium, vena cavae, jugular veins, and femoral or mesenteric veins; these venous thrombi are carried in the venous circulation to the lungs, where they lodge in the pulmonary arteries.
- Abnormal blood flow (stasis), vascular endothelial damage, and altered coagulability (hypercoagulable state) are believed to predispose to thrombus formation. • In most patients, PTE is a complicating feature of another primary disease process.

SYSTEMS AFFECTED

- Cardiovascular—pulmonary hypertension may result, leading to right ventricular enlargement, right ventricular failure (*cor pulmonale*), and reduced cardiac output.
- Respiratory—diminished pulmonary blood flow leads to arterial hypoxemia and dyspnea.

INCIDENCE/PREVALENCE

- Not known—likelihood of pulmonary thromboembolism increases in animals with abnormal coagulation or severe systemic disease. • Uncommon diagnosis in the dog and cat; likely under-diagnosed due to nonspecific clinical signs, lack of clinical suspicion, and paucity of non-invasive, definitive diagnostic tests.

SIGNALMENT

Species

Dog and cat

Mean Age and Range

- More frequently seen in middle-aged to older dogs. • Bimodal age distribution reported in the cat with peak occurrence in cats less than 4 years and greater than 10 years of age.

SIGNS

Historical Findings

- Often reflect the primary disease process.
- Occasionally the reason for initial examination; in such a patient presenting signs may include paroxysmal dyspnea, anorexia, syncope or collapse, cough or hemoptysis, weakness, exercise intolerance, and inability to sleep or get comfortable.

Physical Examination Findings

- Tachypnea and dyspnea in most animals; adventitious lung sounds in some animals.
- Tachycardia, weak arterial pulses, jugular

vein distension, pale or cyanotic mucous membranes, delayed capillary refill time, right-sided cardiac murmur, and split or loud second heart sound in severely affected animals.

CAUSES

- Heartworm disease
- Neoplasia
- Hyperadrenocorticism (Cushing's disease) or corticosteroid administration
- Protein-losing nephropathy (renal loss of antithrombin) or enteropathy
- Immune-mediated hemolytic anemia
- Pancreatitis
- Pulmonary hypertension (primary or secondary)
- Orthopedic trauma or surgery
- Sepsis
- Disseminated intravascular coagulopathy
- Liver disease

RISK FACTORS

- Coagulopathy, especially any hypercoagulable state.
- Diseases listed under "Causes" are associated.
- Estrogen administration and air travel may be causative in humans.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other diseases that cause clinically important dyspnea and hypoxemia without profound radiographic findings include upper airway obstruction, laryngeal paralysis, and diffuse airway disease processes (e.g., toxin inhalation and interstitial lung disease).
- Upper airway obstruction often manifests as inspiratory dyspnea; breath sounds often loudest over the trachea or larynx. • Should be a leading diagnostic consideration in a patient with acute onset of dyspnea or collapse and a disease known to be associated with pulmonary thromboembolism.

CBC/BIOCHEMISTRY/URINALYSIS

CBC—may be normal; thrombocytopenia may be seen in up to 50% of dogs with PTE; leukocytosis may develop. Chemistry profile—results often reflect the underlying disease. Urinalysis—results often reflect the underlying disease; evaluate for proteinuria.

OTHER LABORATORY TESTS

- Arterial blood gases often show arterial hypoxemia (PaO_2 often $< 65 \text{ mmHg}$) and low PaCO_2 with respiratory alkalosis.
- Metabolic and respiratory acidosis may develop in severely affected patients.
- D-dimers result from the breakdown of cross-linked fibrin and are indicators of physiologic or pathologic thrombosis. D-dimer testing plays a pivotal role in diagnostic algorithms for PTE in humans; however, their utility for diagnosis of PTE in veterinary patients is uncertain. Plasma D-dimer levels may be inconsistently elevated in dogs with PTE and a low D-dimer level does not exclude the possibility of PTE.
- Thromboelastography is a technique that

provides a global assessment of coagulation and thrombolysis; may be useful in diagnosing systemic hypercoagulability but not widely available. • Coagulation profile may show high fibrin degradation products, abnormal fibrinogen, or alterations in one-stage PT and activated PTT. • Heartworm serology (antigen testing in dogs; both antigen and antibody testing in cats) should be performed in any animal with suspected PTE. • Cardiac biomarkers—cardiac troponin I and NT-proBNP levels may be elevated.

IMAGING

Thoracic Radiographic Findings

May be normal or show pulmonary artery enlargement or pruning, cardiomegaly, interstitial and alveolar lung patterns, small-volume pleural effusion, or areas of regional hyperlucency (Westerman sign).

Echocardiographic Findings

Right ventricular enlargement, an enlarged pulmonary artery segment, flattening of the interventricular septum, diminished size of the left ventricular cavity, or high velocity tricuspid or pulmonic regurgitation jets provide evidence of pulmonary arterial hypertension in some patients; infrequently a thrombus is imaged in the right heart or the main pulmonary artery segments.

Computed Tomography, Angiographic Findings, and Radionuclide Studies

- One or more of these tests are usually required for definitive diagnosis. • CT angiography is the gold standard for the diagnosis of PTE. • Spiral CT non-selective angiography may show intraluminal filling defects created by emboli, peripheral wedge-shaped pulmonary infiltrates, or pleural effusion. • Right-sided cardiac catheterization with pulmonary angiography may permit identification of intraluminal filling defects or regions of reduced pulmonary blood flow. • Non-selective angiography using conventional radiographic techniques has a low level of diagnostic success. • Combined ventilation and perfusion scans with radioisotopes permit identification of well-ventilated lung regions that are not receiving normal blood flow.

DIAGNOSTIC PROCEDURES

Electrocardiography

- Acute *cor pulmonale*—right axis deviation, *P pulmonale*, ST segment deviation, large T waves • Arrhythmias

PATHOLOGIC FINDINGS

- Thrombi in the major branches of the pulmonary arteries. • Some patients exhibit multiple smaller thrombi in small vessels of the pulmonary arteries, eventually leading to marked respiratory dysfunction and death.
- Concurrent pulmonary pathology such as pneumonia, pulmonary edema, pulmonary neoplasia or interstitial fibrosis is common.

PULMONARY THROMBOEMBOLISM

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

Treat patients documented to have pulmonary thromboembolism as inpatients until hypoxemia is resolved.

NURSING CARE

- Administer IV fluids cautiously unless pre-existing volume depletion exists; they may contribute to the development of right-sided congestive heart failure.
- Administer oxygen if dyspnea exists and/or $\text{PaO}_2 < 65 \text{ mmHg}$; response to oxygen therapy is variable.

CLIENT EDUCATION

- Alert client that disease is often fatal; further episodes are likely unless an underlying cause is identified and corrected; sudden death is not unusual.
- Treatment with traditional anticoagulant medications can lead to bleeding complications necessitating frequent re-evaluation of clotting times (e.g., PT and PTT) for successful management; LMWHs are safer and require less monitoring but are associated with greater expense; anticoagulant administration may be required for several months, even after resolution of the causative disease.

MEDICATIONS

DRUG(S) OF CHOICE

- Always identify and treat the underlying disease; if this is unlikely to be successful, aggressive efforts to treat pulmonary thromboembolism will probably be in vain.
- Unfractionated heparin may help to prevent further thrombi from developing; low dosages are probably inadequate for initial management; a dosage of 200–300 units/kg SC q8h or alternatively a bolus of 200 units/kg IV followed by a CRI at 15–30 units/kg/h adjusted to maintain the PTT at 1.5–2 times the baseline value.
- Thrombolytic drug administration (e.g., urokinase, streptokinase or tissue plasminogen activator) may also be useful in hemodynamically unstable cases; these drugs are expensive and carry a higher risk of bleeding complications.
- Warfarin—may be considered for long-term treatment (0.1 mg/kg q24h), with dosage adjustments to maintain a PT 1.5–2 times the baseline value; animals must be heparinized prior to warfarin therapy to avoid initial hypercoagulable phase.
- The low molecular weight heparins are likely associated with fewer bleeding complications than UFH or warfarin, require less intensive monitoring, and are more suitable for long-term management; however,

the expense of these drugs may be a limiting factor in their use.

- Thromboprophylactic effects have been demonstrated for dalteparin (150 units/kg SC q12h) in the absence of prolonged bleeding times or adverse effects; enoxaparin has been used at 1 mg/kg SC q12h.
- Sildenafil (1–2 mg/kg PO q 8–12 h) may be helpful in selected animals with PTE and concomitant pulmonary hypertension.

PRECAUTIONS

Warfarin—interacts with many other drugs; degree of anticoagulation may change after giving these drugs; or with diet alterations. Dose titration may be difficult in patients with diseases that result in coagulopathy. Review the mechanism of action and pharmacology of the antithrombotic drugs before use.

FOLLOW-UP

PATIENT MONITORING

- Serial arterial blood gases and/or pulse oximetry—may help determine improvement in respiratory function.
- Check PT every 3 days initially for adjusting warfarin dosage to achieve a PT 1.5–2 times the baseline value. International normalization ratios (INR) are recommended to minimize the effects of variability in thromboplastin preparations on PT results. Check weekly after an effective dosage is achieved (typically no sooner than 2 weeks).

PREVENTION/AVOIDANCE

- Activity or physical therapy may improve venous blood flow and prevent development of venous thrombi in immobile patients with severe systemic disease.
- Aspirin (0.5–5 mg/kg PO q12–24h) may have some preventive role but is inadequate as treatment.
- Clopidogrel (1–2 mg/kg PO q24h) is an alternative antiplatelet drug that may have some role in prevention. A single loading dose, up to 10 mg/kg, can be administered for rapid platelet inactivation in cases with active thrombosis.
- Heparin may be administered to animals predisposed to the development of pulmonary thromboembolism (200 units/kg IV initially and 75–200 units/kg SC q8h).
- Alternatively, dalteparin (150 units/kg SC q12h) may be used for thromboprophylaxis.
- Newer oral anticoagulants such as rivaroxaban, apixaban, or dabigatran may be as effective as warfarin for prevention of recurrent thrombosis in people and require less monitoring; these drugs may play a future role in longer-term anticoagulation of veterinary patients but further study on dosing and safety in animals is needed.

POSSIBLE COMPLICATIONS

Clinically important bleeding complications may arise in patients treated with

anticoagulant drugs. Bleeding may occur from any organ system. Anticipate active bleeding or anemia necessitating blood or plasma transfusion and have blood products readily available.

EXPECTED COURSE AND PROGNOSIS

Generally guarded to poor; depends on resolution of the precipitating cause. For irreversible diseases (e.g., some neoplasias and advanced protein-losing nephropathy), prognosis is poor long-term; it is somewhat better for patients with thromboembolism due to trauma or sepsis.

PULMONIC STENOSIS

BASICS

DEFINITION

Congenital narrowing of the right ventricular outflow tract, obstructing the passage of flow from the right ventricle to the pulmonary artery; usually valvular, but may be subvalvular or supravalvular. Double-chambered right ventricle is a variant of subvalvular pulmonic stenosis characterized by a focal muscular or fibromuscular stenosis in the mid right ventricle.

PATHOPHYSIOLOGY

The stenosis causes a pressure overload of the right ventricle, resulting in concentric hypertrophy. The right ventricle develops high systolic pressures to overcome the stenosis, whose magnitude correlates with the severity of the stenosis. The difference between the high right ventricular pressure and the normal pulmonary artery pressure (i.e., the pressure gradient) is often used to describe the severity of the stenosis. Hypertrophy of the right ventricle increases the risk of ischemia and arrhythmias. The geometric changes in right ventricular shape may result in secondary tricuspid insufficiency, although tricuspid insufficiency can also be associated with concurrent tricuspid dysplasia. With exercise, the right ventricle may be unable to increase stroke volume adequately. Tricuspid insufficiency with or without myocardial failure of the right ventricle may lead to high right atrial pressures and R-CHF. A concurrent atrial septal defect or patent foramen ovale may cause right-to-left shunting, especially with exercise, which may result in cyanosis on exertion. Mild pulmonic stenosis usually produces no significant hemodynamic effects apart from an ejection murmur.

SYSTEMS AFFECTED

- Cardiovascular—R-CHF, arrhythmias
- Hepatobiliary—hepatomegaly with R-CHF
- Nervous—cerebral hypoperfusion during exercise

GENETICS

Inherited defect in beagles; polygenic mode of transmission suggested.

INCIDENCE/PREVALENCE

- Most surveys show PS to be among the three most common congenital cardiac defects in dogs; comprising 21–32% of congenital heart defects.
- Uncommon in cats, especially as an isolated defect; comprised 3% of congenital heart defects in one study.

SIGNALMENT

Species

Dog and cat

Breed Predilections

English bulldog, Chihuahua, French bulldog, miniature schnauzer, West Highland white terrier, Samoyed, cocker spaniel, beagle, boxer, Pomeranian, German shepherd dog.

Mean Age and Range

Present from birth and may be detected as a murmur in puppies; if murmur is not detected, affected animals may not be identified until clinical signs develop later in life.

Predominant Sex

A predilection for males in English bulldogs and possibly other breeds.

SIGNS

General Comments

- Mild stenosis—usually no clinical signs.
- Severely affected patients—may develop CHF, exertional syncope, or sudden death.

Historical Findings

- Abdominal distension
- Dyspnea
- Exertional syncope, exercise intolerance, or sudden death
- Asymptomatic

Physical Examination Findings

- Systolic murmur loudest over the left heart base; may radiate widely but particularly dorsally on left.
- Murmur—midsystolic or holosystolic, and crescendo-decrescendo.
- Louder murmurs with a precordial thrill—generally associated with more severe stenosis.
- Arrhythmias may occur; the heart rate may be high in CHF.
- Other signs of CHF include ascites, jugular venous distension, and tachypnea.

CAUSES

Congenital

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Similar murmurs may be found with:
 - Aortic stenosis
 - Ventricular or atrial septal defects with marked left-to-right shunting
 - Tetralogy of Fallot.
- R-CHF associated with a left-sided murmur may be seen with:
 - Acquired valvular disease (endocardiosis)
 - Dilated cardiomyopathy.

CBC/BIOCHEMISTRY/URINALYSIS

- Generally unremarkable.
- Polycythemia may be present with right-to-left shunting.
- NT-proBNP is increased, particularly with severe stenosis or if clinical signs present.

IMAGING

Radiographic Findings

- Thoracic radiographs usually show right-sided cardiac enlargement, with a post-stenotic pulmonary artery bulge visible on the dorsoventral view at 1–2 o'clock.
- The caudal vena cava may be wide, and ascites may be present with or without pleural effusion in congestive failure.

Echocardiographic Findings

- Right ventricular hypertrophy, with flattening of the interventricular septum and a “figure-eight” appearance on short axis views in severe cases.
- Can usually image the site of the stenosis, but may be more difficult when the valve is hypoplastic; dysplastic pulmonic valves appear as thickened echodense leaflets; fused leaflets have abnormal motion with systolic doming; discrete subvalvular or supravalvular stenoses may appear as a localized hyperechoic narrowing.
- Post-stenotic dilation of the pulmonary artery often present.
- Double-chambered right ventricle can be difficult to image in conventional views.
- Localized hypertrophy may be seen in the right ventricular infundibular region.

Doppler Echocardiography

- Can use spectral Doppler to measure the elevated pulmonary artery flow velocity to calculate the pressure gradient across the stenosis. Pressure gradients under 50 mmHg generally represent mild stenosis; those over 100 mmHg indicate severe stenosis.
- Color-flow Doppler may reveal tricuspid regurgitation.

Angiography

- Selective cardiac angiography can help identify the precise morphologic abnormalities prior to surgery; may image dysplastic valves and hypertrophy of the infundibulum more clearly.
- Useful in identifying pulmonic stenosis caused by an anomalous coronary artery encircling the right ventricular outflow tract, which may affect the choice of therapy; recommended for English bulldogs (predisposed to this anomaly).

CT Angiography

Best technique to delineate coronary artery anomalies if resolution adequate and images are ECG-gated.

DIAGNOSTIC PROCEDURES

Electrocardiography

- QRS complex waveform changes include deep S waves in leads I, II, III, and aVF and right axis deviation.
- Atrial fibrillation may occur with severe right atrial enlargement.

PULMONIC STENOSIS

(CONTINUED)

PATHOLOGIC FINDINGS

- Various forms exist; most result in right ventricular hypertrophy and post-stenotic dilation of the pulmonary artery; infundibular hypertrophy may occur proximal to the obstruction.
- Hypoplastic pulmonic valve, with thickened leaflets ("dysplastic pulmonic valve").
- Normal pulmonic valve annulus with fused commissures, often attached to vessel at supravalvular level.
- Anomalous coronary arteries.
- Discrete supravalvular or subvalvular stenosis, with possible concurrent tricuspid dysplasia.
- Fibromuscular bands dividing the right ventricular inflow and outflow tracts in double-chambered right ventricle.

TREATMENT

APPROPRIATE HEALTH CARE

Most managed as outpatients.

NURSING CARE

Rarely, pleural effusions may need draining; ascites is usually treated medically.

ACTIVITY

Exercise should be restricted in cases with syncope or congestive failure, and severe exertion should be avoided in asymptomatic cases with severe stenosis.

DIET

Low-salt diets may benefit those with refractory ascites.

CLIENT EDUCATION

- Mildly affected animals may lead normal lives.
- Moderately severely affected patients may benefit from interventions such as balloon catheter dilation or surgery; improved clinical signs and survival has been associated with successful balloon procedures.
- Prognosis is guarded once congestive signs develop.
- Do not breed affected animals.

SURGICAL CONSIDERATIONS

Balloon catheter dilation—relatively safe procedure that involves passing a catheter across the stenosis and inflating a balloon to dilate the obstruction; in many cases, the pressure gradient is significantly reduced, especially when the lesion is caused by fused commissures; less successful with dysplastic or hypoplastic valves and should be used with caution with anomalous coronary arteries.

- Generally unsuccessful in double-chambered right ventricle.
- Alternative surgical techniques include valvulotomy or patch-graft procedures; mortality rates tend to be higher than with balloon valvuloplasty.

MEDICATIONS

DRUG(S) OF CHOICE

If signs of CHF, treat ascites with furosemide (2–4 mg/kg PO q8–12h); in refractory failure, it may be worth adding spironolactone (1–2 mg/kg PO q12h); aim should be to control CHF signs prior to catheter intervention.

CONTRAINDICATIONS

Vasodilators (e.g., hydralazine) may cause hypotension without relieving the stenosis, positive inotropes may further increase myocardial oxygen consumption.

PRECAUTIONS

Avoid overuse of diuretics. ACE inhibitors may be helpful with congestive signs, but may cause hypotension. Start with low doses and monitor blood pressure.

FOLLOW-UP

PATIENT MONITORING

Use serial echocardiograms to follow the pressure gradient and cardiac chamber size.

PREVENTION/AVOIDANCE

Do not breed affected animals.

POSSIBLE COMPLICATIONS

- R-CHF
- Arrhythmias
- Exercise intolerance
- Exertional syncope
- Sudden death

EXPECTED COURSE AND PROGNOSIS

- Mildly affected animals may remain asymptomatic with a normal lifespan.
- Severely affected animals have a guarded prognosis because they may develop CHF or sudden death; clinical signs are generally more common in animals > 1 year of age.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Ventricular septal defects, atrial septal defects, and patent foramen ovale.
- English bulldogs described with a single right coronary artery from which an anomalous left main coronary artery arises and then encircles and constricts the base of the pulmonic valve; other coronary variations have also been described.

AGE-RELATED FACTORS

Defect and murmur are present from birth

PREGNANCY/FERTILITY/BREEDING

Do not breed affected animals

SYNONYM

Pulmonary stenosis

PUPPY STRANGLES (JUVENILE CELLULITIS)

BASICS

OVERVIEW

- Uncommon granulomatous and pustular disorder of puppies.
- Rarely seen in adult dogs.
- Affects primarily the face, pinnae, and submandibular lymph nodes.
- Immunopathogenesis unknown.

SIGNALMENT

- Dogs.
- Age range—usually between 3 weeks and 4 months.
- Predisposed breeds—golden retriever, dachshund, and Gordon setter.

SIGNS

- Acutely swollen face (eyelids, lips, and muzzle).
- Submandibular lymphadenopathy.
- Marked pustular and exudative dermatitis; frequently fistulates; develops within 24–48 hours.
- Purulent otitis externa.
- Lesions often become crusted.
- Affected skin is usually painful.
- Lethargy—50% of cases.
- Anorexia, pyrexia, and sterile suppurative arthritis—25% of cases.
- Sterile pyogranulomatous panniculitis (rare) over the trunk, preputial, or perianal area; lesions may appear as fluctuant subcutaneous nodules that fistulate.

CAUSES & RISK FACTORS

Unknown: an immune dysfunction with a heritable cause is suspected.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bacterial folliculitis/furunculosis
- Demodicosis
- Drug reaction/eruption
- Deep fungal infection
- Cutaneous hypersensitivity
- Vaccination reaction
- Hymenoptera or insect envenomation

OTHER LABORATORY TESTS

- Cytology—pyogranulomatous inflammation with no microorganisms; non-degenerate neutrophils.
- Culture—often sterile in early cases; secondary infection with chronicity.

DIAGNOSTIC PROCEDURES

Skin biopsy

PATHOLOGIC FINDINGS

- Multiple discrete or confluent granulomas and pyogranulomas—clusters of large epithelioid macrophages and neutrophils.
- Sebaceous glands and apocrine glands may be obliterated.
- Suppurative changes in the dermis—predominate in later stages.
- Panniculitis.
- Exudate culture: important for selection of antibiotics if secondary infection suspected.

TREATMENT

- Early and aggressive therapy necessary because scarring may be severe.
- Topical therapy—may be soothing and palliative; adjunct to corticosteroids.

MEDICATIONS

DRUG(S)

- Corticosteroids—high doses required; prednisone (2.2 mg/kg divided q12h for at least 2 weeks then decreased over 2–4 weeks).
- Do not taper too rapidly.
- Chemotherapeutics—rare resistant cases.
- Adult dogs with panniculitis may require longer therapy.
- Antibiotics—only if there is evidence of secondary bacterial infection; as an adjunct therapy with immunosuppressive doses of corticosteroids.

FOLLOW-UP

- Most cases do not recur.
- Scarring may be a problem, especially around the eyes.

MISCELLANEOUS

SYNOMYMS

- Juvenile pyoderma
- Juvenile sterile granulomatous dermatitis and lymphadenitis

PYELONEPHRITIS

BASICS

DEFINITION

Microbial colonization of the upper urinary tract including the renal pelvis, collecting diverticula, renal parenchyma, and ureters; because it is not usually limited to the renal pelvis and parenchyma, a more descriptive term is upper urinary tract infection; this chapter is limited to bacterial pyelonephritis.

PATOPHYSIOLOGY

- Infection of any portion of the urinary tract usually requires some impairment of normal host defenses against urinary tract infection (see Lower Urinary Tract Infection chapters); normal defenses against ascending urinary tract infection include mucosal defense barriers, ureteral peristalsis, ureterovesical flap valves, unidirectional flow of urine and an extensive renal blood supply. Pyelonephritis usually occurs by ascension of microbes causing lower urinary tract infection. In dogs and cats, hematogenous seeding of the kidneys does not usually cause pyelonephritis. Regardless of the route of infection, an upper urinary tract infection is frequently accompanied by lower urinary tract infection.
- Pyelonephritis can develop secondarily to infection of metabolic nephroliths. Upper urinary tract infection with urease-producing bacteria can predispose to formation of struvite nephroliths (see Urolithiasis, Struvite—Dogs).
- Obstruction of an infected kidney or ureter can rapidly cause septicemia (so-called urosepsis).

P

SYSTEMS AFFECTED

- Renal/Urologic
- Can cause urosepsis, thus affecting any body system

INCIDENCE/PREVALENCE

- Unknown.
- Probably occurs much more commonly than is recognized clinically, because many animals with pyelonephritis are asymptomatic or have signs limited to lower urinary tract infection.

SIGNALMENT

Species

Detected more frequently in dog than cat

Mean Age and Range

- Dogs of any age can be affected.
- Cats urinary tract infection is uncommon (1–3%) in young to middle-age cats. It is more common in cats > 10 years of age (~10%).

Predominant Sex

- Unknown; dogs—urinary tract infection affects more females than males.
- Cats—similar frequency in males and females.

SIGNS

General Comments

Many patients are asymptomatic or have signs of lower urinary tract infection only.

Historical Findings

- Maybe asymptomatic.
- Polyuria/polydipsia.
- Abdominal or lumbar pain (uncommon).
- Signs associated with lower urinary tract infection—e.g., dysuria, pollakiuria, perirenia stranguria, hematuria, and malodorous or discolored urine.

Physical Examination Findings

- May be asymptomatic.
- Pain upon palpation of kidneys.
- Fever.
- One or both kidneys may be reduced in size, and/or increased in size.

CAUSES

Usually, ascending urinary tract infection caused by aerobic bacteria; most common isolates are *Escherichia coli* and *Staphylococcus* spp.; other bacteria, including *Proteus*, *Streptococcus*, *Klebsiella*, *Enterobacter*, and *Pseudomonas* spp., which frequently infect the lower urinary tract, may ascend into the upper urinary tract. Anaerobic bacteria, ureaplasma, and fungi uncommonly infect the upper urinary tract.

RISK FACTORS

- Ectopic ureters, vesicoureteral reflux, congenital renal dysplasia, and lower urinary tract infection.
- Conditions that predispose to urinary tract infection—e.g., diabetes mellitus, hyperadrenocorticism, exogenous steroid administration, renal failure, transurethral catheterization, urine retention, uroliths, urinary tract neoplasia, perineal urethrostomy.
- In cats with experimentally induced lower urinary tract disease, indwelling urinary catheters combined with administration of exogenous steroids frequently resulted in pyelonephritis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Clinical diagnosis of pyelonephritis is usually presumptive, based on results from CBC, biochemical analysis, urinalysis, urine culture, and diagnostic imaging; definitive diagnosis is not usually required for planning treatment.
- Since many dogs and cats lack specific symptoms attributable to pyelonephritis, any patient with urinary tract infection could potentially have pyelonephritis; the best methods for differentiating between upper and lower urinary tract infection are ultrasonography or excretory urography. Remember, most patients with pyelonephritis are asymptomatic.

- Consider pyelonephritis as a rule-out in dogs or cats with fever of unknown origin, PU/PD, chronic renal failure, and/or lumbar/abdominal pain.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—results often normal with chronic pyelonephritis; leukocytosis and immature neutrophilia may be detected in some patients.
- Biochemistry—values usually normal unless chronic pyelonephritis leads to chronic renal failure (azotemia with an inappropriate urinary specific gravity).
- Urinalysis reveals hematuria, pyuria, proteinuria, bacteriuria, and leukocyte casts in some animals. Leukocyte casts are diagnostic for renal inflammation, but unfortunately are very uncommon. Observe dilute urine specific gravity in patients with nephrogenic diabetes insipidus, which may occur secondary to pyelonephritis. Absence of these abnormalities does not rule out pyelonephritis.

OTHER LABORATORY TESTS

- Quantitative urine culture to confirm urinary tract infection; see Lower Urinary Tract Infection chapters for interpretation.
- Dogs with chronic pyelonephritis may have a negative urine culture and require multiple urine cultures to confirm urinary tract infection.

IMAGING

- Ultrasonography and excretory urography are the best methods for presumptively differentiating between upper and lower urinary tract infection. Ultrasonography is more sensitive than excretory urography for identification of mild-to-moderate acute pyelonephritis.
- Ultrasonographic findings supporting pyelonephritis include dilation of the renal pelvis and proximal ureter and a hyperechoic mucosal margin line within the renal pelvis and/or proximal ureter.
- Intravenous urography may reveal decreased opacity of the nephrogram phase of the IVU, dilation and blunting of the renal pelvis with lack of filling of the collecting diverticula, decreased opacity of contrast media in the collecting system, and dilation of the proximal ureter.
- In patients with acute pyelonephritis, the kidneys may be large; in patients with chronic pyelonephritis, the kidneys may be small, with an irregular surface contour.
- Concomitant nephroliths detected in some patients by survey radiography, ultrasonography, or excretory urography.

DIAGNOSTIC PROCEDURES

- Definitive diagnosis requires urine cultures obtained from the renal pelvis or parenchyma, or histopathology from a renal biopsy. Pyelocentesis can be performed percutaneously using ultrasound guidance or during exploratory surgery; can obtain

(CONTINUED)

- specimen for culture from the renal pelvis (or from nephroliths) during nephrotomy.
- To confirm the diagnosis, the biopsy specimen must include the renal cortex and medulla; thus renal biopsy should be performed by an individual very familiar with the technique of ultrasound guided renal biopsy, or by open surgery and only if necessary.
 - The renal lesions may be patchy in distribution and therefore the renal biopsy sample may not be representative of the light microscopic lesions.

PATHOLOGIC FINDINGS

- Kidneys affected by chronic pyelonephritis may have areas of infarction and scarring on the capsular surface. The renal pelvis and collecting diverticula may be dilated and distorted from chronic infection and inflammation. Purulent exudate is occasionally observed in the renal pelvis.
- Light microscopic findings include papillitis, pyelitis, interstitial nephritis, and leukocyte casts in tubular lumens.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient unless animal has septicemia or symptomatic renal failure.

ACTIVITY

Unlimited

DIET

Modified renal diet (e.g., Prescription Diet k/d for dogs or cats) recommended in cats or dogs with concomitant chronic renal failure or nephrolithiasis.

CLIENT EDUCATION

- Recurrent pyelonephritis may be asymptomatic. Unresolved chronic pyelonephritis may lead to chronic renal failure; diagnostic follow-up is important to document resolution or progression of pyelonephritis.
- In patients with nephroliths, resolution is unlikely unless the nephroliths are removed.

SURGICAL CONSIDERATIONS

- Complete obstruction of the upper urinary tract of a patient with pyelonephritis may rapidly progress to septicemia and therefore should be regarded as a medical emergency. The cause of the obstruction should be corrected by surgery (or lithotripsy for nephroliths).
- Infected nephroliths—surgically remove, medically dissolve (struvite), or fragment by extracorporeal shock wave lithotripsy; use periprocedural antibiotics to reduce the risk of urosepsis when manipulating infected nephroliths.

- Unilateral nephrectomy is usually not effective for elimination of suspected unilateral pyelonephritis.

MEDICATIONS

DRUG(S) OF CHOICE

- Base antibiotic selection on urine culture and susceptibility testing.
- Antibiotics should be bactericidal, achieve good serum and urine concentrations, and not be nephrotoxic.
- High serum and urinary antibiotic concentrations do not necessarily ensure high tissue concentrations in the renal medulla; thus chronic pyelonephritis may be difficult to eradicate.
- Give orally administered antibiotics at full therapeutic dosages for 4–6 weeks.
- Do not use drugs that achieve good concentrations in urine but poor concentrations in serum (e.g., nitrofurantoin).

CONTRAINdications

Do not use aminoglycosides unless no other alternatives exist on the basis of urine culture and susceptibility testing.

PRECAUTIONS

Trimethoprim/sulfa combinations can cause side effects (keratoconjunctivitis sicca, blood dyscrasias, and polyarthritis) when administered for more than 4 weeks.

FOLLOW-UP

PATIENT MONITORING

Perform urine cultures and urinalysis during antibiotic administration (~5–7 days into treatment) and 1 and 4 weeks after antibiotics are finished.

PREVENTION/AVOIDANCE

Eliminate factors predisposing to urinary tract infection; correct ectopic ureters.

POSSIBLE COMPLICATIONS

Renal failure, recurrent pyelonephritis, struvite nephrolithiasis, septicemia, septic shock, metastatic infection (e.g., endocarditis, polyarthritis).

EXPECTED COURSE AND PROGNOSIS

- Patients with acute or subacute pyelonephritis—fair to good, with a return to normal health unless the patient also has nephrolithiasis, chronic renal failure, or some other underlying cause for urinary tract infection (e.g., obstruction or neoplasia).
- Established chronic infection of the renal medulla may be difficult to resolve because of poor tissue penetration of antibiotics.

PYELONEPHRITIS

- Patients with chronic renal failure caused by pyelonephritis—prognosis determined by the severity and rate of progression of the chronic renal failure.
- Recurrent pyelonephritis is likely if infected nephroliths are not removed.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Hyperadrenocorticism, exogenous glucocorticoid administration, chronic renal failure, hyperthyroidism (cats), and diabetes mellitus are associated with lower urinary tract infection, which can ascend into the ureters and kidneys.

PREGNANCY/FERTILITY/BREEDING

Use antibiotics that are safe for the pregnant bitch or queen.

SYNONYMS

Upper urinary tract infection, pyelitis

P

PYODERMA

BASICS

DEFINITION

- Bacterial infection of the skin.
- Surface bacterial infections—often referred to as a “hot spot;” represents an acute moist dermatitis involving the surface of the skin.
- Superficial pyoderma—involves the epidermis and the intact hair follicle; includes mucocutaneous pyoderma.
- Deep pyoderma—involves the dermis and possibly subcutis; furunculosis is often present; patients can be systemically ill.

PATOPHYSIOLOGY

- Skin infections occur when the surface barrier of the skin has been broken, the skin has become macerated by chronic exposure to moisture, the population of resident bacterial flora has been altered, circulation has been impaired, and/or immunocompetency of the patient has been negatively impacted by systemic illness or immunosuppressive therapy.
- Pyoderma is usually secondary to an underlying cause; the primary, underlying cause should be identified and managed to reduce the frequency and recurrence of skin infections.

SYSTEMS AFFECTED

Skin/Exocrine

GENETICS

N/A

INCIDENCE/PREVALENCE

- Dogs—very common
- Cats—uncommon

P

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dog—short-coated breeds, especially those with excessive skin folds.
- German shepherd dog—severe, deep pyoderma that responds to antibiotics and may frequently relapse.

Mean Age and Range

Age of onset is usually directly related to the underlying cause.

Predominant Sex

None

SIGNS

General Comments

- Superficial—usually involves the trunk; extent of lesions may be obscured by hair coat.
- Deep—often affects the chin, bridge of the nose, pressure points, and feet; may be generalized and associated with symptoms of systemic illness, such as pyrexia and/or pain.

Historical Findings

- Acute or gradual onset.
- Variable pruritus—typically pruritic; the underlying cause may be pruritic or the staphylococcal infection itself may be pruritic; may not be pruritic if associated with hypercortisolism.

Physical Examination Findings

- Papules
- Pustules
- Crusted papules
- Crusts
- Epidermal collarettes
- Circular erythematous or hyperpigmented patches (macules)
- Alopecia; moth-eaten hair coat
- Hemorrhagic bullae
- Scaling
- Lichenification
- Target lesions
- Abscess
- Furunculosis, cellulitis

CAUSES

- *Staphylococcus pseudintermedius*—most frequent.
- *Pasteurella multocida*—cats.
- Deep bacterial skin infections may be complicated by gram-negative organisms (e.g., *Escherichia coli*, *Proteus* spp., *Pseudomonas* spp.).
- Rarely caused by higher bacteria (e.g., *Actinomycetes*, *Nocardia*, *Mycobacteria*, *Actinobacillus*).

RISK FACTORS

- Hypersensitivity—flea allergic dermatitis; atopic dermatitis; cutaneous adverse reaction to food; contact allergic dermatitis.
- Parasites—especially *Demodex* spp.
- Fungal infection—dermatophytosis (*Microsporum canis*, *Microsporum gypseum*, or *Trichophyton mentagrophytes*) most common.
- Endocrine diseases—hypothyroidism; hyperadrenocorticism; sex hormone imbalance.
- Immunosuppression—excessive corticosteroid administration; young animals.
- Seborrhea—chin acne; schnauzer comedo syndrome.
- Conformation—short coat; skin folds; redundant interdigital skin.
- Trauma—pressure points; grooming; scratching; rooting behavior; irritants.
- Foreign body—foxtail; grass awn.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypersensitivity—pruritus precedes lesions; persists with resolution of pyoderma.
- Endocrinopathy—relapsing pyoderma; consider if pruritus resolves with resolution of the pyoderma; may be associated with systemic symptoms.

- Flea allergic dermatitis or atopic dermatitis—may be seasonal.

- Pustular diseases—dermatophytosis; demodicosis; pemphigus foliaceus; and subcorneal pustular dermatosis.

- Furunculosis—higher bacterial infection; demodicosis; dermatophytosis; opportunistic fungal infections; deep fungal infections; panniculitis; and zinc-responsive dermatosis.
- Superficial pyoderma in short-coated breeds often misdiagnosed as urticaria due to acute onset of pruritic papules and follicular tufting.

CBC/BIOCHEMISTRY/URINALYSIS

- Superficial pyoderma—normal or may reflect underlying cause (e.g., anemia due to hypothyroidism; stress leukogram and high serum alkaline phosphatase due to hyperadrenocorticism; eosinophilia due to parasitism).
- Generalized, deep pyoderma—may show leukocytosis with a regenerative left shift and hyperglobulinemia; abnormalities related to an underlying cause may be present.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Multiple skin scrapings—demodicosis.
- Direct smear from intact pustule—neutrophils with intracellular bacteria, typically cocci.
- Cytology from underneath a crust or edge of an epidermal collarette; help differentiate pemphigus foliaceus (acantholytic keratinocytes) and deep fungal infections (blastomycosis, cryptococcosis) from pyoderma; tissue grains may identify filamentous organisms characteristic of higher bacteria.
- Skin scrapings—demodicosis.
- Trichograms—dermatophytosis, follicular abnormalities.
- Dermatophyte culture—fungal infection.
- Surface or papule/pustule cytology—pemphigus foliaceus.
- Intradermal allergy testing—atopy.
- Elimination diet trial—food hypersensitivity.
- Endocrine tests—hypothyroidism, hyperadrenocorticism.
- Skin biopsy is rarely useful unless the infection is deep in nature; utilized to obtain tissue sample for macerated tissue culture.

Culture

- Usually positive for *S. pseudintermedius*.
- Other organisms besides staphylococci and higher bacteria may be cultured from the lesions of deep pyoderma.
- Contents of an intact pustule—most reliable results for superficial infections.
- Punch biopsy obtained by sterile technique for macerated tissue culture; especially for

(CONTINUED)

PYODERMA

deep pyoderma; more likely false-negative results with superficial pyoderma.

- Freshly expressed exudate from a draining tract or beneath a crust—may yield the pathogen or a contaminant if the lesion is not intact; least reliable method.

PATHOLOGIC FINDINGS

- Subcorneal pustules.
- Intraepidermal neutrophilic microabscesses.
- Perifolliculitis.
- Folliculitis.
- Furunculosis.
- Nodular to diffuse dermatitis.
- Panniculitis.
- Inflammatory reaction—suppurative or pyogranulomatous.
- Tissue grains within pyogranulomas—observed most often with *Actinomyces*, *Actinobacillus*, and *Nocardia*.
- Special stains—used to identify gram-negative bacteria or acid-fast organisms.

**TREATMENT****APPROPRIATE HEALTH CARE**

Usually outpatient, except for severe, generalized deep pyoderma.

NURSING CARE

- Severe, generalized, deep pyoderma—may require IV fluids, parenteral antibiotics, and/or daily whirlpool baths.
- Benzoyl peroxide or chlorhexidine shampoos—remove surface debris.
- Whirlpool baths—deep pyoderma; remove crusted exudate; encourage drainage; decrease inflammation and improve tissue oxygenation.

ACTIVITY

No restriction

DIET

- Novel protein or hydrolysate diet if secondary to cutaneous adverse reaction to food.

CLIENT EDUCATION

N/A

SURGICAL CONSIDERATIONS

Fold pyoderma may require surgical correction to prevent recurrence; frequent topical therapy can help reduce the severity and frequency of recurrence.

**MEDICATIONS****DRUG(S) OF CHOICE**

- *S. pseudintermedius* isolates—usually susceptible to cephalosporins, cloxacillin, oxacillin, methicillin, amoxicillin-clavulanate, erythromycin, clindamycin, and trimethoprim-sulfamethoxazole; somewhat

less responsive to lincomycin; frequently resistant to amoxicillin, ampicillin, penicillin.

- Amoxicillin-clavulanate—most isolates of *Staphylococcus* and *P. multocida* susceptible; generally effective for skin infections in cats.
- Superficial pyoderma—initially treated empirically with one of the antibiotics listed above.
- Recurrent, resistant, or deep infections—choose antibiotic therapy based upon culture and sensitivity testing (e.g., chloramphenicol).
- Multiple organisms with different antibiotic sensitivities—choose antibiotic on basis of the staphylococcal susceptibility.

CONTRAINdications

Corticosteroids—mask inflammation causing therapy to be discontinued prematurely and resulting in selection for resistant organisms; if used concurrently, therapy should be extended and the infection should be re-evaluated before discontinuing antibiotics.

PRECAUTIONS

- Cephalosporins, erythromycin, lincomycin, clindamycin and oxacillin—vomiting; administer with food.
- Aminoglycosides—renal toxicity usually precludes prolonged systemic use.
- Trimethoprim-sulfamethoxazole—keratoconjunctivitis sicca, fever, hepatotoxicity, polyarthritis, and hematologic abnormalities, especially neutropenia.
- Chloramphenicol—use with caution in cats; may cause mild, reversible anemia in dogs; associated with aplastic anemia in humans; rear limb muscle weakness should be mentioned to owners as a possible side effect.

POSSIBLE INTERACTIONS

Trimethoprim-sulfamethoxazole—falsey decrease thyroid hormone test results.

ALTERNATIVE DRUG(S)

Bacterin (Staphage Lysate—Delmont Laboratories), staphoid AB, or autogenous injections—may improve antibiotic efficacy and decrease infection recurrence.

**FOLLOW-UP****PATIENT MONITORING**

Administer antibiotics for a minimum of 7–10 days beyond clinical cure; approximately 3–4 weeks for superficial pyoderma; 6–10 weeks for deep pyoderma.

PREVENTION/AVOIDANCE

- Routine bathing with benzoyl peroxide or chlorhexidine shampoos—may help prevent recurrences.
- Padded bedding—may ease pressure point pyoderma; also consider causes for poor wound healing including hypothyroidism.
- Topical benzoyl peroxide gel or mupirocin 2% ointment may be helpful adjunct

therapies—chin acne, fold pyoderma, respectively.

- Identification and management of the underlying cause is crucial to prevent recurrence.

POSSIBLE COMPLICATIONS

Bacteremia and septicemia

EXPECTED COURSE AND PROGNOSIS

Likely to be recurrent or non-responsive if underlying cause is not identified and effectively managed.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

- Impetigo—affects young dogs before puberty; can be associated with poor husbandry; often requires only topical therapy.
- Superficial pustular dermatitis—occurs in kittens; associated with overzealous “mouthing” by the queen.
- Pyoderma secondary to atopic dermatitis—usually begins between 1 and 3 years of age.
- Pyoderma secondary to endocrine disorders—usually begins in middle adulthood.

ZOONOTIC POTENTIAL

- Cutaneous tuberculosis—rare
- Feline leprosy—unknown

PYODERMA—METHICILLIN-RESISTANT

BASICS

OVERVIEW

- Staphylococcal bacterial skin infection resistant to all β -lactam antibiotics; associated with exposure to one or more courses of antibiotic therapy.
- Most often caused by *Staphylococcus pseudintermedius*; rarely *Staphylococcus aureus*.

SIGNALMENT

Dogs

- Any age, breed, sex, size.
- More common with chronic, primary skin conditions, especially patients with recurrent skin infection.

Cats

- Any age, breed or sex may be affected.
- Pyoderma less common in cats.

SIGNS

Dogs & Cats

- Papules • Pustules • Crusts • Crusted papules • Epidermal collarettes
- Furunculosis, cellulitis if deep • Circular erythematous or hyperpigmented spots (macules) • Alopecia, moth-eaten hair coat, especially in short-coated breeds
- Hemorrhagic bullae • Scale
- Lichenification • Abscess • Pyoderma that persists when active disease remains or develops during appropriate therapy.

CAUSES & RISK FACTORS

- Hypersensitivity—flea allergic dermatitis; atopic dermatitis; cutaneous adverse reaction to food; contact allergic dermatitis.
- Parasites—especially *Demodex* spp.
- Endocrine—hypothyroidism; hyperadrenocorticism (especially if non-pruritic); sex hormone imbalance.
- Immunosuppression—iatrogenic due to chronic glucocorticoid therapy; young animals.
- Seborrhea—chin acne; schnauzer comedo syndrome.
- Additional—short coat; skin folds; redundant interdigital skin; trauma of pressure points, especially in hypothyroid dogs; excessive grooming; scratching; rooting behavior; irritants; foreign bodies (foxtail; grass awn).

P

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dogs

- Demodicosis • Dermatophytosis
- Methicillin-sensitive pyoderma
- Pemphigus foliaceus • Systemic lupus erythematosus • Other primary causes for pyoderma • Epitheliotropic lymphoma (older animals)

Cats

- Dermatophytosis • Flea-allergic dermatitis
- Demodicosis • Pemphigus foliaceus
- Methicillin-sensitive pyoderma
- Epitheliotropic lymphoma in older animals

CBC/BIOCHEMISTRY/URINALYSIS

- Superficial pyoderma—normal or may reflect underlying cause.
- Generalized, deep pyoderma—may demonstrate leukocytosis with regenerative left shift and hyperglobulinemia; in addition, may reflect underlying cause; sepsis a concern, especially if patient is immunosuppressed.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Multiple skin scrapings—demodicosis.
- Direct smear from intact pustule—neutrophils with intracellular bacteria.
- Cytology from underneath crust or edge of epidermal collarette useful if intact pustules absent; cytology utilized to help differentiate pemphigus foliaceus (acantholytic keratinocytes) and deep fungal infections (blastomycosis) from pyoderma.
- Culture and sensitivity essential when MR infection suspected.
- Skin biopsy rarely useful unless infection deep; used to obtain tissue sample for macerated tissue culture.
- Dermatophyte culture—fungal infection.
- Intradermal allergy testing—atopy.
- Elimination diet trial—food hypersensitivity.
- Endocrine tests—hypothyroidism, hyperadrenocorticism.

PATHOLOGIC FINDINGS

- Subcorneal pustules • Intraepidermal neutrophilic microabscesses • Perifolliculitis
- Folliculitis • Furunculosis—deep infection
- Nodular to diffuse dermatitis
- Panniculitis—deep infection
- Inflammatory reaction—suppurative; pyogranulomatous with deep infections

TREATMENT

- Antibiotic choice based on culture and sensitivity.
- Topical therapy.
- Generalized, deep pyoderma—hospitalization, IV fluids, IV antibiotics, whirlpool baths, depending on severity and risk for sepsis.

MEDICATIONS

DRUG(S)

- Antibiotic therapy must be based on culture and sensitivity.
- Topical therapy essential—chlorhexidine shampoo or spray, dilute bleach bathing, mupirocin ointment, for localized disease.
- Some cases resolve with topical therapy only—must be consistent/frequent.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Corticosteroid therapy—masks inflammation and suppresses immune system function; therapy should be discontinued.

FOLLOW-UP

PATIENT MONITORING

- Recheck examinations crucial, since fewer antibiotics to choose from.
- Re-evaluation of patient while still receiving treatment aids in decision making regarding continuation of therapy, or need for additional diagnostic tests.

PREVENTION/AVOIDANCE

- Choose antibiotic therapy from culture and sensitivity data—treatment failure occurs when antibiotic changes made without evidence.
- Successful management of underlying disease.
- Hand washing before and after handling patient.

EXPECTED COURSE AND PROGNOSIS

- Good if antibiotic choice is based on culture and sensitivity data and underlying cause is managed.
- MR infections not more virulent, but fewer antibiotic medications for treatment.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Exposure of humans and animals to MRSA and MRSP is common.
- MRSP infections in humans are rare.
- MRSP is not MRSA.
- MRSA infections in animals are rare and most associated with exposure to humans with MRSA infection.

SEE ALSO

- Pyoderma • Pododermatitis

ABBREVIATIONS

- MR = Methicillin resistant
- MRSP = Methicillin resistant *S. pseudintermedius*
- MRSa = Methicillin resistant *S. aureus*

Suggested Reading

Miller WH, Griffin CE, Campbell KL. Muller & Kirk's Small Animal Dermatology, 7th ed. St. Louis, MO: Saunders, 2013, pp. 184–207.

Author Elizabeth R. May

Consulting Editor Alexander H. Werner

BASICS

DEFINITION

Pyometra is an acute or chronic suppurative inflammation of the endometrium in ovary-intact bitches which leads to intraluminal accumulation of purulent exudates.

PATOPHYSIOLOGY

- Incompletely understood and multifactorial in origin.
- Classic description: Normal cycling bitches—repeated exposure of the endometrium to high concentrations of estrogen during proestrus and estrus followed by high concentrations of progesterone for 2 months during diestrus without pregnancy—leads to development of cystic endometrial hyperplasia (CEH), which predisposes the uterus to a secondary bacterial infection.
- Strains of *Escherichia coli* with uropathogenic virulence factors that allow adhesion to the endometrium and establishment of an infection without the presence of CEH enter the uterus during proestrus and estrus and act as a mucosal irritant—stimulating the development of CEH under the influence of progesterone during diestrus.
- Combination of both disease entities—occurring concurrently.
- Bacteria—ascend from the vagina through the partially open cervix during proestrus and estrus; uterine secretions provide excellent media for growth; uropathogenic *E. coli* most common isolate.
- Regardless of underlying cause—pyometra does not occur without the presence of progesterone (endogenous or exogenous source).

SYSTEMS AFFECTED

- Reproductive
- Hemic/Lymphatic/Immune
- Hepatobiliary
- Renal/Urologic

GENETICS

- Genetic predisposition suspected in some ‘lines’ of related bitches.
- Breed predisposition has been suggested: Bernese mountain dogs, rottweiler, rough-coated collie.

INCIDENCE/PREVALENCE

Incidence—accurate assessment cannot be made because most dogs and cats in the United States undergo elective ovariohysterectomy.

SIGNALMENT

Species

Dog and cat

Mean Age and Range

- Usually > 6 years old; range 4 months to 16 years in dogs.
- Animals treated with exogenous estrogen or progestagen.
- Pyometra of the uterine stump in spayed animals—may develop any time after ovariohysterectomy.

Predominant Sex

Female—ovary intact

SIGNS

Historical Findings

- Dogs—present within 12 weeks after their last estrus.
- Cats—present within 4 weeks of last call (estrus).
- History of treatment with exogenous hormones.

Physical Examination Findings

- Uterus—with closed cervix palpably enlarged; palpate carefully to avoid rupture; with open cervix, may not be palpably enlarged.
- Vaginal discharge and systemic illness—depends on patency of cervix.
- Open cervix—blood-stained, purulent vaginal discharge often only presentation.
- Closed cervix—systemically ill from endotoxemia and bacteremia: polyuria, polydipsia, lethargy, anorexia, vomiting, abdominal distension, dehydration.
- May or may not have pyrexia.

CAUSES

- Dogs—the unique, repeated exposure of the endometrium to estrogen followed by exposure to progesterone without pregnancy.
- Cats—may be the result of estrogen at estrus followed by a progestational (pseudopregnancy) phase, caused by induction of ovulation by coitus, mechanical stimulation, hormones (hCG, GnRH), or spontaneous ovulation (incidence of 30% reported).

RISK FACTORS

- Middle-aged to older, nulliparous ovary-intact females may be predisposed.
- Pharmacologic use of estrogen (mismate) shots during midestrus to early diestrus.
- No correlation with pseudopregnancy in dogs.
- Use of progestagens in both queens and bitches for estrus prevention.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pregnancy
- Other causes of polyuria and polydipsia—diabetes mellitus; hyperadrenocorticism; primary renal disease
- Severe vaginal disease
- Metritis and retained fetal membranes (associated within first days postpartum)
- Hydrometra (serous intrauterine discharge); mucometra (mucoïd intrauterine discharge); hematometra (hemorrhagic intrauterine discharge)

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilia—left shift +/− toxic changes; more severe with closed cervix
- Mild, normocytic, normochromic, nonregenerative anemia
- Hyperglobulinemia, hyperproteinemia, hypoalbuminemia, hypercholesterolemia, elevated C-reactive protein
- Azotemia (elevated BUN and creatinine)
- ALT and ALP—high with

septicemia or severe dehydration • Electrolyte disturbances—depend on clinical course

- Urinalysis—isosthenuria, bacteriuria, glucosuria, and proteinuria can be found. Collect sample by catheterization of urinary bladder or ultrasound-guided cystocentesis to avoid risk of uterine puncture. Midstream urine sample not recommended as contamination with vaginal discharge likely.

OTHER LABORATORY TESTS

- Cytologic examination of vulvar discharge—degenerative polymorphonuclear cells and phagocytized bacteria; may be indistinguishable from the purulent discharge associated with vaginal disease (e.g., vaginitis, vaginal mass, foreign object, and vaginal anatomic anomaly).
- Bacterial culture and sensitivity test of vulvar discharge—not helpful in confirming diagnosis (bacteria cultured are usually normal vaginal flora); useful in determining appropriate antibiotic use—if sample directly taken from the uterus transcervically or the cranial vagina with the aid of a vaginal speculum (guarded swab from caudal vagina/vestibule bacteria).
- Serologic testing for *Brucella canis*—rapid slide agglutination test used as a screen (D-Tec CB®, Zoetis, Corp., (888)-963-8471); sensitive but not specific. If positive, recheck by an agar gel immunodiffusion test (Cornell University Diagnostic Laboratory, (607)253-3900) or bacterial culture of whole blood, lymph node aspirate, or vulvar discharge.
- Prostaglandin $F_{2\alpha}$ metabolites (PGFM) are elevated in dogs with pyometra compared to those with hydrometra or mucometra.
- Hormone assay: progesterone concentration > 2 ng/mL.

P

IMAGING

Radiography

- Detect an enlarged and distended uterus (see Web Figure 1).
- Rule out pregnancy—45 days after ovulation when fetal skeletal ossification is present.

Ultrasonography

- Uterine horns distended with hypo- to hyperechoic intraluminal fluid, with or without flocculation. Uterine wall often thickened with irregular edges and small hypoechoic areas consistent with cystic change (CEH) (see Web Figure 2) or can be thin if uterus is severely distended as with a closed cervix pyometra.
- Rule out pregnancy—20–24 days after ovulation.
- Pyometra—may occur with pregnancy in dogs (rare).

DIAGNOSTIC PROCEDURES

- Vaginoscopy—indicated in dogs with purulent vulvar discharge and no apparent uterine enlargement; allows determination of site of origin of the vulvar discharge; not possible in cats.

PYOMETRA

(CONTINUED)

PATHOLOGIC FINDINGS

- Endometrium (dogs and cats)—described as cobblestone appearance (see Web Figure 3).
- Cystic endometrial surface—covered by malodorous, mucopurulent exudate; thickened because of increased endometrial gland size and cystic gland distension.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient • Pyometra—life-threatening condition if the cervix is closed and bitch is systemically ill.

NURSING CARE

Supportive care—immediate intravenous fluid administration and broad-spectrum antibiotics.

CLIENT EDUCATION

- Recommend medical treatment only for valuable, young breeding animals that are not azotemic and present systemically well. For all other animals not intended for breeding, ovariohysterectomy is the treatment of choice.
- Historically, medical treatment of closed-cervix pyometra can be associated with uterine rupture and peritonitis, but with the development of new pharmacologic agents and treatment protocols this is now a rare event.
- Bitches that are refractory or chronic cases that do not readily respond to medical treatment are candidates for ovariohysterectomy.
- Warn of possible recurrence of pyometra after medical therapy—important to breed at very next heat and spay when desired number of litters is achieved.

SURGICAL CONSIDERATIONS

- Ovariohysterectomy is the preferred treatment in all animals not intended for breeding, older (> 4 years) bitches, bitches with evidence of chronic CEH changes, bitches that present systemically unwell and require immediate emergency care and stabilization. The pus-filled uterus, both ovaries and the entire cervix should all be removed.
- Closed-cervix pyometra—exercise great care in handling the enlarged and friable uterus (see Web Figure 4).
- Place saline-soaked laparotomy sponges in the abdomen to prevent leakage of purulent material into the peritoneal cavity.
- Patients should be systemically stabilized prior to anesthesia for surgery (correction of any acid-base derangements, dehydration, hypotension, shock, electrolyte abnormalities,

arrythmias and endotoxemia) and started on IV fluids and IV broad-spectrum antibiotics.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics

- All patients with pyometra • Empirical (*E. coli* most common isolate)—pending results of bacterial culture and sensitivity test
- Start on broad-spectrum antibiotics prior to receiving culture and sensitivity results—ampicillin (22 mg/kg PO q8h); amoxicillin and clavulanic acid (12.5–25 mg/kg PO q12h) or cefazolin (22 mg/kg IV or IM q8h). Exercise care when using cephalosporins, potentiated sulfonamides and enrofloxacin in dehydrated, potentially septicemic patients with impaired renal or liver function.

Prostaglandins (PGF_{2α})

- Doses listed below for native compound only (dinoprost tromethamine; Lutalyse®); has both luteolytic and ecobolic actions.
- New low-dose protocol: start with low doses to minimize side effects and ecobolic effect especially in closed pyometra cases. Once luteolysis has occurred and the cervix is fully open the dose can be gradually increased depending of the individual patient's tolerance to the drug.
- Side effects: dose dependent and usually not seen with new low dose protocol; tachypnea, vomiting, diarrhea, urination, anxiety; side effects are seen 20 minutes after administration of the drug and last for 15–30 minutes.
- Animals should be hospitalized for 1 hour after each treatment.
- Dogs and cats—10 µg/kg SC q6h for 1 day then 25 µg/kg q6h for 1–2 days; then 50 µg/kg q6h for 3–4 days. The queen is more resistant to the luteolytic effects of PGF_{2α} than bitches—often higher doses for longer periods are required.
- Ovariohysterectomy—performed in patients not responding well to treatment within 5 days and are refractory to prostaglandin treatment (persistent or recurring uterine fluid and vulvar discharge).

Cloprostenol

- Synthetic form of PGF_{2α} • Dogs—1 µg/kg SC daily for 7–14 days; greater side effects and prolonged time to resolution compared to the natural form of PGF_{2α}

Miscellaneous

Transcervical endoscopic catheterization of open- and/or closed-cervix pyometra—a recently described technique; involves

flushing the uterus with warm saline and PGF_{2α}; reported resolution within 3–5 days; no uterine rupture or leakage reported but still should be considered a risk—patient selection important.

CONTRAINDICATIONS

- High-dose PGF_{2α} and cloprostenol with closed-cervix pyometra—strong myometrial contractions may cause uterine rupture or force purulent exudate through the oviducts, causing secondary peritonitis.

PRECAUTIONS

- PGF_{2α} (dinoprost tromethamine) and cloprostenol—not approved for use in dogs and cats.

ALTERNATIVE DRUG(S)

- Progesterone receptor antagonist—aglepristone (10 mg/kg SC days 1, 2, and 8) competitively binds to the progesterone receptor with greater affinity than natural progesterone. Minimal side effects. Excellent choice for closed pyometra cases as it dilates the cervix with minimal uterine contractions. Best results achieved when used in combination with prostaglandin—PGF_{2α} is started 24–48h after aglepristone, allowing the cervix to open prior to stimulation of uterine contractions by PGF_{2α}; not registered in United States; not suitable for use in bitches with poor liver and/or kidney function.
- Dopamine agonists—cabergoline (5 µg/kg PO q24h for 7–14 days) or bromocryptine (10–20 µg/kg q8h); both given with food to reduce risk of vomiting; act as prolactin antagonists; best used in combination with PGF_{2α} to potentiate the ecobolic effect—should see cervical opening within 24–48 h.

FOLLOW-UP

PATIENT MONITORING

- Antibiotics—continued for at least 14 days after resolution of vulvar discharge and removal of all fluid from the uterine lumen (confirmed by ultrasound).
- Clinical improvement and a significant increase in vaginal discharge should be noted within 24 hours of commencing PGF_{2α} treatment; vaginal discharge will change from purulent to serosanguineous to serous; a reduction in the uterine lumen should be seen on ultrasound within 3 days after the start of treatment; resolution of clinical signs (no vulvar discharge and no intrauterine fluid visible by ultrasound) should occur within

(CONTINUED)

PYOMETRA

7 days. • Serum progesterone concentrations decline within 48 hours of treatment and should be < 2 ng/mL at 5–7 days; CBC and neutrophil count normal after 10–15 days. • Follow-up ultrasound of the uterus 4 weeks after discontinuation of treatment to assess uterine health—confirm no intraluminal fluid and determine CEH changes (predictor of future fertility).

PREVENTION/AVOIDANCE

- Animals not intended for breeding should be spayed.
- Breeding females should be spayed as soon as the desired number of litters has been obtained.
- Females should be bred when they are young (< 4 years) and subsequently have the desired number of litters as soon as possible—a pregnant uterus reduces the risk of developing pyometra and maximizes uterine health of the bitch.
- Breed during the estrus immediately following treatment—the gravid uterus is less susceptible to reinfection; a bitch with underlying cystic endometrial hyperplasia has limited breeding life (best to get the desired number of pups as soon as possible); ultrasound examination 28 days after the LH surge for early detection of recurring pyometra allows surgical management before the bitch becomes systemically ill.
- Breeding management at the subsequent heat is important to maximize the chance of pregnancy—use of high-quality semen, timed insemination with extenders containing antibiotics, or timed natural mating with young proven stud dog.
- Antibiotic therapy at subsequent heat—vaginal cytology monitoring; presence of neutrophils during estrus indication to start broad-spectrum antibiotic (amoxicillin or amoxicillin and clavulonic acid) until early ultrasound (for 4 weeks after the LH surge).
- Medical treatment can result in a shortened interestrus interval which can be associated with decreased fertility—lengthen interestrus interval with an androgen-receptor agonist

such as mibolerone to allow sufficient time for the uterus to remodel/recover; start mibolerone 1 month after the end of treatment and continue for 2–3 months to ensure a minimum interval of 6 months from the last heat.

POSSIBLE COMPLICATIONS

- Bitch may enter estrus sooner after treatment than anticipated if medical treatment induces premature luteolysis (see “Prevention/Avoidance”).
- Recurrence of pyometra at subsequent heats.

EXPECTED COURSE AND PROGNOSIS

- Prognosis for survival is good with both medical and surgical treatment if uterine rupture does not occur; 4% mortality rate reported in bitches and 8% in queens.
- Recurrence rate of pyometra is dependent on age, parity, and pre-existing uterine pathology.
- Variable pregnancy rates reported after treatment for pyometra (50–90%).

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Pyometra of the uterine stump in spayed animals—may develop any time after ovariohysterectomy; may be associated with the presence of an ovarian remnant.

PREGNANCY/FERTILITY/BREEDING

- Any of the drugs used for the treatment of pyometra are also abortifacients—always rule out pregnancy before administration to valuable breeding animals.
- See “Prevention/Avoidance” and “Expected Course and Prognosis” for future breeding/fertility after treatment of a pyometra and ways to reduce incidence of pyometra.

Client Education Handout available online

PYOTHORAX

BASICS

DEFINITION

Accumulation of septic suppurative inflammation in the pleural cavity.

PATHOPHYSIOLOGY

- Infectious—from transpulmonary, transesophageal, or transthoracic inoculation of bacteria into the pleural space, with subsequent suppurative pleuritis.
- Dogs—often associated with an inhaled grass awn or other foreign object or a penetrating wound to the thorax.
- Cats—most commonly associated with penetrating bite wounds, foreign bodies, or possibly by extension of pneumonia into the pleural space following aspiration of oropharyngeal flora. • Other causes include extension of discospondylitis, esophageal perforation, parasitic migration, hematogenous spread, previous thoracic surgery, and neoplasia with abscess formation.

SYSTEMS AFFECTED

- Respiratory • Hemic/Lymphatic/Immune
- Renal/Urologic—protein-losing nephropathy

GEOGRAPHIC DISTRIBUTION

Etiology is regionally dependent. For example, inhaled grass awn or foxtails are common in California. *Spirocera lupi* should be considered as a predisposing cause in endemic areas (Africa, Asia, southeastern United States).

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dogs—hunting and sporting breeds; specifically, Labrador retrievers, springer spaniels, and border collies • Cats—domestic shorthair.

Mean Age and Range

Median ~ 4 years, although there is wide variation.

Predominant Sex

Male animals overrepresented.

SIGNS

General Comments

- Often insidious in onset, with few clinical signs until late in the course of disease.
- Respiratory compromise—often not severe unless disease is advanced. • Vomiting/diarrhea may be initial presenting complaint in 25% of canine cases.

Historical Findings

- Diminished activity. • Collapse after exercising and slow recovery. • Weight loss and partial anorexia can be the only clinical signs. • Temporary improvement with antibiotic therapy. • Confirm history of fights or puncture wounds.

Physical Examination Findings

- Tachypnea—usually apparent; may be mild and not associated with respiratory difficulty.
- Cachexia—often observed. • Cough—may be observed. • Pyrexia—usually low-grade, may be observed. • Thoracic auscultation—may reveal muffled heart sounds, diminished lung sounds ventrally, and amplified lung sounds dorsally. • Cats—may show few clinical signs before onset of apparently acute respiratory distress, collapse, and septic shock; bradycardia and hypersalivation associated with poor outcome.
- Injury to the thoracic wall—may not be apparent or may be healed at the time of examination.
- Perform thorough palpation and inspection of the thorax for evidence of scarring or cellulitis.

CAUSES

- Infectious—dogs: *Actinomyces* spp., *Nocardia* spp., Anaerobes (*Bacteroides*, *Peptostreptococcus*, *Fusobacterium*), *Corynebacterium*, *Escherichia coli*, *Pasteurella*, and *Streptococcus* spp.; fungal agents.
- Infectious—cats: oral commensals (e.g., *Pasteurella multocida* and *Bacteroides* spp.) most common; obligate anaerobes (*Peptostreptococcus*, *Fusobacterium*) common.
- Parasitic—dogs: esophageal rupture of *Spirocera lupi* granuloma.
- Neoplastic—rarely with intrathoracic tumors secondary to tumor necrosis.
- Lung lobe torsion—occasionally associated with pyothorax.

RISK FACTORS

- Dogs—hunting, field trials, and other strenuous outdoor sporting activities; *S. lupi* endemic areas.
- Cats—multiple cat households, outdoor cats, pneumonia, upper-respiratory infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other pleural effusions—chylothorax and hemothorax; non-septic exudates (FIP or neoplasia); transudative effusions; differentiated via cytologic examination.
- Other systemic diseases should be considered for nonspecific findings.
- Diseases associated with fever of unknown origin should be considered for animals with non-localizing signs.

CBC/BIOCHEMISTRY/URINALYSIS

- Marked neutrophilic leukocytosis with left shift, monocytosis, and anemia of chronic disease.
- Regenerative anemia—can be seen with substantial hemorrhage into the pleural cavity.
- Hyperglobulinemia—possible due to chronic inflammation.
- Hypoalbuminemia as a negative acute phase reactant or due to renal loss, if glomerulonephritis results from chronic antigenic stimulation.
- Alkaline phosphatase—mildly elevated from

hypoxemia. • Prerenal azotemia—if the patient is dehydrated. • Organ-specific changes—if other organs are secondarily infected (e.g., pyelonephritis and hepatitis).

IMAGING

- Radiography—unilateral or bilateral pleural effusion with pleural fissure lines; pulmonary parenchymal lesions (consolidation, atelectasis, masses) common; mediastinal lesions possible.
- Ultrasonography—pleural effusion; may show marked amount of fibrinous deposition in the pleural space; may identify consolidated lung masses, mediastinal masses, and abscessed or neoplastic lung nodules.
- CT—focal interstitial to alveolar pulmonary opacities; pleural thickening; enlarged intrathoracic lymph nodes; pleural effusion; pneumothorax; and foreign body identification.

DIAGNOSTIC PROCEDURES

Thoracocentesis

- Cytologic evaluation—necessary to confirm the diagnosis; many effusions appear grossly hemorrhagic.
- Gram stains—can facilitate early identification of pathogenic organisms.
- Sulfa granules (small accumulations of purulent debris) in the exudate—characteristic of infection by filamentous organisms (e.g., *Actinomyces* and *Nocardia*).
- Organisms are often seen on cytologic examination, often within degenerative neutrophils.
- The effusion is often malodorous, especially in cats.

Microbiology

- Culture fluid samples aerobically and anaerobically. Consider *Mycoplasma* culture if standard cultures are negative.
- Many of the filamentous, microaerophilic, and anaerobic organisms are slow-growing, so cultures should be maintained longer than standard samples.
- Sulfa granules—maceration may enhance culturing; contain higher concentrations of bacteria.
- Often mixed bacterial populations.
- Fungal organisms—culture depends on history and geographic location.
- Urine samples—culture with suspected pyelonephritis.

Esophagoscopy

- If *S. lupi* is suspected.

PATHOLOGIC FINDINGS

- Fibrinous and suppurative pleuritis, with or without pulmonary abscessation.
- Glomerulonephritis.
- Caudal vena-caval thrombosis (rare).

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient—often for several days to weeks.
- Treat like any abscess; drainage is critical, without which resolution is highly unlikely.
- Surgical exploration, debridement, and potential lobectomy required in some cases.

(CONTINUED)

PYOTHORAX**NURSING CARE**

- Continuous evacuation via tube thoracostomy with low-pressure suction through a perforated tube; use a large-bore tube to minimize occlusion; continue until net drainage is < 2–3 mL/kg/day and intracellular bacteria are no longer visible on gram stain; drainage may be slightly higher with red rubber tubes because they are more irritating.
- Cats—usually require general anesthesia for tube placement.
- Dogs with severe respiratory compromise—may substitute local anesthesia and regional analgesia for general anesthesia.
- Periodic thoracic radiography—to ensure proper tube placement, and lack of pocketing or loculation of exudate, determine whether bilateral tube placement is necessary; document primary pulmonary pathology that may not have been apparent on initial examination.
- Thoracic lavage—every 6–8 hours with warm, sterile saline; may help break down consolidated debris. Consider addition of heparin (1,500 units/liter) to lavage fluid.
- Coupage (rapid thoracic percussion)—may help remove consolidated debris.
- Repeat bacterial culture if the patient fails to improve.

ACTIVITY

- Inpatient—encourage light exercise (10 minutes every 6–8 hours); promotes ventilatory efforts and helps break down pleural adhesions.
- After discharge, gradually increase exercise over 2–4 months.

DIET

- High-calorie food
- Consider feeding tube placement if prolonged anorexia.

CLIENT EDUCATION

Warn client that the duration of treatment (inpatient and outpatient) is long and expensive; recurrence is possible with either medical or surgical management.

SURGICAL CONSIDERATIONS

- Surgery—higher cure rate expected with surgery if pulmonary abscessation, pleural fibrosis, lung-lobe torsion, extensive loculation of pus is present, or if mediastinum is involved.
- Thoracoscopy can be utilized as an intermediate step to assess degree of severity and need for more aggressive intervention.
- Identified foreign body via thoracic imaging (radiography, ultrasound, or CT)—thoracotomy and retrieval indicated; grass awns are uncommonly found, even during surgery.

**MEDICATIONS****DRUG(S) OF CHOICE****Antimicrobials**

- Ultimately, choice determined by results of in vitro sensitivity testing.
- Suspected specific pathogen—initiate treatment before culture

results are available; choose on the basis of common antibiotic sensitivities of particular organisms; *Actinomycetes* spp. and *Bacteroides* (non-*fragilis*) spp. often susceptible to amoxicillin; *Nocardia* spp. often susceptible to potentiated sulfonamides; obligate anaerobic bacteria (including *B. fragilis*) susceptible to amoxicillin-clavulanic acid, chloramphenicol, and usually metronidazole; *Pasteurella* spp. often susceptible to potentiated penicillins.

- Ampicillin or amoxicillin with a β -lactamase inhibitor—good initial choice for most patients; ampicillin and sulbactam (20 mg/kg IV q8h) followed by amoxicillin clavulanic acid (25 mg/kg PO q8h) when medications can be given orally.
- Trimethoprim-sulfa, aminoglycosides, and quinolones—generally ineffective.
- Multiple antibiotics occasionally necessary.
- Dosages are generally high (e.g., amoxicillin, 40 mg/kg PO q8h) to allow adequate distribution into the pleural cavity; may need to continue drug for several months and occasionally indefinitely.

Analgesics

- Required following thoracotomy or during thoracocentesis.
- Consider multimodal analgesia: systemic opioids, nonsteroidal anti-inflammatory drugs; intrapleural analgesia.

CONTRAINdications

Glucocorticoids and immunosuppressive agents—avoid with infectious pyothorax.

PRECAUTIONS

Potentiated sulfas—can be associated with keratoconjunctivitis sicca, polyarthropathy, hypothyroidism, thrombocytopenia, and anemia, especially with prolonged use.

**FOLLOW-UP****PATIENT MONITORING**

- Decreasing thoracic fluid production, decrease in cell count in pleural fluid, and absence of bacteria usually noted within 4–7 days indicate that drains can be removed. Fluid should be submitted for aerobic and anaerobic culture at the time of drain removal.
- Evaluate thoracic radiographs—ensure adequate evacuation of fluid.
- Antibiotics—continue for 1 month after the patient is clinically normal, the hemogram is normal, and there is no radiographic evidence of fluid reaccumulation; average duration of therapy is 3–4 months but may continue for 6–12 months or longer.
- Assess CBC and radiographs monthly—residual radiographic changes may be permanent, but fluid should be absent.

POSSIBLE COMPLICATIONS

- Incorrect insertion of the drainage tube—may prevent adequate drainage or produce pneumothorax; placement too far cranially may put pressure on brachial arteries

and veins, resulting in unilateral limb edema or lameness; lung laceration during placement.

- Persistent, recurrent pyothorax—compartmentalization of pus; premature discontinuation of treatment; pulmonary lesions.
- Chronic fibrosing pleuritis and poor performance after apparent recovery—may occasionally respond to further surgery.
- Persistent granulomatous mediastinitis.

EXPECTED COURSE AND PROGNOSIS

- With aggressive management—prognosis fair to excellent (60–90% survival).
- Dependent on severity of clinical signs.
- Overall better prognosis in dogs (83%) than in cats (62%).
- Return to performance—depends on chronicity of disease and level of management.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Retroperitoneal abscessation and discospondylitis caused by migration of a foreign body through the diaphragm into the retroperitoneal space—occasionally seen.
- Glomerulonephropathy—can be reversible with successful resolution of pyothorax.

ZOONOTIC POTENTIAL

Fungal infection during *in vitro* isolation.

SYNOMYS

- Empyema • Pleurisy • Suppurative pleuritis

SEE ALSO

PYRETHRIN AND PYRETHROID TOXICOSIS

BASICS

OVERVIEW

- Insecticides.
- Pyrethrins—natural.
- Pyrethroids—synthetic; include acrinathrin, allethrin, barthrin, bifenthrin, bioresmethrin, cismethrin, cypermethrin, dimethrin, deltamethrin, cyfluthrin, cyhalothrin, cyphenothrin, esfenvalerate, fenpropothrin, fenvalerate, flumethrin, fluvalinate, imiprothrin, permethrin, phenothrin, tefluthrin, tetramethrin, tralomethrin, and the ether etofenprox.
- Affect the nervous system—reversibly prolong sodium conductance in nerve axons, resulting in repetitive nerve discharges.
- Pyrethrin/pyrethroid exposures represent 45% of all insecticide-related calls to the ASPCA Animal Poison Control Center.

SIGNALMENT

Adverse reactions occur more frequently in cats; small dogs; and young, old, sick, anemic, or debilitated animals. Reactions may occur in cats through direct contact with permethrin spot-on treated dogs.

SIGNS

- Result from immune-mediated allergic hypersensitivity and anaphylactic reactions, genetic-based idiosyncratic reactions, and neurotoxic reactions.
- Mild—hypersalivation; paw flicking; ear twitching; mild depression; vomiting; diarrhea.
- Moderate—protracted vomiting and diarrhea; marked depression; ataxia; muscle tremors.
- Extreme dermal or oral overdose—may produce seizures or death.
- Cats—sensitive to pyrethroids. Cats inappropriately treated with permethrin-containing products for use on dogs, often develop muscle tremors, ataxia, seizures, hyperthermia, and death within hours if not treated.
- Dogs may develop tremors following exposure to liquid or granular lawn products containing bifenthrin.
- Allergic reactions—urticaria; hyperemia; pruritus; anaphylaxis; shock; respiratory distress; (rarely) death.

P

CAUSES & RISK FACTORS

- Cats—more sensitive; less-efficient metabolic pathways, combined with grooming habits.
- Patients with subnormal body temperatures after bathing, anesthesia, or sedation—predisposed to clinical signs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Exposure history (amount and frequency of product usage), type and severity of clinical signs, and onset and duration of clinical

signs—must be consistent before a tentative diagnosis can be made.

- Misapplication of permethrin-containing dog-only flea product on cats.
- Organophosphorous compounds, carbamate, or d-limonene toxicosis.
- Strychnine, metaldehyde, tremorgenic mycotoxins, methylxanthines, amphetamines, serotonergic drug overdose, alcohol intoxication from isopropyl alcohol-based sprays.

OTHER LABORATORY TESTS

- Pyrethrins—analytical tests not generally available.
- Pyrethroids—some compounds can be detected in tissues, especially on hair, to confirm exposure. Hair analysis for permethrin can be valuable when severity of the adverse event in cats is much greater than anticipated based on the reported product application. Cats with generalized full-body tremors or seizures after reported application of a cat-approved flea product are suspect for exposure to a permethrin-containing product.

TREATMENT

- Mild adverse reactions (salivation, paw flicking, and ear twitching)—often mild and self-limiting and resolve with no care.
- Patient saturated with spray products—dry with a warmed towel; brush.
- Continued mild signs—bathe at home with a mild hand dish-washing detergent (strictly avoid hypothermia).
- Progression to tremors and ataxia—hospitalize.
- Seriously affected patient—intravenous fluid support recommended.
- Maintenance of a normal body temperature—critical.
- Bathing upon stabilization (tremors controlled) with liquid hand dish-washing detergent and warm water is critical.

MEDICATIONS

DRUG(S)

- Tremors or seizures—especially for cats exposed to permethrin; methocarbamol (Robaxin-V injectable at 55–220 mg/kg IV not to exceed 330 mg/kg/day; administer one-half dose slowly IV, wait until the patient begins to relax, continue administration to effect; do not exceed 2 mL/minute injection rate, and start with lower dose initially).
- Diazepam at low dosages has been used to control minor hyperesthesia. Seizure control has been achieved with pentobarbital, propofol (3–6 mg/kg IV or 0.1 mg/kg/min CRI) and inhalant anesthetics.

Methocarbamol remains the agent of choice and can also be used orally for treating mild tremors (50–100 mg/kg q8h; 30 minutes onset time).

- Activated charcoal (2 g/kg PO) is rarely beneficial or recommended.
- Emetics—rarely warranted.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Atropine sulfate—not antidotal; avoid; may cause tachycardia, CNS stimulation, disorientation, drowsiness, respiratory depression, and even seizures.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Proper application of flea-control products—greatly reduces reactions.
- Reduction of salivation—spray onto a grooming brush; evenly brush through hair coat.
- Liquids—term *dip* common; never submerge animal; pour on body; sponge to cover dry areas.
- Premise products—do not apply topically unless labeled for such use; after treating house or yard, do not allow animal in the area until product has dried and environment has been ventilated.
- Do not apply dog-only products on cats.
- Do not use permethrin spot-on products on dogs in households where cats groom or sleep in physical contact with dogs.

EXPECTED COURSE AND PROGNOSIS

- Hypersalivation—may recur for several days after use of flea-control product when patient (especially cat) grooms itself.
- Most clinical signs (mild to severe) resolve within 24–72 hours.

PYRUVATE KINASE DEFICIENCY

BASICS

OVERVIEW

- RBCs require energy in the form of ATP for maintenance of shape, deformability, active membrane transport, and limited synthetic activities; mature RBCs lack mitochondria and depend on anaerobic glycolysis for ATP generation.
- PK catalyzes an important rate-controlling, ATP-generating step in glycolysis; consequently, energy metabolism is markedly impaired in PK-deficient RBCs, resulting in shortened RBC lifespan and anemia; bone marrow attempts to compensate by erythroid hyperplasia, with marked reticulocytosis in peripheral blood.

SIGNALMENT

- Autosomal recessive trait recognized in basenji, beagle, West Highland white terrier, cairn terrier, miniature poodle, dachshund, Chihuahua, pug, American Eskimo, and Labrador retriever dogs, and in Abyssinian, Somali, and domestic shorthair cats.
- Affected homozygous animals generally not recognized as abnormal until several months of age or adulthood.

SIGNS

- Affected cats are often asymptomatic.
- Lethargy or exercise intolerance.
- Pale mucous membranes.
- Often splenomegaly.
- Tachycardia.
- Systolic heart murmurs reported in dogs.
- Icterus is occasionally seen in cats but rarely seen in dogs.
- Affected dogs may be slightly smaller than normal for their breed and age and may exhibit weakness and muscle wasting.
- Affected cats may exhibit diarrhea, inappetence, poor coat quality, and weight loss.

CAUSES & RISK FACTORS

- RBCs from normal adult dogs exhibit only one PK isozyme (the R-type).
- Breed-specific defects in the *PKLR* gene result in erythrocyte PK deficiency in dogs.
- A common molecular defect has been described in cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of hemolytic anemia—immune-mediated hemolytic anemia, hemotropic mycoplasmosis, babesiosis, Heinz body hemolytic anemia, microangiopathic hemolytic anemia, and phosphofructokinase deficiency (dogs).
- Affected animals—negative Coombs' test, no parasites or Heinz bodies in stained blood films, seronegative for *Babesia* spp., and no evidence of DIC or heartworm disease.
- In contrast to phosphofructokinase deficiency, PK-deficient

dogs do not exhibit episodes of intravascular hemolysis and hemoglobinuria; these deficiencies are differentiated by specific enzyme assays or DNA tests.

CBC/BIOCHEMISTRY/URINALYSIS

- Persistent macrocytic hypochromic anemia, with HCT values of 16–28% and uncorrected reticulocyte counts of 15–50% in dogs.
- Anemia is intermittent (HCT 13–40%), with slightly to markedly increased aggregate reticulocyte counts in cats.
- Normal or slightly high total leukocyte counts.
- Normal to slightly high platelet count.
- Moderate to marked polychromasia, anisocytosis, and increased nucleated RBCs on stained blood films.
- Poikilocytosis reported in splenectomized dogs.
- Possible abnormal clinical chemistry findings, such as hyperferremia, hyperbilirubinemia, and slightly high ALT and ALP activities; hyperglobulinemia common in cats; dogs with liver failure may have hypoalbuminemia.
- Normal urinalysis, except for bilirubinuria in dogs.

OTHER LABORATORY TESTS

- Total RBC PK activity—low value diagnostic in cats and some dogs; many affected dogs have normal or high activities because of the expression of an M2 isozyme that does not normally occur in mature RBCs; approximately 50% of normal activity in heterozygous animals.
- Additional assays (e.g., enzyme heat stability test, measurement of RBC glycolytic intermediates, electrophoresis of isozymes, and enzyme immunoprecipitation)—to reach a diagnosis in dogs whose total enzyme activity is not low.
- DNA diagnostic tests—for screening several breeds.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Affected animals can only be cured by bone marrow transplantation.
- Splenectomy may reduce the severity of the anemia in cats.

MEDICATIONS

DRUG(S)

Although not adequately evaluated, long-term treatment with iron-chelating drugs might prolong the life expectancy of an affected dog.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None

FOLLOW-UP

- Hepatic iron overload—develops in affected dogs; can result in cirrhosis and liver failure.
- Myelofibrosis and osteosclerosis—develop in affected dogs with age; thus most die by 5 years of age as a result of bone marrow or liver failure.
- Severe anemia with minimal reticulocytosis or abnormal liver function tests and ascites secondary to hypoalbuminemia indicate the terminal stage of the disease in dogs.
- Extrahepatic biliary obstruction with bilirubin cholelithiasis has been reported in two cats.

PYTHIOSIS

BASICS

DEFINITION

An infectious disease primarily affecting the skin or GI tract of dogs and cats. It is caused by the aquatic pathogen *Pythium insidiosum*, an organism in the class Oomycetes.

PATHOPHYSIOLOGY

- The infective form of *P. insidiosum* is thought to be the motile biflagellate zoospore, which is released into warm water environments and is chemotactically attracted to damaged tissue and animal hair. Animals are likely infected when they enter or ingest water that contains infective zoospores.
- P. insidiosum* is considered a pathogenic rather than opportunistic organism because immune suppression is not a prerequisite for infection.
- In the GI tract, *P. insidiosum* infection causes chronic pyogranulomatous disease manifested by severe segmental transmural thickening of one or more areas of the stomach or intestine.
- In the skin, pythiosis typically results in the development of non-healing wounds and invasive masses that contain ulcerated nodules and draining tracts.

SYSTEMS AFFECTED

GI and cutaneous forms of the disease are encountered with equal frequency in the dog. In cats, which are infrequently infected, the cutaneous form is more common. With the exception of occasional dissemination to regional lymph nodes, pythiosis usually affects only one body system in each patient.

- GI pythiosis most often affects the gastric outflow region, proximal small intestine, ileocolic junction, or colon. The surrounding mesentery is often involved. Rarely, the esophagus may be affected.
- In dogs with GI disease, *P. insidiosum*-induced local thromboembolic events or vascular invasion may lead to bowel wall ischemia and GI perforation or hemoabdomen.
- Dogs with cutaneous pythiosis most often are presented for solitary or multiple cutaneous or subcutaneous lesions involving the extremities, tailhead, ventral neck, or perineum.
- In cats, cutaneous lesions or subcutaneous masses involving retrobulbar, periorbital, or nasopharyngeal regions, the tailhead, or the footpads have been observed.

GI lesions are rare in cats.

- Multisystemic involvement is rare.

GENETICS

Although large-breed dogs are most often affected, no genetic predisposition has been documented.

INCIDENCE/PREVALENCE

- Dependent on geographic distribution.
- Affected animals more often are presented for signs of disease in the fall or early winter months.

GEOGRAPHIC DISTRIBUTION

Disease caused by *P. insidiosum* occurs primarily in tropical and subtropical areas of the world.

- In the United States, pythiosis occurs most often in states bordering the Gulf of Mexico; however, it has also been documented in Oklahoma, Arkansas, Missouri, Kentucky, Tennessee, North and South Carolina, Virginia, southern Indiana, New Jersey, Arizona, Wisconsin, and California.
- Outside the United States, pythiosis has been reported in Australia, Brazil, Burma, Colombia, Costa Rica, Indonesia, Japan, New Guinea, and Thailand.

SIGNALMENT

Species

Dog and less commonly cat

Breed Predilections

- Large-breed dogs, especially those used in hunting or field trial work near water.
- Labrador retrievers are overrepresented.
- German shepherds may be predisposed to cutaneous pythiosis.

Mean Age and Range

Animals < 6 years old are most likely to be infected.

Predominant Sex

Males are affected more often than females, possibly because of increased exposure.

SIGNS

General Comments

Affected dogs are not usually severely ill until late in the course of disease.

Historical Findings

- Chronic weight loss and intermittent vomiting are the most common signs.
- Diarrhea may be evident if the colon or a large segment of the small intestine is affected.
- Regurgitation is noted with esophageal disease.
- Cutaneous disease is characterized by non-healing wounds with nodules that ulcerate and drain.

Physical Examination Findings

GI Pythiosis

- Emaciation is common.
- An abdominal mass is often palpable.
- Despite severe weight loss, affected dogs are usually bright and alert.
- Fever is usually absent.
- Systemic signs and abdominal pain may occur with intestinal obstruction, infarction, or perforation.

Cutaneous Pythiosis

- Cutaneous or subcutaneous lesions appear as non-healing wounds; boggy, edematous regions; or poorly defined nodules that become ulcerated.
- Multiple tracts draining a serosanguineous or purulent exudate often are present.

CAUSES

P. insidiosum

RISK FACTORS

- Environmental exposure to swampy areas, bayous, ponds, or lakes containing infective

zoospores.

- Outdoor activities such as hunting.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

GI Pythiosis

- Intestinal obstruction caused by a foreign body or chronic intussusception.
- Histoplasmosis.
- Gastric or intestinal lymphosarcoma.
- Gastric carcinoma.
- Other GI neoplasia.
- Inflammatory bowel disease.
- Basidiobolomycosis, protothecosis.
- Histiocytic or idiopathic colitis.

Cutaneous Pythiosis

- Lagenidiosis (caused by oomycotic pathogens in the genus *Lagenidium*).
- Zygomycosis (infections caused by *Basidiobolus* or *Conidiobolus* spp.).
- Other mycotic skin diseases, such as cryptococcosis, coccidioidomycosis, sporotrichosis, eumycotic mycetoma, and phaeohyphomycosis.
- Nodular bacterial skin diseases, such as actinomycosis, mycobacteriosis, botryomycosis, and brucellosis.
- Protothecosis or nodular leishmaniasis.
- Non-infectious pyogranulomatous diseases, such as foreign-body reaction, idiopathic nodular panniculitis, sebaceous nodular adenitis, and canine cutaneous sterile pyogranuloma/granuloma syndrome.
- Cutaneous neoplasia.
- Systemic vasculitis and cutaneous embolic disease.

CBC/BIOCHEMISTRY/URINALYSIS

- Laboratory findings are nonspecific.
- Eosinophilia, leukocytosis, and anemia of chronic disease may occur.
- Hyperglobulinemia and/or hypoalbuminemia may be noted in chronically affected dogs.
- Hypokalemia, hyponatremia, hypochloridemia, and metabolic alkalosis may be noted in dogs with gastric outflow obstruction.
- Hypercalcemia was reported in a single affected dog.
- Urinalysis usually normal.

OTHER LABORATORY TESTS

Serology—a sensitive and specific ELISA test for anti-*Pythium* antibody is available at Auburn University College of Veterinary Medicine.

IMAGING

- Abdominal radiography may reveal an obstructive pattern, bowel wall thickening, or abdominal mass.
- Abdominal ultrasonography may reveal segmental transmural thickening of the stomach, proximal small intestine, or ileocolic junction. Granulomas or enlarged lymph nodes may be evident in the mesentery.

DIAGNOSTIC PROCEDURES

- Biopsy of gastrointestinal or skin lesions demonstrates histologic changes that are

(CONTINUED)

PYTHIOSIS

suggestive of, but not definitive for, pythiosis. • Definitive diagnosis is based on serology or culture; tissue samples should be submitted to an experienced laboratory via overnight shipping at room temperature. • A nested PCR assay can be used for the definitive identification of cultured isolates or organisms in tissue samples.

PATHOLOGIC FINDINGS

- Histologically, GI and skin lesions are characterized by pyogranulomatous and eosinophilic inflammation associated with broad (4–6 micron), irregularly branching, infrequently septic hyphae with thick, non-parallel walls. • Predominance of eosinophils within the inflammatory reaction helps to differentiate pythiosis, lagenidiosis, and zygomycosis from other mycotic infections. • Hyphal organisms are usually not visible on hematoxylin and eosin-stained sections, but are readily visualized with a silver stain. • Dogs with GI lesions typically have severe segmental thickening of portions of stomach and/or bowel, often with obstruction of the intestinal lumen. • Mesenteric lymphadenopathy is often noted, but the presence of *P. insidiosum* hyphae within lymph nodes is uncommon. • Histologically, GI pythiosis is characterized by eosinophilic and pyogranulomatous inflammation with necrotic foci and discrete granulomas that contain hyphae.

**TREATMENT****APPROPRIATE HEALTH CARE**

The treatment of choice is aggressive surgical excision of all infected tissue. Unfortunately, many animals are not presented to the veterinarian until late in the disease, when complete resection is not possible.

NURSING CARE

Supportive care should include fluids, potassium, and nutritional support. Antibiotics may be indicated to treat secondary pyoderma in dogs with cutaneous lesions.

ACTIVITY

Limit activity

DIET

Feed a highly digestible, calorie-dense diet

CLIENT EDUCATION

- Treatment is expensive. • Prognosis is guarded to poor unless a complete resection is feasible.

SURGICAL CONSIDERATIONS

- Attempt wide surgical excision to obtain 5- to 6-cm margins even if medical therapy is contemplated. • Amputation is recommended for treatment of extremity lesions. • Enlarged

mesenteric lymph nodes should be biopsied but often do not contain infective hyphae, thus do not have to be removed. • Dogs often improve after obstructive lesions are resected, even if significant disease is still grossly evident. • Postoperative medical therapy with itraconazole and terbinafine (see below) for 2–3 months may decrease the chance of recurrence. • Reevaluation of ELISA serology 2–3 months after surgery is an excellent prognostic indicator.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Itraconazole (10 mg/kg PO daily) combined with terbinafine (10 mg/kg PO daily) appears to be most effective. Although controlled studies have not been performed, the efficacy of this combination is probably < 10% in dogs with non-resectable or partially resectable lesions. • Prednisone (1–2 mg/kg PO daily and then tapered over 2–3 months) added to antifungal drugs may improve clinical outcome. • Medical therapy should be continued for a minimum of 6 months.
- Give itraconazole with food.

PRECAUTIONS

- Azole drugs should not be used in animals with severe liver disease. • Anorexia, high liver enzymes, and cutaneous vasculitis are the most common adverse effects of itraconazole.

POSSIBLE INTERACTIONS

Antacids and anticonvulsants may decrease blood levels of itraconazole.

ALTERNATIVE DRUG(S)

Prednisone (1–2 mg/kg PO daily and then tapered over several months) routinely improves clinical signs in the short term. In addition, the author has observed complete long-term resolution of clinical signs in a small number of dogs with GI pythiosis treated with prednisone alone. This is not recommended as a primary treatment for dogs with resectable lesions, but should be considered as palliative therapy in dogs with nonresectable disease.

**FOLLOW-UP****PATIENT MONITORING**

- ELISA serology can be used to monitor response to therapy; serology should be checked 2–3 months after surgery or every 3 months during medical therapy.
- Abdominal ultrasonography is useful in reevaluating intestinal lesions. • Liver enzymes should be evaluated monthly while patient is on itraconazole.

PREVENTION/AVOIDANCE

Monitor for signs of recurrence.

POSSIBLE COMPLICATIONS

Acute abdomen and death from GI thrombosis and perforation

EXPECTED COURSE AND PROGNOSIS

Prognosis is guarded to poor unless a complete resection is possible.

**MISCELLANEOUS****AGE-RELATED FACTORS**

Young animals are predisposed.

ZOONOTIC POTENTIAL

Infections in humans are very rare and are from a common environmental source. There is no evidence of direct transmission from animals to humans.

PREGNANCY/FERTILITY/BREEDING

Azole antifungals are teratogenic and should not be used in pregnant animals.

SYNONYMS

- Phycomycosis • Swamp Cancer

ABBREVIATIONS

- ELISA = enzyme-linked immunosorbent assay • GI = gastrointestinal • PCR = polymerase chain reaction

P

PYURIA

BASICS

DEFINITION

- WBCs (i.e., neutrophils, eosinophils, monocytes, lymphocytes, or plasma cells) in urine.
- More than 5 WBCs per high-power field is generally considered abnormal, but the number of WBCs found in urinary sediment varies with method of collection, sample volume and concentration, degree of cellular destruction after collection, and laboratory technique.

PATHOPHYSIOLOGY

- Large numbers of WBCs in voided urine samples indicate active inflammation somewhere along the urogenital tract.
- Can be associated with any pathologic process (infectious or non-infectious) that causes cellular injury or death; tissue damage evokes exudative inflammation characterized by evidence of leukocytic extravasation (pyuria) and increased vascular permeability (hematuria and proteinuria).

SYSTEMS AFFECTED

- Renal/Urologic—urethra, urinary bladder, ureters, and kidneys
- Genital—prepuce, prostate, vagina, and uterus

SIGNALMENT

Dog and cat

SIGNS

General Comments

- Inflammation can cause clinical signs localized to the site(s) of injury or may be accompanied by systemic manifestations. Historical and physical examination findings depend on the underlying cause, organ(s) affected, degree of organ dysfunction, and magnitude of systemic inflammatory responses.
- Non-obstructive lesions confined to the urinary bladder, urethra, vagina, or prepuce rarely cause systemic signs of inflammation. Systemic signs may accompany generalized inflammatory lesions of the kidneys, prostate, or uterus.

Physical Examination Findings

Local Effects of Inflammation

- Erythema of mucosal surfaces—e.g., redness of vaginal or preputial mucosa
- Tissue swelling—e.g., renomegaly, prostatomegaly, mural thickening of urinary bladder or urethra
- Exudation of leukocytes and protein-rich fluid—e.g., pyuria, purulent urethral or vaginal discharge, pyometra, or prostatic abscess
- Pain—e.g., adverse response to palpation, dysuria, pollakiuria, stranguria
- Loss of function—e.g., polyuria, dysuria, pollakiuria, urinary incontinence

Systemic Effects of Inflammation

- Fever
- Depression
- Anorexia
- Dehydration

CAUSES

Kidney

- Pyelonephritis—e.g., bacterial, fungal, parasitic, or mycoplasmal
- Nephrolith(s)
- Neoplasia
- Trauma
- Immune-mediated

Ureter

- Ureteritis—e.g., bacterial
- Ureterolith(s)
- Neoplasia

Urinary Bladder

- Cystitis—e.g., bacterial, mycoplasmal, fungal, or parasitic
- Urocystolith(s)
- Neoplasia
- Trauma
- Overdistension—urethral obstruction
- Pharmacologic—cyclophosphamide

Urethra

- Urethritis—e.g., bacterial, fungal, or mycoplasmal
- Urethrolith(s)
- Neoplasia
- Trauma
- Foreign body

Prostate

- Prostatitis/abscess—e.g., bacterial or fungal
- Neoplasia

Penis/Prepuce

- Balanoposthitis
- Neoplasia
- Foreign body

Uterus

Pyometra/metritis—e.g., bacterial

Vagina

- Vaginitis—bacterial, mycoplasmal, viral, or fungal
- Neoplasia
- Foreign body
- Trauma

RISK FACTORS

- Any disease process, diagnostic procedure, or therapy that alters normal host urinary tract defenses and predisposes to infection.
- Any disease process, dietary factor, or therapy that predisposes to formation of metabolic uroliths.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Voided Specimens

- Rule out vaginitis—signs include vaginal discharge, erythema of vaginal mucosa, licking of vulva, and attracting male dogs.
- Rule out pyometra, metritis—signs include vaginal discharge, large uterus, pyrexia, depression, anorexia, polyuria, polydipsia, and a recent history of estrus, parturition, or progestin administration.
- Rule out balanoposthitis—signs include preputial discharge, erythema of preputial or penile mucosa, and licking of prepuce.
- Rule out prostatitis, prostatic abscess, or prostatic neoplasia—signs include urethral discharge, prostatomegaly, pyrexia, depression, dysuria, tenesmus, caudal abdominal pain, and stiff gait.
- Rule out urethritis, urethroliths, urethral neoplasms—signs include dysuria, pollakiuria, stranguria, and/or palpable uroliths or mass lesions in the urethra.
- Rule out inflammatory disorders of urinary bladder and kidneys.

Specimens Collected by Cystocentesis

- Rule out urethral obstruction—signs include stranguria, anuria, and a large overdistended urinary bladder.
- Rule out prostatic and urethral disorders (see above); purulent prostatic or urethral exudates can reflux into the urinary bladder.
- Rule out cystitis, urocystoliths, and urinary bladder neoplasia—signs may include dysuria, pollakiuria, stranguria, and/or palpable uroliths or mass lesions in the urinary bladder.
- Rule out pyelonephritis—signs may include pyrexia, depression, anorexia, polyuria, polydipsia, renal pain, and renomegaly.
- Rule out post-traumatic pyuria—signs may include history of trauma, including iatrogenic causes.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

- WBCs lyse rapidly in hypotonic or alkaline urine. Administration of alkalinizing agents (e.g., sodium bicarbonate, potassium citrate, chlorothiazide, or acetazolamide) or agents that produce hypotonic urine (e.g., diuretics and glucocorticoids) may falsely decrease urine WBC numbers.
- Leukocyte esterase reagent strip (dipstick) methods are not recommended for use in canine (not sensitive) or feline (not specific) urine samples. In addition, nitrofurantoin, cephalosporins, and gentamicin can cause false-positive leukocyte esterase reactions.
- Urinary WBC concentrations can be low in patients with inflammatory disorders who have been given steroidal or nonsteroidal anti-inflammatory drugs.

Disorders That May Alter Laboratory Results

- Disorders associated with diminished WBC function or absolute neutropenia can artificially lower WBC values.
- Disorders associated with production of hypotonic urine or alkaline urine artificially lower WBC values.

Miscellaneous Factors That May Alter Laboratory Results

- False-negative leukocyte esterase reaction in dogs when urine is tested by the reagent strip (dipstick) method.
- False-positive and false-negative leukocyte esterase reaction in cats when urine is tested by the reagent strip (dipstick) method.

Valid if Run in Human Laboratory?

Valid if urinary sediment is examined microscopically; invalid if only leukocyte esterase reagent strip (dipstick) method is used.

CBC/BIOCHEMISTRY/URINALYSIS

- Pyuria in specimens collected by voiding, manual compression, or transurethral catheterization indicates an inflammatory lesion involving at least the urinary or genital tracts.
- Pyuria in specimens collected by cystocentesis localizes the site of inflammation

(CONTINUED)

PYURIA

to at least the urinary tract, but does not exclude the urethra and genital tract. Reflux of prostatic exudates into the urinary bladder may result in pyuria in patients with prostatic disease. • Pyuria associated with WBC casts is unequivocal evidence of renal parenchymal inflammation. • Generalized renal injury may be associated with concomitant leukocytosis, isosthenuria, and azotemia. • Pyuria associated with bacteria, fungi, or parasite ova in sufficient numbers to be seen by microscopic sediment examination indicates that the inflammatory lesion was caused or complicated by urinary tract infection. Detection of bacteria in urine sediment by light microscopy may be enhanced by placing a drop (20 µL) of urine sediment on a glass slide, allowing it to dry without spreading, staining with Diff-Quik and examining for bacteria under oil immersion (1,000 ×).

- Pyuria associated with neoplastic cells indicates neoplasia. Diagnosis of urinary tract neoplasia by cytologic examination of urine may be complicated by epithelial cell hyperplasia and atypia caused by urinary tract inflammation or the physicochemical properties of urine (pH and tonicity causing cell scalding).

OTHER LABORATORY TESTS

- Perform quantitative urine culture on all patients with pyuria; it provides the most definitive means of identifying and characterizing bacterial urinary tract infection. It is important to note that the absence of pyuria does not rule out the bacteriuria as patients with bacteriuria frequently do not have pyuria. • Negative urine culture results suggest a non-infectious cause of inflammation (e.g., uroliths, neoplasia) or inflammation associated with urinary tract infection caused by fastidious organisms (e.g., mycoplasmas and viruses) or by organisms capable of forming intracellular bacterial colonies or biofilms. False-negative culture results may also be due to recent antimicrobial therapy, sample mishandling, or delays between specimen collection and culture. • Cytologic evaluation of urinary sediment, prostatic fluid, urethral or vaginal discharges, or biopsy specimens obtained by catheter or needle biopsy may help evaluate patients with localized urinary or genital tract disease. Cytologic examination may establish a definitive diagnosis of urinary tract neoplasia, but negative cytologic findings do not rule out neoplasia.

IMAGING

Survey abdominal radiography, contrast urethrocystography and cystography, urinary tract ultrasonography, and excretory urography are important means of identifying and localizing underlying causes.

DIAGNOSTIC PROCEDURES

- Urethrocystoscopy—indicated in patients with persistent lesions of the lower urinary tract for which a definitive diagnosis has not been established by other, less invasive, means. • Light microscopic evaluation of tissue specimens—indicated in patients with lesions of the urinary or genital tracts for which a definitive diagnosis has not been established by other, less invasive, means; tissue specimens may be obtained by membrane disruption (traumatic) catheterization biopsy, cystoscopy and forceps biopsy, or exploratory laparotomy; aspiration and punch biopsy techniques may be used to evaluate the prostate gland.

**TREATMENT**

- Treatment varies, depending on the underlying cause and specific organs involved.
- Pyuria associated with systemic signs of illness (i.e., pyrexia, depression, anorexia, vomiting, dehydration, leukocytosis, polyuria, and polydipsia) or urinary obstruction warrants aggressive diagnostic evaluation and initiation of specific, supportive, and/or symptomatic treatment.

**MEDICATIONS****DRUG(S)**

Depend on underlying cause

CONTRAINDICATIONS

- Avoid glucocorticoids or other immunosuppressive agents in patients suspected of having urinary or genital tract infection. • Avoid potentially nephrotoxic drugs (e.g., gentamicin) in febrile, dehydrated, or azotemic patients and those suspected of having pyelonephritis, septicemia, or pre-existing renal disease.

**FOLLOW-UP****PATIENT MONITORING**

Response to treatment by serial urinalyses, including examination of urine sediment; collect specimens from most patients by cystocentesis to avoid contamination by preputial or vaginal exudates; perform transurethral catheterization if the expected benefits outweigh the risk of iatrogenic bacterial urinary tract infection.

POSSIBLE COMPLICATIONS

- Infectious and non-infectious inflammatory disorders of the urinary tract can cause primary renal failure, urinary obstruction, uremia, septicemia, and death. • Pyuria is a potential risk factor for formation of matrix or matrix-crystalline urethral plugs and subsequent urethral obstruction in male cats.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Hematuria • Proteinuria • Bacteriuria

SYNOMYMS

Leukocyturia

SEE ALSO

Q FEVER

BASICS

OVERVIEW

- Caused by the zoonotic rickettsia *Coxiella burnetii*.
- Infection—most commonly by inhalation or ingestion of organisms while feeding on infected body fluids (urine, feces, milk, or parturient discharges), tissues (especially placenta), or carcasses of infected animal reservoir hosts (cattle, sheep, goats); can occur after tick exposure (many species of ticks implicated).
- Lungs—thought to be main portal of entry to systemic circulation.
- Organism replicates in vascular endothelium; causes widespread vasculitis; severity depends on the pathogenicity of the strain of organism; vasculitis results in necrosis and hemorrhage in lungs, liver, and CNS.
- An extended latent period exists after recovery until chronic immune-complex phenomena develop; organism reactivated out of the latent state during parturition, resulting in large numbers entering the placenta, parturient fluids, urine, feces, and milk.
- Endemic worldwide. Most cases in the United States occur in western states.

SIGNALMENT

Cats and dogs of any age, sex, or breed.

SIGNS

Historical Findings

- Often a history of contact with farm animals or ticks.
- Fever.
- Lethargy.
- Depression.
- Anorexia.
- Abortion—especially cats.
- Ataxia and seizures—especially dogs.

Physical Examination Findings

- Usually asymptomatic.
- Splenomegaly is often the only clinical finding.
- Multifocal neurologic signs—dogs.

CAUSES & RISK FACTORS

- *C. burnetii*.
- Exposure to infected animals (especially following parturition) and ticks.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cats—other causes of abortion: infections (viral rhinotracheitis, panleukopenia, FeLV,

toxoplasmosis, bacteria including coliforms, streptococci, staphylococci, salmonellae); fetal defects; maternal problems (nutrition, genital tract abnormalities); environmental stress; endocrine disorders (hypoluteidism).

- Dogs—other causes of encephalitis.

CBC/BIOCHEMISTRY/URINALYSIS

Nonspecific

OTHER LABORATORY TESTS

Serology

- Serology—IF and ELISA methods are available; a four-fold increase in IgG titer over a 4-week period is diagnostic; the use of newer serologic techniques that measure IgM on one sample have not been well documented in small animals.
- Collect 2–3 mL of serum and refrigerate, for organism identification.
- Collect tissue sample (e.g., placenta) and refrigerate, for animal inoculation.
- Tests available from the New Mexico Department of Agriculture, Veterinary Diagnostic Services, 700 Camino de Salud NE, Albuquerque, NM 87106.
- PCR—also performed by above laboratory; used to detect organisms in tissue culture or tissue specimens derived from the patient.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Alert client of possible zoonotic risk.
- Inpatient—avoids zoonotic risk to client.
- Wear gloves and masks when treating an infected animal or when attending an aborting cat.

MEDICATIONS

DRUG(S)

- Tetracycline 22 mg/kg PO q8h for 2 weeks.
- Doxycycline 20 mg/kg PO q12h for 1 week.
- Enrofloxacin 10 mg/kg PO q12h for 1 week; should be effective but no clinical reports; effective in vitro.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Tetracycline drugs are associated with yellowing of teeth in young animals; do not use in animals with renal failure.

- Doxycycline may cause esophagitis and stricture.

- Enrofloxacin may cause cartilage defects in young animals.

- Enrofloxacin may cause retinal degeneration when used in cats with concurrent liver or kidney disease or at high doses.

FOLLOW-UP

- Difficult to determine success of therapy because many animals spontaneously improve.
- Even asymptomatic cases should be aggressively treated because of the zoonotic potential.
- Utility of predicting success of therapy based on serologic improvement unknown.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Major zoonotic potential.
- By the time a diagnosis is made in a cat or dog, human exposure and infection have occurred.
- Instruct owners and people in contact with the pet to seek medical advice immediately.
- Humans contract the disease by inhaling infected aerosols (e.g., after parturition); children commonly infected from ingesting raw milk but are usually asymptomatic.
- Previous urban outbreaks have been related to exposure to infected cats.
- Incubation period from time of contact until the first signs of illness—5–32 days.
- Person-to-person transmission possible.

ABBREVIATIONS

- CNS = central nervous system
- ELISA = enzyme-linked immunosorbent assay
- FeLV = feline leukemia virus
- IF = immunofluorescence
- PCR = polymerase chain reaction

Consulting Editor Stephen C. Barr

QUADRIGEMINAL CYST

BASICS

OVERVIEW

- CSF-filled diverticula within the subarachnoid space at the quadrigeminal cisterna (dorsal to the midbrain and adjacent to the third ventricle). CSF may be secreted by the arachnoid cells lining the cyst cavity. It is suspected that an anomaly of CSF flow from the choroid plexus during the stage of development forces a separation within the arachnoid layer.
- Clinical signs may develop as a result of gradual expansion of the subarachnoid space by a valve mechanism associated with pulsating CSF flow.
- May be an incidental finding.

SIGNALMENT

Dog and cat

Breed Predilections

Mainly in small breeds and brachycephalic patients—Shih Tzu, Maltese, Pug, Cavalier King Charles, Yorkshire terrier, Lhasa Apso, Chihuahua, Pekingese, Pomeranian and Bulldog.

Mean Age and Range

- Mean—5 years
- Range—2 months–10 years

SIGNS

- Seizures.
- Abnormal behavior.
- If associated with hydrocephalus, could manifest with disorientation, behavioral changes, cortical blindness, compulsive circling, head pressing.

CAUSES & RISK FACTORS

- Disturbance of embryogenesis where splitting of the primitive arachnoid membrane leads to fluid accumulation.
- Inflammatory conditions affecting the meninges.
- Post-surgical trauma (intervertebral disc disease, spinal tumor).
- Neoplasia and hemorrhage.
- Intracystic hemorrhage secondary to trauma may result in expansion of the cyst and subsequent compression of the adjacent brain parenchyma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congenital brain anomalies (anencephaly, hydrocephalus, other).
- Storage disease.
- Infectious inflammatory diseases—viral (distemper virus, other viruses); fungal (*Blastomyces dermatitidis*, *Coccidioides* spp., *Cryptococcus neoformans*); rickettsial (*Rickettsia rickettsii*); bacterial (*Ehrlichia* spp., *E. coli*, *Streptococcus*); protozoal (*Neospora caninum*, *Toxoplasma gondii*).
- Other inflammatory disease—breed-related encephalitis (necrotizing encephalitis of the Yorkshire terrier, Maltese, and Pug).
- Brain tumor—

meningioma, glioma, choroid plexus papilloma, lymphoma.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

IMAGING

- MRI—extra-axial CSF-filled cyst at the quadrigeminal cisterna. On T1-weighted images, the lesion is hypointense to brain tissue and isointense to CSF. On T2-weighted images, the lesion is hyperintense to brain tissue and isointense to CSF. On fluid attenuated inversion recovery (FLAIR) sequences, the cyst is hypointense, confirming the presence of CSF. Dilation of the ventricular system may be present if the cyst is obstructing CSF flow.
- MRI may reveal other compressive, parenchymal (syringohydromyelia) or space occupying lesions.

DIAGNOSTIC PROCEDURES

CSF—rule out concomitant inflammation. If CSF inflammatory, the cyst may be an incidental finding.

TREATMENT

- Medical therapy to control seizures and reduce CSF production.
- If signs are progressive, surgical cyst fenestration through craniotomy or craniectomy can result in clinical improvement. When hydrocephalus is present surgical shunting can be considered.
- Other disease process must be ruled out before considering surgery. The cystic structure may be an incidental finding.
- Stable patients can be discharged with recommended medical therapy.
- Inpatient—for severely affected dogs; monitor patient closely to assess progression of neurologic deficits.
- Sequential assessment of pupillary size and reaction to light, and mentation are helpful to determine risk of brain herniation.

MEDICATIONS

DRUG(S)

- Glucocorticosteroids—dexamethasone 0.1 mg/kg IV or PO q24h for 3 days followed by prednisone 0.25–0.5 mg/kg PO q24h for 10 days, then reassess response and adjust dose. To prevent gastrointestinal ulceration, add omeprazole 0.5 mg/kg PO q 24h or famotidine 0.5–1 mg/kg IV or PO q12h to steroid therapy.
- Antiepileptic drugs—phenobarbital 2 mg/kg IV or PO q12h, levetiracetam 20 mg/kg PO q8–12h or zonisamide 5–10 mg/kg PO q12h.
- Diuretic—acetazolamide 10 mg/kg q6–8h as a carbonic anhydrase inhibitor that may help reduce CSF production and intracranial pressure. Omeprazole may act as an agent to

reduce CSF production and provide gastric protection during steroid therapy.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Do not use acetazolamide in dehydrated patients.
- The combination of glucocorticosteroid and diuretic may cause marked dehydration and increased blood viscosity that can result in poor cerebral perfusion and neurologic deterioration.

FOLLOW-UP

PATIENT MONITORING

- Repeat neurologic examination periodically (every 2–4 weeks).
- Corticosteroid may be necessary for a long period or for life. The goal is to find the dose that keeps the clinical signs controlled with minimal side effects.
- Evaluate phenobarbital levels after 4–5 weeks of starting therapy.
- If phenobarbital is continued, recheck biochemical profile and bile acids to assess hepatic function every 6 months.

POSSIBLE COMPLICATIONS

- Deterioration of clinical signs despite aggressive treatment.
- Status epilepticus, dementia, brain herniation, and death.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is variable depending on severity of clinical signs and response to therapy.
- Quadrigeminal cyst may be incidental or may result in progressive neurologic deterioration.

RABIES

BASICS

DEFINITION

A severe, invariably fatal, viral polioencephalitis of warm-blooded animals, including humans.

PATHOPHYSIOLOGY

Virus—enters body through a wound (usually from a bite of rabid animal) or via mucous membranes; replicates in myocytes; spreads to the neuromuscular junction and neurotendinal spindles; travels to the CNS via intra-axonal fluid within peripheral nerves; spreads throughout the CNS; finally spreads centrifugally within peripheral, sensory, and motor neurons.

SYSTEMS AFFECTED

- Nervous—clinical encephalitis, either paralytic or furious.
- Salivary glands—contain large quantities of infectious virus particles that are shed in saliva.

GENETICS

None

INCIDENCE/PREVALENCE

- Incidence of disease within infected animals—high (approaches 100%).
- Prevalence—overall low; can be significant in enzootic areas; especially high in underdeveloped countries where vaccination of dogs and cats is not routine.

GEOGRAPHIC DISTRIBUTION

- Worldwide.
- Exceptions—New Zealand, Hawaii, Japan, Iceland, and parts of Scandinavia.
- Species-adapted strains—specific geographic distributions within endemic countries.

SIGNALMENT

Species

- All warm-blooded mammals, including dogs, cats, and humans.
- United States—five strains endemic within fox, raccoon, skunk, coyote, and insectivorous bat populations; all five strains can be transmitted to dogs and cats.

Breed Predilections

None

Mean Age and Range

None, but adult animals that come in contact with wildlife at most risk.

Predominant Sex

None

SIGNS

General Comments

- Quite variable; atypical presentation is the rule rather than the exception.
- Three progressive stages of disease—prodromal; furious; and paralytic; 90% of rabid cats have the furious form.

Historical Findings

- Change in attitude—solitude; apprehension, nervousness, anxiety; unusual shyness or aggression.
- Erratic behavior—biting or snapping; licking or chewing at site of wound; biting at cage; wandering and roaming; excitability; irritability; viciousness.
- Disorientation.
- Muscular—incoordination; seizures; paralysis.
- Change in tone of bark.
- Excess salivation or frothing.

Physical Examination Findings

- All or some of the historical findings.
- Mandibular and laryngeal paralysis, with dropped jaw.
- Inability to swallow.
- Hypersalivation.
- Fever.
- Dilated pupils—unresponsive to light; anisocoria.

CAUSES

Rabies virus—a single-stranded, enveloped, bullet-shaped RNA virus; genus *Lyssavirus*; family *Rhabdoviridae*.

RISK FACTORS

- Exposure to wildlife, especially skunks, raccoons, bats, and foxes.
- Inadequate vaccination against rabies.
- Bite or scratch wounds from unvaccinated dogs, cats, or wildlife.
- Exposure to aerosols in bat caves.
- Immunocompromised animal—use of modified live virus rabies vaccine.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Must seriously consider rabies for any dog or cat showing unusual mood or behavior changes or exhibiting any unaccountable neurologic signs; caution: handle with considerable care to prevent possible transmission of the virus to individuals caring for or treating the animal.
- Any neurologic disease—brain tumor; viral encephalitis.
- Head wound—identify lesions from wound.
- Laryngeal paralysis.
- Choking.
- Pseudorabies virus infection.

CBC/BIOCHEMISTRY/URINALYSIS

No characteristic hematologic or biochemical changes

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- CSF—minimal increased protein and leukocyte counts may be seen.
- DFA test of nervous tissue—rapid and sensitive test; collect brain, head, or entire body of a small animal that has died or has been euthanized; chill sample immediately; submit to a state-approved laboratory for rabies diagnosis; CAUTION: use extreme care when collecting, handling, and shipping these specimens.
- DFA test of dermal tissue—skin biopsy of the sensory vibrissae of the maxillary area, including deeper subcutaneous hair follicles; approved for human diagnostics, but not for animal diagnostics; accurate if positive, but negative test does not rule out rabies.
- Rabies antibody titer—a serologic antibody titer of 0.5 IU/ml is considered adequate for protection in vaccinated people and animals.

PATHOLOGIC FINDINGS

- Gross changes—generally absent, despite dramatic neurologic disease.
- Histopathologic changes—acute to chronic polioencephalitis; gradual increase in the severity of the non-suppurative inflammatory process in the CNS as disease progresses; large neurons within the brain may contain the classic intracytoplasmic inclusions (Negri bodies).

TREATMENT

APPROPRIATE HEALTH CARE

Strictly inpatient

NURSING CARE

Administer with extreme caution

ACTIVITY

- Confine to secured quarantine area with clearly posted signs indicating suspected rabies.
- Runs or cages should be locked; only designated people should have access.
- Feed and water without opening the cage or run door.

DIET

Soft, moist food; most patients will not eat.

CLIENT EDUCATION

- Thoroughly inform client of the seriousness of rabies to the animal and the zoonotic potential.
- Ask client about any human exposure (e.g., contact, bite) and strongly urge client to see a physician immediately.
- Local public health official must be notified.

SURGICAL CONSIDERATIONS

- Generally none.
- Skin biopsy—may help establish antemortem diagnosis; must be confirmed by identification from CNS tissue.

(CONTINUED)

RABIES**MEDICATIONS****DRUG(S) OF CHOICE**

- No treatment.
- Once the diagnosis is certain, euthanasia is indicated.

CONTRAINDICATIONS

None

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

- All suspected rabies patients should be securely isolated and monitored for any development of mood change, attitude change, or clinical signs that might suggest the diagnosis.
- An apparently healthy dog or cat that bites or scratches a person should be monitored for a period of 10 days; if no signs of illness occur in the animal within 10 days, the person has had no exposure to the virus; dogs and cats do not shed the virus for more than 3 days before development of clinical disease.
- An unvaccinated dog or cat that is bitten or exposed to a known rabid animal must be quarantined for up to 6 months or according to local or state regulations.

PREVENTION/AVOIDANCE

- Vaccines (dogs and cats)—vaccinate according to standard recommendations and state and local requirements; all dogs and cats with any potential exposure to wildlife or

other dogs; vaccinate after 12 weeks of age; then 12 months later; then every 3 years using a vaccine approved for 3 years; use only inactivated or recombinant vector vaccines for cats.

- Rabies-free countries—entering dogs and cats are quarantined for long periods, usually 6 months.
- Disinfection—any contaminated area, cage, food dish, or instrument must be thoroughly disinfected; use a 1:32 dilution (4 ounces/gallon) of household bleach to quickly inactivate the virus.

POSSIBLE COMPLICATIONS

From paralysis or attitude changes

EXPECTED COURSE AND PROGNOSIS

- Prognosis—grave; almost invariably fatal.
- Dogs and cats with clinical infection usually succumb within 1–10 days of onset of clinical signs; often within 3–4 days.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

None

AGE-RELATED FACTORS

None

ZOONOTIC POTENTIAL

- Extreme.
- Humans must avoid being bitten by a rabid animal or an asymptomatic animal that is incubating the disease.
- Rabies cases must be strictly quarantined and confined to prevent exposure to humans and other animals.
- Local and state regulations must be adhered to carefully and completely.

PREGNANCY/FERTILITY/BREEDING

Infection during pregnancy is fatal to dam

R

RECTAL AND ANAL PROLAPSE

BASICS

OVERVIEW

- Eversion of one or more layers of the rectum through the anus.
- An anal prolapse (incomplete prolapse) is a protrusion of anorectal mucosa through the external anal orifice.
- A rectal prolapse (complete prolapse) is a double-layer invagination of the full thickness of the rectal tube through the anal orifice.

SIGNALMENT

- Dog and cat (especially Manx).
- Any age, sex, or breed.
- High prevalence for young, parasitized dogs or cats with diarrhea.

SIGNS

- Persistent tenesmus.
- Incomplete prolapse—protrusion of a portion of the circumference of the rectal mucosa that typically appears worse immediately after defecation and then subsides.
- Complete prolapse appears as a tubular hyperemic mass protruding from the anus.
- Chronic prolapses may be dark blue or black in color or the mucosa may be ulcerated.

CAUSES & RISK FACTORS

- Gastrointestinal disorders that cause diarrhea and tenesmus, such as parasitism, colitis/enteritis, constipation/obstipation, rectal foreign body, rectal deviation and diverticulum, proctitis, and rectal or anal tumors.
- Urogenital disorders, such as cystitis, urolithiasis, prostatitis, prostatic hypertrophy, and dystocia.
- Tenesmus following perineal, rectal, or urogenital surgery (e.g., perineal herniorrhaphy).

R

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Prolapsed intussusception—rule-out by passing a finger or blunt probe between the mass and the anus (the probe should not penetrate more than 1–2 cm before contacting the fornix; if the probe easily passes 5–6 cm, then suspect prolapsed intussusception) or by abdominal ultrasonography (look for increased intestinal layering).
- Neoplasia—rule-out by palpation, fine-needle aspiration and cytology, and/or biopsy and histopathology.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually unremarkable.
- Inflammatory or stress leukogram may be present.

OTHER LABORATORY TESTS

Fecal examination may confirm parasitism.

IMAGING

- Abdominal radiography and ultrasonography—usually unremarkable.
- Abdominal radiography—may demonstrate foreign body, prostatomegaly, cystic calculi, or colonic fecal distention.
- Abdominal ultrasonography—may demonstrate prostatomegaly, cystic calculi, bladder wall thickening, or intussusception.

DIAGNOSTIC PROCEDURES

- Rectal examination to palpate for perineal hernia.
- Colonoscopy may help evaluate recurrent prolapse for an underlying cause.

PATHOLOGIC FINDINGS

Assess viability of the prolapsed tissue by surface appearance and tissue temperature—vital tissue appears swollen and hyperemic, and red blood exudes from the cut surface; devitalized tissue appears dark purple or black, and dark cyanotic blood exudes from the cut surface; ulcerations may be present.

TREATMENT

- Must identify and treat underlying cause.
- Conservative medical management—gently replace prolapsed tissue through the anus with the use of lubricants and gentle massage; osmotic agents may help if severe swelling exists.
- Use of an epidural may facilitate treatment and relieve discomfort.
- Place a purse string suture to aid retention and prevent acute recurrence; place the suture loose enough to allow room for defecation.
- Decrease straining with stool softeners.
- Colopexy recommended for recurrent viable prolapses or if straining persists after rectal resection and anastomosis.
- When prolapse is non-reducible and/or devitalized, rectal resection and anastomosis are necessary.

MEDICATIONS

DRUG(S) OF CHOICE

- Appropriate anesthetic/analgesics as needed.
- Consider epidural to facilitate surgery and

reduce postoperative straining.

- Appropriate perioperative antibiotics are recommended (e.g., cefoxitin sodium 30 mg/kg IV) for resection anastomosis.
- Topical agents to aid in reduction—50% dextrose solution and KY Jelly.
- Stool softeners—docusate sodium (dogs, 50–200 mg PO q8–12h; cats, 50 mg PO q12–24h) or lactulose (10 g/15 mL solution or syrup, 1 mL/4.5 kg q8–12h to effect); continue for 2–3 weeks after removal of the purse-string suture.
- Feed a low-residue diet until purse-string suture is removed.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Purse-string suture removal in 3–7 days.
- Examine for rectal stricture if straining persists following anastomosis.

POSSIBLE COMPLICATIONS

- Recurrence—especially if underlying cause is not eliminated.
- Postoperative—may include infection, anastomosis dehiscence within 5–7 days postoperatively, or rectal stricture.
- Fecal incontinence after resection (sensory incontinence resulting from removal of receptors in rectal wall).

MISCELLANEOUS

ASSOCIATED CONDITIONS

Intestinal parasitism

Consulting Editor Stanley L. Marks

RECTAL STRICTURE

BASICS

OVERVIEW

- Diminution in the size of the rectal or anal lumen either from cicatricial contracture or scarring as a result of wound healing or chronic inflammation or from proliferative neoplastic disease.
- Gastrointestinal function is compromised because of outflow obstruction.
- No genetic basis reported.

SIGNALMENT

- Dog and cat
- No age, breed, or gender predilection reported

SIGNS

- Vary with severity of the lesion
- Tenesmus
- Dyschezia
- Constipation
- Hematochezia
- Mucoid feces
- Large-bowel diarrhea
- Secondary megacolon can develop

CAUSES & RISK FACTORS

- Inflammatory—rectoanal abscess, anal sacculitis, perianal fistulas, proctitis, foreign body, fungal infection (e.g., histoplasmosis, pythiosis).
- Traumatic—lacerations.
- Neoplastic—rectal adenocarcinoma, leiomyoma, rectal polyps.
- Iatrogenic—rectal anastomosis, rectal mass excision, rectal biopsy.
- Congenital—atresia ani.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Space-occupying processes that lead to diminished rectal capacity (extraluminal rectal compression [e.g., prostatic disease, pelvic fractures], intraluminal rectal obstruction [e.g., pseudocoprostasis, foreign body]) and functional constriction (rectal muscle spasms).
- Differentiate by rectal palpation and imaging.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually unremarkable.
- Patients with inflammation or infection may have an inflammatory leukogram.

OTHER LABORATORY TESTS

N/A

IMAGING

- Survey abdominal radiography and contrast studies (e.g., barium, air, or double-contrast enema and barium gastrointestinal series) may reveal consistent narrowing of the rectal luminal diameter.
- A combination of air and barium allows the best visualization of the colonic mucosa and aids in determining the extent of the lesion.
- Abdominal ultrasonography may reveal thickening and altered architecture if infiltrative rectocolonic disease is present (e.g., pythiosis, neoplasia).

DIAGNOSTIC PROCEDURES

- Digital rectal palpation.
- Proctoscopy/colonoscopy may be useful to

visualize a stricture, determine the extent of the lesion, and procure a biopsy specimen.

- Colonic scrapings may aid in cytologic diagnosis of fungal (histoplasmosis) and neoplastic diseases.
- Biopsy and evaluate the lesion histopathologically to classify the disease process and establish a prognosis.

TREATMENT

- Resolve the underlying cause before specifically treating the stricture when possible.
- Medical treatment directed at either palliation by use of stool softeners and enemas or the elimination of infective agents or inflammatory conditions.
- Give fluid therapy to optimize hydration prior to administering an enema to constipated or obstipated patients.
- Anesthesia may be necessary for enema administration.
- Balloon dilatation of non-neoplastic and postoperative strictures—more than one procedure may be needed based on patient response.
- Surgical reconstruction of focal strictures (plasty procedures) (see “Suggested Reading” for greater detail).
- Complete resection and anastomosis may be necessary for extensive lesions and recurrent strictures.
- Placement of a colorectal stent may be successful in relieving obstructions due to nonresectable neoplasms and potentially for non-neoplastic lesions.
- Radiotherapy and/or chemotherapy may benefit the treatment of some neoplasms.

MEDICATIONS

DRUG(S)

- Stool softeners—docusate sodium; lactulose (see Appendix IX for dosages). Intraluminal injection of corticosteroids such as triamcinolone prior to dilatation may improve outcome and reduce the likelihood of recurrence. Injection can be repeated one time if additional dilatations are necessary.
- Corticosteroids—can use prednisone to treat non-infectious inflammatory conditions (0.5–1 mg/kg PO q24h or divided q12h) and after balloon dilation or bougienage to prevent stricture recurrence.
- Chemotherapy may be indicated for various neoplasms.
- Antifungal therapy if fungal infection present.
- Appropriate perioperative antimicrobial therapy with a broad spectrum of activity against anaerobes and coliforms (e.g., cefoxitin sodium 30 mg/kg IV) in conjunction with balloon dilation or surgical therapy.
- Antibiotics can be administered after dilatation if mucosal tearing occurs (e.g., amoxicillin or metronidazole).

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Corticosteroids when infection is possible.
- Corticosteroids may adversely affect healing after surgical correction of the stricture.

FOLLOW-UP

PATIENT MONITORING

- Resolution or recurrence of clinical signs.
- Patients with neoplastic lesions—recurrence and metastatic disease.
- Patients with strictures that have undergone balloon dilation should be re-evaluated for restenosis formation within 7–14 days of the dilation procedure to determine the need for additional dilation procedures.

POSSIBLE COMPLICATIONS

- Medical treatment—can include inefficacy, diarrhea, and adverse effects of medications.
- Balloon dilation can result in deep rectal tears, hemorrhage, or possibly full-thickness perforation.
- Surgical treatment—fecal incontinence, secondary stricture formation, and wound dehiscence.

EXPECTED COURSE AND PROGNOSIS

- Varies with the severity of the stricture.
- Patients with benign strictures that are readily managed medically or with balloon dilation or bougienage may have a good long-term outcome.
- Surgical resection has more guarded prognosis because of the frequency of complications.
- Most patients with recognizable clinical signs due to neoplasia have a guarded-to-poor prognosis for complete resolution.

MISCELLANEOUS

AGE-RELATED FACTORS

Atresia ani is seen within weeks of birth.

Consulting Editor Stanley L. Marks

R

RECTOANAL POLYPS

BASICS

OVERVIEW

Most rectoanal polyps are benign growths located in the distal rectum. Histopathologic evaluation typically reveals adenomas, but lesions may undergo malignant transformation.

SIGNALMENT

- Dog and rarely cat
- Middle-aged to old
- No breed or sex predilection

SIGNS

- Hematochezia with relatively well-formed feces.
- Mucus-covered feces.
- Pencil-thin or ribbon-like feces.
- Tenesmus.
- Dyschezia.
- Soft, well-vascularized, friable, and often ulcerated mass(es) may be seen or palpated rectally.
- Usually single but multiple polyps can occur.
- May be pedunculated or broad-based sessile masses.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Carcinoma *in situ* and adenocarcinoma.
- Other neoplasias—leiomyoma, lymphoma, papilloma.
- Proctitis.
- Pythiosis.
- Colitis (clinical signs are characterized by diarrhea with a marked increase in frequency, scant volume of feces, increase fecal mucus, and tenesmus. These clinical signs are vastly different to those of dogs with rectoanal polyps which do not cause diarrhea).
- Incomplete rectal prolapse.

CBC/BIOCHEMISTRY/URINALYSIS

Usually unremarkable

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Rectal palpation.
- Direct visualization through anus.

• Proctoscopy—viable low-cost procedure that allows one to visualize the descending colon after cleansing the animal's colon. This method is suitable in most dogs and cats because the polyps are usually localized to the rectoanal or colorectal region and tend not to metastasize.

- Colonoscopy—recommended to evaluate the entire rectum and colon for additional polyps.
- Cytologic examination of polyp aspirate or scraping may help the initial diagnosis, although cytology should be interpreted with caution given the inherent challenges of differentiating benign adenomas from adenocarcinomas cytologically.
- Histopathologic examination of excised tissue is required for definitive diagnosis and to assess completeness of the excision.

PATHOLOGIC FINDINGS

- Adenomatous polyp
- Adenomatous hyperplasia
- Carcinoma *in situ*

TREATMENT

- Surgical excision is the treatment of choice.
- Most polyps can be exteriorized directly through the anus and removed with submucosal resection.
- Close the mucosal defect with absorbable sutures, avoiding compromise of the lumen diameter.
- Lesions that cannot be exteriorized may be removable transanally by electrosurgery with endoscopic guidance or can be directly exposed through a dorsal rectal approach.
- One study in dogs showed significant improvement in clinical signs following administration of piroxicam, but long-term follow-up is not available. Numerous NSAIDs have been evaluated in humans with mixed results (see "Internet Resources").

MEDICATIONS

DRUG(S)

- Appropriate perioperative antibiotics are recommended (e.g., cefoxitin sodium 30 mg/kg IV).
- Stool softeners may help decrease tenesmus—docusate sodium (dogs, 50–200 mg PO q8–12h; cats, 50 mg PO q12–24h) or docusate calcium (dogs, 50–100 mg PO q12–24h; cats, 50 mg PO q12–24h).

- Alternative stool softener—lactulose (1 mL/4.5 kg PO q8h to effect).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Examine the excision site 14 days after surgery and again at 3 and 6 months to ensure absence of recurrence or stricture.
- Twice yearly examination thereafter to assess for recurrence.

POSSIBLE COMPLICATIONS

- Recurrence
- Rectal stricture (rare)

EXPECTED COURSE AND PROGNOSIS

- Dogs with focal single adenomas have a good prognosis with a low rate of recurrence.
- Dogs with multiple and/or diffuse lesions (involvement of > 50% of circumference of rectal wall) have much higher rates of recurrence.
- Malignant transformation of benign lesions can occur in up to 50% of dogs.
- Excised tissues should be submitted for histopathology even when preoperative biopsies have been performed. The diagnosis may change in up to one-third of the cases in which preoperative endoscopic biopsies are performed.

MISCELLANEOUS

SEE ALSO

- Adenocarcinoma, Anal Sac

RED EYE

BASICS

DEFINITION

Hyperemia of the eyelids or ocular vasculature, or hemorrhage within the eye.

PATHOPHYSIOLOGY

- Active dilation of ocular vessels—in response to extraocular or intraocular inflammation or passive congestion.
- Hemorrhage from existing or newly formed blood vessels.

SYSTEMS AFFECTED

Ophthalmic—eye and/or ocular adnexa

SIGNALMENT

Dog and cat

SIGNS

Historical Findings

Depends on cause

Physical Examination Findings

- Depends on cause.
- May affect one or both eyes.
- Result of systemic disease—abnormalities in other organ systems common.

CAUSES

- Virtually every case fits into one or more of the following categories.
- Blepharitis.
- Conjunctivitis.
- Keratitis.
- Episcleritis or scleritis.
- Anterior uveitis.
- Glaucoma.
- Hyphema.
- Orbital disease—usually the orbital abnormality is more prominent.

RISK FACTORS

- Systemic infectious or inflammatory diseases.
- Immunocompromise.
- Coagulopathies.
- Systemic hypertension.
- Irritation by potentially any topical ophthalmic medication.
- Neoplasia.
- Trauma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

More than one cause may occur simultaneously.

Similar Signs

- Rule out normal variations.
- Palpebral conjunctiva—normally redder than bulbar conjunctiva.
- One or two large episcleral vessels—may be normal if the eye is otherwise quiet.

- Transient mild hyperemia—with excitement, exercise, and straining.
- Horner's syndrome—may cause mild conjunctival vascular dilation; differentiated by other signs and pharmacologic testing.

Causes

- Superficial (conjunctival) vessels—originate near the fornix; move with the conjunctiva; branch repeatedly; blanch quickly with topical 2.5% phenylephrine or 1:100,000 epinephrine; suggest ocular surface disorders (e.g., conjunctivitis, superficial keratitis, blepharitis).
- Deep (episcleral) vessels—originate near the limbus; branch infrequently; do not move with the conjunctiva; blanch slowly or incompletely with topical sympathomimetics; suggest episcleritis or intraocular disease (e.g., anterior uveitis or glaucoma).
- Discharge—mucopurulent to purulent: typical of ocular surface disorders and blepharitis; serous or none: typical of intraocular disorders.
- Swollen or inflamed eyelids—suggest blepharitis.
- Corneal opacification, neovascularization, or fluorescein stain retention—suggest keratitis.
- Aqueous flare or cell (increased protein or cells in the anterior chamber)—confirms diagnosis of anterior uveitis.
- Pupil—miotic: common with anterior uveitis; dilated: common with glaucoma; normal: with blepharitis and conjunctivitis.
- Abnormally shaped or colored irides—suggest anterior uveitis.
- Luxated or cataractous lenses—suggest glaucoma or anterior uveitis.
- IOP—high: diagnostic for glaucoma; low: suggests anterior uveitis.
- Loss of vision—suggests glaucoma, anterior uveitis, or severe keratitis.
- Glaucoma and anterior uveitis—may complicate hyphema.

CBC/BIOCHEMISTRY/URINALYSIS

- Typically normal, except with anterior uveitis, glaucoma, or hyphema secondary to systemic disease.
- See Anterior Uveitis—Dogs; Anterior Uveitis—Cats; Hyphema.

OTHER LABORATORY TESTS

Depends on cause

IMAGING

- Chest radiographs—consider with anterior uveitis or if intraocular neoplasia is a possibility.
- Abdominal radiography or ultrasonography—may help rule out infectious or neoplastic causes.
- Ocular ultrasonography—if the ocular media are opaque; may define the extent and nature of intraocular disease or identify an intraocular tumor.

DIAGNOSTIC PROCEDURES

Tonometry—must perform in every patient with an unexplained red eye.

Ocular Surface Disorders

- Aerobic bacterial culture and sensitivity profile—with a purulent discharge, chronic disease, or if the response to treatment is poor.
- Schirmer tear test.
- Cytologic examination of affected tissue—lid; conjunctiva; cornea.
- Cats—consider PCR or IFA test on corneal or conjunctival scrapings for feline herpesvirus and *Chlamydia*; collect sample before fluorescein staining to avoid false-positive results on IFA.
- Fluorescein stain.
- Conjunctival biopsies—with chronic conjunctivitis or with a mass lesion.
- See specific disease—Conjunctivitis—Cats; Conjunctivitis—Dogs; Blepharitis; Keratitis chapters.

Intraocular Disorders

- Fluorescein stain.
- See specific disease—Anterior Uveitis—Cats; Anterior Uveitis—Dogs; Hyphema; Glaucoma.

TREATMENT

- Usually outpatient.
- Elizabethan collar—considered to prevent self-trauma.
- Avoid dirty environments or those that may lead to ocular trauma, especially if topical corticosteroids are used.
- Because there is a narrow margin for error, consider referral if you cannot attribute the condition to one of the listed causes, if you cannot rule out glaucoma on the initial visit, or if the diagnosis is so uncertain that administration of a topical antibiotic alone or a topical corticosteroid alone would be questionable.
- Few causes are fatal; however, a workup may be indicated (especially with anterior uveitis and hyphema) to rule out potentially fatal systemic diseases.
- Deep corneal ulcers and glaucoma—may be best treated surgically.

R

MEDICATIONS

DRUG(S)

- Depends on specific cause.
- Generally, control ocular pain, inflammation, infection, and IOP.
- Aspirin 10–15 mg/kg PO q8–12h (dogs); may control mild ocular inflammation and pain pending test results.
- Carprofen 2.2 mg/kg q12h or 4.4 mg/kg q24h.

RED EYE

(CONTINUED)

- Flunixin meglumine 0.5 mg/kg IV once; may be used in dogs with severe ocular inflammation pending test results.

CONTRAINDICATIONS

- Topical corticosteroids—contraindicated if the cornea retains fluorescein stain.
- Systemic corticosteroids—avoid until infectious systemic causes have been ruled out.

PRECAUTIONS

- Topical aminoglycosides—may be irritating; may impede reepithelialization if used frequently or at high concentrations.
- Topical solutions—may be preferable to ointments if corneal perforation is possible.
- Atropine—may exacerbate KCS and glaucoma.
- NSAIDs—use with caution in hyphema.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

- Depends on cause.
- Repeat ophthalmic examinations—as required to ensure that IOP, ocular pain, and inflammation are well controlled.
- The greater the risk of loss of vision, the more closely the patient needs to be followed; may require daily or more frequent examination.

POSSIBLE COMPLICATIONS

- Death
- Loss of the eye or permanent vision loss
- Chronic ocular inflammation and pain

BASICS

DEFINITION

Passive, retrograde movement of undigested gastric or esophageal contents into the oral cavity. Reflux refers to the retrograde movement of gastric juice across the gastroesophageal sphincter into the esophagus.

PATOPHYSIOLOGY

Regurgitation results from a loss of normal esophageal motility. In the normal esophagus, the presence of a food bolus in the proximal esophagus stimulates afferent sensory neurons. Signals are transferred centrally, via the vagus and glossopharyngeal nerves, to the tractus solitarius and nucleus ambiguus. Motor impulses travel back via the vagus nerve to stimulate striated muscle (canine) and striated and smooth muscle (feline) to cause esophageal peristalsis. Lesions anywhere along this pathway may lead to regurgitation.

SYSTEMS AFFECTED

- Gastrointestinal—dysphagia, weight loss
- Musculoskeletal—weakness, weight loss
- Nervous—polyneuropathies, CNS disease
- Respiratory—aspiration pneumonia

GENETICS

• Regurgitation due to megaesophagus can be inherited in wirehaired fox terriers (autosomal recessive) and miniature schnauzers (autosomal dominant or 60% penetrance autosomal recessive). A breed predisposition also exists for the German shepherd, great Dane and Irish setter. The site and pathogenesis of the lesion in idiopathic megaesophagus is unknown. Suggested hypotheses include abnormalities of the afferent limb of the reflex arc (receptors, neurons) or of the swallowing center in the CNS.

• Boxers and Newfoundlands have a genetic predisposition for inflammatory myopathy that is associated with esophageal dysmotility.

• Brachycephalic breeds are predisposed to sliding hiatal hernias (type I) that is typically associated with gastroesophageal reflux.

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog (more commonly) and cat

Breed Predilections

- Wirehaired fox terriers, miniature schnauzers. Other predisposed breeds include Great Dane, German shepherd, Irish setter, Labrador retriever, Newfoundland, and boxer, brachycephalic breeds (Shar-Pei, pug, Boston terrier, English bulldog, French bulldog).
- Siamese and Siamese-related cats.

Mean Age and Range

- Congenital cases present soon after birth (congenital megaesophagus) or at weaning (vascular ring anomalies) from liquid diet to solid foods.
- Acquired cases may be seen at any age, depending on the etiology.

Predominant Sex

No gender predilection has been identified.

SIGNS

General Comments

- Clients often report vomiting; the veterinarian must differentiate vomiting from regurgitation using a comprehensive history. Having owner videotape events may be helpful.
- Regurgitation: passive process; little to no abdominal effort; no prodromal phase; regurgitated material has increased amounts of thick mucus.
- Vomiting: active process; prodromal phase is identified; vomited material may have increased amounts of bile staining.
- The shape of the expelled material (i.e., tube-like), presence of undigested food, and length of time from ingestion to regurgitation or vomiting are less helpful to differentiate.

Historical Findings

- Vomiting (as perceived by owner)
- Dysphagia
- Coughing
- Ravenous appetite
- Weight loss
- Ptyalism
- Other signs, depending upon underlying etiology

Physical Examination Findings

- Cervical swelling may be noted
- Ptyalism
- Halitosis
- Increased respiratory noises
- Nasal discharge and fever (if concurrent pneumonia)
- Cachexia
- Weakness

CAUSES

Congenital Pharyngeal or Pharyngoesophageal

- Cleft or short palate (typically associated with nasal reflux)
- Cricopharyngeal achalasia (typically associated with nasal reflux and dysphagia)
- Myasthenia gravis

Congenital Esophageal

- Vascular ring anomaly (e.g., persistent right aortic arch)
- Megaesophagus
- Glycogen storage disease
- Esophageal diverticulum
- Bronchoesophageal fistula

Acquired Pharyngeal or Pharyngoesophageal

- Cricopharyngeal dysphagia
- Foreign bodies
- Neoplasia

Rabies

- Toxicity (botulism)
- Myopathy/neuropathy/junctionopathy

Acquired Esophageal

- Megaesophagus
- Myasthenia gravis
- Stricture
- Neoplasia
- Hypoadrenocorticism
- Hypothyroidism
- Hiatal hernia
- Dysmotility
- Gastroesophageal intussusception
- Gastroesophageal reflux
- Periesophageal masses
- Dysautonomia
- Myopathy/neuropathy
- Foreign bodies
- Granulomatous disease
- Toxicity (lead)
- Idiopathic
- Gastric dilatation/volvulus
- Parasitic infection (*Spirocerca lupi*)
- Bronchoesophageal fistula

RISK FACTORS

Increased risk of gastroesophageal reflux with general anesthesia; the resultant esophagitis may lead to stricture formation and regurgitation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Regurgitation is a clinical sign, not a diagnosis, and is the hallmark of esophageal disease.
- It is important to differentiate vomiting from regurgitation.

CBC/BIOCHEMISTRY/URINALYSIS

- There are no pathognomonic changes for regurgitation.
- Inflammatory leukogram may be seen if aspiration pneumonia is present.
- Most helpful for evaluation of possible underlying etiologies: e.g., erythrocyte changes with lead toxicosis, elevated CK with myopathy, hyperkalemia and hyponatremia with hypoadrenocorticism, hypercholesterolemia with hypothyroidism.

OTHER LABORATORY TESTS

These elucidate etiologies of acquired conditions causing regurgitation and include ACTH stimulation test or baseline cortisol level (hypoadrenocorticism); thyroid serology (hypothyroidism); acetylcholine receptor antibody level (myasthenia gravis); blood lead levels (toxicosis).

IMAGING

- Thoracic and cervical radiography—evidence of a gas-, fluid-, or ingesta-filled esophagus with megaesophagus; may also show aspiration pneumonia, neoplasia, foreign bodies, hiatal hernia, etc.

REGURGITATION

(CONTINUED)

- Contrast studies—both liquid barium and barium-coated food for radiolucent foreign bodies or esophageal strictures. Iohexol may also be used. Esophagram does not allow one to evaluate functional disorders such as intestinal dysmotility or cricopharyngeal achalasia. **Caution:** contrast studies may increase the risk for aspiration pneumonia with regurgitation.
- Videofluoroscopy—for pharyngeal weakness, cricopharyngeal dysphagia, esophageal motility disorders, hiatal hernia or gastroesophageal reflux.
- Other imaging studies include scintigraphy and high-resolution manometry for motility evaluation and ultrasound for pharyngeal or cervical masses.
- Cervical and thoracic CT scans may also be utilized.

DIAGNOSTIC PROCEDURES

- Esophagoscopy can be useful for esophagitis, strictures, vascular ring anomalies, neoplasia, and foreign bodies.
- Electromyography and nerve/muscle biopsies may be used for neuropathic or myopathic conditions.
- Transtracheal wash or bronchoalveolar lavage if aspiration pneumonia is present or suspected.

PATHOLOGIC FINDINGS

Gross and histologic findings depend upon the underlying etiology and the presence of complicating factors.

TREATMENT

APPROPRIATE HEALTH CARE

- Therapy for underlying etiology should be instituted.
- Important to meet nutritional requirements and treat or prevent aspiration pneumonia.

NURSING CARE

- Aspiration pneumonia may require supplemental oxygen therapy, nebulization/coupage, and fluid therapy with balanced electrolyte solution.
- These animals may be recumbent and require soft bedding. They should be maintained in sternal recumbency or turned to alternate down sides every 4 hours.

ACTIVITY

Depending on etiology, restricted activity is not necessary.

DIET

- Experimentation with different food consistencies is essential. Liquid gruel, small meatballs, or blenderized slurries may be used.
- Some cases benefit from gastrostomy feedings, though regurgitation may still occur.
- Both food and water should be elevated, and animal should be maintained in an upright position for 10–15 minutes after

eating or drinking. Use of a Bailey chair facilitates keeping the dog upright for 10–15 minutes after a meal.

- The recommended caloric requirement amount should be calculated and the diet should be monitored so that basic energy requirements are met.

CLIENT EDUCATION

- If regurgitation is due to megaesophagus, most cases require life-long therapy, even if an underlying etiology is found. Client dedication is important for long-term management.
- Most animals succumb to aspiration pneumonia or intractable regurgitation.
- Placement of a PEG tube in dogs with megaesophagus can reduce the frequency of aspiration pneumonia.

SURGICAL CONSIDERATIONS

- Surgical intervention is indicated for vascular ring anomalies, cricopharyngeal achalasia, bronchoesophageal fistula, and others.
- Esophageal dysfunction is permanent in most cases.
- Balloon dilation is indicated for cases of esophageal stricture.

MEDICATIONS

DRUG(S) OF CHOICE

- Antibiotics for aspiration pneumonia (broad-spectrum or based on culture and sensitivity from TTW or BAL).
- Specific therapy for underlying etiology if indicated.
- Prokinetics—metoclopramide (0.2–0.4 mg/kg SC or PO q6–12h, or 1–2 mg/kg q24h as a CRI) increases lower esophageal sphincter tone and increases gastric motility. Cisapride (0.5 mg/kg PO q8–12h) is more effective for esophageal reflux than metoclopramide and has been documented to enhance gastric emptying and increase lower esophageal sphincter tone in dogs.
- Other motility agents (e.g., nizatidine) have not been evaluated for esophageal motility.
- H₂ blockers for esophagitis—ranitidine (1–2 mg/kg PO, IV q12h), famotidine (0.5–1 mg/kg PO, SC, IM, IV q12h). Proton pump inhibitors may be used in severe cases—omeprazole (0.7–1.5 mg/kg PO q24h).

CONTRAINDICATIONS

N/A

PRECAUTIONS

- Absorption of orally administered drugs may be compromised.
- Injectable forms should be used when applicable.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Animals with aspiration pneumonia should have thoracic radiographs and complete blood counts checked until resolution, or if recurrence is suspected.
- Animals should be monitored, weighed, and body condition scores applied to ensure adequate caloric intake.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Aspiration pneumonia.
- Others depending on presence of underlying diseases (e.g., hypothyroidism).

EXPECTED COURSE AND PROGNOSIS

- Older animals with idiopathic megaesophagus have a poor prognosis.
- Aspiration pneumonia is the typical cause of death or euthanasia.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Aspiration pneumonia
- Megaesophagus

AGE-RELATED FACTORS

Young animals may regain some esophageal function with appropriate therapy, depending on etiology.

ZOONOTIC POTENTIAL

RENAL FAILURE, ACUTE

BASICS

DEFINITION

Acute uremia is a clinical syndrome characterized by sudden onset of renal outflow or excretory failure; accumulation of uremic toxins; dysregulation of fluid, electrolyte, and acid-base balance; and clinical signs of uremia. Depending on the underlying cause, acute uremia is potentially reversible if diagnosed quickly and treated aggressively. This chapter refers to intrinsic acute kidney injury and ureteral obstruction.

PATHOPHYSIOLOGY

- AKI may be initiated by ischemia, nephrotoxins, infection, prolonged urine outflow obstruction and severe non-renal systemic diseases (e.g., pancreatitis, neoplasia).
- AKI may be divided into four sequential stages: (1) initiation, (2) extension, (3) maintenance, and (4) recovery. Clinically, transition from one stage to the next may not be clearly evident, and not all stages need be present in an individual patient.
- Renal excretory failure is perpetuated by multiple factors including (1) reduced glomerular surface area and permeability, (2) low renal blood flow, (3) intratubular obstruction by tubular debris, (4) cellular and interstitial edema, and (5) “backleak” of filtrate across damaged tubular epithelia. Resolution occurs by renal regeneration and repair.
- Ureteral obstruction results from ureteroliths, inspissated blood, strictures or inflammatory debris.

SYSTEMS AFFECTED

- Renal/Urologic
- Endocrine/Metabolic
- Gastrointestinal
- Hemic/Lymph/Immune
- Musculoskeletal
- Nervous
- Respiratory

INCIDENCE/PREVALENCE

- Prevalence is lower than chronic kidney disease.
- Prevalence may increase in the fall and winter with greater exposure to antifreeze containing ethylene glycol, and wet environments that support *Leptospira*.
- Ureteral obstruction is the most common cause of severe acute uremia in cats.

SIGNALMENT

Species

Dog and cat

Breed Predilections

None

Mean Age and Range

• 6–8 years peak prevalence in dogs and cats.

- Older animals at greater risk due to decreased renal reserve.

SIGNS

Historical Findings

Sudden onset of anorexia, listlessness, depression, vomiting (\pm blood), diarrhea (\pm blood), halitosis, ataxia, seizures, known toxin or drug exposure, recent medical or surgical procedure, and oliguria/anuria.

Physical Examination Findings

Normal body condition and hair coat, depression, dehydration (or iatrogenic overhydration), scleral injection, oral ulceration, glossitis, necrosis of the tongue, uremic breath, hypothermia, fever, tachypnea, bradycardia, non-palpable urinary bladder, and asymmetrically enlarged, painful, firm, kidneys.

CAUSES

Hemodynamic/Hypoperfusion

Shock, trauma, thromboembolism (e.g., DIC, vasculitis, transfusion reaction), heatstroke, excessive vasoconstriction (e.g., administration of NSAIDs), adrenal insufficiency, excessive vasodilation (e.g., ACEI or antihypertensive drugs), prolonged anesthesia, significant hypertension, heart failure.

Nephrotoxic

Ethylene glycol, aminoglycoside, amphotericin B, chemotherapeutic agent (e.g., cisplatin, doxorubicin), thiocetarsamide, NSAIDs, radiographic contrast agents, heavy metals (e.g., lead, mercury, arsenic, thallium), insect or snake venom, heme pigment, calcium, grape or raisin ingestion (dogs), and lily ingestion (cats).

Intrinsic and Systemic Disease

Leptospirosis, Lyme disease, immune-mediated glomerulonephritis, pancreatitis, septicemia, DIC, hepatic failure, heat stroke, transfusion reaction, bacterial endocarditis, pyelonephritis, cortical necrosis, and lymphoma. Unilateral or bilateral ureteral obstruction.

RISK FACTORS

- Endogenous—preexisting CKD, dehydration, sepsis, hypovolemia, hypotension, advanced age, concurrent disease, hyponatremia, hypokalemia, hypocalcemia, and acidosis.
- Exogenous—drugs (e.g., furosemide, NSAIDs, ACEI, aminoglycoside), prolonged anesthesia, acidifying diets, trauma, multiple organ disease, and high environmental temperature.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Prerenal azotemia—oliguria, concentrated USG (dogs, ≥ 1.030 ; cats, ≥ 1.035), correctable with fluid repletion.

- Post-renal azotemia—anuria, dysuria, stranguria, large bladder, urethral obstruction, enlarged prostate, urethral tear, uroperitoneum.

- CKD—polyuria, polydipsia, history of chronic illness, loss of body condition, anemia.

- Prerenal on CKD—clinical and laboratory features of CKD but partially correctable with fluid repletion.

- Prerenal on AKI—acute onset uremia, partially correctable with fluid repletion.

- Hypoadrenocorticism—hyponatremia, hyperkalemia, low serum cortisol.

- Pancreatitis—cranial abdominal pain, high trypsin-like immunoreactivity, hyperbilirubinemia, and increase in liver enzyme activity.

CBC/BIOCHEMISTRY/URINALYSIS

- Normal or high PCV, variable leukocytosis, and lymphopenia.

- Progressive (moderate to severe) increases in SUN, creatinine, and phosphorus; variably high potassium and glucose; and variably low bicarbonate and calcium concentration.

- USG ≤ 1.020 , mild-to-moderate proteinuria, glucosuria; variable number of cellular, and/or granular casts, WBCs, RBCs, and tubular epithelial cells; variable bacteriuria and calcium oxalate monohydrate crystalluria (sometimes seen in association with ethylene glycol toxicosis).

OTHER LABORATORY TESTS

- Metabolic acidosis common; mixed disorders may occur.

- *Leptospira* titer $\geq 1:800$ to non-vaccinal serovar, or rising titers.

- Ethylene glycol concentration—“spot test” positive if ingested, increased serum osmolality and/or osmolar or anion gap.

IMAGING

- Survey and contrast radiography—kidneys are normal to large, with bilateral smooth contours; asymmetric kidneys in cats (“big kidney-little kidney” syndrome) with ureteral obstruction—small radiodense uroliths may be visible in the retroperitoneum.

- Percutaneous nephropyleography or contrast CT for ureteral obstruction.

- Ultrasonography—severe cortical hyperechogenicity suggests ethylene glycol toxicosis. Moderate cortical hyperechogenicity suggests glomerulonephritis or nephrosis. Pelvic and/or ureteral dilation or calcific densities suggest outflow obstruction.

DIAGNOSTIC PROCEDURES

- Monitor urine output—helps establish diagnosis and helps in formulation of therapy and prognosis: anuria; oliguria, ≤ 0.25 mL/kg/h (≤ 1 mL/kg/h during fluid administration); non-oliguria, ≥ 2 mL/kg/h.

- Fine-needle aspiration—may establish lymphoma as cause of renomegaly.

RENAL FAILURE, ACUTE

(CONTINUED)

- Percutaneous renal biopsy—helps establish the cause, severity, and potential reversibility of injury; later in the course of disease (4–6 weeks) it may help predict ongoing renal repair and permanence of renal damage.

PATHOLOGIC FINDINGS

Nephrosis or nephritis, glomerulonephritis, calcium oxalate crystals, interstitial edema, and lack of interstitial fibrosis; the subacute stage is characterized by attenuated tubular epithelium, interstitial fibrosis and mineralization, cellular infiltration, and variable tubular regeneration.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient management; eliminate inciting causes; discontinue nephrotoxic drugs; establish and maintain hemodynamic stability; ameliorate life-threatening fluid imbalances, biochemical abnormalities, and uremic toxicities; initiate gastric lavage, induce emesis and administer activated charcoal, cathartics, and specific antidotes to patients with acute poisoning; early hemodialysis/hemoperfusion can eliminate many toxins.

NURSING CARE

- Hypovolemia—correct estimated fluid deficits with 0.9% saline or balanced polyionic solution within 2–4 hours if patient condition permits; once hydrated, ongoing fluid requirements are provided by 5% dextrose for insensible requirements (approximately 20–25 mL/kg/day) and balanced electrolyte solution equal to urinary and other losses (i.e., vomiting and diarrhea); avoid overhydration; replace blood losses by blood transfusion.
- Hypervolemia—stop fluid administration and eliminate excess fluid by diuretics or dialysis.
- Monitor body weight at least four times daily and adjust fluids to maintain stable weight once rehydrated. Avoid overhydration.

DIET

- Rapid control of vomiting and early nutritional support. Endogenous fat and protein stores are consumed while patient is anorexic; resting energy requirements must be provided within 3 days using moderately protein-restricted diets, or enteral feeding solutions formulated to control azotemia and supply caloric requirements.
- Parenteral nutrition (intractable vomiting)—provide caloric requirements by dextrose and emulsified lipid solution; protein requirements (dogs, 2–3 g/100 kcal; cats, 3–4 g/100 kcal) provided by amino acid mixtures.

- Enteral feeding (anorectic, non-vomiting animals)—caloric and protein requirements supplied by blended renal diets, liquid enteral solutions, or formulated diets delivered by nasoesophageal, esophagostomy, gastrostomy, or enterostomy tube.

CLIENT EDUCATION

Guarded prognosis for complete recovery; potential for morbid complications of treatment (e.g., fluid overload, sepsis, and multiple organ failure); expense of prolonged hospitalization; alternatives to conventional medical management (i.e., peritoneal dialysis, hemodialysis, and renal transplantation); zoonotic potential of leptospirosis.

SURGICAL CONSIDERATIONS

- For acute ureteral obstruction unresponsive to medical management, consider surgical intervention via ureteral stenting, subcutaneous ureteral bypass or ureteral resection and re-implantation.
- Renal transplantation may provide long-term survival for cats with fulminating, nonresponsive AKI.

Peritoneal or Hemodialysis

- Dialysis can stabilize the patient until renal function is restored or corrective surgery (removal of ureteral obstruction, renal transplantation); without dialysis, most oliguric patients die before renal repair occurs.
- Specific indications include severe oliguria or anuria, life-threatening fluid overload or acid-base/electrolyte disturbances, $\text{SUN} \geq 100 \text{ mg/dL}$, serum creatinine $\geq 10 \text{ mg/dL}$, clinical course refractory to conservative treatment, perioperative stabilization, and poisoning/overdosage with a dialyzable toxin.

MEDICATIONS

DRUG(S) OF CHOICE

Inadequate Urine Production

- Ensure patient is fluid-volume-replete; provide additional isonatric fluid to achieve 3% volume expansion; failure to induce diuresis indicates severe parenchymal damage or underestimation of fluid deficit; if fluid-replete, administer diuretics.
- Hypertonic mannitol (20%) 0.5 g/kg IV over 15–30 minutes; if effective, continue as intermittent IV bolus q6h; do not repeat dosage if ineffective.
- Furosemide (alternative or subsequent to mannitol)—4 mg/kg IV; if effective, continue CRI at 0.5 mg/kg/h or 2 mg/kg q6h; discontinue if ineffective.
- Dopamine—lack of documented efficacy and potential side effects contraindicate its use except for pressor control.
- If these treatments fail to induce diuresis within 4–6 hours, consider dialysis.

Metabolic Disorders, Acid-Base Disorders

Administer bicarbonate if serum bicarbonate $\leq 16 \text{ mEq/L}$; bicarbonate replacement: $\text{mEq} = \text{bicarbonate deficit} \times \text{body weight (kg)} \times 0.3$; give half IV over 30 minutes and the remainder over 2–4 hours; then reassess.

Hyperkalemia

- Correct dehydration with potassium free (0.9% NaCl) fluids.
- Minimize potassium intake.
- Discontinue medications that promote hyperkalemia (e.g., ACEI, potassium sparing diuretics).
- Loop diuretics: furosemide 2–4 mg/kg IV.
- Sodium bicarbonate, sufficient to correct existing bicarbonate deficit, if bicarbonate status unknown, 1–2 mEq/kg IV.
- Dextrose \pm insulin: 1–2 mL/kg of 50% dextrose (diluted to 25%) IV or regular insulin 0.1–0.2 U/kg IV bolus followed by 1–2 g dextrose/unit insulin.
- Calcium gluconate: 0.5–1.0 mL/kg of 10% calcium gluconate IV over 10–15 minutes.
- Refractory hyperkalemia—dialysis.

Vomiting

- Reduce gastric acid production—famotidine (0.5 mg/kg IM, IV q24h) or omeprazole (0.5–1 mg/kg PO q24h [dogs]).
- Mucosal protectant—sucralfate (0.25–1 g PO q6–8h).
- Antiemetics—maropitant (1 mg/kg SC/IV q24h); or ondansetron (0.1–0.3 mg/kg IV q8–12h); or dolasetron (0.5 mg/kg SC, IV q24h).

PRECAUTIONS

Modify dosages of all drugs that require renal metabolism or elimination.

FOLLOW-UP

PATIENT MONITORING

Fluid, electrolyte, and acid-base balances; body weight; blood pressure; urine output; and clinical status; daily.

PREVENTION/AVOIDANCE

- Anticipate the potential for AKI in aged patients or those with systemic disease, sepsis, trauma, hemodynamic instability, receiving nephrotoxic drugs, multiple organ failure, or those undergoing prolonged anesthesia.
- Maintenance of hydration, mild saline volume expansion, and administration of mannitol may be preventive.
- Monitor urine production, SUN, and creatinine in high-risk patients.

POSSIBLE COMPLICATIONS

Seizures, coma, cardiac arrhythmias, hypertension, congestive heart failure,

(CONTINUED)

RENAL FAILURE, ACUTE

pulmonary edema, uremic pneumonitis, aspiration pneumonia, GI bleeding, hypovolemic shock, sepsis, cardiopulmonary arrest, and death.

EXPECTED COURSE AND PROGNOSIS

- Prognosis depends on underlying cause, extent of renal injury, concomitant disease or organ failure, age of patient and response to therapy.
- Survival rates average 50% overall for both cats and dogs, ranging from 20% for ethylene glycol toxicosis up to 80% for acute leptospirosis.
- Infectious and obstructive etiologies have a better prognosis for recovery than toxic causes.
- Non-oliguric AKI—typically milder than oliguric; recovery may occur over 2–6 weeks, but the prognosis remains guarded.
- Oliguric AKI—extensive kidney injury, difficult to manage, and has a poor prognosis for recovery without dialysis; recovery signaled by a sudden (and often excessive) polyuria and a sluggish and possibly incomplete return of renal function over 4–12 weeks; dialysis extends the potential for renal regeneration and repair.
- Anuric AKI—poor prognosis without dialysis; often incomplete recovery of renal function.

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

Leptospirosis—avoid contact with infective urine.

PREGNANCY/FERTILITY/BREEDING

A rare complication of pregnancy in animals; promoted by acute metritis, pyometra, and postpartum sepsis or hemorrhage.

SYNONYMS

Acute renal failure, acute tubular necrosis, acute uremia

SEE ALSO

R

RENAL FAILURE, CHRONIC

BASICS

DEFINITION

Kidney disease encompasses functional or structural lesions in one or both kidneys as detected by blood or urine tests, imaging studies, or kidney biopsy. Chronic kidney disease has been present for > 3 months. This definition includes all cases previously described by the terms renal insufficiency or renal failure, as well as less advanced forms of kidney disease. Patients are categorized into stages along a continuum of progressive CKD (IRIS CKD stages 1–4) based on two or more serum creatinine values obtained over several weeks when the patient is fasted and well hydrated. The IRIS system uses the term “kidney” rather than “renal” because it is more universally recognized by pet owners.

PATHOPHYSIOLOGY

More than approximately 75% reduction in renal function results in impaired urine-concentrating ability (leading to PU/PD) and retention of nitrogenous waste products of protein catabolism (leading to azotemia). More advanced CKD results in uremia. Decreased erythropoietin and calcitriol production by the kidneys results in hypoproliferative anemia and renal secondary hyperparathyroidism, respectively.

SYSTEMS AFFECTED

- Cardiovascular—hypertension; uremic pericarditis; cardiomegaly.
- Endocrine/Metabolic—renal secondary hyperparathyroidism, activation of the renin-angiotensin-aldosterone system, erythropoietin deficiency.
- Gastrointestinal—uremic stomatitis, uremic halitosis, enhanced dental calculus, nausea, vomiting, anorexia, gastrointestinal bleeding, diarrhea (may be hemorrhagic).
- Hemic/Lymphatic/Immune—anemia; hemorrhagic diathesis.
- Musculoskeletal—renal osteodystrophy; sarcopenia.
- Neuromuscular—seizures and other neurologic signs due to hypertension and/or uremia; muscle tremors, muscle wasting.
- Ophthalmic—retinal detachment, hemorrhage or edema due to hypertension.
- Reproductive—impaired reproductive capacity.
- Respiratory—uremic pneumonitis.
- Skin/Exocrine—calcinoses cutis.

GENETICS

• Inherited in the following breeds (mode of inheritance, known or suspected, indicated in parentheses):

- Abyssinian cats (autosomal dominant with incomplete penetrance)
- Persian cats (autosomal dominant)
- Bull terrier (autosomal dominant)
- Cairn terrier (autosomal recessive)

- German shepherd (autosomal dominant)
- Samoyed (X-linked dominant)
- English cocker spaniel (autosomal recessive)
- Renal dysplasia (mode of inheritance unresolved): shih tzu, Lhasa apso, golden retriever, Norwegian elkhound, chow chow, standard poodle, soft-coated Wheaten terrier, Alaskan malamute, miniature schnauzer, Dutch kooiker, and sporadically in many other breeds).

INCIDENCE/PREVALENCE

- 9 cases per 1,000 dogs examined and 16 cases per 1,000 cats examined.
- Prevalence increases with age—age > 15 years, reportedly 57 cases per 1,000 dogs examined and 153 cases per 1,000 cats examined.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat

Breed Predilections

See “Genetics”

Mean Age and Range

Mean age at diagnosis is approximately 7 years in dogs and 9 years in cats. Animals of any age can be affected, but prevalence increases with increasing age.

Predominant Sex

None

General Comments

Clinical signs are related to the stage of CKD and the presence of complications such as proteinuria and hypertension. Cats and dogs with CKD stages 1 and 2 may be asymptomatic; overt clinical signs typically become apparent in stages 3 and 4. An animal with stable CKD (particularly stages 3 and 4) may decompensate, resulting in a uremic crisis.

Historical Findings

- PU/PD (less frequent in cats than dogs); litter box more wet; less color to urine
- Anorexia
- Lethargy
- Vomiting
- Weight loss
- Nocturia
- Constipation
- Diarrhea
- Acute blindness—due to hypertension
- Seizures or coma—late
- Cats may have ptalism and muscle weakness with cervical ventroflexion (because of hypokalemic myopathy).

Physical Examination Findings

- Small, irregular kidneys, or enlarged kidneys secondary to polycystic kidney disease or lymphoma
- Dehydration
- Cachexia

- Lethargy, weakness
- Mucous membrane pallor
- Oral ulceration
- Uremic halitosis
- Constipation
- Hypertensive retinopathy
- Renal osteodystrophy (may manifest as bone pain, particularly in the skull)
- Reduced body temperature

CAUSES

- Origin unknown in most cases due to late diagnosis.
- Include familial and congenital renal disease, nephrotoxins, hypercalcemia, hypokalemic nephropathy, glomerulopathies, amyloidosis, pyelonephritis, polycystic kidney disease, nephroliths, chronic urinary obstruction, drugs, lymphoma, leptospirosis (following acute renal failure), and FIP.

RISK FACTORS

Age, proteinuria, hypercalcemia, hypokalemia (cats), hypertension, urinary tract infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- See Polyuria and Polydipsia chapter for differential diagnosis.
- Azotemia—includes causes of prerenal and post-renal azotemia, acute renal failure, and hypoadrenocorticism.
 - Prerenal azotemia—azotemia with urine specific gravity > 1.030 in dogs and > 1.035 in cats; Rapid reduction in azotemia after correcting fluid volume/perfusion issues indicates prerenal azotemia. Prerenal azotemia commonly occurs concurrent with primary renal azotemia when gastrointestinal signs of uremia are present.
 - Post-renal azotemia—azotemia with obstruction or rupture of the excretory system; rapid correction of azotemia following elimination of obstruction or resolution of leakage from the urinary tract supports post-renal azotemia.
- Acute renal failure—differentiated by normal to large renal size, cylindruria, lack of indications of chronicity, (absence of small kidneys, hypoproliferative anemia and renal osteodystrophy), and a history of recent nephrotoxin exposure or hypotensive episode.
- Hypoadrenocorticism—characterized by hyponatremia and hyperkalemia with resting cortisol value < 1 µg/dL or decreased adrenal response to ACTH stimulation.

CBC/BIOCHEMISTRY/URINALYSIS

- Hypoproliferative anemia
- High BUN and creatinine
- Hyperphosphatemia
- Metabolic acidosis (normal or high anion gap)
- Hypokalemia or hyperkalemia
- Hypercalcemia or hypocalcemia

(CONTINUED)

- Urine specific gravity < 1.030 in dogs and < 1.035 in cats
- Proteinuria

OTHER LABORATORY TESTS

- Urinary protein:creatinine ratio to assess proteinuria
- Microalbuminuria assay to screen for early evidence of glomerular injury

IMAGING

- Abdominal radiographs may demonstrate small kidneys, or large kidneys secondary to polycystic kidney disease or lymphoma.
- Ultrasound demonstrates small kidneys and hyperechoic renal parenchyma with less apparent distinction between the cortex and medulla in some animals. Animals with lymphoma often have renomegaly with hypoechoic renal parenchyma.
- See also Congenital and Developmental Renal Diseases; Pyelonephritis; Nephrolithiasis; Hydronephrosis; Polycystic Kidney Disease.

DIAGNOSTIC PROCEDURES

- Blood pressure measurement to detect hypertension.
- Measurement of glomerular filtration rate may be useful for detection of loss of kidney function before the onset of azotemia.
- Renal biopsy is not indicated in patients with small kidneys; it may be indicated in proteinuric patients with normal to large kidneys.

PATHOLOGIC FINDINGS

- Gross—small kidneys with a lumpy or granular surface; renal capsule frequently adheres to the renal parenchyma.
- Histopathologic—variable. Patients with proteinuric stage 1 CKD may have changes consistent with various forms of glomerulopathy. Depending on the cause for kidney disease, complete evaluation of biopsy material from these patients may require light, immunofluorescent, and electron microscopy. In patients with more advanced CKD, nonspecific changes including interstitial fibrosis and foci of interstitial mononuclear cells; chronic generalized nephropathy or “end-stage” kidneys.
- Findings may be specific for diseases causing CKD in some patients with less advanced disease.

**TREATMENT****APPROPRIATE HEALTH CARE**

Patients with compensated CKD may be managed as outpatients; patients in uremic crisis should generally be managed as inpatients.

NURSING CARE

- Patients in uremic crisis—correct fluid and electrolyte deficits with intravenous fluid

therapy (e.g., lactated Ringer's solution). Generally provide 25% of calculated fluid deficit in the first hour. Thereafter, serially monitor perfusion (capillary refill time, pulse pressure, heart rate, and temperature of feet), blood pressure and urine output to assess adequacy of fluid therapy. If perfusion has not improved, additional fluid should cautiously be administered. Provide the remaining fluid deficit over the next 12–24 hours.; Avoid excessive fluid administration.

- Subcutaneous fluid therapy (q24–48h) may benefit patients (especially cats) with moderate-to-severe CKD. Continue therapy only if clinical improvement is noted.

ACTIVITY

Unrestricted

DIET

- Diets designed for dogs and cats with CKD delay the onset of uremic crisis and extend survival in dogs and cats with CKD stages 2–4. They are a standard of care for these patients.
- Foods containing reduced protein and n-3 fatty acids may be beneficial for proteinuric patients with stage 1 CKD.
- Important components of renal foods include: reduced protein, phosphorus, sodium and net acid content and supplementation of n-3 fatty acids and antioxidants.
- Free access to fresh water at all times.

CLIENT EDUCATION

- Dogs and many cats—CKD typically progresses to terminal kidney failure over months to years.
- CKD may not be progressive in some cats.
- Higher levels of proteinuria associated with shorter survival times. This effect may be mitigated by therapy for proteinuria.
- Heritability of familial renal diseases.

SURGICAL CONSIDERATIONS

- Avoid hypotension during anesthesia to prevent additional renal injury.
- Renal transplantation has been successfully performed in cats with CKD.

**MEDICATIONS****DRUG(S) OF CHOICE*****Uremic Crisis***

- Famotidine (0.5–1 mg/kg PO, IM, IV q12–24h) to minimize nausea and vomiting (primarily dogs).
- Antiemetics (maropitant 1 mg/kg q24h up to 5 days; or ondansetron 0.1–0.2 mg/kg slow IV q12h) to minimize vomiting and impaired appetite due to nausea.
- Potassium chloride in IV fluids or potassium gluconate PO (2–6 mEq/cat/day) as needed to correct hypokalemia.
- Sodium bicarbonate to correct metabolic acidosis (IV to raise blood pH > 7.1).

RENAL FAILURE, CHRONIC**Compensated CKD**

- Famotidine (dogs, 0.5–1 mg/kg PO q24h) to minimize uremic gastritis and possible nausea and inappetence.
- Antiemetic (maropitant) and potassium gluconate as above.
- Intestinal phosphate binders (e.g., aluminum carbonate, 30–100 mg/kg/day PO with meals) as needed to correct hyperphosphatemia (see Hyperparathyroidism, Renal Secondary).
- Calcitriol (start at 2 ng/kg PO q 24h and monitor effect on PTH and ionized calcium—avoid inducing hypercalcemia) (see Hyperparathyroidism, Renal Secondary).
- Darbepoetin (see Anemia of Chronic Kidney Disease).
- Amlodipine (dogs, 0.1–0.6 mg/kg PO q24h; cats, 0.625–1.25mg/cat PO q24h) or ACE inhibitors (e.g., enalapril or benazepril, 0.5 mg/kg PO q24h) as needed for hypertension. Amlodipine is more effective than ACE inhibitors in cats with CKD-induced hypertension. If refractory to monotherapy, consider combination of amlodipine and ACE inhibitor with frequent monitoring of blood pressure.
- ACE inhibitor (benazepril or enalapril) for proteinuria (start at 0.5 mg/kg PO q24 h; may increase to 1 mg/kg PO q12h if needed to reduce proteinuria).

CONTRAINDICATIONS

Avoid nephrotoxic drugs (aminoglycosides, cisplatin, amphotericin B) and corticosteroids.

PRECAUTIONS

- Drug dosage or dosing interval may need to be modified for some drugs eliminated by the kidneys.
- Use ACE inhibitors with caution; monitor for worsening of azotemia.
- Generally avoid NSAIDs.

POSSIBLE INTERACTIONS

Cimetidine or trimethoprim may cause artifactual increases in the serum creatinine concentration by reducing tubular secretion in dogs with CKD.

ALTERNATIVE DRUG(S)

- Metoclopramide (0.2–0.4 mg PO or SC q6–8h) can be used in addition to H₂-receptor antagonists to treat uremic vomiting.
- Ranitidine (0.5–2 mg/kg PO or IV q12h) or cimetidine (5 mg/kg q8–12h for dogs; 2.5–5 mg/kg q8–12h for cats) may be used instead of famotidine.
- Hemodialysis and renal transplantation are available at selected referral hospitals.

**FOLLOW-UP****PATIENT MONITORING**

- Dogs and cats with CKD—monitor at regular intervals; initially weekly for patients

RENAL FAILURE, CHRONIC

(CONTINUED)

receiving calcitriol or erythropoietin; every 1–3 months for stable patients with CKD stages 3 and 4 (minimum: chemistry profile and PCV).

- Proteinuric patients—monitor at least every 3–4 months (minimum: serum creatinine and urine protein:creatinine ratio).

PREVENTION/AVOIDANCE

- Do not breed animals with familial renal disease.
- Include urinalysis and serum creatinine in yearly examination for older dogs and cats.

POSSIBLE COMPLICATIONS

- Systemic hypertension
- Uremia
- Anemia
- Urinary tract infection
- Nephrolithiasis and uretrolithiasis
- Exuberant dental calculus

EXPECTED COURSE AND PROGNOSIS

- Short-term—depends on severity.
- Long-term—guarded to poor in dogs (CKD tends to be progressive over months to years); poor to good in cats (CKD does not progress in some cats).

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Hyperthyroidism in cats
- Urinary tract infection

- Systemic hypertension
- Nephrolithiasis and ureterolithiasis

AGE-RELATED FACTORS

Renal function may decrease with aging.

ZOONOTIC POTENTIAL

Leptospirosis

PREGNANCY/FERTILITY/BREEDING

Patients with mild CKD may maintain pregnancy; those with moderate-to-severe disease may be infertile or have spontaneous abortions; breeding of female patients not recommended.

RENAL TUBULAR ACIDOSIS

BASICS

OVERVIEW

- A syndrome characterized by hyperchloremic metabolic acidosis due either to decreased bicarbonate reabsorption from the proximal renal tubule (proximal or type 2 RTA) or decreased hydrogen ion secretion in the distal tubule (distal, classic or type 1 RTA) in patients with normal or near normal glomerular filtration rate and absence of diarrhea.
- Aldosterone deficiency or resistance can cause type 4 distal RTA leading to hyperkalemia. Proximal RTA has not been documented as an isolated entity in dogs but has been observed as part of Fanconi syndrome.
- The following discussion is limited to classic distal RTA. In distal RTA, the urine cannot be maximally acidified despite moderately to markedly decreased plasma bicarbonate concentration as a consequence of impaired hydrogen secretion in the collecting ducts. Urine pH typically is above 6.0 (normally urine pH should be 4.5–5.0 in the presence of systemic acidosis).

SIGNALMENT

- Reported in 8 dogs and 4 cats • No apparent breed or sex predilection • Age range at time of diagnosis, 1–12 years

SIGNS

- Associated with acidemia and may include lethargy, muscle weakness (may be related to hypokalemia), inappetence, nausea, weight loss, stunted growth, and neurologic signs.
- Other signs depend on the associated diseases (e.g., pyelonephritis). • Panting.
- Polyuria and polydipsia (usually associated with hypokalemia or calcuiresis). • Vomiting.
- Hematuria and dysuria (secondary to urolithiasis). • Osteomalacia associated with chronic metabolic acidosis (not yet reported in dogs and cats).

CAUSES & RISK FACTORS

- May be primary (i.e., inherited), or secondary to hypercalcuria, toxins, drugs (e.g., amphotericin B), altered calcium metabolism causing nephrocalcinosis (e.g., hypervitaminosis D, primary hyperparathyroidism), autoimmune (e.g., immune-mediated hemolytic anemia, systemic lupus erythematosus, renal transplant rejection), hypergammaglobulinemic disorders (e.g., multiple myeloma, systemic lupus erythematosus), and tubulointerstitial nephropathies. • In cats, distal RTA has been associated with pyelonephritis (2 cases), hepatic lipidosis (1 case), and idiopathic with secondary hyperaldosteronism (1 case). • In

dogs, clinical cases were idiopathic or associated with immune-mediated hemolytic anemia (3 cases), leptospirosis (1 case), or experimentally-induced renal ischemia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Consider other causes of hyperchloremic (normal anion gap) metabolic acidosis (e.g., diarrhea, carbonic anhydrase inhibitors, ammonium chloride, cationic amino acids, post-hypocapnic metabolic acidosis, dilutional acidosis, hypoadrenocorticism). Small bowel diarrhea is the most important differential diagnosis.

CBC/BIOCHEMISTRY/URINALYSIS

- Results vary depending on associated diseases. • Hypokalemia (due to increased renal excretion) in some animals; may be severe enough to cause muscle weakness.
- Alkaline urine ($\text{pH} > 6.0$); rule out urease-positive urinary tract infection (e.g., *Staphylococcus aureus*, *Proteus* spp.) as a cause of alkaline urine.

OTHER LABORATORY TESTS

Evaluation of blood gases and serum electrolytes indicates hyperchloremic (normal anion gap) metabolic acidosis. Urine pH is > 6.0 in distal RTA versus < 5.5 in proximal RTA.

IMAGING

Radiography—may detect uroliths or osteomalacia (uncommon).

DIAGNOSTIC PROCEDURES

- The key diagnostic feature is normal anion gap metabolic acidosis accompanied by an inappropriately alkaline urine pH (> 6.0).
- Ammonium chloride tolerance test—administer 200 mg/kg PO in dogs; measure urine pH before and at hourly intervals for 5 hours; empty the bladder hourly. Urine pH in normal dogs decreases to < 5.5 within 4 hours. Avoid this test if severe acidosis is present.
- Type 1 and 2 RTA can be differentiated based on response to NaHCO_3 infused at 0.5–1.0 mEq/kg/h. Fractional excretion of bicarbonate will increase markedly in type 2 RTA.

TREATMENT

- Individualize depending on the nature and severity of associated conditions. • Typically, less bicarbonate is needed to resolve metabolic acidosis associated with distal RTA than is

needed to resolve acidosis associated with proximal RTA. • Hypokalemia may resolve with bicarbonate or citrate administration alone, or additional potassium supplementation may be required.

MEDICATIONS

DRUG(S)

- Potassium citrate alone or in combination with sodium citrate (depending on the serum potassium concentration) at a total dosage of 1–5 mEq/kg/day PO, divided into two doses, or sodium bicarbonate at 10–50 mg/kg q8–12h PO (1–3 mEq/kg/day).
- Potassium supplementation—potassium gluconate; cats, 2–8 mEq/day divided q12h PO; dogs (depending on body size), 2–44 mEq/day divided q12h PO, if required.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Citrate should be avoided in patients with renal failure receiving aluminum hydroxide because citrate increases intestinal permeability and can lead to excessive aluminum absorption.

FOLLOW-UP

- Serial blood gas analyses (e.g., every 3–5 days) until acid-base status has normalized.
- Monitor serum electrolytes, especially potassium, as needed.
- Long-term prognosis depends on the nature and severity of associated conditions; may be reasonably good in patients without other diseases, but little information exists on the long-term course of this disease in dogs and cats.

RENOMEGLY

BASICS

DEFINITION

One or both kidneys are abnormally large as detected by abdominal palpation or diagnostic imaging.

PATHOPHYSIOLOGY

The kidneys may become abnormally large because of abnormal cellular infiltration (e.g., inflammation, infection, and neoplasia), urinary tract obstruction, acute tubular necrosis, or development of renal cysts or pseudocysts.

SYSTEMS AFFECTED

- Endocrine/Metabolic—metabolic acidosis due to decreased elimination of acid by kidneys and inability to reclaim bicarbonate
- Gastrointestinal—inappetence, vomiting, diarrhea, or melena due to gastrointestinal irritation or ulceration in patients with uremia
- Hemic/Lymphatic/Immune—anemia due to blood loss or decreased red blood cell survival in patients with uremia; increased susceptibility to infections due to immune dysfunction in patients with uremia, and impaired production of erythropoietin
- Hepatobiliary—bilateral renomegaly may occur in patients with portosystemic shunts.
- Nervous—depression and lethargy associated with effect of uremic toxins on central nervous system.
- Renal/Urologic—one or both kidneys are abnormally large.
- Respiratory—tachypnea or respiratory distress due to uremic pneumonitis or compensatory response for metabolic acidosis

SIGNALMENT

- Cat and dog
- Polycystic kidney disease, a cause of renomegaly, occurs in several breeds of dogs (bulldog, cairn terrier, and West Highland white terrier) and cats (Persian, longhaired cats, others)
- Mode of inheritance is autosomal dominant in Bulldogs and Persian cats and autosomal recessive in cairn terriers and West Highland white terriers.

SIGNS

Historical Findings

- May be asymptomatic, especially if only one kidney is affected
- Lethargy
- Loss of appetite
- Weight loss
- Vomiting
- Diarrhea
- Polyuria and polydipsia
- Discolored urine
- Abdominal enlargement
- Lameness (rarely) because of hypertrophic osteopathy associated with renal neoplasia

Physical Examination Findings

- Abdominal mass
- Abdominal pain
- One or both kidneys palpably large
- Abdominal enlargement
- One kidney enlarged; one kidney abnormally small
- Dehydration
- Pale mucous membranes
- Oral ulcers
- Uremic halitosis

CAUSES & RISK FACTORS

Developmental/Acquired Disorders

- Hydronephrosis—can cause unilateral or bilateral renomegaly in dogs and cats; develops secondary to ureteral obstruction (e.g., urolithiasis, ureteral strictures, and neoplasia at trigone of urinary bladder) and ectopic ureters.
- Polycystic kidney disease—causes bilateral renomegaly in cats and often leads to chronic kidney disease; more common in Persians and domestic longhair cats.
- Hematoma—occurs secondarily to trauma; infrequent cause of renomegaly.
- Compensatory hypertrophy—causes unilateral renomegaly and occurs secondary to abnormality of the other kidney (e.g., renal hypoplasia, renal dysplasia, previous damage or nephrectomy).
- Perinephric pseudocyst—causes apparent unilateral or bilateral enlargement. Kidney size may be normal, but the subcapsular fluid accumulation makes the kidney appear large on palpation and radiography.

Metabolic

- Portosystemic shunt, acromegaly
- Males have larger kidneys than females

Neoplastic

- Lymphoma—most often occurs in cats and causes bilateral renomegaly; some patients have unilateral renomegaly.
- Renal carcinoma—most common renal tumor of dogs; often causes unilateral renomegaly; very malignant and rapidly metastatic to distant sites such as lungs.
- Nephroblastoma—also called Wilms' tumor; a congenital renal tumor that affects young dogs, although it may not be diagnosed until the patient is much older; biologic behavior varies; usually unilateral.
- Sarcomas—usually cause unilateral renomegaly and behave malignantly.
- Cystadenocarcinoma—bilateral renal tumor that occurs in German shepherd dogs; often associated with skin lesions (i.e., nodular dermatofibrosis).

Infectious/Inflammatory

- Amyloidosis.
- Leptospirosis (dogs).
- Feline infectious peritonitis.
- Feline leukemia virus infection predisposes cats to development of renal lymphoma.

- Acute kidney injury.
- Renal abscess—localized abscess within renal parenchyma usually causes unilateral renomegaly in dogs and cats.

Toxic

- Ethylene glycol toxicosis—can cause bilateral renomegaly secondary to renal tubular swelling and renal infiltration by calcium oxalate crystals.
- Other toxins that cause acute renal injury (e.g., grapes/raisins, lilies).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Must distinguish from other abdominal masses.
- Confirmation may require diagnostic imaging procedures or exploratory celiotomy.

CBC/BIOCHEMISTRY/URINALYSIS

- Azotemia, hyperphosphatemia, and inappropriately low urine-concentrating capacity.
- Leukocytosis—infectious, inflammatory, and neoplastic causes of renomegaly.
- Nonregenerative anemia—chronic kidney disease or inflammatory disorders.
- Hyperglobulinemia—infectious or inflammatory disorders (e.g., feline infectious peritonitis).
- Hematuria and proteinuria—renal neoplasia.
- Polycythemia and extreme leukocytosis rarely accompany some renal neoplasms.
- Neoplastic cells rarely observed in urine of patients with renal neoplasia.

OTHER LABORATORY TESTS

- Test cats for feline leukemia virus infection if renal lymphoma is suspected.
- Perform serum protein electrophoresis to distinguish between polyclonal and monoclonal hyperglobulinemia.
- Evaluate paired titers for *Leptospira* spp. 2–3 weeks apart in dogs with suspected leptospirosis.

IMAGING

Radiographic Findings

- Survey abdominal radiographs indicated to confirm renomegaly and identify potential causes of ureteral obstruction (e.g., radiopaque ureteroliths).
- Enlarged kidneys on the ventrodorsal view are > 3 or 3.5 times the length of the second lumbar vertebra in cats or dogs, respectively.
- Excretory urography or CT to confirm presence of renomegaly, hydronephrosis, and space-occupying masses of the kidneys.
- Antegrade pyelography may be needed to exclude ureteral obstruction in some cats.
- Thoracic radiography indicated to detect metastases in patients with renal neoplasia.

(CONTINUED)

RENOMEGLY***Ultrasonographic Findings***

- Helps distinguish between causes of renomegaly including polycystic kidney disease, perinephric pseudocysts, hydronephrosis, neoplasia, abscess, and subcapsular hematoma.
- Acute inflammation (e.g., leptospirosis, ethylene glycol toxicosis) may be associated with increased cortical echogenicity, perinephric effusion, or a medullary band of increased echogenicity.

DIAGNOSTIC PROCEDURES

- Cytologic examination of fine-needle aspirate can confirm presence of renal cyst, abscess, and/or neoplasia (lymphoma). Due to potential for “seeding” of neoplastic cells in the abdominal wall, fine-needle aspiration should be avoided if other renal tumors (e.g., renal carcinoma) are suspected.
- If no definitive diagnosis is made by cytologic evaluation of renal aspirates, renal biopsy may be indicated.

**TREATMENT**

- Diagnose and treat underlying cause of renomegaly.
- Usually treat as an outpatient unless dehydration or decompensated renal failure exist.
- Therapeutic renal diet is indicated to prolong survival time for dogs and cats with chronic kidney disease when serum creatinine exceeds 2 mg/dL.
- If patient is healthy otherwise, feed normal diet and allow normal exercise.

- If the patient cannot maintain hydration, administer balanced electrolyte solution either intravenously or subcutaneously.

- If the patient has dehydration or continuing fluid losses such as vomiting or diarrhea, administer fluids intravenously to correct hydration deficits, maintain daily fluid requirements, and replace ongoing losses.

**MEDICATIONS****DRUG(S)**

Vary with the cause

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid nephrotoxic drugs.

**FOLLOW-UP****PATIENT MONITORING**

- Perform physical examination and weigh patient to assess hydration status.
- Other tests (CBC, serum chemistries, urinalysis, blood pressure measurements) are indicated depending on the underlying cause and presence of other conditions (e.g., anemia, azotemia, hypertension, proteinuria).

POSSIBLE COMPLICATIONS

- Chronic kidney disease, depending on underlying cause of renomegaly.

- Paraneoplastic syndromes associated with renal tumors that produce hormone-like substances.

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

Leptospirosis can be spread by contact with infected urine.

REOVIRUS INFECTIONS

BASICS

OVERVIEW

- Respiratory enteric orphan virus (reovirus)—genus in the family Reovirus; non-enveloped, double-stranded RNA virus; isolated from respiratory and enteric tracts; not associated with any known disease (hence orphan).
- Ubiquitous in geographic distribution and host range, virtually every species of mammal, including humans.
- Virus—infests mature epithelial cells on luminal tips of the intestinal villi; causes cellular destruction, resulting in villous atrophy (similar to rotavirus and coronavirus).
- Loss of absorptive capability and loss of brush border enzymes (e.g., disaccharidases) leads to osmotic diarrhea.

SIGNALMENT

Dogs and cats

SIGNS

Dogs

- Conjunctivitis
- Rhinitis
- Tracheobronchitis—minor role
- Pneumonia
- Diarrhea
- Encephalitis—rare

Cats

- Generally mild disease
- Respiratory illness
- Conjunctivitis
- Gingivitis
- Ataxia
- Diarrhea

CAUSES & RISK FACTORS

- Predominantly excreted from respiratory and digestive tract; acquired by inhalation and oral ingestion.
- Infection is common; specific disease has not been reproduced.
- Other viral pathogens— infections observed repeatedly; speculated that reovirus may have an immunosuppressive effect that aggravates such infections.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Canine viral enteritis—canine parvovirus; canine coronavirus; canine astrovirus; canine calicivirus; canine herpesvirus; canine distemper virus; canine rotavirus.
- Canine infectious tracheobronchitis—canine parainfluenza; *Bordetella bronchiseptica*; *Mycoplasma*; canine adenovirus types 1 and 2; canine herpesvirus; canine distemper virus; canine influenza virus; canine respiratory coronavirus.
- Feline upper respiratory disease—feline rhinotracheitis virus; feline calicivirus; *Chlamydia*; *Mycoplasma*; bacterial infection.

CBC/BIOCHEMISTRY/URINALYSIS

Non-contributory

OTHER LABORATORY TESTS

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Infection can spread among individuals of the same or different species.
- The role (if any) that animals serve as a reservoir for virus or as a possible source of human infection is unknown.
- Humans—by early childhood, the vast majority demonstrate serologic evidence of past reovirus infection; difficult to link to disease; majority of infections must be asymptomatic or blend imperceptibly with minor respiratory and gastrointestinal illness of infancy and early childhood.
- Candidate virus for oncolytic therapy of cancer (e.g., malignant glioma).

ABBREVIATIONS

- EM = electron microscopy
- RT-PCR = reverse transcription polymerase chain reaction

RESPIRATORY PARASITES

BASICS

DEFINITION

Helminths, arthropods, and protozoa that reside in the respiratory tract or pulmonary vessels of dogs and cats.

PATHOPHYSIOLOGY

Infestation with parasites causes rhinitis, bronchitis, pneumonitis, or arteritis, depending on the location of the organism within the respiratory system. Eosinophilic inflammation usually results from invasion of the parasite.

SYSTEMS AFFECTED

- Respiratory.
- Cardiovascular.
- Hepatic—with hepatopulmonary migration of some parasites (*Toxocara* spp.).
- Neurologic—with migration of parasites to the brain (*Cuterebra*) or cerebral hemorrhage (*Angiostrongylus*).

GENETICS

There is no genetic basis.

INCIDENCE/PREVALENCE

Depends on parasite

GEOGRAPHIC DISTRIBUTION

- *Pneumonyssoides caninum*, *Aelurostrongylus abstrusus*, *Linguatula serrata*, *Oslerus (Filaroides) osleri*, *Crenosoma vulpis*, *Eucoleus (Capillaria) aerophilus*, *Toxoplasma gondii*, *Toxocara* spp.—worldwide.
- *Eucoleus boehmi*, *Cuterebra* spp., *Filaroides hirthi*, *Paragonimus kellicotti*—primarily North America.
- *Andersonstrongylus (Filaroides) milksi*—North America; Europe.
- *Angiostrongylus vasorum*—various countries of Europe, Africa, South America, North America.

SIGNALMENT

Species

Dog and cat

SIGNS

General Comments

- Four basic categories—upper airway (nasal cavity and sinuses), lower respiratory (trachea and bronchi), pulmonary parenchyma, and vascular; based on location and lifestyle of parasite.
- Often insidious and chronic, with few clinical signs.
- Respiratory compromise often not severe.

Historical Findings

- Upper respiratory—sneezing; nasal discharge (serous, sanguinous); reverse sneezing; nasal irritation or rubbing; neurologic signs with *Cuterebra* spp.
- Lower respiratory and parenchyma—may have no clinical signs, variable coughing, tachypnea, or altered respiratory pattern.
- Vascular—can have weight loss, lethargy, coughing, exercise intolerance. Acute onset of respiratory distress if embolization or hemorrhage occurs.

Physical Examination Findings

- Upper respiratory—similar to historical findings; variable.
- Lower respiratory and parenchyma—cough elicited on tracheal palpation; occasionally harsh lung sounds.
- Vascular—may present with signs of pulmonary disease, right-sided heart failure, anemia, coagulopathy, neurologic signs.

CAUSES

- Upper respiratory (nasal cavity and sinuses)—*Pneumonyssoides caninum*, *Eucoleus boehmi*, *Linguatula serrata*, *Cuterebra* spp.
- Lower airway (trachea and bronchi)—dogs and cats: *Eucoleus (Capillaria) aerophilus* (rare in cats); dogs: *Oslerus osleri*, *Filaroides hirthi*, *Andersonstrongylus milksi*, *Crenosoma vulpis*, *Cuterebra* spp. in the trachea.
- Pulmonary parenchyma—dogs and cats: *Paragonimus kellicotti*, *Toxoplasma gondii*; dogs: *Filaroides hirthi*, *Andersonstrongylus milksi*; cats: *Aelurostrongylus abstrusus*, *Troglotrypanosoma brevior*, *Troglotrypanosoma subcrenatus*.
- Vascular—dogs and cats: *Dirofilaria immitis*, larval migration of *Toxocara canis* and *cati*; dogs: *Angiostrongylus vasorum*.

RISK FACTORS

- Depends on the specific parasite—some have intermediate or paratenic hosts that must be ingested by the definitive host, putting hunting or scavenging animals at higher risk.
- *Crenosoma vulpis*—snails.
- *Paragonimus kellicotti*—snails; crabs; shellfish.
- *Aelurostrongylus abstrusus*—snails and slugs; transport hosts: rodents, frogs, lizards, birds.
- *Linguatula serrata*—ingestion of sheep offal.
- *Toxoplasma gondii*—ingestion of infected small mammals and birds or less commonly by ingesting sporulated oocysts in soil or water.
- Multi-animal households with unhygienic living conditions—allows fecal-oral or direct-contact transmission.
- *Angiostrongylus vasorum*—gastropod (slug/snail) or frogs are the intermediate host. Frogs can also serve as paratenic hosts.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Upper respiratory—other causes of epistaxis, rhinitis, or sinusitis (see specific chapters).
- Lower respiratory—acute bronchitis (non-parasitic); chronic bronchitis; infectious tracheobronchitis.
- Pulmonary parenchyma—eosinophilic lung disease; bronchopneumonia; granulomatous pneumonia; pulmonary granulomatosis.
- Vascular—other causes of coagulopathy, right-sided heart failure, or pulmonary artery disease.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—variable; may note eosinophilia, basophilia, neutrophilia, and monocytosis;

can see anemia with *Angiostrongylus vasorum*.

- Biochemistry—often normal; high liver enzyme activity with some parasites during early stages as a result of hepatic migration if burden is substantial.
- Urinalysis—normal.

OTHER LABORATORY TESTS

Coagulopathy with *Angiostrongylus vasorum* or severe cases of heartworm disease (DIC).

IMAGING

Thoracic Radiography

- Often nonspecific findings—generalized interstitial pattern; peribronchiolar infiltrates, nodular to alveolar pattern.
- *Oslerus*—soft tissue nodular densities within the trachea at the level of the carina.
- *Paragonimus*—can see bullae, cystic lesions or pneumothorax due to bulla or cyst rupture.
- *Dirofilaria*—right-sided heart enlargement, tortuous and truncated pulmonary arteries, pulmonary infiltrates (dogs). Few cardiac changes in cats, large pulmonary arteries possible.

DIAGNOSTIC PROCEDURES

Sputum examination

May reveal eggs or larvae (L-1).

Fecal Examination

- Multiple examinations often necessary; negative results do not rule out infection.
- Direct fecal smear: *Angiostrongylus* (larvae).
- Standard fecal flotation: *Eucoleus aerophilus* (eggs), *Eucoleus boehmi* (eggs).
- Zinc sulfate centrifugation: *Aelurostrongylus* (larvae), *Oslerus osleri*, *Andersonstrongylus milksi*, *Filaroides hirthi* (larvae, larvated eggs), *Angiostrongylus vasorum* (larvae).
- Baermann: *Aelurostrongylus* (larvae), *Oslerus osleri*, *Andersonstrongylus milksi*, *Filaroides hirthi* (larvae, eggs), *Crenosoma* (larvae, larvated eggs), *Angiostrongylus* (larvae).
- Sedimentation: *Paragonimus* (eggs).

Rhinoscopy

- Upper respiratory—examination via retrograde pharyngoscopy or rhinoscopy with antegrade flushing of anesthetic gas can allow visualization of nasal mites; retrograde nasal lavage and cytologic examination of fluid can be helpful.
- *Eucoleus boehmi*—histopathology can reveal eggs deep within the epithelium.
- *Linguatula serrata*—diagnosis made by observation of eggs in nasal secretions or around the nares.

Bronchoscopy

- Lower respiratory and parenchyma—rarely can see tracheal and bronchial parasites and parasitic nodules; occasionally can be removed for definitive identification.
- Tracheal wash or bronchoalveolar lavage can allow identification of larvae (*Oslerus osleri*, *Aelurostrongylus*, *Crenosoma*, *Filaroides hirthi*, *Andersonstrongylus milksi*, *Angiostrongylus*); eggs (*Eucoleus aerophilus*, *Paragonimus*); organisms (*Toxoplasma*).
- *Oslerus osleri*—can also be diagnosed by brushings or histopathology of nodules at the carina.

RESPIRATORY PARASITES

(CONTINUED)

PATHOLOGIC FINDINGS

- Upper respiratory—may find nasal mites or worms in epithelium of sinuses and nasal cavity.
- Lower respiratory and parenchyma—can see pulmonary nodules containing parasites throughout the parenchyma or within bronchi.
- Vascular—changes include thrombi and intimal proliferation of the vascular walls.
- *Cuterebra* spp. can be found in brain sections when associated with neurologic signs.

TREATMENT

APPROPRIATE HEALTH CARE

Most commonly outpatient—upper and lower respiratory parasites; may need repeated examinations to monitor response.

NURSING CARE

Supportive care and oxygen therapy can be needed depending on the severity of disease.

ACTIVITY

Strict cage rest if severe pulmonary dysfunction occurs with upper or lower respiratory parasites; also with vascular parasite infection or bullous lung disease associated with *Paragonimus*.

DIET

No special restrictions

CLIENT EDUCATION

- Explain that treatment duration and response depend on the type of parasite.
- Warn client of the risk of recurrence in animals that maintain lifestyles conducive to transmission of the parasites (e.g., hunting, sporting dogs, multidog households, outdoor cats).

SURGICAL CONSIDERATIONS

Ruptured *Paragonimus* cysts generally require surgical excision.

R

MEDICATIONS

DRUG(S) OF CHOICE

- Anthelmintics—few studies confirm efficacy; most data anecdotal. For treatment of *Dirofilaria*, see chapters on Heartworm Disease.
- *Pneumonyssoides caninum*—selamectin at 6–24 mg/kg applied every 2 weeks for three treatments, milbemycin oxime at 0.5–1 mg/kg PO weekly for 3 weeks, ivermectin at 200 µg/kg SC or PO for two treatments 3 weeks apart; note: not labeled for use in dogs at this dosage.
- *Cuterebra*—ivermectin at 300 µg/kg SC or PO every other day for three doses combined with a tapering dose of corticosteroids.
- *Linguatula serrata*—physical removal of organisms from the sinuses.
- *Eucoleus aerophilus*, *Eucoleus boehmi*—ivermectin 200 µg/kg PO once;

fenbendazole 25–50 mg/kg q12h for 10–14 days, very difficult to clear.

- *Oslerus osleri*—efficacious therapy not fully determined. Consider ivermectin at 400 µg/kg SC or PO q3 weeks for four doses.
- *Crenosoma vulpis*—levamisole 7.5 mg/kg SC q48h (two doses); fenbendazole at 50 mg/kg PO q24h for 7 days; milbemycin oxime 0.5 mg/kg PO once.
- *Aelurostrongylus abstrusus*—fenbendazole at 25–50 mg/kg PO q24h for 10 days; ivermectin 400 µg/kg SC, selamectin spot-on formula 45 mg/cat, two doses, 23 days apart.
- *Filaroides hirthi*, *Andersonstrongylus milksi*—fenbendazole 50 mg/kg PO q24h for 14 days; albendazole 50 mg/kg PO q12h for 5 days, repeat in 3 weeks.
- *Paragonimus kellicotti*—praziquantel at 25 mg/kg PO, SC q8h for 3 days; fenbendazole at 25–50 mg/kg PO q12h for 14 days.
- *Toxoplasma*—clindamycin 12.5 mg/kg PO q12h for 28 days.
- *Angiostrongylus vasorum*—fenbendazole at 20–50 mg/kg PO q24h for 5–21 days; milbemycin oxime 0.5 mg/kg PO weekly for 4 weeks; single topical application of moxidectin at 2.5 mL/kg.
- *Toxocara* spp. larval migration—fenbendazole 50 mg/kg PO q24h for 10 days.
- Anti-inflammatory agents—recommendations for concurrent use of steroids vary.

CONTRAINdications

Ivermectin—not labeled for use in dogs or cats other than for heartworm prophylaxis; contraindicated at dosages > 100 µg/kg in breeds with known sensitivity (collies, collie breeds, and Australian shepherds).

PRECAUTIONS

None

ALTERNATIVE DRUGS

None

FOLLOW-UP

PATIENT MONITORING

• Serial fecal Baermann larval extractions or examination for eggs—some anthelmintics can suppress egg or larval production in some species and intermittent shedding reduces value of repeated fecal exams.

- Resolution of clinical signs—suggests response to treatment; does not indicate complete clearance of parasites.
- Peripheral eosinophilia, if noted initially, may subside with treatment.
- Repeat bronchoscopic examination—can help assess efficacy of treatment for *Oslerus osleri*.

PREVENTION/AVOIDANCE

- Avoid activity that predisposes to infestations (often not practical).
- Avoid contact with wildlife reservoirs (especially wild canids and felids).
- Consider prophylactic treatment for heartworm.

POSSIBLE COMPLICATIONS

- Chronic pulmonary damage—possible with persistent and heavy lower respiratory parasite burdens.
- Infestations generally not fatal; however, severe pulmonary damage can result with some species; *Cuterebra* spp. and *Angiostrongylus* can cause fatal neurologic complications.
- *Pneumonyssoides caninum* has been associated with gastric dilation and volvulus.

EXPECTED COURSE AND PROGNOSIS

- With aggressive management—prognosis usually fair to excellent; variable.
- Return to performance—depends on chronicity of disease and level of chronic pulmonary damage by lower respiratory parasites.
- Recurrence possible.

MISCELLANEOUS

ZONOTIC POTENTIAL

None

SYNOMYMS

- Lungworm infestation—*Aelurostrongylus*, *Eucoleus (Capillaria) aerophilus*, *Crenosoma*, *Oslerus osleri*, *Filaroides hirthi*, *Andersonstrongylus milksi*.
- Nasal mite infestation—*Pneumonyssoides caninum*, *Pneumonyssus caninum*.
- French heartworm—*Angiostrongylus vasorum*.

RETAINED PLACENTA

BASICS

OVERVIEW

- Dogs—placenta retained beyond the immediate postpartum period; placentas usually passed within 15 minutes of birth of a puppy; may develop acute metritis secondary to retained placenta.
- Cats—may retain placentas for days without signs of illness.
- Extremely uncommon.

SIGNALMENT

- Dog—rare, most common in toy dog breeds
- Cat—rare

SIGNS

Historical Findings

- Recent parturition.
- Continued vulvar discharge of lochia.
- Owner may note number of placentas passed, although this information is frequently unreliable.

Physical Examination Findings

- Green lochia vulvar discharge
- Palpation of firm mass in uterus—not always possible
- Concurrent clinical signs of postpartum metritis

CAUSES & RISK FACTORS

- Toy breed
- Large litter size
- Dystocia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Postpartum metritis—physical examination and vaginal cytologic examination show no signs of infection with uncomplicated retained placenta; metritis may develop concurrently.
- Retained fetus—differentiated by radiography or ultrasonography.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal when uncomplicated

OTHER LABORATORY TESTS

Vaginal cytologic examination—parabasal epithelial cells; may note erythrocytes; biliverdin clumps.

IMAGING

Ultrasonography—echogenic but non-fetal mass within the uterus.

DIAGNOSTIC PROCEDURES

Celiotomy or hysterotomy—may be required for diagnosis.

TREATMENT

- Outpatient for healthy bitch or queen.
- Instruct owner to monitor temperature and observe for signs of systemic illness.
- Ovariohysterectomy—curative; recommended if future breeding is not a consideration.
- Surgical removal—indicated if medical treatment is unsuccessful and the bitch develops metritis.

MEDICATIONS

DRUG(S)

- Oxytocin—known or suspected condition in otherwise healthy cats and dogs; dogs, 0.5 IU/kg IM up to 5 IU; cats, 0.5–1 IU IM. Oxytocin may be ineffective after 48 hours postpartum.
- May precede oxytocin treatment with calcium gluconate (10%); dogs and cats, 0.5–1.5 mL/kg IV slow over 15 minutes; monitor for arrhythmia during injection.
- Metritis—treat accordingly (see Metritis).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Do not give progestational drugs.

FOLLOW-UP

- Monitor temperature and physical condition.
- Acute metritis (dogs)—may develop if the placenta is not passed; fair to good prognosis for recovery with treatment.
- Prognosis for future reproduction—good without metritis; fair to poor with metritis.

MISCELLANEOUS

RETINAL DEGENERATION

BASICS

DEFINITION

- Degeneration of the retina from any cause, inherited or acquired.
- Inherited—generalized PRA; a group of progressive retinal diseases; may be subdivided into photoreceptor dysplasias (begin before the retina fully develops, < 12 weeks) and photoreceptor degenerations (begin after the retina matures).

PATHOPHYSIOLOGY

- A number of genetic defects in photoreceptor metabolism have been identified.
- May be secondary to retinal pigment epithelial or choroidal disease; amino acid metabolic disorders, and storage diseases.
- Central PRA: genetic defect in vitamin E metabolism, can be acquired with vitamin E deficiency.
- Also may be idiopathic, secondary to diffuse or focal inflammation and scarring (e.g., chorioretinitis), toxin exposure, nutritional deficiency, or previous retinal detachment.
- SARDS.

SYSTEMS AFFECTED

- Nervous system with lysosome storage diseases
- Ophthalmic

GENETICS

Dogs

- PRA—autosomal recessive most breeds (see breed predilection).
- Neuronal ceroid lipofuscinosis—autosomal recessive in most breeds.
- Hemeralopia—cone degeneration, autosomal recessive.
- Inheritance in many breeds not determined.

Cats

- Early onset—mixed breed and Abyssinian retinal dysplasia (rod-cone dysplasia), autosomal dominant. Persians (autosomal recessive). Clinical signs at 4 months; may be blind by 2 years.
- Late onset—Abyssinian autosomal recessive rod cone degeneration: blind by 4 years of age.

INCIDENCE/PREVALENCE

- Hereditary—prevalence greater in dogs than in cats.
- Taurine deficiency—uncommon now that cat foods are appropriately supplemented.

GEOGRAPHIC DISTRIBUTION

Central PRA—more common in dogs from Europe than from the United States.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Hereditary—Dogs

- Retinal dysplasia—Bedlington terrier, Sealyham terrier, English springer spaniel, cocker spaniel, and others.
- Early-onset PRA—Irish setter, collie, Norwegian elkhound, miniature schnauzer, Belgian

shepherd, mastiff, Cardigan Welsh corgi, American Staffordshire terrier, pit bull terrier, and Briard (congenital stationary night blindness); late-onset PRA—miniature and toy poodle, American and English cocker spaniel, Basenji, Labrador retriever, Tibetan terrier, miniature longhaired dachshund, Akita, Samoyed, Siberian huskie.

- Central PRA—Labrador, golden retriever, border collie, collie, Shetland sheepdog, Briard, others.
- Cone degeneration disease—German shorthaired pointer, Alaskan malamute, and Australian shepherd.

- Neuronal ceroid lipofuscinosis—English setter, border collie, American bulldog, Dalmatian, Tibetan terrier, collie.
- SARDS—Brittany spaniel, miniature schnauzer, dachshund, any breed.

Hereditary—Cats

- Abyssinian and Somali (longhaired Abyssinian)
- Siamese
- Persians—autosomal recessive

Mean Age and Range

- Early PRA and dystrophies—3–4 months–2 years
- Late PRA—clinical signs > 4–6 years
- Cone degeneration disease—3–4 months
- SARDS—middle-aged to old

Predominant Sex

- PRA—X-linked recessive condition in Siberian huskie and Samoyed, therefore more likely to be present in males.
- SARDS—70% are females.

SIGNS

Historical Findings

- PRA (dog)—a gradually progressing nyctalopia that ultimately affects vision in bright light; may note dilated pupils or brighter tapetal reflex; may appear to be acutely blind (when patient becomes totally blind or is moved to unfamiliar surroundings). Dysplasias will have early onset and may be blind by 2 years. Degenerations are later onset and blind in later life.
- Hemeralopia or cone degeneration disease—rare. Between 8 and 12 weeks of age puppies show photophobia and trouble navigating in bright light. Progresses to total day blindness. Night vision remains normal.
- Central PRA (dogs)—rare in the United States; central vision lost; may never become completely blind.
- SARDS—vision lost in 1–4 weeks; polyuria, polydipsia, and polyphagia common.

Physical Examination Findings

- If severe—direct and consensual pupillary light reflexes impaired or nearly abolished.
- Tapetal hyperreflectivity and non-tapetal depigmentation or mottled hyperpigmentation; retinal blood vessel attenuation and optic nerve atrophy.
- PRA (dogs)—cataracts and vitreous degeneration can occur.
- SARDS (dogs)—obesity; may note slow or absent pupillary light reflexes. Chromatic PLR testing (melan 100), reduce red PLR with escape, normal blue PLR.
- Borzoi chorioretinopathy—multifocal

chorioretinal lesions (hyperpigmented and hyperreflective).

- Taurine-deficient retinopathy (cats)—begins as a spot in area centralis; then horizontal band forms superior to the optic nerve; finally, diffuse degeneration and hyperreflectivity.
- Post-inflammatory retinal scars—focal or multifocal lesions manifest as areas of tapetal hyperreflectivity or altered pigmentation.
- Skeletal dysplasia may be associated with Samoyed and Labrador retriever, i.e., dwarfism.
- Retinal dysplasia may also be associated with multiple other ocular anomalies in Akita, Doberman pinscher, or any breed.
- Storage diseases—may have cloudy corneas and possibly neurologic signs.
- Neuronal ceroid lipofuscinosis—mental deterioration, CNS signs, paralysis, and death.

CAUSES

Degenerative

- PRA—affects both eyes symmetrically; most forms of PRA are recessively inherited except for dominant PRA in mastiffs.
- Chronic or uncontrolled glaucoma—retinal and optic nerve atrophy.
- Secondary to scarring from previous multifocal or diffuse retinal detachment or inflammation.

Anomalous

- Rod-cone dysplasias—affect both eyes.
- Other dysplasias—may be multifocal and non-blinding (e.g., in English springer spaniel and Labrador retriever).
- Oculoskeletal dysplasia in Labrador and Samoyed.

Metabolic

- Storage disease—mucopolysaccharidosis, gangliosidosis, mannosidosis, fucosidosis (English springer spaniel).
- Ornithine aminotransferase deficiency—progressive and total atrophy of the choroid and retina, manifests in older cats.

Neoplastic

Neoplastic cell infiltrate may lead to scars from previous retinal detachment if treated.

Nutritional

- Severe deficiency of vitamin E or A (dogs and cats)—dogs fed poor diets (high in polyunsaturated fats) may cause partial or complete degeneration.
- Taurine deficiency (cats)—causes retinal degeneration and dilated cardiomyopathy.

Infectious/Immune

Retina will degenerate from inflammation; may be focal, multifocal, or generalized.

Idiopathic

SARDS—dogs; post-inflammatory—dogs and cats.).

Toxic

- Idiosyncratic reaction to griseofulvin or enrofloxacin (cats).
- Radiation—dogs or cats treated for nasal or CNS neoplasia.
- Phototoxicity—operating microscopes, welding light exposure.

(CONTINUED)

RETINAL DEGENERATION**RISK FACTORS**

- Ocular disease—cataracts; panuveitis; chorioretinitis; retinal detachment; glaucoma.
- Cats—enrofloxacin dose should not exceed 5 mg/kg/day. Toxicity noted at lower doses especially in compromised animals, i.e., renal disease.

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

- Acute vision loss—pupillary light reflex slow or absent: SARDs, optic neuritis, retinal detachment, unrecognized PRA, or glaucoma; pupillary light reflex normal: rapidly developing diabetic cataracts or visual cortex disease.
- Slowly progressive visual loss—PRA; cataracts; severe corneal disease (e.g., pigmentation, scarring, or edema); chronic retinitis; chorioretinitis; vitreal inflammation.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal, unless systemic disease.
- SARDs (dogs)—results may be suggestive of hyperadrenocorticism, which patient may have.

OTHER LABORATORY TESTS

- Test for Cushing's disease, evaluate sex hormone levels, check blood pressure, evaluate for proteinuria—with SARDs.
- Taurine concentration (cats)—especially with dilated cardiomyopathy.
- Serum and urine ornithine concentrations (cats)—elevated with ornithine aminotransferase deficiency.
- Genetic testing—OptiGen, VetGen or Michigan State University. New tests for a variety of breeds are steadily being developed. Details on tests available, samples needed, and how to interpret test results may be found at testing center websites. Test results often allow identification of affected, non-affected, and probable carriers with good confidence.

IMAGING

- Thoracic radiographs and cardiac ultrasound—may be indicated in cats with suspected taurine-deficient condition.
- Abdominal radiographs and ultrasound (dogs)—with SARDs if Cushing's disease is suspected.
- CT or MRI—used to rule out causes of central blindness (e.g., optic nerve damage, cortical blindness).

DIAGNOSTIC PROCEDURES

- Ophthalmic examination.
- Electroretinography—localizes cause of blindness (when retina not visible or appears normal).
- Chromatic PLR (Melan 100)—can help screen for outer retinal layer problems (red reduced) vs. inner retina layers (absent blue). Definitive diagnosis requires electroretinogram as assessment of PLR is subjective and interpretation can be confounded by iris atrophy and stress-induced mydriasis.
- CSF tap—may be performed for cases of suspected optic neuritis.

PATHOLOGIC FINDINGS

- Thin retina.
- Edges of focal retinal scars—sharply delineated.
- Hyperpigmented areas—associated with post-inflammatory scars or central PRA.
- End-stage degenerations—marked photoreceptor atrophy and reduction in retinal cell density.
- Lipopigment accumulated in the neuroepithelium—central PRA, ceroid lipofuscinosis, congenital stationary night blindness.
- Lysosome storage diseases—accumulation in neuronal/retinal layers/cornea.

**TREATMENT****DIET**

- Cats—food should contain 500–750 ppm taurine.
- Dogs—balanced diet, avoid all meat high in polyunsaturated fats.

CLIENT EDUCATION

- Inform client that most blind animals function well in stable environment.
- Advise client that blind dogs should be supervised if they are outside, not in fenced yards or in an area with a pool.
- Suggest playing with toys that make sounds.
- Some old blind animals with other problems such as hearing loss or senility may not adapt well.
- Some blind animals experience behavioral changes such as increased aggression or reduced activity.
- Animals with only one blind eye can function normally.
- Blind cats should be kept indoors.

SURGICAL CONSIDERATIONS
Not indicated unless painful eye.**MEDICATIONS****DRUG(S)**

- None currently effective.
- Pyridoxine supplementation (cats)—for ornithine aminotransferase deficiency.
- Adequate dietary taurine—may halt the progression of the taurine-deficient retinopathy.

GENE THERAPY

Experimental—RPE dystrophy in the Briard.

CONTRAINdicATIONS

N/A

PRECAUTIONS

Cataract surgery—not recommended if retinal degeneration is severe; perform preoperative electroretinogram.

**FOLLOW-UP****PATIENT MONITORING**

- Serial fundic examinations—will note signs of degeneration over weeks with SARDs; months PRA.
- Cataract formation—with PRA or SARDs.

PREVENTION/AVOIDANCE

- Do not breed animals suspected of having PRA.
- Do not breed known carriers (e.g., offspring of affected).
- Do genetic testing on breeding animals.

POSSIBLE COMPLICATIONS

- Cataracts
- Glaucoma
- Uveitis
- Ocular trauma as a result of visual impairment
- Obesity—secondary to reduced activity

EXPECTED COURSE AND PROGNOSIS

- Inherited PRA—progresses to blindness; progression often slow enough for patient to adapt to visual loss; non-painful.
- Degeneration from previous inflammation—usually does not progress unless a systemic disease or autoimmune etiology causes persistent or recurrent inflammation.
- SARDs—irreversible blindness.
- Transient taurine deficiency (cats)—degeneration may halt at any stage.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

SARDs—hyperadrenocorticism, proteinuria, hypertension, elevated sex hormones

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

RETINAL DETACHMENT

BASICS

DEFINITION

Any separation of the neural retina from the retinal pigment epithelium.

PATHOPHYSIOLOGY

- Subretinal space—a potential space between the RPE and neural retina in which fluid or exudates accumulate.
- Characterized by its etiopathogenesis—one or a combination of rhegmatogenous (retinal tear), subretinal exudation, or traction.

Rhegmatogenous

A tear or hole in the retina that may be related to age, cataracts, traction from inflammatory debris or vitreal degeneration, trauma, or retinal degeneration. Vitreous fluid moves into the subretinal space, which results in detachment. Probably the predominant type that occurs in association with cataracts and after cataract or lens surgery. Requires some vitreous abnormality (e.g., liquefaction, traction).

Exudative

Fluid accumulates in the subretinal space because of breakdown of the blood-retinal barrier. Subretinal fluid—may be serous, hemorrhagic, or exudative (e.g., granulomatous in patients with blastomycosis). Hematogenous/systemic pathogenetic factors—common. Vasculitis, hypertension, and hyperviscosity—may cause serous detachment with or without hemorrhage.

Traction

Usually by fibrous or fibrovascular tissue; detaches retina and/or may cause retina hole or tear. May be associated with trauma, intraocular foreign bodies, or any cause of severe vitreal inflammation.

SYSTEMS AFFECTED

- Nervous—dogs with GME will often develop neurologic symptoms.
- Ophthalmic—retina, uvea. May be manifestation of a systemic disease or neoplasia.

GENETICS

Depends on cause—dogs with hereditary cataracts or lens luxations may develop rhegmatogenous detachment. Some breeds may have retinal tears and detachment from primary vitreous abnormalities.

INCIDENCE/PREVALENCE

- Exudative—most common in dogs and cats.
- Rhegmatogenous—more common in dogs because of the greater prevalence of cataracts and cataract surgery.

SIGNALMENT

Species

Dog and cat

Breed Predispositions

- Depends on cause.
- Terrier breeds—predisposed to primary lens luxation, which may contribute to retinal tear and detachment with or without surgery.
- Breeds that develop cataracts.
- Shih-Tzu, Boston terrier, Italian greyhound, Chihuahua—appear to be predisposed to spontaneous rhegmatogenous detachments owing to abnormal liquefied vitreous.
- Dogs with merle coat color; Australian shepherd, Shetland sheepdog, harlequin Great Dane, collie.
- Breeds that may have severe retinal dysplasia: springer spaniel, Labrador, Bedlington terrier.
- Breeds with serous retinopathy (also known as RPE dysplasia, canine multifocal retinopathy): Great Pyrenees, mastiff, Coton de Tulear.

Mean Age and Range

- Depends on cause.
- Older patients—cataracts and systemic diseases (e.g., hypertension, neoplasia, and immune-mediated disease).
- Young dogs: affected with severe retinal dysplasia, canine multifocal retinopathy.

SIGNS

- Blindness or reduced vision in affected eye.
- Dilated pupil with slow or no PLR. PLR may be near normal if detachment is acute.
- Blood vessels or a “membrane” may be observed easily through the pupil just behind the lens.
- Vitreous abnormalities—floaters, hemorrhage, or syneresis (liquefaction); common.
- Interruption or alteration of the course of blood vessels owing to retinal elevation.
- With clear subretinal fluid—vessels may cast shadows.
- With exudative fluid or blood, tapetum may not be visible.
- Other symptoms will depend on any underlying systemic diseases.
- See chapter, Chorioretinitis, for signs of inflammation.
- Canine multifocal retinopathy: multifocal gray to tan elevated lesions (focal detachments) of various size. Starts around 11 weeks, progresses with time.

CAUSES

Bilateral—suggests a systemic problem led to disruption of blood-retinal barrier unless severe vitreal degeneration is present in breed known to have predisposition e.g., Shih Tzu.

Degenerative

- End-stage progressive retinal degeneration—may lead to retinal hole formation and detachment: see Retinal Degeneration.

Anomalous

- Colobomas—collie eye anomaly: abnormal retina around colobomatous optic nerve or large choroidal staphylomas may lead to rhegmatogenous detachments; border collies, Australian shepherds, and other breeds in which dogs have merle coats (merle ocular dysgenesis).
- Multiple ocular anomalies—Akitas, any breed.
- Severe retinal dysplasia—oculoskeletal dysplasia in Labrador retrievers and Samoyeds; retinal dysplasia; English springer spaniels and Bedlington terriers.

- Canine multifocal retinopathy—suspect RPE dysplasia; Great Pyrenees, mastiffs, Coton de Tulear.

Metabolic

- Hyperviscosity.
- Polycythemia.
- Hypoxia with hemorrhagic complications.
- Dogs—systemic hypertension (any cause such as renal failure or pheochromocytoma), hypothyroidism, hypercholesterolemia, and hyperproteinemia (e.g., with multiple myeloma).
- Cats—most often caused by systemic hypertension either as a primary condition or secondary to renal failure or hyperthyroidism. Multiple myeloma, adrenal tumors also can cause RD due to hyperviscosity or hypertension.

Neoplastic

- Any primary or metastatic neoplasm.
- Commonly associated with multiple myeloma, lymphoma, granulomatous meningoencephalitis, and intraocular masses—ciliary body adenocarcinoma or melanoma.
- Hypertension secondary to adrenal tumors like pheochromocytoma; rare.

Infectious

- Infectious retinitis or chorioretinitis—may cause focal or diffuse detachment.
- Infection may extend from or to the CNS.
- See Chorioretinitis.

Immune Mediated/Inflammatory

- Immune complex disease—may cause vasculitis or inflammation resulting in exudative detachment.
- Dogs—SLE; uveodermatologic syndrome.
- Cats—periarteritis nodosa; SLE.

Idiopathic

- If all other causes are ruled out, including retinal tears.
- Idiopathic steroid-responsive detachment—reported in giant-breed dogs but may occur in any breed.

Trauma and Toxic

- Bilateral—traumatic probably never occurs.
- Penetrating injury or foreign body.
- Severe blunt trauma with inflammation or hemorrhage.
- Surgical trauma—may contribute to retinal tearing.
- Toxic—idiosyncratic reactions to drugs (e.g., trimethoprim-sulfa, ethylene glycol in dogs, griseofulvin in cats).

RISK FACTORS

- Systemic hypertension.
- Old age: retinal thinning, severe vitreal degeneration.
- Hypermature cataracts.
- Luxated lenses.
- Lens extraction.
- Hereditary: young dogs that have more severe retinal dysplasia and/or multiple ocular anomalies.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Blindness or impaired vision—optic neuritis; glaucoma; cataracts; progressive

(CONTINUED)

- retinal atrophy; SARDs (see Retinal Degeneration); CNS disease.
- Dilated pupil with slow or absent pupillary light reflexes—glaucoma; oculomotor nerve lesion; optic neuritis; progressive retinal atrophy; SARDs.
- Membrane or vessels associated with or behind lens—persistent tunica vasculosa lentis; persistent pupillary membranes; fibrovascular membrane secondary to intraocular neoplasia or inflammation.

CBC/BIOCHEMISTRY/URINALYSIS

- Typically normal if the problem is confined to the eye.
- Abnormalities consistent with an associated systemic disease process.

OTHER LABORATORY TESTS

- Depends on suspected systemic problem.
- Protein electrophoresis.
- Documentation of Bence-Jones protein in urine.
- Coagulation profile.
- Bacterial culture of ocular or body fluids.
- Thyroid hormone measurement.
- Serologic or PCR testing for infectious diseases—see Chorioretinitis.

IMAGING

- Thoracic radiograph, abdominal X-rays, and abdominal ultrasound—search for lymphadenopathy, primary neoplasia, metastatic disease, or infiltrates consistent with infectious agents.
- Radiographs of the spine—may reveal bony changes consistent with multiple myeloma.
- Ocular ultrasound—identify retinal detachments, intraocular masses; helpful if the ocular media is not clear.
- Cardiac ultrasound—cats with hypertensive retinopathy.

DIAGNOSTIC PROCEDURES

- Ophthalmic examination.
- Single or repeated blood pressure measurement—may reveal hypertension; normal mean arterial pressure in dogs and cats usually $< 160 \text{ mmHg}$.
- CSF tap—indicated with signs of CNS disease or optic neuritis.
- Vitreocentesis or subretinal fluid aspirate—may be performed if other diagnostic tests failed to yield a cause and an infectious agent or neoplasia is suspected; may aggravate the inflammation or induce hemorrhage.

PATHOLOGIC FINDINGS

- Retina separated from the RPE and underlying choroid.
- May note masses or subretinal exudate or etiologic infectious organism.
- Chronic—results in retinal atrophy and a tombstone appearance to the RPE.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Depends on the physical condition of the patient.
- Usually outpatient.
- Acute blindness—vision may be restored if the underlying cause is rapidly identified and treated; make every attempt to determine the

cause.

- Degeneration occurs rapidly—provide therapy as soon as possible after diagnosis.

CLIENT EDUCATION

- Explain that RD may be a sign of systemic disease, so diagnostic testing is important.
- Inform client that RD associated with vitreal degeneration, lens luxation or cataract surgery has a bilateral potential, minimize head shaking.
- Inform client that with short-duration RD return of vision may occur if the underlying cause is treated.
- Advise client that blind pets can adapt remarkably well and live a good-quality life (see Retinal Degeneration).

SURGICAL CONSIDERATIONS

- Rhegmatogenous—may be surgically repaired by an ophthalmologist.
- Laser retinopexy—may reverse detachments associated with optic disk colobomas with collie eye anomaly; may stabilize partial/small detachments. May prevent detachment in predisposed fellow eye.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Depends on underlying systemic cause, which should be identified and treated.
- Systemic prednisone 2 mg/kg divided q12h for 3–10 days, then taper; if systemic mycosis is ruled out and the detachment is believed to be immune mediated; may facilitate retinal reattachment; for immune-mediated disease, taper medications very slowly over months.
- Anti-inflammatory doses of prednisone 0.5 mg/kg, then taper; may be useful for exudative detachments of an infectious nature as long as the underlying disease is being definitively treated.
- Antihypertensive agents—amlodipine 0.5–1 mg/kg PO q24h in dogs; cats 0.625–1.25 mg. Propranolol and/or enalapril (0.25–0.5 mg/kg q12–24h) or benazapril (0.25–0.5 mg/kg q24h) for cats with hypertension not responsive to amlodipine alone. Calcium channel blockers may be important in cats that have renal failure and proteinuria. Consult with internist. See Renal Failure chapters.

CONTRAINDICATIONS

Systemic corticosteroids—do not use unless systemic mycosis is ruled out or is being definitively treated.

ALTERNATIVE DRUG(S)

- Chemotherapeutic agents—suggested for treatment of neoplastic conditions.
- Other immunosuppressive drugs may be needed in some immune-mediated RD if prednisone not effective long term at safe dose, i.e., uveodermatologic syndrome.
- Azathioprine: dogs, 2 mg/kg PO q24h initially, then 0.5–1 mg/kg q48h; to control inflammation.

RETINAL DETACHMENT

- Oral cyclosporine: dogs, 5 mg/kg/day then taper.
- Leflunomide, mycophenolate; also can be used if prednisone is not effective at a safe dose; consult with internist.

**FOLLOW-UP****PATIENT MONITORING**

- Immunosuppressive drugs such as azathioprine—obtain an initial CBC, chemistry panel, then every 1–2 weeks to monthly (depending on which medication) to monitor for bone marrow suppression, liver, renal, or pancreas toxicity.
- Monitor blood pressure in hypertensive cases.

POSSIBLE COMPLICATIONS

- Permanent blindness.
- Cataracts.
- Glaucoma.
- Chronic ocular pain.
- Death if secondary to a systemic disease/neoplastic process.

EXPECTED COURSE AND PROGNOSIS

- Prognosis for vision with complete detachment—guarded. The exception is hypertensive retinopathy that is diagnosed and treated promptly.
- Vision may return if the underlying cause is removed and reattachment occurs.
- Blindness—may develop in days to weeks even if reattachment occurs (more likely and rapid with exudative than with serous detachments).
- Focal or multifocal chorioretinitis—does not markedly impair vision; will leave scars.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Exudative—systemic disease.
- Cataracts.
- Trauma.
- Vitreous abnormalities.
- CNS signs with GME or systemic disease affecting CNS.

R

ABBREVIATIONS

- CNS = central nervous system
- CSF = cerebrospinal fluid
- GME = granulomatous meningoencephalomyelitis
- PLR = pupillary light reflex
- RD = retinal detachment
- RPE = retinal pigment epithelium
- SARDs = sudden acquired retinal degeneration syndrome
- SLE = systemic lupus erythematosus

RETINAL HEMORRHAGE

BASICS

DEFINITION

- Focal or generalized areas of bleeding into part or all layers of the retina.
- May be acute or chronic.

PATHOPHYSIOLOGY

- Depends on cause.
 - Trauma-induced retinal detachments—may tear retinal blood vessels.
 - Often involved in congenital malformations, concurrent vascular abnormalities, and neovascularization syndromes.
 - Intoxications, vasculitis, systemic clotting, neoplastic disorders, systemic infectious disease—may cause focal or more widespread hemorrhage.
 - Systemic hypertension and immune-mediated diseases (e.g., those causing anemia)—may cause local hemorrhage in conjunction with vascular abnormalities and/or complete or partial retinal detachments.
 - May note a retinopathy in conjunction with diabetes mellitus—includes the formation of vascular microaneurysms with accompanying hemorrhage or exudation.

SYSTEMS AFFECTED

Ophthalmic

GENETICS

- Collie eye anomaly—autosomal recessive trait.
- Retinal dysplasia—suspected to be autosomal recessive inheritance.
- Retinal detachment—depends on causative factor, hereditary type when observed in conjunction with collie eye anomaly or retinal dysplasia.

INCIDENCE/PREVALENCE

- Common in hypertensive retinopathy of elderly cats.
- Low incidence in collie eye anomaly.

SIGNALMENT

Species

Dog and cat: any breed, age, or sex

Breed Predilections

- Cause may have a genetic basis and be highly breed- and age-specific—young collies with collie eye anomaly; Labrador retrievers with congenital vitreoretinal dysplasia.
- Hereditary breed-specific congenital defects that might cause detachment or severe retinal dysplasia—collies and shelties with collie eye anomaly; Australian shepherds with merle ocular dysgenesis; Labradors, Sealyhams, Bedlington terriers, and springer spaniels with retinal dysplasia; and miniature schnauzers with retinal dysplasia and persistent hyperplastic primary vitreous.

Mean Age and Range

- Old cats of both sexes—often affected by systemic hypertension.
- Collie eye anomaly and retinal dysplasia are congenital defects and can be observed in 5- to 7-week-old dogs.

Predominant Sex

No sex predilection

SIGNS

General Comments

Signs depend on underlying causes such as inflammatory disease in the posterior segment, systemic disease, or ocular malformations.

Historical Findings

- Often none
- Vision loss
- Bumping into objects

Physical Examination Findings

- Depends on underlying cause
 - Light or dark red appearance of the posterior segment
 - Blood-filled anterior chamber (hyphema)
 - Evidence of bleeding elsewhere—petechia, ecchymoses, melena, hematuria
 - Leukocoria (whitish-appearing pupil) with or without reddish coloration behind the lens
 - Absence of menace response
 - Abnormal pupillary responses

CAUSES

Congenital

- Retinal detachment secondary to severe congenital malformations in the eye.
- Vitreoretinal defects; e.g., in PHTVL/PHPV.
- Retinal defects in geographic or complete retinal dysplasia or in partial or complete retinal detachment.

Acquired

- Trauma.
- Systemic hypertension (especially old cats)—renal disease; cardiac disease; hyperthyroidism; hyperadrenocorticism; idiopathic.
- Intoxication—dicumarol; paracetamol; sulfonamide; estradurin.
- Rickettsia—*Rickettsia rickettsiae*, *Ehrlichia* spp. associated.
- Systemic mycosis—cryptococcosis.
- Neoplasia—lymphosarcoma.
- Plasma cell myeloma.
- Hematologic disorders—blood-clotting disorder (von Willebrand disease); severe anemia; thrombocytopenia; monoclonal gammopathy and hyperviscosity syndrome.
- Diabetic retinopathy.
- Retinal detachment.
- Immune-mediated vasculitis.

RISK FACTORS

- Systemic hypertension or clotting disorders
- Hematologic such as anemia and polycythemia
- Vascular membranes

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Normal choroidal vessel pattern in a subalbinotic fundus. Lightly pigmented eyes. Blood is contained in vascular channels and not outside of the vessel lumen.

- Vitreal opacities (blood or inflammation).
- Vitreal hemorrhage—reddish coloration of the pupil, impossible to rule out concurrent retinal hemorrhage.
- Vitreal inflammation—

generalized or local blurring or lack of fundus detail—usually no reddish coloration. Vitreal opacities can be caused by persistent hyaloid arteries, neoplasia—especially lymphoma or ciliary body tumors; uveitis; glaucoma; lens luxation; blunt or sharp trauma, foreign bodies, and spread from local or systemic diseases (e.g., rickettsial or systemic mycosis).

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal unless secondary to a systemic disease.
- Hyperglycemia and/or glucosuria—may note with diabetic retinopathy.
- High BUN or serum creatinine and proteinuria—common in cats with retinal detachment and hemorrhage secondary to systemic hypertension.
- Thrombocytopenia or other changes consistent with systemic hematologic disorders.

OTHER LABORATORY TESTS

Complete workup—suspected systemic disease; includes thyroid and adrenal endocrine tests, serologic tests for infectious agents, and immune studies.

IMAGING

- Ocular ultrasound to evaluate position of lens and retina in cases with blood-filled posterior segment.
- If neoplasia is possible consider chest radiographs.
- Abdominal ultrasound may be considered if systemic disease is suspected.

DIAGNOSTIC PROCEDURES

- Ophthalmic examination with a penlight—usually permits diagnosis of complete retinal detachment with partial retinal hemorrhage; detached neuroretina may often be visualized through the pupil as a whitish veil of tissue.
- Indirect ophthalmoscopy—diagnosis of funduscopic and vitreal changes.
- Vitreous paracentesis and cytologic examination—aid in the diagnosis for suspected neoplasia or mycotic disease.
- Blood pressure measurement—indicated in all patients with severe retinal and vitreal hemorrhage.

PATHOLOGIC FINDINGS

- Depends on the cause.
- Findings include preretinal, intraretinal, or subretinal hemorrhage that may be focal or involve large areas.
- Secondary morphologic changes include fibrotic areas with proliferation of cellular extensions into the subretinal space, intraretinal, and thickening of the external limiting membrane.

TREATMENT

APPROPRIATE HEALTH CARE

- Infections and intoxications—often require specific treatment. Systemic hypertension should be treated in a timely fashion to improve chances of retinal reattachment.
- Consider referral for a more detailed ophthalmic examination, including

(CONTINUED)

RETINAL HEMORRHAGE

ultrasound, before attempting empirical therapy.

NURSING CARE

- Depends on the cause.
- Supportive care often needed with well-trained veterinary technicians to monitor progress several times daily.

ACTIVITY

Retinal detachment—cage rest until the retina is reattached in trauma cases.

DIET

Depends on underlying cause; there may be dietary restrictions if the primary disorder is due to hepatic or renal disease.

CLIENT EDUCATION

- Discuss living with a blind dog or euthanasia of young puppies with severe bilateral hemorrhage due to congenital abnormalities (of the breeds listed under "Signalment").
- Advise client that unilaterally affected dogs can function as pets but should not be used for breeding, a fact not always obvious to the owner.

SURGICAL CONSIDERATIONS

Surgery—refer patient to an ophthalmologist for vitrectomy and/or reattachment surgery.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Depends on underlying cause.
- Systemic corticosteroids—if workup is declined and infectious disease is unlikely; prednisolone (1–2 mg/kg/day for 7–14 days, then taper; long-term treatment up to 4–6 weeks); especially for retinal detachment as a sequela to trauma in dogs and cats. Doxycycline (4 mg/kg PO q12h for 14–21 days) or other appropriate systemic antibiotic based on infectious disease testing; may be administered concurrently with corticosteroids.
- Primary systemic hypertension—treat as required; often combined with diuretics (e.g., furosemide, 3–4 mg/kg/day for 5–7 days), and calcium channel blockers.
- Oral azathioprine 1–2 mg/kg/day up to a week, then taper; for immune-mediated retinal detachments; combine with systemic corticosteroids; perform a CBC, platelet count, and liver enzyme analysis every 2 weeks for the first 2 months, then periodically.
- Itraconazole—for cryptococcosis or other deep fungal infection; see Cryptococcosis or appropriate systemic mycosis.

CONTRAINDICATIONS

- Systemic corticosteroids and other immunosuppressive drugs—use with extreme caution in patients with systemic infection.
- Systemic NSAIDs—contraindicated with bleeding disorders, impaired renal function, or preexisting hypersensitivities; predispose patient (especially cats) to gastrointestinal ulceration.

PRECAUTIONS

NSAIDS—carprofen and meloxicam commonly used but may exacerbate bleeding; either may be administered to control intraocular inflammation in dogs. Use with caution in cats.

ALTERNATIVE DRUG(S)

Oral azathioprine—may be used in immune-mediated fundus disease; see "Drug(s) of Choice."

**FOLLOW-UP****PATIENT MONITORING**

- Repeated monitoring—required to ensure that condition subsides and retinal morphology normalizes.
- Preretinal hemorrhages—usually absorbed within a few weeks to several months if localized.
- Larger or repeated hemorrhages—may be followed by fibroplastic processes; may lead to the formation of fibrous preretinal membranes and vitreoretinal adhesions, which may cause vitreoretinal traction and retinal detachment.
- Intraretinal hemorrhage—reabsorbed within several weeks to months; may produce retinal scarring.

POSSIBLE COMPLICATIONS

- Retinal detachment
- Blindness
- Impaired vision
- Chronic uveitis
- Glucoma

EXPECTED COURSE AND PROGNOSIS

- Depends on underlying cause.
- Most retinal hemorrhagic lesions are small, observed during routine ophthalmoscopic examination, usually heal rapidly, and cause no visual problems.
- Retinal hemorrhage due to systemic diseases or retinal malformations is usually more serious, and most have an uncertain prognosis.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Trauma—may often note concurrent lesions in other parts of the eye or body.

- Hypertension—cardiac, renal disease, hyperthyroidism, or hyperadrenocorticism—common; may cause systemic medical problems that must be monitored.

- Intoxication—often a generalized bleeding disorder affecting other organs.
- Cryptococcus infection—often causes concurrent leptomeningitis and pneumonitis.
- Lymphoma—may affect several parts of the body; fatal disease.
- Hematologic disorders—cause systemic disease; symptoms depend on pathophysiology; anemia and recurrent bleeding common.
- Secondary cataracts—may develop within weeks after the onset of diabetes mellitus in dogs.

AGE-RELATED FACTORS

- May occur at any age.
- Often due to congenital diseases (usually have a hereditary background) or to developmental disease processes (see "Causes").

PREGNANCY/FERTILITY/BREEDING

- Dogs affected with hereditary retinal disease causing retinal hemorrhage should not be used in the breeding program.
- Corticosteroids and immunosuppressive drugs may cause complications in regards to pregnancy.

SEE ALSO

- Chorioretinitis
- Hypertension, Systemic
- Hyphema
- Retinal Detachment

ABBREVIATIONS

- NSAID = nonsteroidal anti-inflammatory drug
- PHPV = persistent hyperplastic primary vitreous
- PHTVL = persistent hyperplastic tunica vasculosa lentis

RHINITIS AND SINUSITIS

BASICS

DEFINITION

- Rhinitis—inflammation of nasal epithelium.
- Sinusitis—inflammation of paranasal sinuses. Includes frontal sinus and maxillary recess in dogs, frontal and sphenopalatine sinuses in cats.
- The nasal cavity communicates directly with the sinuses; thus rhinitis and sinusitis often occur together (rhinosinusitis).

PATOPHYSIOLOGY

Inflammation and irritation stimulate serous glandular secretion in the nasal mucosa. With chronicity, opportunistic bacterial infections develop in the compromised nasal mucosa causing discharge to become mucoid or mucopurulent. The inflammatory process can lead to turbinate destruction and erosion of the vasculature that results in epistaxis.

SYSTEMS AFFECTED

- Respiratory—sneezing and nasal discharge usually indicate upper respiratory tract disease. Nasal discharge may occasionally be seen with lower airway disease or chronic vomiting disorders.
- Nervous—fungal and neoplastic disease can destroy the cribriform plate and invade the brain.
- Ocular—epiphora with inflammation or obstruction of the nasolacrimal ducts. Conjunctivitis, keratitis, and/or corneal ulcerations with FHV-1 related disease. Chorioretinitis with canine distemper or *Cryptococcus*.
- Oral Cavity—calicivirus, FeLV, FIV are associated with stomatitis, glossitis, faulitis. Tooth root abscess, oronasal fistula or cleft palate possible.

INCIDENCE/PREVALENCE

- Primary bacterial rhinosinusitis is rare, secondary infection associated with dental-related disease common.
- Cats—chronic rhinosinusitis common.
- Dogs—neoplasia, inflammatory rhinitis (lymphoplasmacytic rhinitis), fungal disease common. Nasal foreign body a cause for acute sneezing.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Brachycephalic cats more prone to chronic rhinitis and *Aspergillus* infection.
- Dolichocephalic dogs more prone to *Aspergillus* infection and nasal tumors.

Mean Age and Range

- Cats—acute viral rhinosinusitis and nasopharyngeal polyps more common in young kittens (6–12 weeks).
- Congenital diseases (cleft palate, ciliary dyskinesia) more common in young animals.
- Neoplasia and dental disease—older animals.
- Foreign bodies more common in young dogs.

Predominant Sex

No sex predilection

SIGNS

Historical Findings

- Sneezing, nasal discharge, epistaxis.
- Discharge usually is serous initially and becomes mucoid, mucopurulent, serosanguinous, or hemorrhagic.
- Unilateral discharge suggests foreign body, tooth root abscess, early neoplasia, or early fungal infection. Idiopathic inflammatory rhinitis can also present with unilateral signs.
- Bilateral discharge more common with viral or bacterial rhinosinusitis, inflammatory rhinitis, pharyngeal disease, or congenital abnormalities. Chronic presentation of neoplasia or fungal rhinitis is often bilateral.
- Facial deformity or facial pain—usually with fungal or neoplastic disease.
- Reverse sneezing more common in dogs, inappetence more common in cats.

Physical Examination Findings

- Check for decreased nasal air flow, bilateral or unilateral, which would suggest an obstructive mass lesion.
- Evaluate oral cavity for tooth root abscess, oronasal fistula, cleft palate or ulcers.
- Increased tracheal sensitivity or cough possible with lower airway causes of nasal signs.
- Look for epiphora, conjunctivitis. Horner's syndrome can be seen with middle ear disease.
- Fundic examination—chorioretinitis possible with infectious diseases; hypertension can result in tortuous retinal vessels or hemorrhage, platelet abnormalities can be associated with retinal hemorrhage or petechiation.

CAUSES

Dogs

Primary Inciting Causes

- Fungal disease—*Aspergillus fumigatus* most common. *Penicillium* spp., *Rhinosporidium seeberi*, *Blastomycoses dermatitidis*, *Cryptococcus neoformans* are rare causes.
- Tooth root abscess.
- Foreign body.
- Congenital abnormalities such as cleft palate or primary ciliary dyskinesia.
- Parasitic causes—nasal mites (*Pneumonyssoides caninum*), *Capillaria aerophila*, *Eucoleus boehmii*.
- Intranasal neoplasia—adenocarcinoma most common (31.5%). Others include lymphoma, chondrosarcomas, or osteosarcomas.
- Immune-mediated rhinitis—allergic rhinitis rare, idiopathic lymphoplasmacytic rhinitis more common.
- Other infectious diseases include canine distemper or *Bordetella bronchiseptica*; *Bartonella* not associated with rhinitis.
- Local trauma can cause bone or turbinate deformity and predispose to chronic rhinitis or *Aspergillus* infection.

Secondary Causes

- Lower airway disease (bronchopneumonia) or vomiting can result in nasal signs through nasopharyngeal regurgitation.
- Nasal discharge can occur with eosinophilic bronchopneumopathy.
- Epistaxis can be related to hypertension, thrombocytopenia, thrombocytopathia, or rarely other

coagulopathies; trauma or foreign body also possible.

Cats

Primary Inciting Causes

- Viral infections—feline herpesvirus-1 and calicivirus account for 90% of acute infections in kittens.
- Bacteria—*Bordetella bronchiseptica* can be a primary pathogen in cats but its significance is uncertain.
- Bartonella* not associated.
- Neoplasia—adenocarcinoma and lymphoma most common.
- Fungal disease—*Cryptococcus neoformans* most common, *Aspergillus felis*, *Penicillium* (rare).
- Nasopharyngeal polyps in young cats > dogs.
- Nasopharyngeal webbing/stenosis—congenital or secondary to chronic infection or inflammation.
- Tooth root abscess or oronasal fistula.
- Foreign bodies.
- Congenital abnormalities include cleft palate.

Secondary Causes

- Epistaxis due to coagulopathy or hypertension.
- Aspiration of vomitus into the nasopharynx

RISK FACTORS

- Dolichocephalic breeds—fungal disease
- Brachycephalic cats—rhinosinusitis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Rule-out secondary causes of rhinitis including coagulopathy, hypertension, lower airway disease, chronic vomiting.

CBC/BIOCHEMISTRY/URINALYSIS

- Hemogram is nonspecific—may show leukocytosis (neutrophilia or eosinophilia) with infectious agents. Regenerative anemia with severe blood loss from coagulopathy. Nonregenerative anemia with chronic disease or neoplasia. Thrombocytopenia seen with coagulopathies or severe blood loss.
- Serum biochemistry and urinalysis typically normal.

OTHER LABORATORY TESTS

- FeLV and FIV serologic tests
- Latex agglutination test for cryptococcal capsular antigen
- *Aspergillus* titers: AGID in dogs—false negatives possible, false positives uncommon. ELISA in cats (research tool currently)—high sensitivity and specificity for disease
- Coagulation profile—if epistaxis present

IMAGING

- Radiography—chest radiographs if lower airway disease or neoplasia suspected.
- Dental radiographs highly sensitive for detecting periodontal disease.
- Skull radiographs are useful but do not differentiate among inflammatory rhinitis, fungal infection, and neoplastic disease. Loss of turbinate structures can be seen with all causes. Open-mouth or intraoral ventrodorsal

(CONTINUED)

views provide superior evaluation of the nasal cavity and avoid superimposition of the mandible. • Nasopharyngeal polyps occasionally seen within the nasopharynx. • CT/MRI—superior to plain radiography in evaluating the extent of disease and assessing the integrity of the cribriform plate. Also useful in evaluating disease of the palate, nasopharyngeal meatus, maxillary sinus, periorbital tissues, middle ear canal.

DIAGNOSTIC PROCEDURES

Arterial Blood Pressure

- Evaluate for hypertension if epistaxis.

Lymph Node Aspirate

- Can be diagnostic for neoplasia or *Cryptococcus*.

Cytology

- Nasal swab may reveal *Cryptococcus*.

Culture

- Usefulness of culture is controversial—most animals have secondary bacterial infection. Potential bacterial pathogens are more commonly isolated in cats with rhinosinusitis than healthy cats. • Fungal culture of a plaque lesion visualized on endoscopy aids in diagnosis of aspergillosis. Blindly collected specimen less likely to be useful.
- Asymptomatic intranasal carriage of *Cryptococcus* possible.

Endoscopy

- An otoscope evaluates only the rostral nasal cavity. A rigid endoscope can be guided to the ethmoid turbinates; flexible endoscope provides good visualization rostrally, and can be retroflexed in the nasopharynx to visualize the caudal choanae. • Guided biopsy is possible with rigid and flexible endoscopy. Other techniques include core or blind pinch biopsies. Excessive hemorrhage can be controlled with topical epinephrine at 1:100,000.

Surgery

- Exploratory rhinotomy most invasive diagnostic tool, can be required for difficult foreign body or mass removal, if endoscopy is unsuccessful. Rarely required to obtain a definitive biopsy sample.

PATHOLOGIC FINDINGS

Chronic inflammation causes turbinate resorption, mucosal ulceration and necrosis. Lymphoplasmacytic infiltrate indicates chronicity; neutrophilic usually signifies acute component. Neoplasia and fungus also cause bony lysis or destruction.

TREATMENT

NURSING CARE

Humidification can aid in moistening and mobilizing nasal secretions. Saline intranasal drops helpful if tolerated. Keep nares clean of obstructive mucus.

CLIENT EDUCATION

Signs of chronic rhinitis can be variably controlled but are rarely eliminated.

SURGICAL CONSIDERATIONS

- Rhinotomy is reserved for obtaining a biopsy or foreign body/mass removal when endoscopic intervention is unsuccessful. Rarely provides an advantage over endoscopy.
- Surgery useful for polyp removal, dental-related nasal disease (tooth root abscess, oronasal fistula, cleft palate).

MEDICATIONS

DRUG(S)

Antibiotics

Antibiotics help control secondary bacterial rhinitis; however, they will not resolve disease. Selection of antibiotic is mainly empirical (common isolates include *Staphylococcus*, *Streptococcus*, *Bacillus*, *E. coli*, and *Pasturella multocida*). Long-term use often needed.

Antifungals

See Cryptococcosis and Aspergillosis chapters for detailed treatment discussion.

L-lysine

Inhibits FHV-1 replication; may be useful—250 (kitten)–500 (cat) mg PO q12h.

Anti-inflammatory Agents

Piroxicam (nonsteroidal anti-inflammatory agent) used for palliation of nasal tumors (via COX-2 inhibition), either as sole agent or in conjunction with chemotherapy. Sometimes helpful in animals with rhinitis.

Steroids

Consider use with chronic rhinosinusitis in cats or lymphoplasmacytic rhinitis in dogs at anti-inflammatory doses when mucus obstruction limits appetite.

Antihistamines

Efficacy is debated

Anti-parasitics

Ivermectin 300 µg/kg PO or SC once weekly for 3–4 treatments or milbemycin oxime 1 mg/kg PO once weekly for 3 weeks for treatment of nasal mites.

CONTRAINDICATIONS

Avoid chronic steroid use owing to danger of immunosuppression.

PRECAUTIONS

- NSAIDs can cause GI ulceration.
- Tetracycline may stain teeth of young animals.

POSSIBLE INTERACTIONS

Use of NSAIDs and corticosteroids together is contraindicated.

RHINITIS AND SINUSITIS

FOLLOW-UP

PREVENTION/AVOIDANCE

Vaccinations in kittens can lessen severity and duration of viral infection.

POSSIBLE COMPLICATIONS

- Extension of fungal or neoplastic invasion into brain. • Seizures and other neurologic signs are possible if topical antifungal therapy is used when the cribriform plate is not intact.

EXPECTED COURSE AND PROGNOSIS

- Dependent on etiology and extent of disease. • Acute viral/bacterial rhinitis—good prognosis, chronic rhinitis—guarded for control of signs. • Fungal—fair to guarded prognosis depending on invasiveness and response to therapy. • Neoplastic—3–5 months with no treatment. Life expectancy can be extended up to 9–23 months with radiation therapy.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Cryptococcus, *Aspergillus*, *Penicillium* are transmissible to humans via shared environment. No direct transmission.

SEE ALSO

- Aspergillosis • Cryptococcosis • Epistaxis
- Nasal and Nasopharyngeal Polyps • Nasal Discharge • Respiratory Parasites • Stertor and Stridor

ABBREVIATIONS

- CT = computed tomography • FeLV = feline leukemia virus • FHV = feline herpesvirus • FIV = feline immunodeficiency virus • GI = gastrointestinal • MRI = magnetic resonance imaging • NSAID = nonsteroidal anti-inflammatory drug

RHINOSPORIDIOSIS

BASICS

OVERVIEW

- A rare chronic infection of the mucous membranes of dogs, resulting in a fibromyxoid reaction that develops into polypoid growths that may be single or multiple and often protrude from the nostril. Reported in two cats; horses, cows, and humans reported rarely.
- Respiratory system affected.
- Worldwide distribution.
- Endemic areas—Argentina, Venezuela, Uganda, Cuba, Brazil, Iran, Sri Lanka, and India.
- United States—most infections have been reported in the southeastern states.

SIGNALMENT

- Reported in 13 dogs, 7 of which were males.
- No apparent breed predilection.
- Reported in 2 cats.

SIGNS

- Anterior nasal cavity—most common site.
- Sneezing, epistaxis, and stertorous breathing—most prominent.
- Mass—often seen protruding from the nostril; usually single and polypoid; may be lobulated or sessile; surface may have white or yellowish superficial flecks.
- Humans—reported sites: vagina, penis, conjunctival sac, and ears.

CAUSES & RISK FACTORS

- *Rhinosporidium seeberi* now classified as one of five protists in the DRIPS clade.
- Suspected that stagnant fresh water, standing water, and arid (dusty) environment increase likelihood of occurrence.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Nasal neoplasia
- Nasal inflammatory polyp

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

None

IMAGING

Radiographs of nasal cavity—generally normal; mass located in the anterior nasal cavity and does not invade turbinates.

DIAGNOSTIC PROCEDURES

- Impression smears—reveal organisms from nasal mass; use new methylene blue stain, H&E, or periodic acid-Schiff stains. The organisms are 6–8 μm in size and round to oval. A large nucleus is seen in many organisms.
- Histopathology—spores and sporangia (the sac in which spores are produced) can usually be seen with H&E, PAS, Gridley's toluidine blue, and Grocott's stains. In areas where sporangia have ruptured, a purulent neutrophilic inflammation is common.

PATHOLOGIC FINDINGS

Histopathology

- Examination of mass—papillomatous hyperplasia; ulceration of the epithelium; fibrovascular stroma.
- Identification of the organism is diagnostic.
- An intense inflammatory reaction will be seen if organisms are released into the surrounding tissues.

TREATMENT

- Good nursing care—important; anorexia and dehydration not typically reported.
- Cage confinement or other means of exercise restriction—helpful if epistaxis occurs.
- Surgical excision of the mass—treatment of choice; approach through the external nares or rhinotomy; failure to remove the entire mass will likely result in regrowth.

MEDICATIONS

DRUG(S)

- Ketoconazole and itraconazole have been used, but they have been consistently ineffective because this is not a fungal disease.
- Dapsone—used to treat humans; report of use in one dog (1.1 mg/kg PO q8–12h) with favorable response but no cure; however, it has severe side effects.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Dapsone (dogs)—hepatotoxicity; anemia; neutropenia; thrombocytopenia; gastrointestinal signs; skin reactions.

FOLLOW-UP

If surgical approach was through the external nasal orifice, monitor patient closely for mass regrowth; difficult to remove the entire mass.

MISCELLANEOUS

ZOONOTIC POTENTIAL

The organism is infectious to humans, but there is no known risk of direct transmission to humans by handling of infected dogs. The organism may be acquired in humans from the same source as dogs.

RIGHT BUNDLE BRANCH BLOCK

BASICS

DEFINITION

Conduction delay or block in the right bundle branch resulting in late activation of the right ventricle; the block can be complete or incomplete.

ECG Features

- A right axis deviation and wide QRS (≥ 0.08 second in dogs; ≥ 0.06 in cats) in most patients.
- Large, wide S waves in leads I, II, III, and aVF.
- Incomplete right bundle branch block has right axis deviation with normal width QRS complexes.

PATHOPHYSIOLOGY

- The right bundle branch is anatomically vulnerable to injury because it is a thin strand of tissue and has a long undivided course.
- No hemodynamic compromise.

SYSTEMS AFFECTED

Cardiovascular

GENETICS

N/A

INCIDENCE/PREVALENCE

- Dog—most frequent form of intraventricular conduction defect.
- Cat—not as frequent as left anterior fascicular block.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog and cat

Breed Predilections

In beagles, incomplete right bundle branch block can result from a genetically determined localized variation in right ventricular wall thickness.

Predominant Sex

N/A

SIGNS

Historical Findings

- Usually an incidental ECG finding—does not cause hemodynamic abnormalities.
- Observed signs are usually associated with the underlying condition.

Physical Examination Findings

- Splitting of heart sounds because of asynchronous activation of ventricles in some patients.
- Does not cause signs of hemodynamic compromise.

CAUSES

- Occasionally seen in normal and healthy dogs and cats.
- Congenital heart disease.
- Chronic valvular fibrosis.
- After surgical correction of a cardiac defect.
- Trauma caused by cardiac needle puncture to obtain blood sample.
- Trauma from other causes.
- Chronic infection with *Trypanosoma cruzi* (Chagas' disease).
- Neoplasia.
- Heartworm disease.
- Acute thromboembolism.
- Cardiomyopathy.
- Hyperkalemia (most commonly in cats with urethral obstruction).

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Right ventricular enlargement—absence of right ventricular enlargement on thoracic radiographs or echocardiogram supports a diagnosis of right bundle branch block.
- Can also be confused with ventricular ectopic beats (especially if the block is intermittent), but consistent PR intervals and no pulse deficits with right bundle branch block.

CBC/BIOCHEMISTRY/URINALYSIS

- None specific.
- Serum potassium may be extremely high in cats with urethral obstruction.

OTHER LABORATORY TESTS

- Occult heartworm test may be positive in dogs or cats.
- Chagas' indirect fluorescent antibody test, direct hemagglutination, and complement fixation test may be positive in dogs.

IMAGING

- Echocardiogram may show structural heart disease; absence of right heart enlargement supports the diagnosis.
- Thoracic and abdominal radiographs may show masses or pulmonary metastatic lesions; traumatic injuries could cause localized or diffuse pulmonary densities.

DIAGNOSTIC PROCEDURES

- Electrocardiography
- Echocardiography

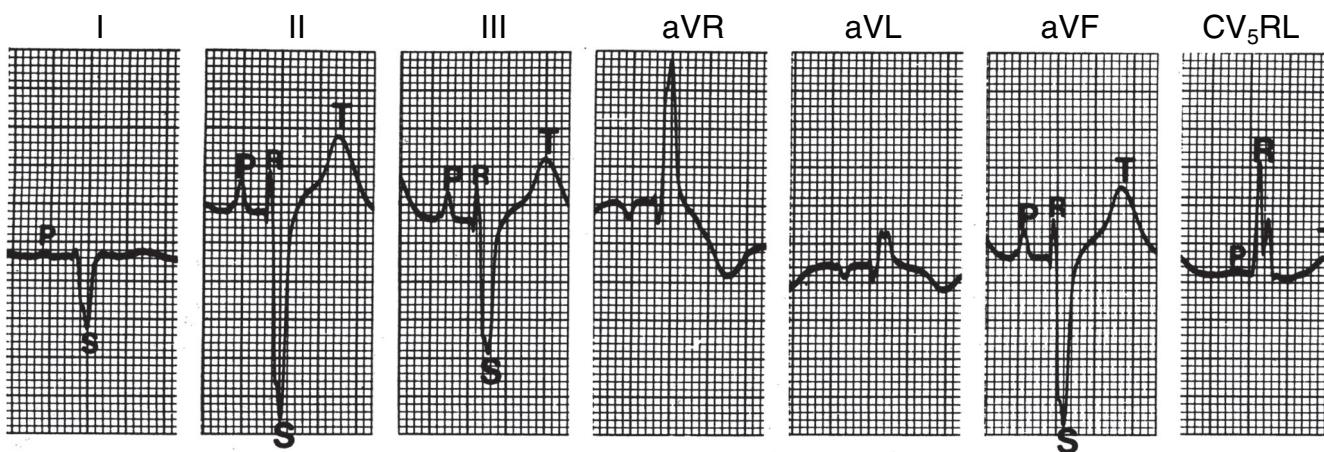

Figure 1.

Right bundle branch block in a dog. The electrocardiographic features include QRS duration of 0.08 second; positive QRS complex in aVR, aVL, and CV₅RL (M-shaped); and large wide S waves in leads I, II, III, and aVF. There is a right axis deviation (approximately -110°) (50 mm/second, 1 cm = 1 mV). (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

RIGHT BUNDLE BRANCH BLOCK

(CONTINUED)

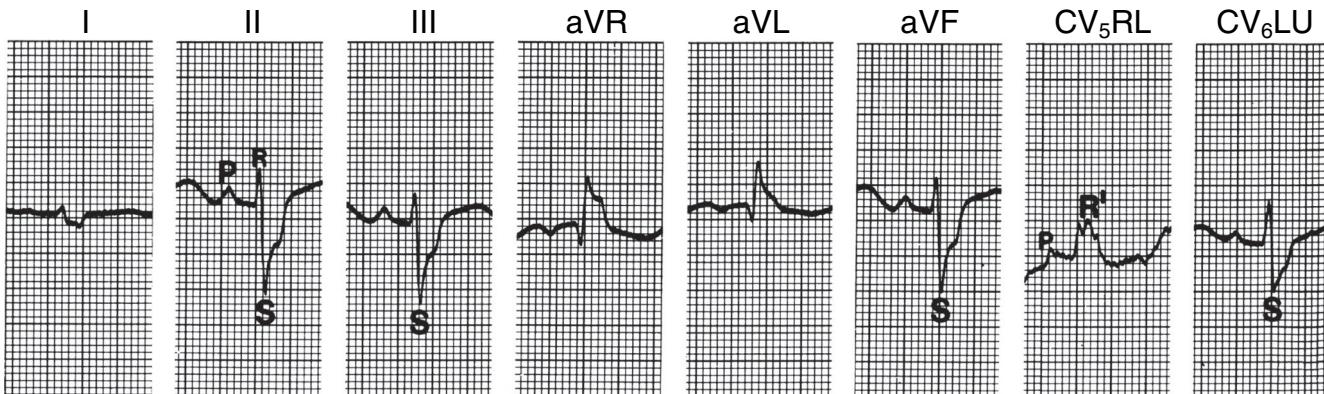

Figure 2.

Right bundle branch block in a cat with the dilated form of cardiomyopathy. The QRS duration is 0.08 second (4 boxes). Large and wide S waves are present in leads I, II, III, aVF, and CV_6 LU. The QRS in CV_5 RL has a wide R wave (M-shaped). There is a marked axis deviation (approximately -90°). (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

PATHOLOGIC FINDINGS

Possible lesions or scarring on endocardial surface in the path of the bundle branches; applying Lugol's iodine to the endocardial surface within 2 hours post-mortem gives clear visualization of the conduction system.

**TREATMENT****APPROPRIATE HEALTH CARE**

Direct treatment toward the underlying cause

ROCKY MOUNTAIN SPOTTED FEVER

BASICS

DEFINITION

A tick-borne rickettsial disease, caused by *Rickettsia rickettsii*, that affects dogs and is considered the most important rickettsial disease in humans.

PATHOPHYSIOLOGY

- Vector—American dog tick (*Dermacentor variabilis*), found east of the Great Plains; wood tick (*D. andersoni*), found from the Cascades to the Rocky Mountains. • Novel vectors (*Rhipicephalus sanguineus*) might explain the expansion of the disease into other regions of North America. • Transmission—via the saliva of the vector or blood transfusion; tick must be attached for 5–20 hours to infect host (humans, dogs, cats) or reservoir host (rodents and dogs).
- Incubation period—2 days–2 weeks.
- Infection—organism invades and multiplies in vascular endothelium; causes microvascular hemorrhage; platelet aggregation and antiplatelet antibodies cause thrombocytopenia, vasoconstriction, increased vascular permeability, increased plasma loss into the interstitial space (organ swelling), hypotension, and eventually DIC and shock; leads to widespread vasculitis in organs with endarterial circulation (cause of clinical signs).

SYSTEMS AFFECTED

- Multisystemic involvement.
- Cardiovascular—vasculitis, hypotension, shock. • Hemic/Lymphatic/Immune—bleeding tendency from thrombocytopenia, vasculitis, lymphadenopathy, splenomegaly.
- Musculoskeletal—joint pain. • Nervous—stupor, seizures, vestibular deficits, coma, cervical pain. • Ophthalmic—conjunctivitis, scleral injection. • Respiratory—dyspnea, cough. • Skin/Exocrine—edema of extremities, face.

GENETICS

N/A

INCIDENCE/PREVALENCE

- Tick season—late March to the end of September. • Prevalence—overall infections in ticks < 2%; varies by geographic locality.

GEOGRAPHIC DISTRIBUTION

- North and South America. • United States—no accurate data for dogs; similar distribution as for humans: eastern seaboard states (especially the Carolinas), Mississippi River valley, and south-central states.

SIGNALMENT

Species

Dog

Breed Predilections

- Purebred dogs seem more prone to developing clinical illness than mixed-breed dogs. • German shepherds—more common.

Mean Age and Range

Any age

Predominant Sex

None

SIGNS

Historical Findings

- Fever—within 2–3 days of tick attachment.
- Lethargy. • Depression. • Anorexia.
- Swelling (edema)—lips, scrotum, prepuce, ears, extremities. • Stiff gait—especially with scrotal or preputial swelling. • Spontaneous bleeding—sneezing, epistaxis. • Respiratory distress. • Neurologic—ataxia, head tilt.
- Ocular pain.

Physical Examination Findings

- Both clinical and subclinical illness occurs.
- Clinical—variable in severity; lasts 2–4 weeks untreated. • Ticks may still be present in acute cases. • Pyrexia. • Cutaneous lesions—edema of face, limbs, prepuce, scrotum. • Extremities—necrosis.
- Conjunctivitis. • Scleral injection.
- Respiratory—dyspnea, exercise intolerance resulting from pneumonitis, increased bronchovascular sounds. • Generalized lymphadenopathy. • Neurologic—vestibular dysfunction, altered mental status, seizures.
- Myalgia/arthritis. • Petechia.
- Ecchymoses—ocular, oral, genital regions; 20% of patients. • Hemorrhagic diathesis—epistaxis, melena, hematuria; in severe cases.
- Cardiac arrhythmias—sudden death. • DIC and death from shock—in severe acute cases.

CAUSES

R. rickettsii

RISK FACTORS

- Exposure to ticks • Co-infection with other pathogens (tick-borne)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Canine ehrlichiosis—*Ehrlichia canis*; not seasonal; can be clinically indistinguishable from Rocky Mountain spotted fever (especially acute cases); differentiate with serologic testing; both respond to same treatment. • Immune-mediated thrombocytopenia—not usually associated with fever or lymphadenopathy; differentiate with serologic testing; may treat for both until results are known. • Systemic lupus erythematosus—antinear antibody titer usually negative with Rocky Mountain spotted fever; serologic testing diagnostic.
- Brucellosis—scrotal edema; serologic testing diagnostic.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Thrombocytopenia (~ 40% of cases)—partly due to antiplatelet antibody.
- Megathrombocytosis mild anemia (normochromic, normocytic), mild leukopenia (early in infection), leukocytosis occasionally with toxic changes in neutrophils (and monocytosis)—as disease becomes more chronic.

Biochemistry

- Usually nonspecific. • Mild increases in ALT, ALP, BUN, creatinine, and total bilirubin (rare). • Hypercholesterolemia—consistently found; cause unknown.
- Hypoalbuminemia—from vascular endothelial damage. • Azotemia, hyponatremia, hypochloremia, and metabolic acidosis have all been reported.

Urinalysis

- Proteinuria—with or without azotemia; from glomerular/tubular damage.
- Hematuria—coagulation defects.

OTHER LABORATORY TESTS

- Several serologic tests available including the micro-IF, ELISA, and latex agglutination tests. Micro-IF test—most commonly used in diagnostic laboratories; measures IgG; serum titers take 2–3 weeks to rise; may be negative in very acute cases; paired titers—perform 3 weeks apart; four-fold increase between acute and convalescent titers; avoid misdiagnosis because of considerable cross-reactivity with other rickettsial organisms; high titers can be detected for up to 1 year after treatment. • ELISA—high sensitivity as can measure both IgG and IgM; detect infection earlier than tests measuring IgG alone. • Latex agglutination test—higher specificity, lower sensitivity than the micro-IF test (false-negative results occur), single increased titer is diagnostic. • PCR on whole blood and tissue specimens—more sensitive than culture, although might be detecting non-viable DNA. May detect DNA before sero-conversion in some dogs. Available from North Carolina State University.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Direct immunofluorescence—skin biopsies obtained by local anesthesia and punch biopsies from affected lesions; detect rickettsial antigens as early as 3–4 days post-infection. • CSF—often normal; may show an increase in protein and nucleated cells.

PATHOLOGIC FINDINGS

- Widespread petechia, splenomegaly, and generalized hemorrhagic lymphadenopathy.
- Necrotizing vasculitis with perivascular cell infiltration (mononuclear and neutrophilic).
- Vascular lesions—most prominent in the skin, kidneys, myocardium, meninges, retina,

R

ROCKY MOUNTAIN SPOTTED FEVER

(CONTINUED)

pancreas, gastrointestinal tract, and urinary bladder. • Hepatic and focal myocardial necrosis, nodular gliosis in the brain, and interstitial pneumonia common. • Special stains—to identify organisms.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient until stable and showing response to treatment.

NURSING CARE

- Dehydration—balanced electrolyte solution; use cautiously because of increased vascular permeability and expanded extracellular fluid volume (exacerbating cerebral and pulmonary edema). • Anemia—blood transfusion. • Hemorrhage from thrombocytopenia—platelet-rich plasma or a blood transfusion.

ACTIVITY

Restricted

DIET

N/A

CLIENT EDUCATION

- Prognosis—good in acute cases with appropriate and prompt therapy. • Response occurs within hours of treatment. • If treatment is not instituted until CNS signs occur or later in the disease process, mortality is high; patient with CNS signs may die within hours.

SURGICAL CONSIDERATIONS

If surgery is required for other reasons, blood transfusion may be needed to correct anemia and/or thrombocytopenia.

MEDICATIONS

DRUG(S) OF CHOICE

- Doxycycline—synthetic derivative of tetracycline, 10 mg/kg PO q12h for 10 days; or IV for 5 days if patient is vomiting.
- Prednisone—concurrent use; anti-inflammatory or immunosuppressive dose; given early in course of disease does not seem to be detrimental to the clinical recovery. May alleviate immune-mediated thrombocytopenia and cerebral edema but is not generally recommended as antibiotic therapy is curative.

CONTRAINDICATIONS

- Tetracycline (or derivatives)—do not use in patients < 6 months because of permanent yellowing of the teeth. • Renal

insufficiency—do not use tetracycline; doxycycline may be given (also excreted via the gastrointestinal tract). • Enrofloxacin—avoid in young dogs because articular cartilage damage can occur (preceded by lameness); gastrointestinal upset (vomiting, anorexia).

PRECAUTIONS

Chloramphenicol

- Avoid if serologic confirmation will be conducted after treatment has started; reduces titers to a greater extent than will tetracyclines.
- Warn client of public health risks; directly interferes with heme and bone marrow synthesis. • Avoid use in dogs with thrombocytopenia, pancytopenia, or anemia.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

- Tetracycline, chloramphenicol, and enrofloxacin—equally efficacious if used early.
- Oxytetracycline and tetracycline—22 mg/kg PO q8h for 14 days; effective and less expensive. • Chloramphenicol—puppies < 6 months of age; 20 mg/kg PO q8h for 14 days; recommended to avoid yellow discoloration of erupting teeth or in pregnant patients. • Enrofloxacin—3 mg/kg PO q12h for 7 days.

FOLLOW-UP

PATIENT MONITORING

Monitor platelet count every 3 days until normal.

PREVENTION/AVOIDANCE

- Control tick infestation on dogs—use dips or sprays containing dichlorvos, chlорfenvinphos, dioxathion, propoxur, or carbaryl. • Flea and tick collars—may reduce reinfestation; reliability is unproven. • Avoid tick-infested areas. • Environment—tick eradication impossible; organism maintained in rodents and other reservoir hosts.
- Removing ticks by hand—use gloves (see “Zoonotic Potential”); ensure mouth parts are removed because a foreign body reaction is likely to result if they are left in place.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Early antibiotic treatment—reduces fever and albumin extravasation and improves patient's attitude within 24–48 hours.
- Platelet counts—repeat every 3 days after initiating treatment until within normal

range; should return to normal within 2–4 days after initiating treatment.

- Serologic titers—lower in treated than in untreated dogs; titers remain positive during convalescence. • Naturally infected dogs never seem to become reinfected. • Acute cases—excellent prognosis with appropriate treatment. • With CNS disease—poor prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

None

AGE-RELATED FACTORS

None

ZOONOTIC POTENTIAL

- Incidence (humans)—dropping in the United States; mid-1992–mid-1993: 300 cases; earlier incidence: up to 1,000 cases/year. • Mainly young adults and children infected. • Source of infection (humans)—from ticks that are transferred from dogs; not from dogs directly; when removing infected ticks from dogs. • Major clinical signs (humans)—mimic those in dogs; mainly fever and headache; neurologic signs occur later; skin rash appreciated in only 50% of patients. • Treatment with tetracycline results in a rapid recovery.

PREGNANCY/FERTILITY/BREEDING

RODENTICIDE TOXICOSIS—ANTICOAGULANTS

BASICS

DEFINITION

- Anticoagulant rodenticide intoxication results in a delayed onset (3–5 days) coagulopathy caused by the reduction of vitamin K₁–dependent clotting factors (II, VII, IX, X).
- There are two primary types of anticoagulant rodenticides, first- and second-generation. First-generation anticoagulants, such as warfarin, are generally less toxic and shorter acting than second-generation which tend to persist longer in the liver and require 3–4 weeks of antidote therapy.

PATHOPHYSIOLOGY

- Anticoagulant rodenticides inhibit vitamin K₁ epoxide reductase, DT diaphorase, and possibly other enzymes involved in the reduction of vitamin K₁ epoxide to vitamin K₁.
- Vitamin K₁ is required for carboxylation of clotting factors II, VI, IX, and X; uncarboxylated clotting factors do not bind calcium sufficiently to participate in clot formation.

SYSTEMS AFFECTED

- Hemic/Lymphatic/Immune
- Respiratory

INCIDENCE/PREVALENCE

Common. Anticoagulant rodenticide exposures are the most frequently reported type of rodenticide exposure to animal poison control centers. Traditionally, most rodenticides sold for in-home use contained anticoagulant baits. In 2011, the United States Environmental Protection Agency banned the use of second-generation anticoagulants (i.e., brodifacoum, bromadiolone, difenacoum, and difethialone) for residential use unless placed by a pest control operator. Although first-generation anticoagulants (e.g., warfarin, chlorophacinone, and diphacinone) are still allowed, some manufacturers switched to non-anticoagulant baits such as bromethalin. Between 2011 and 2014, Pet Poison Helpline reported a 65% increase in bromethalin exposures in cats and dogs.

SIGNALMENT

- No breed or gender predilections; younger animals may ingest bait more readily.

SIGNS

General Comments

- May be slightly more prevalent in the spring and fall when rodenticide products are used.
- Clinical signs typically begin 3–5 days after ingestion.

Historical Findings

- Use of anticoagulant rodenticides.

- Evidence of rodenticide dye in vomitus or feces.
- Coughing, dyspnea, tachypnea, or exercise intolerance are often the first clinical signs.
- Bleeding from body orifices; subcutaneous or joint swelling may also be observed.

Physical Examination Findings

- Evidence of hemorrhagic shock (i.e., tachycardia, hypovolemia, hypotension, poor pulse quality, pallor).
- Coughing, dyspnea, tachypnea, pale mucous membranes.
- Hematomas—often ventral and at venipuncture sites; subcutaneous hematomas.
- Bleeding from body orifices, periorbital bleeding, scleral hemorrhage.
- Hemarthrosis, lameness.
- Exercise intolerance, lethargy, depression.
- Muffled heart or lung sounds.
- Distended abdomen (hemoabdomen).

CAUSES

Ingestion of anticoagulant rodenticides or, rarely, ingestion of prey that have been exposed to anticoagulant rodenticides (see “Risk Factors”).

RISK FACTORS

- Dogs are much more sensitive to anticoagulant rodenticides than cats.
- Small doses over several days may add up to a toxic dose.
- Secondary or relay toxicosis by consumption of poisoned rodents is possible but unlikely.
- There is a wide range of toxicity between anticoagulant rodenticides. In general, if the ingestion exceeds 1/5–1/10 the LD₅₀, decontamination and monitoring for coagulopathy are indicated.
 - Dogs
 - Brodifacoum, LD₅₀ 0.25–2.5 mg/kg
 - Bromadiolone, LD₅₀ 11–20 mg/kg
 - Chlorophacinone, LD₅₀ 50–100 mg/kg
 - Difethialone, LD₅₀ 4 mg/kg
 - Diphacinone, LD₅₀ 3–7.5 mg/kg
 - Warfarin, LD₅₀ 20–50 mg/kg
 - Cats
 - Brodifacoum, LD₅₀ 25 mg/kg
 - Bromadiolone, LD₅₀ > 25 mg/kg
 - Difethiolone, LD₅₀ > 16 mg/kg

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congenital clotting factor deficiencies.
- Immune-mediated thrombocytopenia: platelet count will reveal severe thrombocytopenia.
- Coagulation factor deficiency secondary to hepatic disease: assay for factor deficiencies (e.g., factor VII), liver function, bile acids.
- Disseminated intravascular coagulopathy which is typically associated with neoplasia, sepsis, pancreatitis, or concurrent disease. Lab evidence includes prolonged PT, PTT,

- elevated fibrin degradation products, d-dimer with thrombocytopenia.
- Fat malabsorption.
- Hemorrhagic shock from trauma, neoplasia, bone marrow suppression, immune mediated hemolytic anemia.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia with marked hemorrhage, often acute and nonregenerative.
- Thrombocytopenia, mild. Typically 50,000–150,000 × 10³/µL.

OTHER LABORATORY TESTS

- Activated clotting time > 150 seconds supports coagulopathy but is not specific for anticoagulant rodenticide poisoning.
- Prolonged PT and PTT support exposure to anticoagulant rodenticide; PT will be prolonged 6–18 hours earlier than PTT. These values will normalize with vitamin K₁ therapy.
- PIVKA assay, although this is rarely used.
- Anticoagulant rodenticide detection in the blood or liver will confirm exposure to a specific product.
- Anticoagulant rodenticide detection in the stomach or intestinal contents is not reliable due to the delay between consumption of bait and appearance of clinical signs.

IMAGING

- Thoracic radiography may reveal pleural effusion (i.e., hemothorax); multilobular, alveolar infiltration (i.e., pulmonary hemorrhage), or an enlarged cardiac silhouette (i.e., hemopericardium).
- Ultrasound of both the pleural and peritoneal cavities may reveal effusion consistent with hemorrhage.

DIAGNOSTIC PROCEDURES

Thoracentesis may confirm hemothorax.

PATHOLOGIC FINDINGS

- Free blood in the thoracic cavity, lungs, and abdominal cavity is a common post mortem finding.
- Hemorrhage into the cranial vault, gastrointestinal tract, subcutaneous space, intramuscular space, and urinary tract is less common.

TREATMENT

APPROPRIATE HEALTH CARE

- Patients in acute crisis should be hospitalized.
- Patients without active hemorrhaging or a stabilized coagulopathy may be treated on an outpatient basis.
- Vitamin K₁ is antidotal at 2.5–5 mg/kg q24h or divided q12h. The preferred route of administration is oral; however, in case of a coagulopathic patient, the subcutaneous route is preferred due to the potential for limited GI absorption. Use a small needle in multiple locations, if needed.

RODENTICIDE TOXICOSIS—ANTICOAGULANTS

(CONTINUED)

- Treat acute hemorrhagic shock with IV crystalloids, colloids, or blood products as needed. Initial crystalloid boluses of 10–20 mL/kg can be given over 15–20 min during stabilization. Repeat 2–3 times as needed to increase blood pressure.
- The use of packed RBCs, whole blood, fresh frozen plasma (FFP), or frozen plasma (FP) may be necessary to replace coagulation factors.
- Treat life-threatening cardiac tamponade or hemothorax with pericardiocentesis or thoracocentesis as indicated. If the patient is stable and responding to treatment, these procedures should be avoided. With time, the blood will reabsorb.

NURSING CARE

Provide supportive care as needed.

ACTIVITY

Confine the patient until the coagulopathy is stabilized as activity enhances blood loss.

DIET

Feed a nutritious, high-quality protein diet to support coagulation factor synthesis.

CLIENT EDUCATION

- Warn client that re-exposure, even months to years later, could be a serious problem due to persistence of second-generation anticoagulants in the liver.
- Encourage the owner to pick up all loose/unprotected bait on the property.
- Do not discontinue vitamin K₁ therapy early, even if the patient is asymptomatic.

SURGICAL CONSIDERATIONS

- Thoracentesis may be important for removing free thoracic blood, which causes dyspnea and respiratory failure (see "Appropriate Health Care").
- The coagulopathy must be corrected before surgery.

**MEDICATIONS****DRUG(S) OF CHOICE**

Vitamin K₁, 2.5–5.0 mg/kg PO q12h for 5–7 days for most first-generation anticoagulants and PO q24h for 4–6 weeks for most second-generation anticoagulants; bioavailability may be enhanced by the concurrent feeding of a small amount of fat, such as canned dog food.

CONTRAINDICATIONS

- Vitamin K₃ is not efficacious in the treatment of anticoagulant rodenticide toxicosis and should not be used.
- Intravenous vitamin K₁ has been reported to cause anaphylactoid reactions. Avoid this route of administration.
- Minimize stress, trauma, jugular venipuncture, and cystocentesis due to the risk of acute and catastrophic hemorrhage.

PRECAUTIONS

- Avoid large-bore hypodermic needles, unnecessary surgical procedures, and parenteral injections.
- Use the smallest possible needle when giving an injection or collecting samples.

POSSIBLE INTERACTIONS

Sulfonamides and phenylbutazone may displace anticoagulant rodenticides from plasma binding sites, leading to more free toxicant and increased risk of toxicosis.

**FOLLOW-UP****PATIENT MONITORING**

Use PT (preferred) 2–3 days following the last dose of vitamin K₁ to assess proper duration of therapy. If the PT is prolonged, administer another 1–3 weeks of vitamin K₁ and retest.

PREVENTION/AVOIDANCE

Prevent pet's access to anticoagulant rodenticides by using bait stations and keeping stored bait in a secure location.

POSSIBLE COMPLICATIONS

- Secondary bacterial pneumonia may occur following intrapulmonary hemorrhage.
- Intracranial and intra-articular hemorrhage may occur.
- Pregnant animals can abort due to placental hemorrhage and detachment.

EXPECTED COURSE AND PROGNOSIS

If the patient survives the first 48–72 hours of acute coagulopathy, the prognosis improves.

**MISCELLANEOUS****PREGNANCY/FERTILITY/BREEDING**

- Warfarin, diphacinone, and perhaps other anticoagulant rodenticides may pass into amniotic fluid and to the fetuses of an exposed pregnant animal. These toxicants may also pass via the milk and present concerns for nursing offspring. In general, antidotal treatment of the pregnant or nursing patient is recommended. Alternatively, nursing young should be weaned.
- Pregnant animals can abort due to placental hemorrhage and detachment.

ABBREVIATIONS

- ACT = activated clotting time
- DIC = disseminated intravascular coagulation
- PT = prothrombin time
- PTT = partial thromboplastin time

RODENTICIDE TOXICOSIS—BROMETHALIN

BASICS

OVERVIEW

- Bromethalin produces marked CNS effects.
- Bromethalin uncouples oxidative phosphorylation resulting in cerebral edema and elevated CSF pressure.
- Toxic doses are approximately 0.3 and 2.5 mg/kg in cats and dogs, respectively.
- The reported oral LD₅₀ of bromethalin bait is 0.54 and 3.7 mg/kg in cats and dogs, respectively.
- Trade names include Vengeance, Assault, Trounce, No Pest Rat & Mice Killer, CyKill, Fastrac, and others.
- Chemical name: N-methyl-2,4-dinitro-N-[2,4,6-tribromophenyl]-6-[trifluoromethyl] benzeneamine.

SIGNALMENT

- Dogs and cats. Other species may be affected.
- No breed predilections have been noted.
- Any age may be affected.

SIGNS

- Ingestion of supralethal doses of bromethalin (\geq LD₅₀) may result in an acute onset of CNS excitation, muscle tremors, and seizures.
- Ingestion of lower doses of bromethalin ($<$ LD₅₀) results in a delayed syndrome that develops within 2–7 days of ingestion; however, delays of up to 2 weeks may occur.
- Common clinical signs seen include anorexia, progressive ataxia, paresis, and hind limb paralysis, moderate to severe central nervous system depression, fine muscle tremors, and focal motor or generalized seizures.
- Forelimb extensor rigidity and decerebrate postures are often seen.
- With mild poisoning, clinical signs may resolve within 1–2 weeks of onset of clinical signs, although signs can persist for up to 4–6 weeks in some animals. Prognosis is very guarded in severely affected animals.

CAUSES & RISK FACTORS

Ingestion of rodenticides containing bromethalin occurs most often in animals $<$ 1 year of age.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Neurologic syndromes produced by trauma, neoplasia, cerebral vascular disorders, as well as infectious and other toxic agents.

CBC/BIOCHEMISTRY/URINALYSIS

Alterations in routine serum electrolytes and chemistries are not anticipated.

OTHER LABORATORY TESTS

- Diagnosis dependent upon (1) the presence of an exposure history to a potentially toxic dose of a bromethalin-based rodenticide, (2) the development of appropriate clinical

signs, (3) the presence of diffuse white matter vacuolization, and (4) analytical confirmation of bromethalin residues in tissues.

- EEG abnormalities may include spike and spike-and-wave activity, marked voltage depression, and abnormal high voltage slow wave activities.
- CSF from bromethalin-poisoned dogs generally reveals normal cytology, protein concentration, specific gravity, and cell count.

IMAGING

Neuroimaging (MRI) may reveal generalized brain edema.

PATHOLOGIC FINDINGS

- Lesions are generally confined to the CNS.
- Gross evidence of cerebral edema may occur but is relatively mild.
- Histopathologic changes include spongy degeneration (white matter vacuolization) in the cerebrum, cerebellum, brain stem, spinal cord, and optic nerve white matter due to myelin edema.
- Analytical chemical confirmation of bromethalin residues in fresh frozen fat, liver, kidney, and brain tissue.
- Bromethalin has been detected in formalin-fixed human liver and brain samples by gas chromatography with mass spectrometry detection.

TREATMENT

- Aggressive early treatment with oral activated charcoal and a cathartic to reduce gastrointestinal absorption is warranted.
- Animal Poison Control Centers have recommended the judicious use of intravenous lipid emulsions (ILE) in cases of severe intoxication.
- Many animals recovering from bromethalin toxicosis exhibit prolonged anorexia and may require supplemental feeding to maintain caloric intake.
- Use cage padding to reduce the risk of decubitus ulcer formation in recumbent animals.

MEDICATIONS

DRUG(S)

- Gastrointestinal tract decontamination including early induction of emesis followed by repeated administration of activated charcoal (0.5–1 mg/kg PO) and an osmotic cathartic (sodium sulfate, 125 mg/kg PO) should be given every 4–8 hours for at least 2–3 days.
- Control of cerebral edema with mannitol (250 mg/kg, q6h IV), dexamethasone (2 mg/kg, q6h IV), and furosemide (1–2 mg/kg, q6h IV) has been recommended but shown to have limited clinical efficacy.
- Diazepam (1–2 mg/kg, as needed, IV) and/or phenobarbital

(5–15 mg/kg, as needed, IV) may be given to abolish severe muscle tremors and seizures.

- 20% intravenous lipid emulsions: Bolus dose 1.5 mL/kg over 2–3 min; continuous rate infusion of 0.25 mL/kg/min for 30–60 min. Check serum q2h until it becomes clear; repeat as needed; if no clinical improvement after 3 doses, discontinue.

CONTRAINdications/POSSIBLE INTERACTIONS

- Contraindications for the use of mannitol include renal disease, pulmonary edema, dehydration, and intracranial hemorrhage.
- Animals receiving mannitol therapy may become dehydrated during treatment.
- Rehydration of some animals is associated with a worsening of clinical signs, possibly due to rebound cerebral and pulmonary edema. Maintenance of hydration is important and can be more safely accomplished through the administration of oral fluids.
- Adverse effects of ILE may relate to contamination of the lipid product or direct reaction to the emulsion.

FOLLOW-UP

- May require several weeks to recover from mild poisoning.
- Prognosis is poor for the severely affected animals.
- Prevent ongoing rodenticide ingestion.

MISCELLANEOUS

Relay toxicity arising from the consumption of animals poisoned with bromethalin has been reported.

ABBREVIATIONS

- CNS = central nervous system
- CSF = cerebrospinal fluid
- EEG = electroencephalogram
- ILE = intravenous lipid emulsion
- MRI = magnetic resonance imaging

RODENTICIDE TOXICOSIS—PHOSPHIDES

BASICS

OVERVIEW

- Used as a rodenticide since the early 1930s at various concentrations (2–10%) in a powder, pellet, or paste formulation. Available as zinc, aluminum, and magnesium salts.
- Most have a distinctive odor, often described as acetylene, rotten fish, or garlic.
- Most common route of exposure is ingestion; however, toxicosis can occur via inhalation and absorption through broken skin.
- Hydrolysis leads to phosphine gas production. Phosphine gas has corrosive and irritant effects on the GI mucosa, which leads to vomiting, hematemesis, or melena. The gas is rapidly absorbed and systemically distributed leading to effects on other organ systems.
- Phosphine leads to the production of free radicals and oxidative stress causing direct cellular damage and may inhibit cellular respiration.
- Toxic exposure is reported to be 20–40 mg/kg; however, the gastric pH is reported to affect toxicity.

SIGNALMENT

No known age, breed, or sex predilection

SIGNS

- Clinical signs generally occur within 15 minutes to 4 hours, but can be delayed up to 18 hours.
- Gastrointestinal—anorexia, vomiting, and melena.
- Cardiovascular—direct myocardial damage, arrhythmias, decreased inotropy, hypotension.
- Pulmonary—pulmonary edema, pleural effusion.
- Hemic/lymphatic/immune—methemoglobinemia, Heinz body production.
- Nervous—ataxia, weakness, tremors, hyperesthesia, and seizures.
- Renal/urologic—azotemia, acute renal failure.
- Hepatobiliary—increased ALT, AST, and total bilirubin.
- Endocrine/metabolic—metabolic acidosis, electrolyte imbalance.
- Musculoskeletal—weakness, ataxia.

CAUSES & RISK FACTORS

- Increased hydrolysis in a moist, acidic environment; thus recent food ingestion lowers gastric pH and increases hydrolysis. Owner should be told not to feed their pet.
- Owners and veterinary staff are at risk for inhalation exposure if the animal vomits in a poorly ventilated area. Owners should be told to lower their windows on the way to the clinic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Organophosphate • Metaldehyde
- Serotonin syndrome • NSAID toxicosis
- Tremogenic mycotoxins • Acute GI disease (HGE, gastroenteritis, parvovirus)

- Congestive heart failure • Respiratory disease (non-cardiogenic pulmonary edema—secondary to electrocution, near drowning, seizures, or ARDS) • Metabolic disease (renal, hepatic, pancreatitis)

CBC/BIOCHEMISTRY/URINALYSIS

- May see increased liver enzymes (ALT, AST, and total bilirubin); can be delayed 3–5 days.
- Electrolyte alterations (decreased potassium or magnesium). • Methemoglobinemia, Heinz body formation, and subsequent hemolysis on a CBC.

OTHER LABORATORY TESTS

Confirmation through gas chromatography or a Dräger detection tube (referral laboratory testing). The Dräger detection tube test was validated using canine stomach contents and vomitus. • Post-mortem samples from the liver, kidney.

IMAGING

If respiratory signs, thoracic radiographs to assess for pulmonary edema.

PATHOLOGIC FINDINGS

Are nonspecific

TREATMENT

- There is no antidote.
- The goal of treatment with recent, asymptomatic patients is to safely decontaminate. Administration of a liquid antacid such as magnesium hydroxide, aluminum hydroxide, calcium carbonate, or even a 5% sodium bicarbonate solution may help to increase the gastric pH and thus decrease phosphine gas production.
- Emesis induction with apomorphine, or gastric lavage and hydrogen peroxide may also be considered for gastric emptying.
- Activated charcoal may help decrease toxicity, but should be given only if the patient's clinical status allows.
- The patient should be placed on IV fluid therapy and monitored for any clinical signs or progression of clinical signs for at least 18 hours.
- Supplemental oxygen for hypoxemia.

MEDICATIONS

- GI protectants such as famotidine 0.5–1 mg/kg IV/PO q12–24h, omeprazole 0.5–1 mg/kg PO q24h, sucralfate 0.25–1 g PO q8–12h, and possibly misoprostol 2–5 µg/kg PO q8h.
- Tremors, methocarbamol (50–220 mg/kg IV or to effect; do not exceed 330 mg/kg/day).
- Seizures may require anticonvulsants (diazepam 0.5 mg/kg IV, phenobarbital 4–16 mg/kg IV/to effect, levetiracetam 30–60 mg/kg IV, or propofol 1–8 mg/kg or to effect, followed by a CRI at 0.1–0.6 mg/kg/h).
- If liver effects give hepatoprotectants

(S-adenosyl-methionine 18 mg/kg PO q24h, silymarin/milk thistle 50–250 mg/day PO q24h, and Vit K₁ 2–3 mg/kg PO q12–24h).

- Oxidative damage or for methemoglobinemia, N-acetylcysteine. • If painful consider analgesics, opioids (hydromorphone 0.05–0.1 mg/kg IV) or tramadol 2–4 mg/kg PO q8–12h. Avoid NSAIDs.

FOLLOW-UP

Varies on a case basis

PATIENT MONITORING

Several organ systems may be affected; vitals, heart rhythm, blood pressure, and CNS should be monitored for 18 hours.

PREVENTION/AVOIDANCE

Have owners remove all baits from environment.

POSSIBLE COMPLICATIONS

Liver or renal failure

EXPECTED COURSE AND PROGNOSIS

- Asymptomatic patients should be monitored for up to 12–18 hours.
- Symptomatic patients should be monitored for at least 48 hours or until life-threatening signs have resolved.

MISCELLANEOUS

ABBREVIATIONS

- ALT = alanine transaminase • ARDS = acute respiratory distress syndrome • AST = aspartate transferase • CNS = central nervous system • GI = gastrointestinal • HGE = hemorrhagic gastroenteritis • NSAID = nonsteroidal anti-inflammatory drug

ROTAVIRUS INFECTIONS

BASICS

OVERVIEW

- Non-enveloped, double-stranded RNA virus; *rota* (Latin; “wheel”) for shape of the capsid; genus within the family Reoviridae; relatively resistant to environmental destruction (acid and lipid solvents); unique double capsid protects virus from inactivation in the upper gastrointestinal tract.
- Wide host range, identified in almost every species investigated.
- Most significant cause of severe gastroenteritis in young children (< 2 years) and animals throughout the world.
- Transmission—fecal-oral contamination.
- Infection—affects mature epithelial cells on luminal tips of the intestinal villi; causes swelling, degeneration, and desquamation; denuded villi contract; results in villous atrophy with loss of absorptive capability and loss of brush border enzymes (e.g., disaccharidases); leads to osmotic diarrhea.

SIGNALMENT

- Dogs and cats.
- Pups < 12 weeks old and more often < 2 weeks old—diarrhea.
- Kittens and young cats (< 6 months of age)—more susceptible to infection.

SIGNS

- Dogs—most infections subclinical or limited to relatively mild, nonspecific, watery to mucoid diarrhea, anorexia, and lethargy; rare fatalities reported.
- Cats—primarily subclinical or mild diarrhea; more severe clinical disease may occur with co-infections or in stressed conditions.

CAUSES & RISK FACTORS

- Rotavirus.
- Young animals with immature immune systems at increased risk.
- Presence of other enteric pathogens.
- Overcrowding (virus stable in environment).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Canine viral enteritis—canine parvovirus; canine coronavirus; canine astrovirus; canine calicivirus; canine herpesvirus; canine distemper virus; canine reovirus.
- Feline viral enteritis—feline parvovirus (feline panleukopenia virus); FeLV; feline coronavirus; feline astrovirus; feline calicivirus.

- Other causes of enteritis—bacteria (e.g., *Salmonella*, *Campylobacter*, *Clostridium*); fungi; protozoa; parasites; foreign bodies; intussusception; allergies; toxicants.

CBC/BIOCHEMISTRY/URINALYSIS

Non-contributory

OTHER LABORATORY TESTS

- Serology—not recommended; most animals (e.g., 85% of dogs) carry antibodies owing to previous exposure or from passive antibody immunization transfer from the bitch or queen; must demonstrate four-fold difference in acute and convalescent serum samples.
- Direct electron microscopy—detects virus in feces; rapid; lack of sensitivity.
- Immunoelectron microscopy—more sensitive and specific than direct electron microscopy; not commonly available.
- ELISA—detect common group rotavirus antigen in feces (Remel Xpect Rotavirus test, Oxoid Company, Nepean, ON, Canada).
- Latex agglutination; Virogen Rotatest (Wampole Laboratories, Cranbury, NJ).
- Immunochemical assay (ImmunoCard STAT! Rotavirus Meridian Bioscience, Inc. Cincinnati, OH).
- Immunofluorescence.
- Virus isolation.
- PCR.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Histology—swollen small intestinal villi; mild infiltration by macrophages and neutrophils; virus detected by fluorescent antibody test.

TREATMENT

- Symptomatic for diarrhea—fluids, electrolytes, and dietary restriction.
- Antibiotic therapy not indicated.
- Principal protection—probably antibodies in milk of immune bitch or queen.

MEDICATIONS

DRUG(S)

N/A

CONTRAINdications/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

N/A

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Rotaviruses are not host-specific; thus, affected puppy or kitten may pose a potential human health hazard, particularly for infants.
- Exercise care when handling fecal material from pets with diarrhea.
- Humans—diarrhea; infants in developed countries: high morbidity and low mortality (attributed to fluid therapy); infants and young children in developing countries: leading cause of life-threatening diarrhea (more than 600,000 deaths per year in children < 5 years old); in United States, prior to routine vaccination of infants which began in 2006, more than 3 million episodes of diarrhea, ~500,000 clinic visits, ~60,000 hospitalizations but only 20–40 deaths per year. In US, pentavalent rotavirus oral vaccine has reduced hospitalizations by 60–75%.

ABBREVIATIONS

- ELISA = enzyme-linked immunosorbent assay
- FeLV = feline leukemia virus
- PCR = polymerase chain reaction

R

ROUNDWORMS (ASCARIASIS)

BASICS

OVERVIEW

- Ascariasis caused by *Toxocara canis* (dogs), *T. cati* (cats), and *Toxascaris leonina* (dogs and cats); *Baylisascaris* (raccoons) can infect dogs and causes neurocysticercosis in people.
- Transplacental transmission of *T. canis* larvae from bitch's tissues to pups causes prenatal infection; transmammary transmission of larvae occurs with both *Toxocara* spp.; no transplacental or transmammary transmission occurs with *Toxascaris*. • In first month of life, infected neonatal pups may develop abdominal pain and rapidly deteriorate before eggs appear in feces.
- Older pups and kittens can acquire infection by ingesting eggs disseminated on premises by dams with post-gestational infection; dams can be infected by ingesting immature stages in pups' feces or vomitus, or by predation on vertebrate transport hosts.
- Adult ascarids occur in lumen of small intestine; larval stages of *Toxocara* spp. may migrate in liver and lungs. • If very numerous, ascarids (up to 10–12 cm long) can distend intestine leading to colic, interference with gut motility, inability to utilize food, and, intestinal rupture.

SIGNALMENT

- Dog and cat. • Important clinically in pups and kittens due to transmission *in utero* and/or in colostrum/milk.

SIGNS

- Abdominal distension ("pot belly"); often with palpable intestinal distension. • Colic.
- Weakness, loss of condition, cachexia; poor nursing or appetite; scant feces. • Coughing due to larval lung migration. • Entire litter may be affected.

CAUSES & RISK FACTORS

- *Toxocara* infection of bitch with dormant larvae in tissues or infection of queen during late pregnancy or early lactation. • Access to infected transport hosts. • Concurrent enteric infections. • Larvae undergo extensive migrations throughout the body and can cause granulomatous inflammation (visceral larva migrans). Visceral larva migrans caused by a variety of ascarids is a major cause of morbidity in humans throughout the world.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Transmammary perinatal infection of neonates with hookworms (anemia, melena, weakness, lethargy, pale mucus membranes, enteritis) or *Strongyloides* (diarrhea); coccidiosis, giardiasis also cause enteritis in pups and kittens; examine feces to identify

eggs or larvae. • *Physaloptera* can also occur in vomitus.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Fecal flotation to detect eggs; *Toxocara* eggs spherical pitted outer shell membrane, single dark cell filling interior, 80–85 µm (*T. canis*), ~75 µm (*T. cati*). • *Baylisascaris* eggs similar to *T. canis* eggs but smaller (~76 × 60 µm), more finely pitted shell. • *Toxascaris* eggs ovoid, smooth exterior shell membrane, 1–2 cells with light-colored cytoplasm; cells do not fill interior of egg; 80 × 70 µm in diameter. • Necropsy of siblings that died of similar signs. • Identify ascarids in feces, vomitus, or small intestine by size, presence of three lips, and cervical alae.

TREATMENT

- Anthelmintic treatment as outpatient.
- Acute severe cases treated as inpatients; supplement with intravenous fluids.
- Milbemycin or other anthelmintic effective against *T. canis* suggested for treatment (extra-label) of *Baylisascaris* in dog. • Alert client to possibility of sudden death or chronic debilitation. • Treat bitch or queen with adulticide/larvicide anthelmintic to remove intestinal stages and to limit transmission to subsequent litters.

MEDICATIONS

DRUG(S)

Adulticide/Larvicide Anthelmintics

- Fenbendazole 50 mg/kg PO q24h for 3 days. • Milbemycin oxime 0.5 mg/kg (dogs) or 2 mg/kg (cats) PO q30 days. • Emodepside (3 mg/kg) or praziquantel (12 mg/kg) topically once for cats ≥ 8 weeks old; repeat in 30 days if cat is reinfected.

Adulticide Anthelmintics

- Pyrantel, 5 mg/kg (dogs) or 10–20 mg/kg (cats, extra-label) PO.
- Pyrantel/praziquantel, label dose for cats.
- Febantel/ praziquantel/pyrantel, label dose for dogs. • Ivermectin/pyrantel, label dose for dogs. • Pyrantel pamoate 5 mg/kg (dogs) or 10–20 mg/kg (cats, extra-label). • Selamectin 6 mg/kg topically once (*T. cati*, cats), extra-label in dogs. • Milbemycin oxime, label dosages for dogs and cats. • Moxidectin/ imidacloprid, label dosages topically for dogs and cats.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Repeat post-treatment fecal exams on pups/kittens and/or repeat anthelmintic treatment every 2–3 weeks until old enough for monthly anthelmintic product because migrating larvae acquired from bitch or dam will continue to mature.

PREVENTION/AVOIDANCE

- To minimize environmental contamination with infective eggs, treat infected dogs/cats with anthelmintic and promptly dispose of feces. • Prevent dogs/cats from hunting or ingesting transport hosts. • Extra-label treatment of bitch or queen with adulticide/larvicide anthelmintic to remove intestinal stages and decrease vertical transmission to offspring.

POSSIBLE COMPLICATIONS

- Transplacental transmission of large numbers of larvae can result in fetal death or birth of weak, non-viable pups. • Infection with large numbers of ascarids can cause blockage, possible rupture of small intestine.

EXPECTED COURSE AND PROGNOSIS

Prognosis good after anthelmintic treatment; guarded with severe prenatal *T. canis* infection.

MISCELLANEOUS

AGE-RELATED FACTORS

Greater clinical concern in neonates

ZOONOTIC POTENTIAL

- Visceral larva migrans, ocular larva migrans, neural larva migrans, chronic abdominal or cutaneous problems may follow ingestion of infective *Toxocara* spp. or *Baylisascaris* eggs by humans. • Most likely cause of neural larva migrans is *Baylisascaris*. Virtually all raccoons become infected with *Baylisascaris* and therefore extreme caution should be exercised with clients having raccoons as "pets."

SAGO PALM TOXICOSIS

BASICS

OVERVIEW

- Cycad palms, also called sago palms, belong in the family Cycadaceae.
- Are native to tropical and subtropical regions but have become popular ornamental plants in the US.
- *Cycas revoluta*, *Cycas circinalis*, and *Zamia floridana* are the most common species.
- Contain the toxins, cycasin, beta-methylamino-L-alanine, and an unidentified high molecular weight compound.
- Toxins present in all parts of the plant; highest concentrations in seeds.
- Cycasin is metabolized by the intestinal flora to the active hepatotoxic, carcinogenic, mutagenic, teratogenic, and neurotoxic compound, methylazoxymethanol (MAM).
- Cycad toxicosis has been documented in several animal species (dogs and ruminants) and humans.
- In dogs, gastrointestinal disturbances and hepatic damage predominate; nervous system involvement is less common.

SIGNALMENT

- Dogs—no breed, sex, or age predilection
- Cats—no cases reported.

SIGNS

- Gastrointestinal disturbances such as vomiting, diarrhea, and abdominal pain.
- Signs associated with hepatic damage (ecchymoses, petechiae, hemorrhage, edema, etc.).
- Gait abnormalities; paresis/paralysis; tremors.
- Depression, coma, and death.

CAUSES & RISK FACTORS

Access to and ingestion of cycad palm

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other Causes of Acute Gastrointestinal Upset

- Infectious • Metabolic • Toxic • Dietary

Other Causes of Acute Liver Failure

- Microcystins (hepatotoxic blue-green algal toxins)—access to water with algal bloom, algal material on legs or in stomach contents, detection of microcystins in stomach contents.
- Amanitin—access to mushrooms (*Amanita*, *Galerina*, and *Lepiota* spp.), gastrointestinal signs between 6 and 24 hours after ingestion.
- Cocklebur (*Xanthium* spp.)—access to cocklebur (only seeds and two-leaf cotyledon stage are toxic).
- Aflatoxins—access to moldy food.
- Acetaminophen overdose.
- Xylitol—access to xylitol-containing products (sugar-free gum, chewable vitamins, baked goods); initial hypoglycemia.
- Severe acute pancreatitis.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia • Elevated serum liver enzymes (ALT, AST, ALP, bilirubin)
- Hypoalbuminemia • Hypoglycemia
- Glucosuria, hemoglobinuria, myoglobinuria, bilirubinuria, proteinuria, and increased urine specific gravity

OTHER LABORATORY TESTS

- Ammonia tolerance test—hyperammonemia • Prolonged PT/PTT

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- History of cycad palm ingestion and presence of appropriate clinical signs.
- Identification of plant in ingesta or feces.
- Biopsy and histopathology of liver—hepatocellular necrosis.
- Necropsy—hepatocellular necrosis.

PATHOLOGIC FINDINGS

- Detection of cycad palm material in GI tract and/or in feces.
- Gross detection of liver enlargement.
- Histologic detection of centrilobular and midzonal coagulative hepatocellular necrosis.

TREATMENT

- No antidote available.
- GI decontamination with activated charcoal can be attempted but efficacy is unknown.
- Supportive care including close monitoring and, depending on the severity of clinical signs, intravenous fluids, correction of electrolyte imbalances and hypoglycemia, vitamin K1, and plasma transfusions.

MEDICATIONS

DRUG(S)

- Activated charcoal: Multi-dose activated charcoal at 1–4 g/kg PO q4–6h until 2–3 days post-ingestion. Mix activated charcoal in water at 1 g/5–10 mL of water.
- Intravenous fluids: maintain hydration, induce diuresis, correct hypoglycemia.
- Dextrose: 50% dextrose 1 mL/kg IV slow bolus (1–3 minutes).
- Vitamin K1: 0.5–1.5 mg/kg SC or IM q12h; 1 mg/kg PO q24h.
- Blood products: dependent on hemostatic test results.

ALTERNATIVE DRUGS

- S-adenosylmethionine (SAMe): antioxidant and hepatoprotectant; no data on efficacy in sago palm toxicosis available. Dose 20 mg/kg PO q24h.
- Ascorbic acid and cimetidine: hepatocyte protectors; no data on efficacy in sago palm toxicosis available. Can be given for supportive therapy.
- N-Acetylcysteine

(NAC): antioxidant; no data on efficacy in sago palm toxicosis available. A glutathione precursor that can be included in the treatment regimen for acute fulminant hepatic failure at 140 mg/kg IV load, followed by 70 mg/kg IV q6h for 7 treatments.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Liver enzymes/function • Coagulation status

PREVENTION/AVOIDANCE

Deny access to sago palms.

POSSIBLE COMPLICATIONS

- Hepatic encephalopathy • DIC • Renal failure

EXPECTED COURSE AND PROGNOSIS

- Dogs develop vomiting within minutes, followed by further GI upset.
- Changes in clinical laboratory values occur after 24–48 hours.
- Liver failure within a few days.
- Prognosis is poor to guarded.

MISCELLANEOUS

ABBREVIATIONS

- AC = activated charcoal • ALP = alkaline phosphatase • ALT = alanine transaminase
- AST = aspartate transaminase • DIC = disseminated intravascular coagulation
- GGT = γ -glutamyltransferase • GI = gastrointestinal • PT = prothrombin time
- PTT = partial thromboplastin time

SALIVARY MUCOCELE

BASICS

OVERVIEW

- Salivary mucoceles are non-epithelial-lined cavities filled with saliva that has leaked from a damaged salivary gland or duct; they are surrounded by granulation tissue that forms secondary to inflammation caused by the free saliva.
- There are four major pairs of salivary glands: parotid, mandibular, sublingual, zygomatic. Smaller buccal salivary glands are located in the soft palate, lips, tongue, and cheeks.
- Types of mucoceles are listed in Table 1. The most common type occurs with rupture of the sublingual duct.

SYSTEMS AFFECTED

Gastrointestinal

SIGNALMENT

- Three times more frequent in dog than in cat.
- All breeds are susceptible. Commonly affected breeds include miniature poodle (pharyngeal mucoceles), German shepherd, dachshund, and Australian silky terrier.
- Slight predisposition of males compared to females.
- No age predisposition.

SIGNS

Cervical Mucocele

- Soft, fluctuant, minimal, or nonpainful gradually developing cervical mass.
- Pain is usually manifested only during the acute-manifestation phase of the mucocele.

Ranula

- Sublingual, soft, frog-like swelling (Latin *rana*, frog).
- Often blood-tinged saliva secondary to self-trauma while eating.

Zygomatic Mucocele

- Periorbital facial swelling
- Exophthalmos and protrusion of third eyelid
- Divergent strabismus
- Periorcular pain
- Pressure-related neuropathy of the optic nerve

Pharyngeal Mucocele

- Respiratory distress
- Dysphagia
- Abnormal tongue movement

CAUSES & RISK FACTORS

- Cause is rarely identified. Suspected causes:
 - Blunt trauma to the head and neck (choke chains)
 - Bite wound
 - Penetrating foreign body
 - Ear canal surgery, parotid duct transposition, hemimaxillectomy
 - Sialoliths
 - Dirofilariasis

DIAGNOSIS

- Diagnosis is based on history, visual examination, and paracentesis of the mass.
- Determine the site of origin with help of oral examination, palpation, sialography, or exploration of the mucocele.

DIFFERENTIAL DIAGNOSIS

- Sialadenitis (second most common salivary disease, usually involving the mandibular gland, often concurrent with sialoceles).
- Sialadenosis.
- Salivary neoplasia (rare; mandibular and parotid glands most commonly involved; usually carcinomas or adenocarcinomas in dogs; benign neoplasms exclusively found in cats).
- Sialoliths (calcium phosphate or carbonate).
- Cervical abscess.
- Salivary gland infarction (95% occur in mandibular gland).
- Foreign body.
- Hematoma.
- Cystic or neoplastic lymph nodes.
- Orbital myxoma and myxosarcoma.
- Tonsil cysts.
- Thyroglossal cysts (rare, congenital).
- Cystic Rathke's pouch and branchial cysts (rare congenital).

CBC/BIOCHEMISTRY/URINALYSIS

Laboratory abnormalities are rarely seen.

OTHER LABORATORY TESTS

N/A

IMAGING

- Rarely needed.
- Plain cervical radiographs only to identify sialoliths, foreign bodies, or neoplasia.
- Skull radiographs sometimes helpful to differentiate neoplastic disease from zygomatic mucocele, if cytologic evaluation is indeterminate.
- Sialography (injection of iodinated, water-soluble contrast agent into the salivary duct) is in general reserved for patients with trauma, previous surgeries, or fistulous draining tracts and can be helpful to determine the side and source of mucoceles.
- Retrobulbar ultrasound shows a cavitary lesion in 75% of zygomatic mucoceles and 50% of retrobulbar abscesses.
- Cross-sectional imaging can be valuable to differentiate neoplastic from non-neoplastic disease.

DIAGNOSTIC PROCEDURES

Aseptic Paracentesis

- Differentiates mucoceles from neoplasia, abscesses, and sialadenitis.
- Aspirated fluid is viscous, yellowish, clear, or blood-tinged with a low cell count. Inflamed sialoceles are characterized by low-grade chronic plasmacytic-lymphocytic inflammation.
- Cytologic evaluation (Wright's stain) reveals diffuse or irregular clumps of pink to violet staining mucin, large phagocytic cells with small, round nuclei and foamy cytoplasm, intermixed salivary gland epithelial cells, and non-degenerate neutrophils in small numbers.
- Stain with a mucus-specific stain (e.g., periodic acid-Schiff) for definitive diagnosis.

TREATMENT

- Patients with acute respiratory distress (pharyngeal mucoceles) might need to be intubated or have a temporary tracheostomy performed. Transoral drainage via stab incision may be required prior to intubation.
- Complete surgical excision of the involved gland-duct complex and drainage of the mucocele is the treatment of choice. Prolonged drainage can be achieved with

Table 1

Types of mucoceles.		
Salivary Mucocele Type	Location	Gland/Duct Involved
Cervical mucocele	Intermandibular space, jaw angle, upper cervical region	Sublingual
Ranula	Sublingual tissues	Mandibular or sublingual
Pharyngeal mucocele	Pharyngeal wall	Sublingual
Zygomatic mucocele	Ventral to the globe	Zygomatic
Parotid mucocele	Angle of the jaw, ventral to ear	Parotid
Complex mucoceles	Depending on gland/duct involvement (see above)	Two or more glands/ducts

(CONTINUED)

SALIVARY MUCOCELE

marsupialization of ranulas and pharyngeal mucoceles and with placement of Penrose drains in cervical mucoceles.

**MEDICATIONS****DRUG(S)**

Antibiotics based on bacteriologic evaluation, if concurrent abscess or sialadenitis.

CONTRAINDICATIONS

Nonsurgical treatment of salivary mucoceles with repeated drainage or injection of cauterizing or anti-inflammatory agents is not curative and will complicate subsequent surgery by causing abscessation or fibrosis.

**FOLLOW-UP****PATIENT MONITORING**

- Daily bandage changes with Penrose drain placement.

- Penrose drains are usually removed 24–72 hours following surgery.
- Drain site should heal by second intention and contraction following marsupialization.

POSSIBLE COMPLICATIONS

- Seroma formation (17% for resection of mandibular and sublingual mucoceles).
- Infection.
- Mucocele recurrence (< 5% with complete resection).

EXPECTED COURSE AND PROGNOSIS

- Excellent prognosis with complete surgical excision.
- Previous infection or injection complicates successful surgical excision.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Sialoadenitis

SYNONYMS

- Honey cyst
- Salivary cyst
- Sialocele

Salmon Poisoning Disease

BASICS

OVERVIEW

- Infection with the rickettsial organism *Neorickettsia helminthoeca*, an obligate intracellular pathogen that resides within a trematode (fluke) vector, *Nanophyetus salmincola*, for the course of the trematode's life cycle.
- Organism—invades small intestinal epithelium and associated lymphoid tissue after ingestion of uncooked or under-cooked fluke-infected salmonid fish by dogs; an acute systemic illness with high fever and gastrointestinal signs develops.
- Geographically restricted to coastal regions of northern California, Oregon, Washington and southern British Columbia as a result of the distribution of an aquatic snail intermediate host (*Oxytrema silicula*) for the trematode.

SIGNALMENT

- Dogs of all ages; median age is 3 years.
- Dogs of all breeds and sexes may develop illness, but intact male dogs and Labrador retrievers may be overrepresented because of their popularity among individuals engaged in fishing activities.

SIGNS

- Inappetence • Lethargy • Fever (up to 107.6°F); terminally hypothermia may develop
- Lymphadenopathy • Splenomegaly
- Vomiting • Diarrhea, which may contain melena or frank blood • Weight loss
- Uncommonly, neurologic signs including mental obtundation, cervical pain, twitches, and seizures.

CAUSES & RISK FACTORS

- Residence in an endemic area.
- Ingestion of uncooked or undercooked fish containing the fluke metacercariae that in turn harbor *Neorickettsia helminthoeca*. Salmonid fish (salmon and trout) are most often implicated, but other freshwater fish can occasionally be involved.
- Any part of the fish can be infected (skin, entrails, muscle).
- Supermarket-bought fish have been implicated in some cases.
- Occasionally dogs from areas not endemic for salmon poisoning disease develop disease after ingesting fish that has been transported from endemic areas.
- Infection has also been reported after swimming, without apparent exposure to fish.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lymphoma • Poisoning • Canine parvovirus type 2 infection • *Ehrlichia canis* infection • *Anaplasma phagocytophilum* infection • Canine distemper virus infection

- Rocky Mountain spotted fever
- Salmonellosis • Whipworm infestation
- Pancreatitis • Hypoadrenocorticism
- Disseminated cryptococcosis

CBC/BIOCHEMISTRY/URINALYSIS

- Common hematologic findings are thrombocytopenia (90% of dogs), neutrophilia with a left shift, and lymphopenia.
- Serum chemistry findings are nonspecific and include electrolyte abnormalities secondary to gastrointestinal losses, hypoalbuminemia, increased activity of alkaline phosphatase, hypoglobulinemia and hypocholesterolemia.
- Urinalysis may reveal proteinuria and bilirubinuria.

OTHER LABORATORY TESTS

Some dogs have laboratory findings suggestive of disseminated intravascular coagulation

IMAGING

- Abdominal ultrasound may reveal splenomegaly with a mottled echotexture and abdominal lymphadenomegaly.
- Fluid-distended intestinal loops with wall thickening, corrugation, hypermotility or hypomotility may also be seen using ultrasonographic examination.

DIAGNOSTIC PROCEDURES

- Aspirate of enlarged lymph nodes; reveals increased numbers of histiocytes that contain basophilic granular material in their cytoplasm (rickettsial inclusions).
- Fecal examination—reveals operculated eggs of the trematode *Nanophyetus salmincola*. Use of a combination of centrifugal fecal flotation and fecal sedimentation maximizes the sensitivity of this test (sensitivity 93%).
- Where available, PCR assays for *Neorickettsia helminthoeca* DNA can also be performed on lymph node aspirates or fecal material.

PATHOLOGIC FINDINGS

- Lymphoid tissue enlargement—tissues are often yellowish with prominent white foci.
- Petechial hemorrhages.
- Gastrointestinal tract thickening with white nodules.
- Intestinal contents—frequently contain free blood. Flukes may not be visible grossly.
- Histopathology reveals depletion of lymph node follicles and infiltration of lymphoid tissues and the intestinal submucosa by histiocytes, the cytoplasm of which contains numerous lymphoid follicles. Flukes may also be found embedded in the gastrointestinal mucosa.

TREATMENT

- Inpatient—acutely ill patients.
- Supportive therapy—intravenous fluids with electrolytes; colloids or packed red blood cell transfusions may also be needed. Consider antiemetics and parenteral nutrition.

MEDICATIONS

DRUG(S)

- Oxytetracycline 7.5–10 mg/kg IV q12h for 7–14 days
- Doxycycline 5 mg/kg PO or IV q12h for 7–14 days
- Praziquantel 10–30 mg/kg PO q24h for 1–2 days to kill flukes.

FOLLOW-UP

PATIENT MONITORING

Monitor hydration, electrolytes, acid-base balance, and body temperature.

PREVENTION/AVOIDANCE

- Prevent animals from eating improperly cooked fish.
- Inform client of necessity to act quickly and consider other dogs that may have eaten the same raw fish.

EXPECTED COURSE AND PROGNOSIS

- Animals likely to succumb within 5–10 days of infection unless treated with appropriate antimicrobial drugs and supportive care.
- With early diagnosis and treatment—prognosis excellent. Animals without severe gastrointestinal signs show a rapid clinical response to oral doxycycline (within 24–48 hours). Dogs with severe gastrointestinal signs may require hospitalization and aggressive treatment for more than a week.
- Untreated—often fatal.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Infection with *Nanophyetus salmincola* does not itself cause severe clinical disease.

ZOONOTIC POTENTIAL

Nanophyetus salmincola can cause gastrointestinal disturbances and eosinophilia in humans, but *Neorickettsia helminthoeca* does not cause human disease.

ABBREVIATION

- PCR = polymerase chain reaction

Suggested Reading

Sykes JE. Salmon poisoning disease. In: Sykes JE, ed., *Canine and Feline Infectious Diseases*. St. Louis, MO: Elsevier Saunders, 2014, pp. 311–319.

Author Jane E. Sykes

Consulting Editor Stephen C. Barr

BASICS

DEFINITION

A bacterial disease that causes enteritis, septicemia, and abortions and is caused by many different serotypes of *Salmonella*.

PATHOPHYSIOLOGY

- *Salmonella*—a Gram-negative bacterium; colonizes the small intestine (ileum); adheres to and invades the enterocytes; eventually enters and multiplies in the lamina propria and local mesenteric lymph nodes; cytotoxin (cell death) and enterotoxin (increases cAMP) are produced; inflammation occurs; and prostaglandin synthesis ensues; results in secretory diarrhea and mucosal sloughing.
- Uncomplicated gastroenteritis—organisms are stopped at the mesenteric lymph node stage; patient has only diarrhea, vomiting, and dehydration.
- Bacteremia and septicemia following gastroenteritis—more serious disease; focal extra-intestinal infections (abortion, joint disease) or endotoxemia may result; may lead to organ infarction, generalized thrombosis, DIC, and death.
- Some patients recover from the septicemic form but suffer prolonged recovery as a result of their debilitated state.

SYSTEMS AFFECTED

- Gastrointestinal—enterocolitis; inflammation, mucosal sloughing, secretory diarrhea.
- Systemic disease (e.g., bacteremia, focal infections, septicemia)—multiorgan infarction, thrombosis, abscesses, meningitis, osteomyelitis, abortion.

GENETICS

Genetic susceptibility not well known

INCIDENCE/PREVALENCE

• True incidence unknown. • Most infections subclinical. • Dogs—clinical disease most often seen in the young and pregnant bitches. Common in racing greyhounds and racing sled dogs due to raw meat diets; presence of *Salmonella* does not necessarily imply infection but could reflect transient pass-through. • Cats—have a high natural resistance; stressed hospitalized animals at high risk especially when treated with an oral antimicrobial drug prior to spay-neuter surgery or dentistry or declaw surgery. Shelter cats more likely to have *Salmonella* in feces; pandemics of salmonellosis in migrating songbirds (usually *S. typhimurium*) in spring create epidemics in bird-hunting cats. • New dangers noted in the trend of feeding commercial raw meat diets (especially chicken) to dogs and to cats; *Campylobacter* spp. in addition to *Salmonella* spp. and *Clostridium perfringens* often found in raw diets. Outbreaks linked to pet foods/treats are now common.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dogs and cats

Mean Age and Range

- Dogs—clinical disease manifests in neonatal/immature puppies and in pregnant bitches; most adult carrier dogs clinically normal.
- Cats—adults highly resistant.

SIGNS

General Comments

Disease severity—subclinical (carrier state: *Salmonella* shed in stool) to mild, moderate, and severe clinical cases in neonatal and stressed adult dogs and cats; subclinical infection more common than clinical disease (rare).

Historical Findings

- Diarrhea.
- Vomiting.
- Fever.
- Malaise.
- Anorexia.
- Vaginal discharge/abortion—dogs.
- Chronic febrile illness—persistent fever, anorexia, malaise without diarrhea.

Physical Examination Findings

- Asymptomatic carrier states—no clinical signs.
- Gastroenteritis—anorexia; malaise/lethargy; depression; fever (39–40°C; 102–104°F); diarrhea with mucus and/or blood; progressive dehydration; abdominal pain; tenesmus; pale mucous membranes; mesenteric lymphadenopathy; weight loss.
- Gastroenteritis with bacteremia and septicemia, septic shock, or endotoxemia—pale mucous membranes; weakness; cardiovascular collapse; tachycardia; tachypnea.
- Focal extra-intestinal infections—conjunctivitis; uterus/abortion; cellulitis; pyothorax.
- Cats—may exhibit syndrome of a chronic febrile illness (without gastrointestinal signs); persistent fever; prolonged illness with vague, nonspecific clinical signs; and left shift on leukogram.
- Recovering patients—may exhibit chronic intermittent diarrhea for 3–4 weeks; may shed *Salmonella* in stool for 6 weeks or longer.

CAUSES

- Any one of more than 2,000 serotypes of salmonellae.
- Two or more simultaneous serotypes in a host animal not uncommon.

RISK FACTORS

Disease Agent

- *Salmonella* serotype—virulence factors, infectious dose, and route of exposure.
- Host factors that increase susceptibility.
- Age—neonatal/young dogs and cats; immature immune system.
- Overall health status—debilitated young animals or adults; other concurrent disease, parasitism; young animals: immature gastrointestinal tract, poorly developed normal microbial flora.
- Disrupted gastrointestinal bacteria flora (adult cats)—antimicrobial treatment;

subsequent exposure to salmonellae during hospitalization.

Environmental Factors

- Coprophagy spreads infection.
- Dehydrated (dry) pet food—known to harbor salmonellae; semi-moist foods (e.g., kibble and dog biscuits) usually not as risky.
- Pig ear dog treats contaminated by *Salmonella*.
- Horse and cattle meat fed to exotic felids.
- New dangers noted in the trend of feeding commercial raw meat diets (especially chicken), plus contaminated pet foods and treats.
- Grooming habits—may result in *Salmonella*-contaminated hair coat, which contaminates cage or run environment, feed and water dishes.
- Dense population—research colony, boarded animals, shelter/pound animals; overcrowded housing; unsanitary conditions; exposure to other infected (or carrier) animals—buildup of *Salmonella* in the environment; more efficient fecal-oral cycling; high opportunity for fecal exposure; stress factors.

Hunting/Stray Animals

- Scavenging for food—exposure to garbage, contaminated food/water, dead animals.
- Exposure to other infected (or carrier) animals.

Hospitalized Animals

Nosocomial exposure (plus stress) or activation (by stress) of preexisting asymptomatic (carrier) *Salmonella* infection, especially in animals treated with antimicrobial drugs.

Vaccinated Cats

Death in kittens (likely to be infected by *Salmonella* subclinically) post-vaccination, with high titers of modified live panleukopenia vaccine.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute gastroenteritis—vomiting, diarrhea, infectious enteritis; differentiate by serology and/or culture.
- Viral gastroenteritis—feline panleukopenia, FeLV, FIV, feline enteric coronavirus, canine enteric coronavirus, canine parvovirus, rotavirus, canine distemper.
- Bacterial gastroenteritis—*E. coli*, *Campylobacter jejuni*, *Yersinia enterocolitica*.
- Bacterial overgrowth syndrome—*Clostridium difficile*, *Clostridium perfringens*.
- Parasites—helminths (hookworms, ascarids, whipworms, *Strongyloides*); protozoa (*Giardia*, *Coccidia*, *Cryptosporidium*); *Rickettsiae*; salmon poisoning.
- Acute gastritis—erosions or ulcers.
- Dietary-induced distress—overeating, abrupt changes, starvation, thirst, allergy or food intolerance, indiscretions (foreign material, garbage).
- Drug- or toxin-induced distress.
- Extra-intestinal disorders/metabolic disease.

SALMONELLOSIS

(CONTINUED)

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—variable; depends on stage of illness
- Neutropenia initially • Left shift with toxic neutrophils
- Nonregenerative anemia
- Lymphopenia • Thrombocytopenia
- Hypoalbuminemia • Electrolyte imbalances

DIAGNOSTIC PROCEDURES

- Fecal/rectal bacterial culture—positive; special media needed.
- Fecal leukocytes—positive.
- Blood cultures—positive in patients with bacteremia.
- Joint fluid—may be culture-positive.
- Subclinical carrier states—chronic; intermittent fecal culture positive (> 6 weeks).
- Note: use of antimicrobials in a patient before sampling may produce false-negative cultures.

PATHOLOGIC FINDINGS

- Gross lesions—only in severely affected patients.
- Cultures of ileum, mesenteric lymph node, liver/spleen, and bone marrow—positive.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—uncomplicated gastroenteritis (without bacteremia) and carrier states.
- Inpatient—with bacteremia/septicemia and for gastroenteritis in neonatal/immature animals that are rapidly debilitated by diarrhea.

NURSING CARE

Varies according to severity of illness—assess percentages of dehydration, body weight, ongoing fluid loss, shock, PCV/total protein, electrolytes, acid-base status.

Uncomplicated Gastroenteritis

- Supportive care—fluid and electrolyte replacement.
- Parenteral, balanced, polyionic isotonic solution (lactated Ringer's).
- Oral fluids—hypertonic glucose solutions; for secretory diarrhea.
- Plasma transfusions—if serum albumin < 2 g/dL.

Neonates, Aged, and Debilitated Animals

- Plasma transfusions.
- Supportive care—as outlined above.

ACTIVITY

- Isolate inpatients—all patients in acute stages may shed large numbers of salmonellae in the stool.
- Restrict activity with cage rest, monitor, and provide warmth—acutely ill, bacteremic/septicemic, and chronically ill animals.

DIET

Restrict food 24–48 hours; gradually introduce a highly digestible, low-fat diet.

CLIENT EDUCATION

Instruct client to wash hands frequently and to restrict access to patient in acute stages of the disease; large numbers of salmonellae may be shed in the stool.

MEDICATIONS

DRUG(S) OF CHOICE

Asymptomatic Carrier State

- Antimicrobials—contraindicated.
- Quinolone drugs—demonstrated clearing of carrier states in humans; more controlled trials in animals needed.

Uncomplicated Gastroenteritis

- Antimicrobials not indicated.
- Locally acting intestinal adsorbents and protectants.

Neonates, Aged, and Debilitated Animals

- Glucocorticoids—shown to reduce mortality in endotoxic shock.
- Antimicrobial therapy—indicated; culture and susceptibility testing/MIC necessary to assess drug-resistance problems.
- Trimethoprim-sulfa 15 mg/kg PO or SC q12h.
- Enrofloxacin 5 mg/kg PO or IM q12h; norfloxacin 22 mg/kg PO q12h.
- Chloramphenicol: dogs, 50 mg/kg PO, IV, IM, or SC q8h; cats, 50 mg/kg total PO, IV, IM, or SC q12h.
- Recent strains of *Salmonella* are multidrug resistant; adjust empirical therapy based on later antimicrobial susceptibility testing results.

PRECAUTIONS

- Chloramphenicol and trimethoprim-sulfa—use cautiously in neonatal and pregnant patients.
- Fluoroquinolones—avoid use in pregnant, neonatal, or growing animals (medium-sized dogs < 8 months of age; large or giant breeds < 12–18 months of age) because of adverse effect of arthropathy in dogs 4–28 weeks of age; do not administer to cats at doses higher than 5 mg/kg and do not administer to cats IV.

FOLLOW-UP

PATIENT MONITORING

- Fecal culture—repeat monthly for few months to assess development of carrier state.
- Other animals—monitor for secondary spread of infection.
- Advise client to contact veterinarian if patient shows signs of recurring disease.

PREVENTION/AVOIDANCE

- Keep animals healthy—proper nutrition; avoid raw meat diets; vaccinate for other infectious diseases; clean and disinfect cages, runs, and food and water dishes frequently; store food and feeding utensils properly.
- Reduce overcrowding—pounds, shelters, kennels, catteries, and research colonies.
- New arrivals—isolate and screen; monitor for sickness before mixing with other animals.

- Experimental live attenuated vaccine shows promise, especially for racing dogs.
- Important to protect animals being treated with antimicrobial drugs from exposure to a *Salmonella*-contaminated environment (e.g., animal hospital).

POSSIBLE COMPLICATIONS

- Spread of infection not uncommon within household to other animals or humans.
- Development of chronic infection with diarrhea.
- Recurrence of disease with stress.

EXPECTED COURSE AND PROGNOSIS

- Uncomplicated gastroenteritis—prognosis excellent; frequently self-limited; patients recover with good nursing care.
- Recovered animals may shed *Salmonella* intermittently for months or longer as a recovered carrier.
- Neonatal, aged, pregnant, and stressed animals—can develop septicemia/systemic disease and/or abortion; can be severe and debilitating; may lead to death if untreated.

MISCELLANEOUS

AGE-RELATED FACTORS

Clinical disease is frequently seen in neonatal, pregnant, aged animals.

ZOONOTIC POTENTIAL

- High potential, especially in children, elderly, immunosuppressed, and antimicrobial drug users.
- Multidrug resistant *Salmonella* isolated from kittens with enteritis.
- Acutely ill animals shed large numbers of salmonellae in stool.
- Grooming habits allow rapid contamination of animal's fur and environment.
- Isolation is needed.

PREGNANCY/FERTILITY/BREEDING

- May complicate disease.
- Abortion—may be a sequela to infection.
- Antimicrobial therapy—consider the effect on the fetus.

ABBREVIATIONS

- DIC = disseminated intravascular coagulation
- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus
- MIC = minimal inhibitory concentration
- PCV = packed cell volume

BASICS

OVERVIEW

A non-seasonal, intensely pruritic, highly contagious parasitic skin disease of dogs and other mammalian species caused by *Sarcoptes scabiei* mites. In dogs, the causative parasite is *Sarcoptes scabiei* var *canis*.

PATHOPHYSIOLOGY

Mites burrow through the stratum corneum, induce hypersensitivity, and cause intense pruritus.

SYSTEMS AFFECTED

Skin/Exocrine

SIGNALMENT

- No age/breed predisposition
- All in-contact dogs usually affected.
- Transient pruritus of in-contact other species: cats, humans.

SIGNS

- Non-seasonal, intense pruritus
- Incubation period is variable; pruritus typically develops within 30 days of exposure due to a hypersensitivity response.
- Seroconversion 3 weeks after clinical signs develop
- Rare individuals do not seroconvert and therefore may not develop severe pruritus
- Following exposure, initial pruritus is mild but progresses to severe
- Elbows, pinnal margins, ventrum, and hocks affected first
- Crusted papules leading to generalized alopecia, crusting, and excoriations
- Poor response to antihistamines and anti-inflammatory doses of steroids
- If untreated skin becomes thickened, lichenified, alopecic, and crusted
- Mite numbers often low in most affected cases
- Immunocompromised individuals may harbor larger numbers of mites
- Peripheral lymphadenopathy develops with chronicity.

CAUSES & RISK FACTORS

- Exposure to infected dogs weeks before the development of symptoms
- Close contact with other dogs in animal shelters, boarding kennels, groomers, dog parks, and veterinary offices
- Living in fox- or coyote-endemic areas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Atopy
- food allergy
- Bacterial folliculitis
- Demodicosis
- Dermatophytosis
- *Malassezia* dermatitis
- *Cheyletiella*
- Trombiculosis (chiggers)
- Contact dermatitis
- *Pelodera* dermatitis
- Otodectic dermatitis
- Dirofilariasis
- Zinc-responsive dermatosis
- Ear margin seborrhea
- Pemphigus foliaceus

OTHER LABORATORY TESTS

- ELISA—available in some countries to identify *Sarcoptes*-infested dogs.
- False

positives due to cross-reactivity with other mites; false negatives due to glucocorticoids.

DIAGNOSTIC PROCEDURES

- Positive pinnal-pedal reflex—rubbing the ear margin between the thumb and forefinger induces the dog to scratch with its hind leg.
- Superficial skin scrapings—positive in 20%–50% of scabies cases; false-negative results are common.
- Fecal flotation—may reveal mites or ova.
- Response to scabicidal treatment—most common method for diagnosing scabies.

TREATMENT

- Dogs with non-seasonal pruritus should be treated with a scabicide to definitively rule-out sarcoptic mange.
- When scabicidal dips are used, the entire dog must be treated including face and ears.
- All in-contact dogs must be treated.
- Resolution of pruritus may take several weeks due to hypersensitivity reaction to the mite.
- *Sarcoptes* mites usually die quickly in the environment; however, mites have been reported to survive for up to 3 weeks. Thorough cleaning of the dog's environment is recommended in crowded conditions.

MEDICATIONS

DRUG(S) OF CHOICE

- Selamectin—labeled for treatment of scabies when applied every 30 days; application every 2 weeks for at least three treatments may be more effective.
- Ivermectin—0.2–0.4 mg/kg SC or PO every 1–2 weeks; Milbemycin—2 mg/kg PO every 1–2 weeks.
- Doramectin 0.2–0.6 mg/kg SC or PO weekly.
- Moxidectin 0.2–0.3 mg/kg SC or PO weekly.
- Injectable and oral medications are administered for 3–6 treatments.
- Imidacloprid/moxidectin—applied twice 4 weeks apart.
- Amitraz rinse 0.025–0.03% effective when used weekly for 4–6 treatments.
- Lime-sulfur 2–4% applied weekly for 4–6 weeks.
- Fipronil spray applied to entire skin surface every 2 weeks for three treatments.
- Topical antiseborrheic therapy in conjunction with scabicidal therapy—helps speed clinical resolution of the scaling, crusting lesions.
- Systemic antibiotics—may be needed to resolve secondary pyoderma.
- Prednisone or prednisolone 1 mg/kg for 5–7 days or longer if necessary to relieve pruritus and self-mutilation.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Do not use extra-label macrocyclic lactone medications in heartworm-positive dogs, with spinosad-containing flea preventatives, or in collies, Shetland sheepdogs, Old English

SARCOPTIC MANGE

sheepdogs, Australian shepherds, and their crossbreeds—increased risk of avermectin toxicity in herding breeds (*ABCB1* [formerly *MDR1*] gene mutation). • Amitraz rinses may cause excessive sedation in small dogs.

- Potential increased risk of neurotoxicosis with concurrent use of macrocyclic lactone medications and systemic azole medications.

FOLLOW-UP

- Response to therapy may require 4–6 weeks.
- Topical scabicidal treatments are more prone to failure because of incomplete application of the treatment solution.
- Reinfection may occur if contact with infected animals continues.
- Approximately 30% of dogs with *Sarcoptes* infections will also react to house dust mite antigens on intradermal tests, suggesting that house dust mite allergy may be a possible sequela to scabies infection.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Sarcoptic mange is zoonotic. People in close contact with an affected dog may develop a pruritic, papular rash on body areas in frequent contact with dogs.

• Lesions resolve spontaneously when the affected animals are treated.

ABBREVIATION

ELISA = enzyme-linked immunosorbent assay

SCHIFF-SHERRINGTON PHENOMENON

BASICS

OVERVIEW

- Thoracic limb extension associated with hindlimb paralysis or paresis after acute and usually severe spinal cord lesion caudal to the cervical intumescence, best observed when the patient is in lateral recumbency.
- Posture—caused by damage to the border cells or their ascending processes, which are interneurons located in the lumbar spinal cord (mainly L2–4) and normally inhibiting the extensor motor neurons of the cervical intumescence.

SIGNALMENT

Any dog suffering from thoracolumbar spinal cord injury.

SIGNS

- Forelimbs—rigidly extended; normal gait and postural reactions (because the lesion is caudal to the cervical intumescence).
- Hind limbs—depends on the severity and location of the lesion; usually upper motor neuron in type, but may be lower motor neuron.
- In severe, acute thoracolumbar myelopathies, spinal shock may be present in addition to the Schiff-Sherrington phenomenon: there is an initial flaccid paralysis caudal to the level of the lesion, with loss of myotatic and flexor reflexes. In dogs and cats, spinal shock is uncommon and usually resolves within an hour, with more typical signs of upper motor neuron disease subsequently developing caudal to the spinal cord lesion.

CAUSES & RISK FACTORS

- Trauma (especially road accident) and intervertebral disc disease—most common.
- Vascular myelopathies (e.g., fibrocartilaginous embolism, coagulopathies, etc.).

S

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Decerebrate rigidity—observed with brainstem disease in which all four limbs are rigid and have upper motor neuron dysfunction; opisthotonus present; patient is unconscious.
- Decerebellate rigidity—observed with cerebellar disease in which the forelimbs are rigid but the hind limbs are flexed; consciousness is usually altered.
- Cervical spinal cord injury—may have extensor hypertonia in the forelimbs; upper motor neuron and proprioceptive deficits of all four limbs are also seen.
- The key feature in differential diagnosis is that in the Schiff-Sherrington phenomenon, function and postural reactions in the forelimbs are normal despite their extensor rigidity, while they are abnormal in the rear limbs.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

IMAGING

Radiology (radiography, myelography, computed tomography, magnetic resonance imaging)—demonstrate the thoracolumbar spinal lesion.

TREATMENT

- Directed toward the underlying thoracolumbar spinal cord lesion.
- No specific treatment available.
- Condition resolves if adequate spinal cord function is restored.
- Schiff-Sherrington phenomenon is not a prognostic indicator: prognosis is determined by the severity of signs caudal to the spinal cord lesion.

MEDICATIONS

DRUG(S)

As indicated for underlying spinal cord disease

CONTRAINDICATIONS/POSSIBLE

INTERACTIONS

N/A

FOLLOW-UP

- Posture may persist for days to weeks; not an indication of a hopeless prognosis.
- With rapid and aggressive treatment, the patient may recover, especially if there is pain perception caudal to the lesion.

SCHWANNOMA

BASICS

OVERVIEW

Schwannomas are tumors of nerve sheath origin, arising from Schwann cells. The term peripheral nerve sheath tumor (PNST) has been proposed to include schwannomas, neurofibromas, and neurofibrosarcomas, as these tumors arise from the same cell.

Importantly, schwannomas are grouped with several other soft tissue sarcomas (e.g., hemangiopericytoma and fibrosarcoma) for therapeutic and prognostic purposes, as the biologic behaviors of this group of tumors are similar.

SIGNALMENT

- Dogs—median of 10 years, no sex predisposition, no known breed predilection.
- Cats rarely affected.

SIGNS

Vary depending on tumor location, which can be peripheral (e.g., skin or tongue) or more central (e.g., axillary region).

CAUSES & RISK FACTORS

None identified

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other neoplasia that can involve the connective tissues
- Orthopedic disease
- Other neurologic disease (e.g., intervertebral disc disease)

CBC/BIOCHEMISTRY/URINALYSIS

Results usually normal

OTHER LABORATORY TESTS

None

IMAGING

- Myelography may be helpful in cases with dorsal or ventral nerve root involvement.
- Contrast computed tomography or, ideally, magnetic resonance imaging provides the most information regarding extent and location of disease.

DIAGNOSTIC PROCEDURES

Electromyography consistently reveals abnormal, spontaneous electrical activity in muscles of the affected limb.

TREATMENT

- Surgical excision is the treatment of choice.
- Radiotherapy following incomplete surgical resection is likely to result in excellent long-term outcome.
- Excision of a distal mass may still result in a functional limb; amputation is required in most cases.
- Laminectomy is necessary in cases of nerve root involvement; local recurrence is common if the primary extends into the spinal canal.

MEDICATIONS

DRUG(S)

- Chemotherapy—no successful chemotherapeutic management has been described.
- Corticosteroid therapy—may help to reduce peritumoral edema and temporarily relieve clinical signs.
- Gabapentin for neuropathic pain alleviation.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Recurrence common following incomplete surgical excision (up to 72% of cases).
- The more distal the tumor, the better the possibility of a surgical cure.
- For tumors involving the brachial or lumbosacral plexus, median disease-free interval is 7.5 months.
- For tumors involving dorsal or ventral nerve roots, median disease-free interval is 1 month.
- High histologic-grade tumors (e.g., grade 3) may metastasize to regional lymph nodes or lung.

Chase D, Bray J, Ide A, Polton G. Outcome Following Removal of Canine Spindle Cell Tumours in First Opinion Practice: 104 Cases. J Small Anim Pract 2009, 50:568–574.

Author Ruthanne Chun

Consulting Editor Timothy M. Fan

SEBACEOUS ADENITIS, GRANULOMATOUS

BASICS

OVERVIEW

- A destructive inflammatory disease process directed against cutaneous adnexal structures (sebaceous glands).
- May be genetically inherited, immune-mediated, or metabolic.
- Initial defect—a keratinization disorder or an abnormality in lipid metabolism (accumulation of toxic intermediate metabolites).

SYSTEMS AFFECTED

Skin/Exocrine

SIGNALMENT

- Young adult to middle-aged dogs; very rare in cats.
- Two forms—long- and short-coated breeds (short-coated form now called “idiopathic pyogranulomatous periadnexal dermatitis”).
- Predisposed—standard poodle, Akita, Samoyed, German shepherd, Havanese, and Vizsla.

SIGNS

Long-Coated Breeds

- Symmetrical, partial alopecia.
- Dull, brittle hair.
- Tightly adherent silver-white scale.
- Follicular casts around hair shaft (“keratin-collaring”).
- Small tufts of matted hair.
- Lesions—often first observed along dorsal midline and dorsum of the head.
- Severe—secondary bacterial folliculitis, pruritus, and malodor.
- Akitas—often relatively severely affected; morbidity associated with deep secondary bacterial infections.
- Standard poodles—affected dogs frequently described as having excellent hair coats prior to developing lesions; secondary bacterial folliculitis rare; most patients do not exhibit systemic illness.

Short-Coated Breeds

- Alopecia—moth-eaten, circular, or diffuse.
- Mild scaling.
- Lesions often plaque-like.
- Affects the trunk, head, and pinnae.
- Secondary bacterial folliculitis rare.
- Lesions can produce significant scarring.

CAUSES & RISK FACTORS

- Mode of inheritance is being studied/an autosomal recessive mode of inheritance is documented in the standard poodle and suspected in Akitas.

• Multiple pathophysiologic causes theorized including auto-immunity against sebaceous glands and/or leakage of sebaceous gland contents into surrounding dermis causing an inflammatory reaction and eventual destruction of glands.

- Destruction of sebaceous glands may be secondary—“innocent bystander” from other inflammatory conditions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary seborrhea—keratinization disorder
- Bacterial folliculitis
- Demodexis
- Dermatophytosis
- Pemphigus foliaceus
- Endocrine skin disease

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Skin scrapings—normal
- Dermatophyte culture—negative
- Endocrine function tests—normal
- Skin biopsy

PATHOLOGIC FINDINGS

- Nodular granulomatous to pyogranulomatous inflammatory reaction at the level of the sebaceous glands.
- Orthokeratotic hyperkeratosis and follicular cast formation; more prominent in long-coated breeds.
- Advanced—complete loss of sebaceous glands; periadnexal fibrosis.
- Destruction of entire hair follicle and adnexal unit rare.

TREATMENT

- Clinical signs may wax and wane irrespective of treatment.
- Controlled studies have not been done to document efficacy of any therapy.
- Results extremely variable; response may depend on severity of disease at the time of diagnosis.
- Akita—breed most refractory to treatment.

MEDICATIONS

DRUG(S)

- Propylene glycol and water—50–75% mixture; spray every 24 hours to affected areas.
- Baby oil—soak affected areas for 1 hour; follow with multiple shampoos to remove oil and scales; used monthly or as needed to reduce severe accumulations of crusts.
- Frequent bathing with keratolytic shampoos (twice weekly).
- EFA supplementation and evening primrose oil (500 mg PO q12h); possible side effects include vomiting, diarrhea, and flatulence.
- Isotretinoin (Accutane) 1 mg/kg PO q12h; reduce to 1 mg/kg q24h after 1 month and to 1 mg/kg q48h after 2 months; continue as needed for maintenance; rarely used.
- Cyclosporine 5 mg/kg PO q12–24h; side effects include vomiting, diarrhea, gingival hyperplasia, hirsutism, papillomatous skin lesions, increased incidence of infections, nephrotoxicity, and hepatotoxicity.
- Doxycycline (5 mg/kg PO q12h) and niacinamide (250 mg PO q8h, < 10 kg; 500 mg PO q8h > 10 kg) with vitamin E.
- Bactericidal antibiotics for secondary bacterial folliculitis.

CONTRAINdications/POSSible INTERACTIONS

Isotretinoin (Accutane)—known teratogen; do not use in pregnant dogs; advise owners of risk.

FOLLOW-UP

Urge owners to register affected dogs so that mode of inheritance can be determined.

SEIZURES (CONVULSIONS, STATUS EPILEPTICUS)—CATS

BASICS

DEFINITION

- Epilepsy—recurrence of seizures from primary brain origin.
- Genetic epilepsy—syndrome that is only epilepsy, with no demonstrable underlying brain lesion or other neurologic signs; the genetic origin must be proven through family studies, gene isolation or other specific forms of evidence (ILAE).
- Rare in cats.
- Structural epilepsy—syndrome in which the epileptic seizures are the result of identifiable structural brain lesions; frequent in cats.
- Epilepsy of unknown cause—structural epilepsy suspected but a lesion cannot be demonstrated; frequent in cats.
- Cluster seizures—> 1 seizure/24 hours.
- Status epilepticus—continuous seizure activity, or seizures repeated at brief intervals without complete recovery between seizures. Can be nonconvulsive.
- Convulsive SE—life-threatening medical emergency.

PATHOPHYSIOLOGY

- Paroxysmal disorganization of one or several brain functions originating from the thalamocortex. Any thalamocortical disturbance or disease process may lead to seizure activity.
- Not all cortical regions have the same propensity to seize; from the most to the least likely to cause seizures—temporal, frontal, parietal, and occipital lobes.
- As more seizures occur, the tendency for neuronal damage and propensity for more seizures or SE increases; this kindling effect does not occur in all cortical regions.
- The clinical appearance of the seizure is directly related to the location of the neuronal hyperactivity. If the electrical abnormality remains regional, the seizure is focal. If there is recruitment of both hemispheres, the seizure is generalized.
- The great majority of seizures and SE in cats are secondary to structural brain lesions.

SYSTEMS AFFECTED

Nervous

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Cats of any breed, age, or sex

SIGNS

General Comments

- Nonconvulsive generalized seizures—frequent in cats; movements of facial musculature predominate, such as bilateral twitches of eyelids, whiskers and ears, salivation, lip smacking; may be associated with whole body trembling/shaking, piloerection, dilated pupils. Nonconvulsive SE frequent in cats.
- Focal seizure—when

limited to one hemisphere; frantic running and colliding with objects (aura), unilateral facial twitches or eyelid blinks, unilateral limb motions or head/neck turning to one side. Focal seizures often generalize.

- Generalized convulsive seizures—bilateral symmetrical tonic-clonic contractions of limb muscles and dorsiflexion of the head, often associated with autonomic signs such as salivation, urination, defecation. At time of admission, the gross motor activity may have stopped, but there may still be twitching of the lids and body/limb jerks.
- Mutilation frequent—biting of tongue, nail avulsion.

Historical Findings

- Confirm that seizure activity has indeed occurred.
- Pattern of seizures (age at seizure onset, type and frequency of seizures)—most important factor in listing the possible causes.
- Metabolic diseases may cause GS.
- With most seizurogenic toxins, there is a crescendo of hyperexcitability, shaking, trembling, with ultimately GS and death.
- Asymmetry in the signs (eyelid twitches, limb movements primarily on one side, circling) before, during or after the seizure suggests focal cortical lesion.
- Overdose of insulin, post-renal transplant, bilateral thyroidectomy lead to GS shortly after the fact.
- Presence of abnormal behavior in the days/weeks preceding the seizure activity indicates structural brain disease.
- Presence of concomitant gastrointestinal, respiratory, or other systemic signs indicates multisystem disease.

Physical Examination Findings

- If chorioretinitis present, look for infectious diseases.
- Dark red mucous membranes suggest polycythemia vera.

Neurologic Examination Findings

- Mental status, menace responses, responses to nasal septum stimulation, and proprioceptive positioning are neurologic tests that evaluate the cerebral cortex. Asymmetry indicates structural brain lesion on the contralateral side of the deficits.
- In most cases of structural epilepsy, neurologic deficits are present at presentation.

CAUSES

Extracranial

Metabolic—hypoglycemia from insulin overdose, hypocalcemia from bilateral thyroidectomy, severe hyperthyroidism, hypertension secondary to renal transplant, hepatic encephalopathy, uremia, polycythemia vera, severe hypertriglyceridemia.

Toxins; Intracranial

- Anatomic—congenital malformation.
- Metabolic—cell storage disease (e.g., neuronal ceroid-lipofuscinosis reported in one cat with myoclonus and seizure activity).
- Neoplastic—meningioma, astrocytoma, lymphoma.
- Inflammatory infectious—viral non-FIP, FIP, toxoplasmosis, cryptococcosis.
- Toxicity—organochlorines, pyrethrins, and

pyrethroids; seizures usually observed at end stage; chlorambucil in lymphoma treatment.

- Vascular—polycythemia vera secondary to hyperviscosity, feline ischemic encephalopathy secondary to *Cuterebra* larva.
- Trauma has not been linked to seizures in cats.

RISK FACTORS

- Any forebrain lesion
- Diabetes mellitus
- Treatment with chlorambucil
- Renal failure

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Sleep disorders—the cat does not wake up, or has a normal waking behavior following the episode.
- Syncope—the body is limp with a rapid recovery phase, with no abnormal behavior.
- When seizures are preceded by 2–3 weeks of vague transient systemic illness (decreased appetite, GI signs) in an otherwise healthy cat—viral non-FIP encephalitis or epilepsy of unknown cause.
- When seizures are preceded by systemic signs that persist (> 3 weeks)—FIP, cryptococcosis.
- Insidious abnormal behavior with/without circling in a cat > 10 years old presented for seizure activity suggests meningioma.
- Cats with hepatic encephalopathy drool excessively.
- Cats with polycythemia vera have GI signs and dark mucous membranes.

CBC/BIOCHEMISTRY/URINALYSIS

- Extracranial metabolic causes are diagnosed on history, physical examination, and blood test results.
- High PCV (> 60%) in polycythemia vera.
- Low blood glucose in insulin overdose.
- Low calcium in bilateral post-thyroidectomy.
- High BUN and creatinine with low specific gravity in acute renal failure.
- Creatine kinase—mild to markedly elevated in cats with SE, even nonconvulsive; with or without myoglobinuria; indicates muscle necrosis.

OTHER LABORATORY TESTS

- Serologic testing—FIV, FeLV titers often non-contributory to diagnosis; FIP and *Toxoplasma gondii* titers non-reliable by themselves.
- Bile acid testing—in cats with suspected hepatic encephalopathy.

S

IMAGING

- Thoracic radiographs and abdominal ultrasound—if infectious disease suspected; to evaluate lung pathology if SE; to look for neoplasia if tumor suspected.
- MRI—best to define location, extent, and nature of lesion.

DIAGNOSTIC PROCEDURES

CSF—sensitive to detect structural disease; unspecific in itself to reach diagnosis except when organism is seen (e.g., cryptococcosis).

PATHOLOGIC FINDINGS

- Findings reflect etiology.
- It is unknown if hippocampal necrosis is a cause or the consequence of seizures.
- Small lesions may

SEIZURES (CONVULSIONS, STATUS EPILEPTICUS)—CATS (CONTINUED)

be easily missed in cats diagnosed with epilepsy of unknown cause.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—isolated recurrent seizures in an otherwise healthy cat.
- Inpatient—cluster seizures and SE. Isolated recurrent seizures in an ill cat.

NURSING AND SUPPORTIVE CARE

- Constant supervision.
- Install IV line for drug and fluid administration.
- Draw blood for rapid measurement of blood gases, glucose, calcium, and antiepileptic drug levels if pertinent.
- Cool if hyperthermia.

CLIENT EDUCATION

Antiepileptic treatment in structural epilepsy may not help until the primary cause is addressed. Seizures can be difficult to stop in cases of SE, especially with nonconvulsive status.

SURGICAL CONSIDERATIONS

Craniotomy—tumor excision with meningioma or other accessible mass.

MEDICATIONS

DRUG(S) OF CHOICE

Seizure type and frequency determine therapeutic approach.

Isolated Recurrent Generalized Seizures

- First line—phenobarbital 7.5–15 mg/cat q12h; optimal therapeutic serum levels 100–130 µmol/L (23–30 µg/L).
- Second line— gabapentin 3–8 mg/cat q8–12h.
- Levetiracetam—20 mg/kg q8h (serum levels humans 10–40 µg/mL).
- Initiate gradually to avoid overt sedation.

Convulsive Cluster and Status Epilepticus

- S**
- Treat cluster and GSE early—the more seizures in a given time, and the more drugs for seizure control, time for recovery, and cost for treatment.
 - No ongoing seizure activity at presentation and patient naïve to the drug—phenobarbital IV bolus 10 mg/kg to a maximum of 60 mg/cat over 15 minutes, continued with phenobarbital maintenance dosage PO 12 hours later.
 - Ongoing seizure activity at presentation—diazepam IV bolus 0.5–1 mg/kg, continuing with CRI at 0.25–0.5 mg/cat/h in an in-line burette using a fluid pump; IV bolus of diazepam can be repeated 5 minutes after the first bolus if gross seizure activity persists; in this case, add phenobarbital to CRI at 4 mg/cat/hour.
 - Start oral phenobarbital at maintenance dose as soon as patient can swallow.
 - After

6 hours seizures-free, wean CRI gradually over 4–6 hours.

Persistent Seizures

Sub-anesthetic doses of IV propofol (1–3.5 mg/kg) bolus and 0.01–0.25 mg/kg/minute CRI titrated to effect.

Non-antiepileptic Drug Treatment

- Dexamethasone 0.25 mg/kg IV q24h for 1–3 days, to improve edema secondary to SE and treat the primary cause if systemic infectious disease is not suspected; dexamethasone alters CSF results.
- Thiamin—5–50 mg/cat in any cat presented with acute neurologic signs, including seizures.

CONTRAINdications

- Do not use KBr in cats; side effects include life-threatening respiratory disease.
- Avoid giving aminophylline, theophylline, ketamine, and fentanyl to epileptic cats.

PRECAUTIONS

- Prolonged use of propofol (> 24 hours) may cause Heinz body anemia in cats.
- Cats on CRI of antiepileptic drug(s) are often overtly sedated; cardiovascular and respiratory depression may occur; close monitoring necessary; lubricate eyes, express bladder manually, correct hypothermia.
- Close monitoring necessary to observe if mild ongoing seizure activity persists.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

- Zonisamide—5–10 mg/kg PO q24h (serum levels humans 15–45 µg/mL).
- Diazepam—0.5–2.0 mg/kg/day PO divided q12h.

FOLLOW-UP

PATIENT MONITORING

- CBC, biochemistry, urinalysis prior to initiating AED.
- Phenobarbital-induced hepatotoxicity is not a problem in the cat.
- CK to evaluate muscular necrosis and indirectly subtle ongoing seizure activity in cats presented in SE.
- Measure phenobarbital serum level 2 weeks after initiation; correct dosage accordingly; it is difficult to titrate phenobarbital in cats, i.e., a mild increase in dosage often leads to a major increment of the serum levels.
- CBC and biochemistry—repeat every 6–12 months.
- If structural epileptic patient has recovered from primary disease and remains seizure-free for 6 months—seizures may recur when drug is weaned off.

POSSIBLE COMPLICATIONS

- SE—seizure control may not be reached despite polypharmacy.
- Rare hypersensitivity to phenobarbital—thrombocytopenia, neutropenia, pruritus, swollen feet; do CBC

4–6 weeks after onset of phenobarbital.

- Diazepam rarely may cause acute hepatic necrosis and death.
- Cardiovascular and respiratory collapse from overdose during SE treatment.

EXPECTED COURSE AND PROGNOSIS

- Depends on the underlying cause and response to treatment.
- Cats with epilepsy of unknown cause have good long-term prognosis.
- Cats can recover despite episode of severe cluster-seizures and GSE.

MISCELLANEOUS

AGE-RELATED FACTORS

Cats with seizure onset prior to < 1 year of age and diagnosed with epilepsy of unknown cause have guarded prognosis for seizure control.

SEE ALSO

- Feline Ischemic Encephalopathy
- Meningioma

ABBREVIATIONS

- AED = antiepileptic drug
- CK = creatine kinase
- CRI = constant rate infusion
- CSF = cerebrospinal fluid
- FeLV = feline leukemia virus

SEIZURES (CONVULSIONS, STATUS EPILEPTICUS)—DOGS

BASICS

DEFINITION

- Epilepsy—recurrence of seizures from primary brain origin.
- Genetic epilepsy—epilepsy with no observable underlying brain lesion or other neurologic signs or symptoms.
- Structural epilepsy—seizures are the result of identifiable structural brain lesions.
- Epilepsy of unknown cause—structural epilepsy is suspected but a lesion cannot be demonstrated.
- Cluster seizures—> 1 seizure/24 hours.
- Status epilepticus—continuous seizure activity or seizures repeated at brief intervals without complete recovery between seizures.
- Status epilepticus can be convulsive or nonconvulsive.
- Seizures are classified as focal (limited to one hemisphere), generalized (involve both hemispheres), and focal with secondary generalization.

PATOPHYSIOLOGY

- Any thalamocortical disturbance may lead to seizure activity.
- Not all cortical regions have equal propensity to seize; from the most to the least likely to cause seizures—temporal, frontal, parietal, and occipital lobes.
- As more seizures occur, the tendency for neuronal damage and propensity for more seizures or SE increases; this kindling effect does not occur in all cortical regions.
- The clinical appearance of a seizure is related to the location of the neuronal hyperactivity.

SIGNALMENT

- Dogs of any breed, age, or sex.
- SE—overrepresentation of German shepherd dog, English foxhound, Pug, teacup poodle, Boston terrier, Lakeland terrier.

Mean Age and Range

SE—4.2–5 years (0.15–15 years)

SIGNS

General Comments

- Prodrome—hours to days prior to the seizure; no EEG changes.
- Aura—short period (seconds) prior to generalization of a seizure where the dog seeks help, looks lost, frightened or has a glazed look. Focal seizure. If it precedes the tonic-clonic generalized seizure, the seizure has a focal onset.
- Ictus—may start with an aura and progress to GS; lateral recumbence with bilateral symmetrical tonic-clonic contractions of limb muscles; often with autonomic signs, e.g., salivation, urination, defecation.
- GS—may be mild, the animal remaining sternal or even standing during the event; may be long-lasting, 20 minutes or more. Convulsive or nonconvulsive.
- Post-ictal phase—disorientation, confusion, aimless pacing, blindness, polydipsia, polyphagia.
- A seizure lasts < 2 minutes.
- Most seizures occur when dog is resting or sleeping.

Historical Findings

- Confirm that seizure has occurred.
- Seizure pattern (age at onset of seizure, seizure type and frequency)—most important factor in establishing list of possible causes.
- Metabolic diseases usually cause generalized seizures.
- Asymmetric neurologic signs before, during, or after the seizure suggest structural brain lesion.
- Presence of behavioral changes in the days/weeks preceding seizure onset indicates structural brain disease.

Neurologic Examination Findings

- Mental status, menace responses, responses to nasal septum stimulation, and proprioceptive positioning—neurologic tests that evaluate the cerebral cortex. Asymmetry indicates structural brain lesion contralateral to deficits.
- Compensated SE, first 30 minutes—salivation, hyperthermia, tachycardia, arrhythmia, increased blood pressure.
- Decompensated SE—difficulty breathing, weak pulse, low blood pressure, poor capillary refill.

CAUSES

Extracranial

- Metabolic—electrolyte disturbances, hypoglycemia (insulinoma); hypocalcemia; acute renal failure; hepatic encephalopathy.
- Toxicities—metaldehyde, pyrethrins/pyrethroids, lead, hexachlorophene, chlorinated hydrocarbons, organophosphates, bromethalin, mycotoxins, macadamia nut, theobromine (chocolate), 5-fluorouracil.

Intracranial

- Degenerative—encephalopathy.
- Malformations—cortical dysplasia.
- Genetic epilepsy.
- Metabolic—cell storage diseases.
- Neoplasia—primary (meningioma, gliomas); secondary (metastatic).
- Inflammatory infectious—viral (e.g., canine distemper); fungal; protozoal (*Neospora*, *Toxoplasma*); rickettsial (ehrlichiosis, Rocky Mountain spotted fever).
- Inflammatory non-infectious—meningoencephalomyelitis of unknown origin, eosinophilic meningoencephalomyelitis; breed-related encephalitis (pug, Maltese, Yorkshire terriers, etc.).
- Trauma.
- Vascular—cerebrovascular accident.
- Epilepsy of unknown cause—post-encephalitic glial scar.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Syncope—body is limp, rapid recovery with no abnormal behavior; occurs at exercise, cough, excitement.
- Insulinoma—seizures occur at exercise, excitement.
- Obsessive-compulsive behaviors or stereotypies—complex and goal-directed behaviors; behavior can be stopped.
- Seizurogenic toxins—progression from whole body tremor to SE and death if left untreated.
- Metabolic

encephalopathy—seizures unusual and accompanied with obtunded mental state and abnormal behavior; no lateralizing signs.

- Structural brain disease likely—if acute onset of > 2 GS within first week of onset, acute onset of focal seizures with gradual progression to GS, or presence of interictal neurologic deficits including behavioral changes.
- Genetic epilepsy—differentiated on age, breed, and seizure pattern; progressive onset of GS with/without aura.
- Cervical pain/spasms—may be mistaken for focal seizures.
- Head bobbing or idiopathic head tremor—dog remains active; can eat, drink, walk.

CBC/BIOCHEMISTRY/URINALYSIS

- Infectious CNS diseases—may reflect multisystem involvement.
- Hypoglycemia—small/toy breeds during SE; insulinoma.
- Hepatic and renal dysfunction—advanced SE.
- Urinalysis—rule out myoglobinuria.

OTHER LABORATORY TESTS

- Blood gases—metabolic acidosis frequent with SE. Respiratory acidosis needs immediate treatment.
- Coagulation profile—DIC in advanced SE.
- Bile acids—suspected hepatic encephalopathy.
- Fasting blood glucose and amended insulin:glucose ratio—dogs > 5 years with occasional seizures during exercise.
- Serology (infectious diseases)—as suggested by systemic signs and laboratory abnormalities.
- Toxicity screen—cholinesterase levels.

IMAGING

- Thoracic radiographs and abdominal ultrasound—to identify metastatic or systemic illness, or lung pathology from SE.
- MRI—best to define location, extent, and nature of lesion.

DIAGNOSTIC PROCEDURES

ECG—arrhythmias can occur in SE due to myocardial damage. CSF—if intracranial structural cause is suspected; CSF and serum titers and PCR for diagnosing infectious diseases. EEG—to document ongoing seizure activity once physical manifestations have ceased.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—isolated seizures in an otherwise healthy dog.
- Inpatient—cluster seizures and SE.

NURSING AND SUPPORTIVE CARE

- SE and cluster-seizures—constant supervision.
- Ensure airway patency. May need to be suctioned due to excessive salivation.
- Administer 100% oxygen via non-rebreathing mask.
- Cool down if hyperthermia.
- Install IV line for drug and fluid administration.
- Draw blood for rapid measurement of blood gases, glucose,

SEIZURES (CONVULSIONS, STATUS EPILEPTICUS)—DOGS (CONTINUED)

calcium, renal and hepatic function, and AED levels if pertinent. • Monitor urine output with indwelling urinary catheter.

CLIENT EDUCATION

- Treat cluster of GS and GSE early—the more seizures in a given time, and the more drugs for seizure control, time for recovery, and cost for treatment.
- Antiepileptic treatment in structural epilepsy may not help until the primary cause is addressed.
- Client to keep a seizure calendar noting date, time, severity, and length of seizures to objectively evaluate response to treatment.
- Outline an in-home treatment emergency plan for cluster-seizures.

MEDICATIONS

- Electrolytes imbalance—treat immediately with fluid therapy.
- Low glucose—50% dextrose diluted to 25% (500 mg/kg IV) over 15 minutes or treat with oral glucose syrup.

DRUG(S) OF CHOICE

Seizure type and frequency determine the therapeutic approach. Important to seek and treat primary cause.

Convulsive Cluster Seizures or Status Epilepticus

Diazepam

- Administer 0.5–1 mg/kg IV bolus; repeat 5 minutes later if gross motor activity has not subsided; follow with CRI of 0.5–1 mg/kg/h added to hourly maintenance fluids in an in-line burette or through syringe pump.
- Rectal—only where IV access cannot be obtained; may diminish or stop gross motor seizure activity to allow IV catheter placement.
- Refractoriness may rapidly develop, necessitating the addition of phenobarbital CRI.

Phenobarbital

- Add if seizures persist after second diazepam bolus or during diazepam CRI; administer CRI phenobarbital (2–6 mg/dog/h added to diazepam infusion) if patient already treated with PB, or loading dose if patient naïve to PB.
- Loading dose—12–24 mg/kg given as boluses of 4 mg/kg IV, 20 minutes apart until desired effect is reached, to a maximum of 24 mg/kg. Optimal therapeutic range: 100–120 µmol/L (23–28 mg/L).
- If patient already on PB, obtain serum level prior to initiating PB CRI. IV bolus 2–6 mg/kg can be administered once while waiting results if serum levels believed inadequate.
- Once seizures have been controlled for 4–6 hours, gradually wean the patient off CRI over as many hours.
- Start/resume oral maintenance AED using PB and/or other GS AED as soon as patient can swallow.

Other

- If seizures continue, propofol at 1–2 mg/kg IV slowly over 60 sec, followed with CRI at 0.1–0.6 mg/kg/min to effect; monitor

anesthetized patient with EEG to evaluate treatment response.

- Ketamine is also used occasionally at 5 mg/kg IV bolus followed with CRI at 5 mg/kg/h.
- Dexamethasone—0.2 mg/kg q24h for 1–3 days; reduce cerebral edema.
- Dexamethasone—for acute treatment of cerebral edema secondary to severe inflammatory CNS disease, even if infectious.

Acute Focal Status Epilepticus

- Often harbors brain lesion.
- Diazepam and PB CRI—effective for focal and GS.
- Frequently difficult to reach seizure control.
- Instances of chronic nonconvulsive generalized or focal SE—owner unaware it is occurring (e.g., senile encephalopathy); if seizures remain focal and patient's quality of life not significantly altered, no treatment necessary.
- Long-term antiepileptic treatment if necessary—PB (3–5 mg/kg q12h PO), levetiracetam (20 mg/kg q8h PO), or zonisamide (5 mg/kg q12h PO).

CONTRAINdications

- Potassium bromide—do not use to treat SE; too long half-life; loading dose not recommended.
- Aminophylline, theophylline—CNS excitement; may cause seizure.
- Steroids—alter CSF parameters; avoid if considering CSF analysis.

PRECAUTIONS

- Phenobarbital—liver disease, lower dose; monitor levels closely; for SE, add cautiously to diazepam because the drugs potentiate each other, cardiac/respiratory depression may ensue.
- Steroids—contraindicated in infectious diseases, but one dose of dexamethasone (0.2 mg/kg IV) may decrease brain edema when impending brain herniation or life-threatening edema is suspected.

POSSIBLE INTERACTIONS

- Cimetidine, ranitidine, and chloramphenicol—interfere with PB metabolism; may lead to PB toxic level.
- Phenobarbital decreases zonisamide serum levels. Dosage recommended when drugs are used simultaneously—10 mg/kg q12h.
- If levetiracetam used concomitantly with PB—measure serum levels (humans 10–40 µg/mL).

ALTERNATIVE DRUG(S)

Levetiracetam—20–60 mg/kg IV; use upper end dosage if patient already on oral phenobarbital. Good alternative in liver disease or portosystemic shunts, as the drug is not metabolized in the liver. Use with caution in patients with renal disease.

FOLLOW-UP

PATIENT MONITORING

- Inpatients—constant supervision for seizure monitoring.
- Eyelid or lip twitching in a heavily sedated patient is sign of ongoing

seizure activity.

- Monitor heart rate, respiratory rate, oxygenation/ventilation, body temperature, blood pressure, urine production, neurologic examination.
- EEG monitoring for ongoing seizure activity.
- Patient may need 7–10 days before returning to normal after SE.

POSSIBLE COMPLICATIONS

- Phenobarbital—hepatotoxicity after long-term treatment with serum levels > 140 µmol/L (> 33 µg/L); acute neutropenia (rare) in the first few weeks of use requires permanent withdrawal.
- Paradoxical hyperexcitability.
- Permanent neurologic deficits (e.g., blindness, abnormal behavior, cerebellar signs) may follow severe SE.
- GSE may lead to hyperthermia, acid-base and electrolyte imbalances, pulmonary edema, cardiovascular collapse and death.

EXPECTED COURSE AND PROGNOSIS

- Genetic epilepsy or epilepsy of unknown cause represents a large proportion of dogs with GSE or cluster-seizures. In-home emergency measure using diazepam rectal/nasal should be provided.
- Dogs with encephalitis and GSE—poor outcome.
- Structural epileptic dogs recovered from primary disease (e.g., *Ehrlichia canis*)—slowly (over months) wean patient off AEDs after 6 months seizure-free; if seizures recur, reinstate AED.

MISCELLANEOUS

AGE-RELATED FACTORS

- The immature brain has a higher propensity to seize.
- Genetic epilepsy—6 months–5 years; often epilepsy refractory when onset at < 2 years.
- Phenobarbital—higher dose needed in puppies (< 5 months) to reach therapeutic range.

ABBREVIATIONS

- AED = antiepileptic drug
- CNS = central nervous system
- CRI = constant rate infusion
- CSF = cerebrospinal fluid
- CVA = cerebrovascular accident
- DIC = disseminated intravascular coagulation
- ECG = electrocardiogram
- EEG = electroencephalogram
- GS = generalized seizure
- GSE = generalized status epilepticus
- KBr = potassium bromide
- MRI = magnetic resonance imaging
- PB = phenobarbital
- PCR = polymerase chain reaction
- SE = status epilepticus

SEMINOMA**BASICS****OVERVIEW**

Sex cord stromal tumor of the testicle arising from the spermatogenic epithelium.

SIGNALMENT

- Median age, 10 years.
- Boxer, German Shepherd, Afghan hound, Weimaraner, Shetland sheepdog, Collie, and Maltese may be at increased risk.
- 33–52% of all testicular tumors in dogs, extremely rare in cats.

SIGNS

- Usually none.
- Fertility issues in breeding dogs.
- 4–20% of dogs will have more than one type of testicular tumor.
- Up to 50% of dogs will have bilateral tumors, only 12% of contralateral tumors will be palpable.

CAUSES & RISK FACTORS

Cryptorchidism

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

- Sertoli cell tumor
- Interstitial (Leydig cell) cell tumor

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal unless hormone productive and consequent male feminization syndrome.

IMAGING

- Testicular sonography may aid in differential diagnosis.
- Abdominal sonography for retained testicles and to evaluate for concurrent malignancies.

DIAGNOSTIC PROCEDURES

N/A

**TREATMENT**

- Bilateral orchiectomy and scrotal ablation is the treatment of choice.
- Exploratory laparotomy for retained testicles.
- Histopathologic examination of appropriate tissue.
- Immunohistochemistry may be necessary to identify cell of origin in some cases.
- Radiotherapy—reported effective in patients with regional metastasis.

**MEDICATIONS****DRUG(S)**

None reported in dogs.

**FOLLOW-UP****PREVENTION/AVOIDANCE**

Castration at a young age

POSSIBLE COMPLICATIONS

None likely

EXPECTED COURSE AND PROGNOSIS

Bilateral orchiectomy and scrotal ablation are often curative. Reported rate of regional or distant metastasis < 15%.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Prostate disease
- Perianal adenoma
- Perineal hernia

SEE ALSO

- Interstitial Cell Tumor, Testicle
- Sertoli Cell Tumor

SEPARATION DISTRESS SYNDROME

BASICS

DEFINITION

A distress response of dogs (occasionally cats) separated from the person or persons to whom they are most attached, usually their owner(s). The separation may be real (the owner is gone) or perceived (the pet is just separated from the owner). In other cases the pet may be distressed because some fear-inducing event has occurred while home alone such as thunderstorms or loud noises resulting in distress responses during other departures. The resulting distress may be evident by episodes of destruction, vocalization, and elimination. Separation anxiety is a subset of separation-related problems that may have different underlying motivations including fear, anxiety, overattachment to owner(s), and lack of appropriate stimulation or interactions.

PATHOPHYSIOLOGY

Unknown

SYSTEMS AFFECTED

- Behavioral—escape attempts, howling, whining, depression, hyperactivity.
- Cardiovascular—tachycardia.
- Endocrine/Metabolic—increased cortisol levels, stress-induced hyperglycemia.
- Gastrointestinal—inappetence, gastrointestinal upset.
- Musculoskeletal—self-induced trauma resulting from escape attempts.
- Nervous—adrenergic/noradrenergic overstimulation.
- Respiratory—tachypnea.
- Skin/Exocrine—acral lick dermatitis.
- Oral—dental damage during escape attempts.

GENETICS

None known

INCIDENCE/PREVALENCE

Speculated that 7–28% of companion dogs experience some degree of separation distress syndrome. May be different entities with younger dogs and senior dogs experiencing different underlying pathology.

S

SIGNALMENT

Species

Primarily dogs; possible in cats

Mean Age and Range

Any age, most commonly in dogs > 6 months; may be another increase in prevalence in dogs > 8 years.

SIGNS

General Comments

Destruction, vocalization, and elimination in the absence of the owner alone are not diagnostic for separation anxiety or separation distress.

Historical Findings

- Destruction, vocalization (whining, howling, barking), and indoor elimination are

commonly reported. Destruction targets windows and doors and/or owner possessions.

- Other signs include behavioral depression, anorexia, drooling, hiding, shaking, panting, pacing, attempts to prevent owner departure, and self-trauma from lick lesions. Diarrhea and vomiting are occasionally noted.
- Signs of strong pet-owner attachment may be present: excessive attention-seeking behaviors and following behaviors but not necessary for diagnosis.
- Frequently owners report excessive, excited, and prolonged greeting behavior upon return.
- Separation distress behavior(s) usually occurs regardless of the length of owner absence, often within 30 minutes of owner departure.
- Specific triggers that are predictive of possible departure may initiate the anxiety response: getting keys, putting on outer garments, or packing the car.
- May occur on every departure and absence or only with atypical departures or after-work, evening, or weekend departures; the reverse pattern may also be seen.
- May also occur when fear-inducing stimuli are present such as noises or storms.
- In cats, elimination problems in the owner's absence may be linked to separation-related anxiety.
- Some animals initially show signs in the presence of acute fear or anxiety inducing events such as thunderstorms or fireworks when home alone but may recur with future departures even in the absence of stimuli.
- Distress may also be initiated by a change in daily routine or in the household (e.g., moving).

Physical Examination Findings

- Usually normal.
- Injuries incurred in escape attempts or destructive activities.
- Skin lesions from excessive licking.
- Rare cases of dehydration from drooling or diarrhea due to stress.

CAUSES

Specific causes are unknown. Speculated causal factors include:

- In owner departure and absence.
- Lack of appropriate pet-owner interactions.
- Prolonged contact with humans without learning to be alone.
- Improper or incomplete early separation from the bitch (French behavior school).
- Traumatic episodes during owner absence.
- Change in household routine.
- Medical issues contributing to anxiety including endocrine dysfunction, pain, sensory decline or cognitive decline.

RISK FACTORS

- Suspected but not proven risk factors: adoption from humane shelters, extended time with preferred person such as during vacation or illness, boarding, lack of detachment when young.
- Geriatric animals seem to be overrepresented.
- Possible correlation between separation anxiety and other anxiety disorders including noise phobias.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vocalization: response to outdoor influences, territorial displays, play with other pets in the home or fears.
- Destructive behaviors: occur both when the owner is present and absent (e.g., territorial destructive displays at windows and doors; destruction due to fear-producing stimuli such as noises and thunderstorms).
- Housesoiling: inadequate housetraining, illness, endocrine dysfunction, cognitive decline.
- Licking due to primary dermatologic conditions.
- Fear-based conditions that mimic separation anxiety behaviors.
- Barrier frustration: dogs unable to be confined in crates or behind barriers but who are fine if not confined.
- Underlying medical conditions including endocrinopathies, sensory decline, pain and cognitive dysfunction syndrome.

CBC/BIOCHEMISTRY/URINALYSIS

Abnormalities, if present, suggest alternate diagnosis or concurrent medical disease.

OTHER LABORATORY TESTS

Endocrine testing if indicated based on history and results of CBC and biochemistry panel

IMAGING

MRI or CT if neurologic disorders are suspected

DIAGNOSTIC PROCEDURES

- Behavioral history • Video recordings of the pet when home alone to verify diagnosis.
- Questionnaires targeting cognitive decline are advisable for geriatric dogs.
- Skin biopsies if a dermatologic condition is suspected.
- CSF tap if neurologic disorders are suspected.
- Endoscopy with biopsies if gastrointestinal signs are persistent.

TREATMENT

ACTIVITY

Regular, scheduled daily exercise and playtime are beneficial.

DIET

No dietary changes are necessary unless diarrhea is also present.

CLIENT EDUCATION

General Comments

Set realistic expectations of the time course of treatment and the need for behavior modification to have successful resolution of the problem. Problem behavior may take weeks or months to resolve depending on severity and duration of the problem. Treatment components include the following.

(CONTINUED)

SEPARATION DISTRESS SYNDROME***Independence Training***

- Teach the dog to be more independent of the owner(s). • All attention is at owner initiation—owner begins and ends attention sessions. • No attention on pet demand.
- Have the pet earn attention and food, treat or toy rewards, by performing a task such as “sit.” • Decrease following behavior while the owner is home. Owner must not ignore the dog, but give attention in a predictable and calm manner—requesting a sit or other calm behavior before petting, throwing a ball etc. If the dog is jumping, whining, pawing at the owner they should not receive attention for that excited behavior but the owner should wait until the dog is calm before interaction.
- Teach the dog to calmly stay in another location away from the owner and create a safe haven for the dog to settle and relax on command. The dog must be able to be calm and relaxed when the owner is home for gradually longer times and gradually increasing separation to be calm and relaxed when they are gone.

Changing the Predictive Value of Pre-departure Cues

- Presentation of pre-departure cues (picking up keys, walking to the door) without leaving.
- Repeated 2–4 times daily until the dog does not respond to cues with anxious behaviors (panting, pacing, following, or increased vigilance). • Goal is to disassociate the cues with departures and diminish the anxious response. If the dog becomes more anxious, this step is discontinued.

Counter-Conditioning

- Teach the dog to sit/stay near the typical exit door. • Owner gradually increases the distance between the dog and the exit door. • Owner slowly progresses toward the door, increasing the time away on each trial. • Eventually elements of departure, such as opening and closing the door, are added. • Finally, the owner steps outside the door and returns.

Classical Counter-Conditioning

- Leaving the dog a delectable food treat or food-stuffed toy on departure. • Associating departure with something pleasant.

Changing Departure and Return Routine

- Ignore the pet for 15–30 minutes prior to departure and upon return. • On return, attend to the dog only when it is calm and quiet. • May allow the dog outside to eliminate.

Graduated Planned Departures and Absences

- Begun after dog is not responding to pre-departure cues. • Use short absences to teach the dog how to be home alone.
- Departures must be short enough not to elicit a separation distress response; the pet must be calm when owners depart and calm when they return. • Goal—animal learns consistency of owner return and to experience

departure and absence without anxiety.

- Departures must be just like real departures (owner must do all components of departure, including leaving in the car if that is how he or she usually departs). Owner will leave a safety cue (radio or television on, ring a bell) on planned departures only (must not be used on departures where length of absence is not controlled, such as work departures). • Initial departures must be very short, 1–5 minutes.
- Length of absence is slowly increased at 3–5 minute intervals if no signs of distress were evident at the shorter interval (excited greetings, barking etc.). • Increase in interval must be variable; intersperse short (1–3 minute) with longer (5–20 minute) departures. • If destruction, elimination, or vocalization occur, departure was too long. Use video recordings to assess pet anxiety. • If departures and absences are continued even though distress behaviors are present, the dog will get worse. • Audio recordings for vocalization can help monitor progress.
- Once the pet can be left for 2–3 hours on a planned departure, it often can be left all day.
- Cue is slowly phased out over time or can be used indefinitely.

Arrangements for the Pet During Retraining and Owner Absence

- If possible, allow no more destructive activity. • Mixing up or eliminating triggering departure cues may help diminish the anxious responses. • Doggie daycare arrangements or pet sitters. • Gradual conditioning to a crate.
- Crates must be used cautiously if at all and only in dogs that are calm when left in a crate as they may increase anxiety and result in pet injury.

SURGICAL CONSIDERATIONS

If the animal is on medication, care should be exercised prior to administering anesthesia.

**MEDICATIONS****DRUG(S) OF CHOICE*****Drugs for Chronic Therapy******Clomipramine***

- TCA—approved for use in the treatment of separation anxiety in dogs.
- Approved for dogs older than 6 months of age.
- Dosage: 2–4 mg/kg total daily dose (canine). Administered as one dose or divided twice daily; dogs may do better with dividing the dose and administering twice daily. Must be given daily, not on an “as needed” basis, and in conjunction with a behavior modification plan.
- May take 2–4 weeks before behavioral effect is evident.
- Side effects: vomiting, diarrhea, and lethargy.

Fluoxetine

- SSRI—approved for use in the treatment of separation anxiety in dogs.
- Dosage: 1–2 mg/kg PO q24h.
- Administer in conjunction with a behavior modification plan.
- Side effects: lethargy, decreased appetite, weight loss, and vomiting.

Drugs For Acute Anxiety At Departure

- While waiting for an SSRI or TCA to provide anxiety relief, the use of short-term anxiolytics and pheromones is advisable in many cases.
- Benzodiazepines: alprazolam for panic at owner departure (dog, 0.01–0.1 mg/kg) 30 minutes prior to departure. Some dogs experience paradoxical excitement with benzodiazepines, changing dosages or switching to another one may help. Polyphagia is also common with benzodiazepine administration.
- Trazodone: A serotonin receptor antagonist and reuptake inhibitor and can be used in conjunction with a TCA or SSRI to augment calming effects. Dosage recommendation (dog) is to begin with 2–3 mg/kg PO prior to departure and titrate up gradually to effect (up to 8–10 mg/kg). Dose should be increased cautiously, especially if using with an SSRI or TCA. Side effects include: vomiting, diarrhea, sedation, ataxia, hypotension, excitement or agitation and panting and rare reports of polyphagia.
- Adaptil: synthetic analogue of the natural appeasing pheromones of the nursing bitch that calms puppies; used to calm dogs in fearful, stressful, and anxiety situations such as separation anxiety and noise phobias; available as a plug-in diffuser for the area the dog is housed, a spray for the cage or mat, and collar.

CONTRAINDICATIONS

- Neither clomipramine nor fluoxetine should be used in conjunction with MAOIs such as amitriptyline and selegiline or within 14 days before or after an MAOI. • Use clomipramine with caution in patients showing cardiac conduction disturbances. • Caution advised using in conjunction with CNS active drugs including general anesthesia, neuroleptic, anticholinergic, and sympathomimetic drugs for dogs on either clomipramine or fluoxetine.
- A 6-week wash-out interval should be observed following discontinuation of therapy with fluoxetine prior to administration of any drug that may interact with fluoxetine.
- Fluoxetine should not be used in dogs with epilepsy or a history of seizures or with drugs that lower the seizure threshold (phenothiazines). • Practitioners are urged to read package insert for contraindications.

PRECAUTIONS

- Studies to determine effects of medication in patients less than 6 months of age have not been conducted. • Studies to assess the

SEPARATION DISTRESS SYNDROME

(CONTINUED)

interaction of fluoxetine with TCAs have not been conducted. • Improperly applied behavioral modification may actually increase anxiety. • Crating can result in serious physical damage to the pet if it attempts to escape; it should only be recommended cautiously for those animals that are already crate-trained. • Animals that do not respond may have other concurrent anxieties such as noise and storm phobias.

POSSIBLE INTERACTIONS

Serotonin syndrome with MAOI and SSRI or SSRI and TCA combinations.

ALTERNATIVE DRUG(S)

- TCA such as amitriptyline (dog, 1–2 mg/kg q12h) might be considered in place of clomipramine or fluoxetine. • Clonidine – An alpha agonist which acts as an antihypertensive agent which might be used in combination with a TCA or SSRI at a dose of 0.01–0.05 mg/kg. Begin at the lowest end of the dose range and increased cautiously.
- Nutraceutical preparations: L-theanine (Anxitane), alpha-casosopene (Zyken) alone or in combination with l-tryptophan (Royal Canine Calm diet), or Harmonease may be useful in milder cases or adjunctively.

FOLLOW-UP

PATIENT MONITORING

Good client follow-up is necessary to monitor both the behavioral treatment plan and medication if prescribed. Weekly follow-up is best in the early stages to assess efficacy of the treatment plan and owner compliance with instructions. Once the dog has become more independent, habituated to pre-departure

cues, and calmer on departures and returns, graduated planned departures may be implemented.

PREVENTION/AVOIDANCE

Teaching animals how to be left home alone, making animals independent.

POSSIBLE COMPLICATIONS

- Injuries during escape attempts. • Ongoing destruction and elimination disrupt the human-animal bond and result in pet relinquishment. • Other anxieties causing signs that mimic separation distress; if not identified and treated, the problem may worsen.

EXPECTED COURSE AND PROGNOSIS

Separation anxiety often responds well to behavioral modification with or without medication. Some severe cases can be very resistant to treatment. Other concurrent behavioral disorders may make resolution more difficult. Drug therapy alone is rarely curative for most behavioral disorders. Realistically, drug therapy can be expected to decrease the anxiety associated with owner departure, but the dog still must be taught how to be left alone during owner absences.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Other anxiety conditions including noise phobias, generalized anxiety, fears, and compulsive disorders.

AGE-RELATED FACTORS

Common behavior problem in senior dogs.

SYNOMYS

- Hyperattachment • Separation anxiety

SEE ALSO

- Cognitive Dysfunction Syndrome
- Excessive Vocalization and Waking at Nights • Thunderstorm and Noise Phobias

ABBREVIATIONS

- CNS = central nervous system • CSF = cerebrospinal fluid • CT = computerized tomography • MAOI = monoamine oxidase inhibitor • MRI = magnetic resonance imaging • SSRI = selective serotonin reuptake inhibitor • TCA = tricyclic antidepressant

BASICS

DEFINITION

- Bacteremia—the presence of viable bacterial organisms in the bloodstream.
- Sepsis—systemic inflammatory response to bacterial infection (e.g., fever, hypotension).
- Terms are not synonymous, although often used interchangeably.

PATHOPHYSIOLOGY

- Shedding of bacterial organisms into the bloodstream—may occur transiently, intermittently, or continually.
- The most critical host response for elimination of bacteremia—is provided by mononuclear phagocyte system of the spleen and liver; activation leads to release of numerous cellular mediators (cytokines), some of which are beneficial and others detrimental; may lead to death of the host.
- Neutrophils—relatively more important for defense against extravascular infection.
- Bacteremia—may occur as a transient, subclinical event or escalate to overt sepsis when the immune system is overwhelmed; generally of more pathologic significance when the bloodstream is invaded from venous or lymphatic drainage sites.

SYSTEMS AFFECTED

Cardiovascular

- With peracute development of septicemia—increased or decreased cardiac output, decreased systemic vascular resistance, and increased vascular permeability; ultimately, refractory hypotension develops, leading to multiorgan failure and death.
- Endocarditis—may develop; presence of bacteremia alone is not sufficient for induction; multiple factors involving both the host and the bacterial organism must be favorable for bacterial adherence to heart valves.

Hemic/Lymphatic/Immune

- Coagulation disorders and thromboembolism.
- Kidney and myocardium especially prone to septic embolization.
- With chronic bacteremia—antigenic stimulation of the immune system may lead to immune-complex deposition.

Endocrine

A syndrome of relative adrenal insufficiency has been reported in dogs with sepsis.

Other

- Respiratory
- Gastrointestinal
- Hepatobiliary

SIGNALMENT

Species

- Dog and cat.
- No age, sex, or breed predispositions reported.

- Large-breed male dogs—predisposed to bacterial endocarditis and discospondylitis.

SIGNS

General Comments

- Development may be acute or may occur in a vague or episodic fashion.
- Variable and may involve multiple organ systems.
- May be confused with those of immune-mediated disease.
- Clinical—more severe when gram-negative organisms are involved.
- Dogs—the earliest signs are usually referable to the gastrointestinal tract.
- Cats—respiratory system more commonly involved.

Historical Findings

A thorough history is essential; historical findings highly variable depending upon underlying cause.

Physical Examination Findings

- Intermittent or persistent fever; hypothermia more common than fever in cats in one study.
- Lameness.
- Depression.
- Tachycardia; bradycardia more common than tachycardia in cats in one study.
- Heart murmur.
- Weakness.

CAUSES

- Dogs—gram-negative organisms (especially *E. coli*) most common; Gram-positive cocci and obligate anaerobes also important; polymicrobial infection reported in about 20% of dogs with positive blood cultures.
- Cats—bloodstream pathogens usually Gram-negative bacteria from the *Enterobacteriaceae* family or obligate anaerobes; *E. coli* and *Salmonella* most common Gram-negative organisms cultured.
- *Pseudomonas aeruginosa*—uncommon isolate from animal blood cultures.

RISK FACTORS

- Peracute—pyometra and disruption of the gastrointestinal tract most often associated.
- More protracted onset— infections of the skin, upper urinary tract, oral cavity, and prostate.
- Hyperadrenocorticism, diabetes mellitus, liver or renal failure, splenectomy, malignancy, and burns—predisposing factors.
- Immunodeficient state—chemotherapy, FIV, splenectomy; particular risk.
- Glucocorticoids—considered an important risk factor for bacteremia; allows greater multiplication of bacteria in extravascular tissues.
- Intravenous catheter—provides rapid venous access for bacteria.
- Indwelling urinary catheters—may be a predisposing factor.
- Rectal exam.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Consider other causes of fever, heart murmur, joint or back pain, or hypotension.
- Clinical signs of more chronic bacteremia may be confused with immune-mediated disease.

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilic leukocytosis with a left shift and an associated monocytosis—most common hematologic abnormalities.
- Neutropenia—may develop.
- Hypoalbuminemia and a high ALP (up to two times upper limit of normal)—up to 50% of affected dogs.
- Hypoglycemia—about 25% of affected dogs; hyperglycemia more common than hypoglycemia in cats in one study but another report found most cats with hypoglycemia.

OTHER LABORATORY TESTS

- With suspected catheter-induced sepsis—submit catheter tip for culture.
- Urine culture—may be useful; positive culture does not determine if urinary tract is primary or secondary source of infection.
- Coagulation parameters should be monitored in most cases.

IMAGING

May identify source of bacteremia (e.g., pyometra, prostate) or secondarily infected organs (e.g., discospondylitis).

DIAGNOSTIC PROCEDURES

Blood Culture Indications

- Any patient that develops fever (or hypothermia), leukocytosis (especially with a left shift), neutropenia, shifting leg lameness, recent onset or changing heart murmur, or any sign of sepsis that cannot be explained.
- Essential for confirming suspected bacteremia and for optimizing management of the patient; one study of critically ill animals reported approximately 75% of cats and 50% of dogs had positive blood cultures.
- Clinical findings—not reliable for discriminating between particular types of bacteria.

Guidelines

- Current antimicrobial therapy—does not preclude collection of blood cultures; advise laboratory that patient is receiving antibiotics; steps can be taken to inactivate certain medications.
- Anaerobic cultures—special bottles may not be necessary.
- Sets (pairs) of samples—inform laboratory that for each submitted pair of bottles, one is for aerobic culture and the other for anaerobic.
- Collect at least two (and preferably three) sets of samples—improves chance of

SEPSIS AND BACTEREMIA

(CONTINUED)

obtaining a positive culture and facilitates interpretation of results.

- Volume—the greater the volume of collected blood, the better the chances of obtaining positive cultures; often only a few organisms present per milliliter of blood; 10 mL of blood per culture recommended; may not be possible for cats and small dogs; have an assortment of culture bottles available (including 25, 50, and 100 mL); small bottles useful for small patients for maintaining appropriate blood-to-culture broth ratio.
- Timing—for most patients, sufficient to take three cultures over a 24-hour period; for critically ill patients, take three cultures over a 2-hour period.

Collection

- Bottles—warm to room temperature; apply alcohol or iodine to the rubber stopper.
- Patient—clip hair; thoroughly disinfect skin before venipuncture to avoid contamination; wipe with 70% alcohol, then apply an iodine-based disinfectant; allow a minimum of 1 minute of contact time with the skin.
- Withdrawing blood—wearing a sterile glove, palpate the vein; draw blood into a sterile syringe; evacuate all air from the syringe; attach a new needle before inoculating blood into the bottles.
- Samples—maintain culture bottles at room temperature for transport to the laboratory.

Media

- Commercial multipurpose nutrient broth media—recommended.
- A medium that supports growth of both aerobes and anaerobes—ideal.
- Often the laboratory that processes the culture will supply culture bottles.

Interpretation of Results

- Single positive culture—not possible to distinguish true bacteremia from sample contamination.
- Two or more positive cultures identified as the same organism desired.
- Coagulase-negative staphylococci, α -hemolytic streptococci, and *Acinetobacter*—probably contamination.
- *Enterobacteriaceae*, *Bacteroidaceae*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Staphylococcus intermedius*, β -hemolytic streptococci, and yeasts—nearly always clinically significant bacteremia.
- Negative results from two or three successive cultures—generally eliminates bacteremia owing to common pathogens; some less common bacteria may take several weeks to grow.

PATHOLOGIC FINDINGS

Varies with the underlying cause.

TREATMENT

APPROPRIATE HEALTH CARE

- Success—requires early identification of the problem and aggressive intervention; careful monitoring essential, because the status of patient may change rapidly.
- Hypotension—intravenous fluids; isotonic fluids (e.g., lactated Ringer's) at a rate up to 90 mL/kg/h in dogs and 55 mL/kg/h in cats; use caution when hypoalbuminemia or increased vascular permeability is a concern.
- Volume expanders (e.g., hydroxyethyl starch)—may help maintain oncotic pressure.
- With hypoglycemia—may add dextrose to intravenous fluids.
- Electrolytes and acid-base balance—correct abnormalities.
- External sources of infection—give appropriate attention to wound care and bandage changes.
- Internal sources of infection (e.g., pyometra or disruption of the bowel)—surgical intervention essential.

NURSING CARE

As appropriate for each patient's situation.

DIET

Nutritional support—provide by assisted feeding or placement of a feeding tube.

CLIENT EDUCATION

Prognosis should be discussed with client.

SURGICAL CONSIDERATIONS

Any identifiable focus of infection such as an abscess should be located and removed where possible.

MEDICATIONS

DRUG(S) OF CHOICE

- Antibiotics—usually selected before culture and sensitivity results available; empiric therapy acceptable while waiting for results; do not delay treatment.
- Antimicrobials—give intravenously; direct therapy to cover all possible bacterial organisms (gram-positive and -negative; aerobic and anaerobic).
- If patient not in shock—a good choice is a first-generation cephalosporin; dogs and cats: administer cefazolin at 40 mg/kg IV as a loading dose; then 20–30 mg/kg IV q6–8h (dogs and cats).
- Aminoglycosides—add to protocol if more aggressive therapy is warranted; administer gentamicin at 2–4 mg/kg IV q8h (dogs and cats).

CONTRAINDICATIONS

Glucocorticoids and NSAIDs—value in treating septic shock; do not improve survival unless given within the first few hours of the

onset; may complicate the clinical picture in potentially ischemic organs (e.g., gastrointestinal tract and kidneys).

PRECAUTIONS

Aminoglycosides—use with caution with renal impairment.

FOLLOW-UP

PATIENT MONITORING

- Aminoglycoside therapy—monitor renal function.
- Blood pressure and ECG.

POSSIBLE COMPLICATIONS

Multiple organ failure

EXPECTED COURSE AND PROGNOSIS

Bacteremia is associated with a high rate of mortality; death owing to hypotension, electrolyte, and acid-base disturbances, and endotoxicemic shock.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Suspected discospondylitis (dogs)—may need to screen for *Brucella canis*.
- See "Risk Factors" for possible underlying diseases.

SYNOMYMS

- Septic shock
- Septicemia

SEE ALSO

- Abscessation
- Anaerobic Infections

SERTOLI CELL TUMOR

BASICS

OVERVIEW

Sex cord stromal tumor of the testicle arising from the sustenacular cells of Sertoli.

SIGNALMENT

- Median age, 10 years.
- Boxer, German shepherd, Afghan hound, Weimaraner, Shetland sheepdog, Collie, and Maltese may be at increased risk.
- 8–33% of all testicular tumors in dogs, extremely rare in cats.

SIGNS

- Usually none. Fertility issues in breeding dogs.
- 4–20% of dogs will have more than one type of testicular tumor.
- Up to 50% of dogs will have bilateral tumors, only 12% of contralateral tumors will be palpable.
- > 50% of dogs will have hyperestrogenism. Most common clinical signs include: bilateral symmetric alopecia and hyperpigmentation, pendulous prepuce, gynecomastia, galactorrhea, atrophy of the penis, squamous metaplasia of the prostate.
- Clinical signs associated with severe pancytopenia include weakness, hemorrhage and febrile episodes.
- Abdominal mass—if patient is cryptorchid.

CAUSES & RISK FACTORS

- Cryptorchid testicles 12.7 per 1000 dog-years (versus 0 for scrotally located testicles).
- Cryptorchid and ≥ 6 years of age, 68.1 per 1000 dog-years.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Interstitial cell tumor
- Seminoma
- Hyperadrenocorticism
- Hypothyroidism

- More likely to have an abdominal location than other testicular tumors; high testicular temperature in the abdominal location may destroy spermatogenic cells and leave Sertoli cells unregulated.

CBC/BIOCHEMISTRY/URINALYSIS

Transient neutrophilia followed by progressive neutropenia, thrombocytopenia, and nonregenerative anemia.

OTHER LABORATORY TESTS

Low testosterone to estradiol ratio.

IMAGING

- Testicular sonography may aid in differential diagnosis.
- Abdominal sonography for retained testicles and to evaluate for concurrent malignancies.

DIAGNOSTIC PROCEDURES

- Histopathologic examination of testicular mass.
- Immunohistochemistry may be necessary to identify cell of origin in some cases.

TREATMENT

- Bilateral orchiectomy and scrotal ablation is the treatment of choice.
- Exploratory laparotomy for retained testicles.
- Blood products and/or antibiotics for dogs with bone marrow hypoplasia.

MEDICATIONS

DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Recurrence of feminization may be associated with metastasis.
- Serum hormone levels may be correlated with resolution of clinical signs.

POSSIBLE COMPLICATIONS

Irreversible bone marrow ablation resulting in life-threatening hemorrhage and recurrent infection.

EXPECTED COURSE AND PROGNOSIS

- Good in most patients.
- Guarded if cytopenias exist at diagnosis.
- Poor prognosis if aplastic anemia present.
- Clinical signs of hyperestrogenism expected to resolve within 1–3 months following castration; however, bone marrow hypoplasia might be irreversible.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- 50% of dogs with Sertoli cell tumor associated with hyperestrogenism and feminization.
- Hyperestrogenism can cause hematopoietic failure.

SEE ALSO

Hyperestrogenism (Estrogen Toxicity)

SEXUAL DEVELOPMENT DISORDERS

BASICS

DEFINITION

- Errors in the establishment of chromosomal, gonadal, or phenotypic sex cause abnormal sexual differentiation.
- Variety of patterns from ambiguous genitalia to apparently normal genitalia with sterility.

PATHOPHYSIOLOGY

- Sexual differentiation is a sequential process—chromosomal sex established at fertilization (dog: 78,XX or 78,XY; cat: 38,XX or 38,XY), development of gonadal sex, and finally development of phenotypic sex.
- Testis differentiation normally determined by sex chromosome constitution; *SRY* (on the Y chromosome) and *SOX9* (autosomal gene), expressed by Sertoli cells, are critical for testis differentiation.
- Ovarian differentiation—an active process involving *WNT4/RSP01* and β -catenin.
- Phenotypic sex differentiation (tubular reproductive tract and external genitalia) depends on gonadal sex—basic embryonic plan is female; male phenotype results if testes are capable of secreting MIS and testosterone at the correct time during embryogenesis, and functional androgen receptors (X-linked gene) are present on genital tissues.
- Consensus terminology for categorizing Disorders of Sexual Development recently revised. Previous nomenclature also noted.

S Sex Chromosome DSD

- Defects in number or structure of sex chromosomes—chromosomal non-disjunction during meiosis causes trisomy, monosomy; mitotic non-disjunction of a single zygote causes mosaicism; fusion of zygotes leads to chimerism.
- XXY (Klinefelter) syndrome—79,XXY (dog); 39,XXY (cat); hypoplastic testes; phenotypic male (normal to hypoplastic genitalia); sterile; some tortoiseshell male cats.
- XO (Turner) syndrome—77,XO (dog); 37,XO (cat); dysgenetic ovaries; phenotypic female; infantile genitalia; sterile.
- XXX syndrome—79,XXX (dog); hypoplastic ovaries anestrus to irregular estrous cycles; female phenotype; high FSH and LH; somatic abnormalities common in XXX women.
- True hermaphrodite chimera—XX/XY or XX/XXY; ovarian and testicular tissue; phenotypic sex depends on amount of testicular tissue; dogs and cats.
- XX/XY chimera with testes and XY/XY chimera with testes—vary from phenotypic female with abnormal genitalia to male with possible fertility; dogs and cats (some tortoiseshell males).

XY DSD

Disorders of Testicular Development

- Complete or partial testicular dysgenesis—*SRY*-positive 78,XY dog; genitalia

incompletely-masculinized: (enlarged clitoris); testes undescended or perivulvar; Müllerian and Wolffian duct derivatives variably present.

- Ovotesticular DSD—(XY sex reversal, true hermaphrodite) • *SRY*-positive 38,XY true hermaphrodite cat (one report); ovotestes in ovarian position; Müllerian and Wolffian duct derivatives present; penis • 78,XY (*SRY* status unknown) dog; ambiguous female genitalia (enlarged clitoris, os clitoris); abdominal ovary (hypoplastic) and testis (Sertoli cell tumor, no spermatogenesis).

Disorders in Androgen Synthesis or Action

- Complete androgen insensitivity syndrome—38,XY cat; testes at caudal pole of kidneys; no Wolffian or Müllerian duct derivatives; blind-ended vagina; vulva.
- Partial androgen insensitivity syndrome—78,XY dog; vulva; perivulvar scrotal-like swellings at 6 months of age; blind vaginal pouch; hypoplastic testes; epididymides, partially developed vasa deferentia; vulvar fibroblasts unable to bind dihydrotestosterone.
- Persistent Müllerian duct syndrome (male pseudohermaphrodite)—XY; testes (50% are unilateral or bilateral cryptorchid); epididymides, vasa deferentia, prostate, oviducts, uterus, cervix, cranial vagina; penis, prepuce, and scrotum usually normal; dogs and cats.
- Isolated hypospadias—incomplete masculinization of urogenital sinus during urethral development causing abnormal location of urinary orifice from glans penis (mild) to perineum (severe); external genitalia unambiguous; testes (cryptorchid or scrotal) or bifid scrotum (cats) with spermatogenesis.

XX DSD

Ovotesticular DSD and Testicular DSD

- Canine XX DSD (sex reversal)—*SRY*-negative 78,XX reported in 28 dog breeds, not in cats; the autosomal gene causing testis induction presently unknown; not due to mutation of genes involved with sex reversal in polled goats and humans; two phenotypes:
- Ovotesticular DSD, XX true hermaphrodite (90% of cases)—ovotestis (at least one); masculinized female phenotype; varies from normal to abnormal vulva; normal or enlarged clitoris (os clitoris possible), uterus, oviducts, epididymides, and vasa deferentia; rarely fertile.
- Testicular DSD, XX males (10% of cases)—testes (usually cryptorchid); epididymides, vasa deferentia, prostate; bicornuate uterus, no oviducts; hypoplastic penis and prepuce; hypospadias common.

Androgen Excess

- Fetal origin—single report of congenital adrenal hyperplasia in a phenotypic male cat (38,XX, ovaries, oviducts, epididymides, vasa deferentia, bicornuate uterus); due to 11 β -hydroxylase deficiency; ACTH, testosterone, progesterone, 17-OH-progesterone, androstenedione, deoxycorticosterone, 11-dexoxycorticosterone elevated.
- Maternal origin (female pseudohermaphrodite)—XX; ovaries;

masculinized genitalia (mild clitoral enlargement to nearly normal male genitalia); oviducts, uterus, cranial vagina; prostate variable; caused by sex steroid administration during pregnancy; rare in dogs and cats.

SYSTEMS AFFECTED

- Reproductive—anomalies of the gonads, tubular tract, and external genitalia.
- Renal/Urologic—occasionally affected (e.g., agenesis, incontinence, hematuria, cystitis).
- Skin/Exocrine—perivulvar dermatitis (hypoplastic vulva); perineal or peri-preputial dermatitis (hypospadias); hyperpigmentation (Sertoli cell tumor).

GENETICS

- Chromosomal sex abnormalities—usually caused by random events during gamete formation or early embryonic development.
- XX DSD—autosomal recessive trait in American cocker spaniels and likely in beagles, German shorthaired pointers; familial in English cocker spaniels, Chinese pugs, Kerry blue terriers, Norwegian elkhounds, Weimaraners; other reported breeds include soft-coated Wheaten terriers, vizslas, Walker hounds, Doberman pinschers, basset hounds, American pit bull terriers, border collies, Afghan hounds.
- PMDS—autosomal recessive trait in miniature schnauzers in the US, Basset hounds in the Netherlands, and possibly Persian cats; expression limited to XY individuals.
- Hypospadias familial in Boston terriers.
- Failure of androgen-dependent masculinization (predominantly cats) probably X-linked.

INCIDENCE/PREVALENCE

- Generally rare.
- In affected breeds—may be common within families or within the breed as a whole.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Dogs (see "Genetics").

Mean Age and Range

All are congenital disorders, but individuals with normal external genitalia may not be identified until breeding age or at routine gonadectomy.

Predominant Sex

Phenotypic females and males

SIGNS

General Comments

- Depends on type of disorder.
- Listed are possible findings for any of the conditions; not all occur with each specific disorder.

Historical Findings

- Failure to cycle.
- Infertility and sterility.
- Vulva, clitoris, prepuce, or penis—abnormal size, shape, or location.
- Urine stream—abnormal location.
- Affected phenotypic males attractive to other males.
- Urinary incontinence.
- Vulvar discharge.
- PU/PD.

(CONTINUED)

SEXUAL DEVELOPMENT DISORDERS**Physical Examination Findings**

- Vulva normal or hypoplastic.
- Clitoris normal or enlarged; os clitoris.
- Perivulvar dermatitis and vulvar discharge.
- Testes scrotal, unilateral or bilateral cryptorchid; bifid scrotum.
- Penis and prepuce normal or hypoplastic.
- Urethral meatus normal or abnormal location.
- Dermatologic signs of hyperestrogenism in males.
- Abdominal mass.

CAUSES

- Congenital—heritable or non-heritable
- Exogenous steroid hormone administration during gestation

RISK FACTORS

Androgen or progestagen administration during pregnancy (female pseudohermaphrodite).

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS***Individuals with Unambiguous Genitalia*

- Female infertility—male infertility; mistimed breeding; subclinical cystic endometrial hyperplasia/endometritis; hypothyroidism.
- Failure to cycle (female)—silent heat; hypothyroidism; hypercorticism; previous gonadectomy.
- Male infertility—female infertility; mistimed breeding; exogenous drug use affecting fertility; orchitis or epididymitis; testicular degeneration or hypoplasia; prostatitis.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Neutrophilia; normochromic, normocytic anemia; hyperglobulinemia, hyperproteinemia; azotemia; high ALT, ALP with pyometra (PMDS).
- Urinalysis—may reveal evidence of cystitis with anatomic abnormalities that affect the location of the urethral meatus.

OTHER LABORATORY TESTS

- Sex steroid hormones (progesterone, testosterone, and estradiol)—generally below the normal range; may be normal if disorder mild and patient not sterile.
- Detect testicular tissue—GnRH or hCG simulation test; resting serum AMH (see Cryptorchidism).
- Karyotyping—required to define chromosomal sex (Molecular Cytogenetics Laboratory, Texas A&M University, 979-458-0520; call first).
- Polymerase chain reaction test for SRY—not commercially available.
- Androgen-binding studies on genital fibroblasts—testicular feminization (not commercially available).

IMAGING

- Routine radiography and ultrasonography—may be of diagnostic value for suspected abdominal mass (e.g., testicular neoplasia with PMDS, testicular feminization, or XX DSD); males with signs referable to

pyometra (female pseudohermaphrodite or PMDS).

- Contrast studies of the lower urogenital tract—may be useful in diagnosing female pseudohermaphrodites.

PATHOLOGIC FINDINGS**Gross**

- Precisely describe the genitalia: size and location of the vulva or prepuce; presence and appearance of the clitoris, penis, scrotum, prostate, caudal vagina, or os clitoris; position of the urinary orifice (identifies the phallic structure as penis or clitoris).
- Most patients with no identified chromosomal abnormalities—exploratory laparotomy to determine the location and morphology of the gonads and internal genitalia.

Histopathologic

- Examination of all tissues removed—necessary to define the type of disorder.
- Gonads—vary from nearly normal architecture to dysgenetic or a combination of ovary and testis (ovotestis).
- Essential to describe the components of the Müllerian and/or Wolffian duct system, if found.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Usually outpatient • Inpatient—exploratory laparotomy

NURSING CARE

Phenotypic females with a hypoplastic vulva and perivulvar dermatitis and males with hypospadias—local therapy to improve dermatologic sequelae (see Dermatoses, Erosive or Ulcerative).

SURGICAL CONSIDERATIONS

- Gonadectomy and hysterectomy (if a uterus is found)—recommended.
- Amputation of an enlarged clitoris—recommended if the mucosal surface is repeatedly traumatized.
- Reconstructive surgery of the prepuce and malformed penis—dogs; may be necessary with testicular DSD, XX males, or hypospadias.

**MEDICATIONS****CONTRAINDICATIONS**

Avoid androgen or progestagen use during pregnancy.

**FOLLOW-UP****PREVENTION/AVOIDANCE**

- Sterilize individuals with heritable disorders.
- Remove carriers of heritable disorders from the breeding program.

POSSIBLE COMPLICATIONS

- Infertility • Sterility • Urinary tract problems—incontinence; cystitis • Testicular neoplasia • Pyometra

**MISCELLANEOUS****AGE-RELATED FACTORS**

Patients not diagnosed at an early age—pyometra (e.g., PMDS; female pseudohermaphrodite); testicular neoplasia (e.g., PMDS; any DSD with cryptorchidism).

SYNOMYMS

- Hermaphrodites • Intersexes • Klinefelter syndrome • Pseudohermaphrodites • Sex reversal • Turner syndrome

SEE ALSO

- Breeding, Timing • Cryptorchidism

SHAKER/TREMOR SYNDROME, CORTICOSTEROID RESPONSIVE

BASICS

OVERVIEW

Fine, rapid, whole-body tremor.

SYSTEMS AFFECTED

Nervous

SIGNALMENT

- Primarily dogs, but similar syndrome recently reported in 2 cats.
- Small to medium-size breed (< 15 kg), young adult dogs (< 5 years), regardless of coat color.
- Dogs with white hair coats (e.g., Maltese and West Highland white terriers) historically have been overrepresented.
- Both sexes affected.

SIGNS

- Acute onset, fine, rapid whole-body tremors.
- Clinical signs initially can be confused with signs of apprehension or hypothermia.
- Less commonly, signs can include abnormal nystagmus, hypermetria, head tilt, menace response deficits, and opsoclonus.

CAUSES & RISK FACTORS

Most often associated with mild inflammatory CNS disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Toxin ingestion—mycotoxins (penitrem A, roquefortine); metaldehyde (snail bait); pyrethrins/pyrethroids; organophosphates, many others
- Seizures
- Hypomyelination—seen in puppies; chow chow, springer spaniel, Samoyed, Weimaraner, and Dalmatian
- Metabolic disorder—hypoglycemia, hypoadrenocorticism, hypocalcemia, magnesium imbalance
- Behavioral—fear
- Hypothermia

S

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

Cerebellomedullary cistern CSF analysis—mild mononuclear pleocytosis; CSF can be normal.

TREATMENT

Inpatient or outpatient, depending on severity of clinical signs.

MEDICATIONS

DRUG(S)

- Steroid-responsive disease; prednisolone or prednisone (1–2 mg/kg PO q12h) for the first 1–2 weeks.
- Depending on clinical response, taper dosage slowly (usually over 4–6 months); assess periodically for clinical deterioration; if dosage reduced too rapidly, clinical signs may recur, necessitating reintroduction of initial dosage.
- Many patients do not require further treatment.

CONTRAINdications/POSSIBLE INTERACTIONS

Corticosteroids—may be contraindicated with infectious encephalitis.

FOLLOW-UP

PATIENT MONITORING

Weekly evaluations for approximately 1 month; then monthly until corticosteroids are discontinued.

PREVENTION/AVOIDANCE

N/A

EXPECTED COURSE AND PROGNOSIS

- Clinical signs usually subside in 3–7 days from onset of steroid treatment.
- In some patients, recurrence necessitates reinstitution of corticosteroids.
- A small percentage of patients require every-other-day, low-dose corticosteroids, indefinitely, to maintain remission.

MISCELLANEOUS

SYNOMYMS

- Idiopathic cerebellitis
- White shaker syndrome
- Idiopathic generalized tremor syndrome

SEE ALSO

- Movement Disorders
- Tremors

ABBREVIATIONS

- CNS = central nervous system
- CSF = cerebrospinal fluid

SHOCK, CARDIOGENIC

BASICS

DEFINITION

• A severe manifestation of forward heart failure. Profound impairment of cardiac function results in poor cardiac output, inadequate forward blood flow, and poor tissue perfusion in the presence of adequate intravascular volume. • Cardiac impairment may result from systolic dysfunction (dilated cardiomyopathy, sepsis, myocarditis, and ischemia), diastolic dysfunction (hypertrophic cardiomyopathy, restrictive cardiomyopathy, tension pneumothorax or mediastinum, restrictive pericarditis, and pericardial tamponade), conduction defects and arrhythmias, valvular diseases, obstructive diseases, pulmonary thromboembolism, and structural defects. Understanding the underlying defect and its hemodynamic consequences is imperative to institute appropriate therapy. • In congestive heart failure (CHF), sometimes referred to as backward heart failure, the ventricle cannot pump out all of the blood that comes into it resulting in systemic and/or pulmonary edema. This is in contrast to forward heart failure, when the heart is not pumping enough blood out to meet the needs of the body. Most, but not all, veterinary patients that present in cardiogenic shock will have concurrent CHF.

PATHOPHYSIOLOGY

- Decreased cardiac output leads to hypotension and systemic hypoperfusion.
- Hypotension decreases coronary perfusion pressure resulting in coronary ischemia that provokes further myocardial dysfunction.
- Peripheral vasoconstriction increases myocardial work and exacerbates tissue ischemia and energy depletion resulting in organ dysfunction.

SYSTEMS AFFECTED

- Cardiovascular—cardiac dysfunction is causative. Myocardial ischemia exacerbates cardiac dysfunction. • Endocrine—hyperglycemia and insulin resistance.
- Gastrointestinal—mucosal necrosis and sloughing, hemorrhage, and bacterial translocation. • Hemic—homeostatic imbalances lead to microvascular thrombosis.
- Hepatobiliary—hepatocellular enzyme leakage, cholestasis, reduced clearance of bacteria and bacterial by-products, and abnormal synthetic function. Hepatic congestion may result from right-sided CHF.
- Musculoskeletal—weakness. • Nervous—altered mental status. • Renal—ischemic tubular damage, oliguria and development of acute kidney injury. • Respiratory—as cardiac dysfunction progresses and ventricular end diastolic pressure increases, pulmonary edema and pleural effusion develop. Ultimately

pulmonary gas exchange is affected and hypoxemia results.

GENETICS

Many breeds are predisposed to specific cardiac diseases.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Unknown

SIGNALMENT

- Dogs and cats • Any breed, age, or sex

SIGNS

Historical Findings

- Cardiac decompensation may be associated with a history of previously compensated heart disease and cardiac drug administration.
- A suspicion of previously undiagnosed cardiac disease may result from a history of coughing, exercise intolerance, weakness, or syncope.

Physical Examination Findings

- Markers of poor perfusion: ° Pale mucous membranes ° Prolonged capillary refill time ° Weak femoral pulse quality ° Weakness ° Altered mental status ° Cool extremities and hypothermia ° Oliguria. • Muffled heart sounds if pericardial or pleural effusion is present. • Variable heart rate with possible cardiac arrhythmia, murmur or gallop rhythm. • Variable respiratory rate with possible increased bronchovesicular sounds, crackles, or moist cough (especially if concurrent CHF).

CAUSES

Primary Cardiac Disease

- All cardiomyopathies—dilated, hypertrophic, intermediate and restrictive
- Severe mitral insufficiency or other end-stage valvular disease • Tachy- or bradyarrhythmias • Myocarditis
- Endomyocarditis (cats) • Structural defects

Secondary Cardiac Dysfunction

- Pericardial tamponade • Sepsis • Severe electrolyte derangement (potassium, magnesium, and calcium) • Pulmonary thromboembolism • Tension pneumothorax/mediastinum • Caval syndrome

RISK FACTORS

- Underlying cardiac disease • Concurrent illness causing hypoxemia, acidosis, and electrolyte imbalances, or as in sepsis, the release of myocardial depressant factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiating Similar Signs

Cardiogenic shock is differentiated from other causes of circulatory shock when there is evidence of decreased cardiac output and

tissue hypoxia in the face of adequate intravascular volume.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Mature neutrophilia and lymphopenia secondary to stress

Biochemistry Panel

- Hyperglycemia (stress). • Elevated anion gap (accumulation of lactic and renal acids)
- Elevated hepatocellular enzyme activity (hepatic hypoxia) • Elevated phosphorus (decreased GFR) • Azotemia (decreased GFR or hypoxia induced renal injury)
- Hyponatremia and mild hypoalbuminemia (more common in patients with chronic heart failure)

Urinalysis

- Isosthenuria (concomitant diuretic therapy or acute tubular injury secondary to renal hypoxia)

OTHER LABORATORY TESTS

- Blood gas analysis may reveal metabolic acidosis, hypoxemia (if concurrent CHF), and evidence of increased oxygen extraction by tissues (a widened arteriovenous oxygen difference and or a decreased venous oxygen concentration in a patient that is not hypoxic or anemic). • Hyperlactatemia (tissue hypoperfusion). • Increased cardiac troponin I levels (sensitive and specific marker of myocardial injury). • NT-proBNP may be useful in ruling out significant intrinsic cardiac dysfunction.

IMAGING

Radiographic Findings

Thoracic radiography may reveal cardiomegaly, evidence of pulmonary edema (CHF), and or pleural effusion (CHF).

Echocardiography

To characterize cardiomyopathy, valvular disease, depressed myocardial contractility, structural disease, pericardial disease, or heartworm infection.

DIAGNOSTIC PROCEDURES

Thoracocentesis, abdominocentesis, and pericardiocentesis when indicated may provide insight to underlying etiology.

PATHOLOGIC FINDINGS

Cardiac abnormalities consistent with various underlying etiologies. Other abnormalities consistent with tissue hypoxia.

TREATMENT

APPROPRIATE HEALTH CARE

Emergency inpatient intensive care management

NURSING CARE

- Minimize stress as these patients are extremely fragile and at risk of cardiac arrest.

SHOCK, CARDIOGENIC

(CONTINUED)

- Oxygen supplementation is critical.
- Significant pleural effusion (CHF) should be relieved with thoracocentesis.
- Patients exhibiting respiratory failure may need to be mechanically ventilated.
- Most patients in cardiogenic shock should NOT receive ANY fluid therapy until the etiology of the underlying cardiac dysfunction is understood and cardiac function improved. The exceptions to this rule include patients in cardiogenic shock secondary to pericardial tamponade, tension pneumothorax/mediastinum, and pulmonary thromboembolism.
- Pericardial tamponade should be relieved with emergency pericardiocentesis.

ACTIVITY

Minimize patient exertion

DIET

Free choice access to water; withhold food until shock is resolved.

CLIENT EDUCATION

Warn of the danger of imminent cardiac arrest and discuss a "code status" in advance whenever possible.

SURGICAL CONSIDERATIONS

- Bradyarrhythmia may require implantation of a pacemaker device.
- Tension pneumothorax may require thoracostomy tube placement or exploratory thoracotomy.
- Caval syndrome secondary to *Dirofilaria immitis* infection will require worm extraction.

MEDICATIONS

DRUG(S) OF CHOICE

- Fast-acting positive inotropes to improve cardiac function and preserve end-organ perfusion in patients with reduced myocardial contractility (dobutamine 5–20 µg/kg/min CRI in dogs; 2.5–15 µg/kg/min CRI in cats; pimobendan 0.25 mg/kg PO q12h in dogs only).
- Arrhythmia and conduction abnormalities should be corrected promptly with antiarrhythmic therapy, cardioversion, or pacemaker implantation.
- Ventricular tachycardia:
 - Dogs may respond to lidocaine (2 mg/kg IV loading dose then 50 µg/kg/min CRI) or procainamide (10–15 mg/kg IV loading dose then 25–50 µg/kg/min CRI).
 - Boxers with arrhythmogenic right ventricular cardiomyopathy may respond favorably to sotalol (2 mg/kg PO q12h) alone, or combined with mexiletine (5–8 mg/kg PO q8h).
 - Supraventricular tachyarrhythmia:
 - Treatments to slow the heart rate in dogs with supraventricular tachyarrhythmia include vagal maneuvers, calcium channel blockers (diltiazem 0.125–0.35 mg/kg IV over 2–3 minutes or 0.125–0.35 mg/kg/h CRI),

beta-blockers (esmolol 0.5 mg/kg IV over 1 minute), and procainamide (6–8 mg/kg IV over 5–10 minutes then 20–40 µg/kg/min CRI).

- Patients that do not respond to vagal maneuvers or emergency drug therapy may require DC cardioversion or overdrive pacing.
- Bradyarrhythmia:
 - Treatment of choice for severe bradyarrhythmia is cardiac pacing. However, some patients may benefit from atropine (0.02–0.04 mg/kg IV) or isoproterenol (0.4 mg in 250 mL D5W slowly to effect).
 - Concurrent CHF:
 - Furosemide to treat pulmonary edema and enhance oxygenation in dogs and cats with CHF (2–8 mg/kg IV or IM; or 0.5–1.0 mg/kg/h CRI). The IV route is preferable, but IM is appropriate when IV access would require manual restraint.
 - Relief of pain or anxiety with morphine sulfate (0.1–0.5 mg/kg/h IV CRI, or 0.2–2 mg/kg IM) can reduce excessive sympathetic activity and decrease oxygen demand, preload, and afterload.

CONTRAINdications

- Avoid diuretic therapy in patients with pericardial effusion, tension pneumothorax/mediastinum, and pulmonary thromboembolism.
- Avoid beta-blockers and calcium channel blockers in patients with reduced myocardial contractility.

PRECAUTIONS

- Catecholamine infusions must be carefully titrated to maximize coronary perfusion pressure with the least possible increase in myocardial oxygen demand.
- Afterload reducers and vasodilators (angiotensin-converting enzyme inhibitors, nitroglycerin and nitroprusside) should be used with caution because of the risk for worsening hypotension and decreasing coronary blood flow.

ALTERNATIVE DRUG(S)

Dopamine may be used to improve systolic function as an alternative to dobutamine at a dose of 5–10 µg/kg/min (dogs and cats).

FOLLOW-UP

PATIENT MONITORING

- Serial subjective and objective assessment of perfusion (mentation, mucous membrane color, capillary refill time, pulse quality, muscle strength, temperature, serum lactate, urine output, heart rate, blood pressure, and oxygenation indices), respiratory rate and effort, and pulmonary auscultation is required to optimize therapy.
- Blood gas analysis and pulse oximetry to follow tissue oxygenation, ventilation, and acid-base balance.
- Packed cell volume, serum total protein, serum electrolytes, hepatocellular enzymes, blood urea nitrogen, and serum creatinine to

monitor effects of systemic tissue hypoxia.

- Daily monitoring of cardiac troponin I (cTn-I) to assess level of myocardial injury.
- Blood pressure measurement may document hypotension.
- Electrocardiography may aid in the detection and characterization of arrhythmias.
- Pulse oximetry may document low oxygen saturation in patients with concurrent CHF.
- Central venous pressure monitoring may aid in assessment of cardiac preload and central venous oxygen saturation.
- Hemodynamic monitoring to assess mixed venous oxygen saturation, cardiac output and systemic vascular resistance.

PREVENTION/AVOIDANCE

Prevention strategies aimed at the various underlying etiologies

POSSIBLE COMPLICATIONS

- CHF
- Cardiac arrhythmias
- Syncope
- Acid-base and electrolyte disturbances
- Renal dysfunction
- Cardiac arrest

EXPECTED COURSE AND PROGNOSIS

Dependent on underlying etiology. Patients with primary cardiac disease have generally worse prognosis (poor to grave) as compared to those with secondary cardiac dysfunction.

SHOCK, HYPOVOLEMIC

BASICS

DEFINITION

Fluid loss that results in inadequate circulating volume and perfusion.

PATHOPHYSIOLOGY

- Hemorrhage or other fluid loss results in a critical decrease in intravascular volume, diminished venous return, and decreased cardiac output.
- Compensatory neuroendocrine responses lead to peripheral vasoconstriction thereby exacerbating tissue ischemia and energy depletion resulting in organ dysfunction.

SYSTEMS AFFECTED

- Cardiovascular—compensatory responses include increased heart rate, increased cardiac contractility, and peripheral vasoconstriction. Increased cardiac oxygen demand in the face of reduced oxygen delivery may result in arrhythmia.
- Endocrine—hyperglycemia and insulin resistance.
- Gastrointestinal—mucosal necrosis and sloughing, hemorrhage, and bacterial translocation.
- Hemic—homeostatic imbalances lead to microvascular thrombosis as well as hyper- and hypocoagulability.
- Hepatobiliary—hepatocellular enzyme leakage, cholestasis, reduced clearance of bacteria and bacterial by-products, and abnormal synthetic function.
- Musculoskeletal—weakness.
- Nervous—altered mental status.
- Renal—ischemic tubular damage, oliguria, and development of acute kidney injury.
- Respiratory—hyperventilation in an attempt to compensate for metabolic acidosis.

GENETICS

Unknown

INCIDENCE/PREVALENCE

GEOGRAPHIC DISTRIBUTION

Unknown

SIGNALMENT

- Dogs and cats
- Any breed, age, or sex

SIGNS

Historical Findings

May be associated with a history of trauma, weakness and collapse, surgery, vomiting and diarrhea, or polyuria and polydipsia.

Physical Examination Findings

- Compensated shock is also referred to as warm shock or preshock:
 - Compensatory mechanisms may allow an otherwise healthy pet to be relatively asymptomatic despite a 10% reduction in total effective blood volume. When homeostatic mechanisms can no longer compensate, patients will demonstrate signs of decompensated shock.
- Decompensated hypovolemic shock:
 - Markers of poor perfusion (pale mucous membranes [may be compounded by

anemia], prolonged capillary refill time, weak peripheral pulse quality, weakness, altered mental status, hypothermia and cool extremities, oliguria).

- Absent to minimal jugular vein distension.
- Tachycardia ± arrhythmia.
- Tachypnea.
- Clinical dehydration as evidenced by decreased skin turgor, tacky mucous membranes, and sunken eyes is more common in patients with fluid loss rather than hemorrhage.

CAUSES

Hemorrhage-Induced

- Blunt or penetrating trauma.
- Ruptured neoplasia.
- Gastrointestinal bleeding secondary to ulcerative disease, neoplasia, or severe thrombocytopenia.
- Coagulopathy resulting from anticoagulant rodenticide intoxication, synthetic liver failure, disseminated intravascular coagulation, hemophilia, and significant von Willebrand factor deficiency.

Fluid Loss-Induced

- Gastrointestinal (vomiting and diarrhea).
- Urinary (renal failure, diabetes mellitus, diabetes insipidus, hypercalcemia, Addison's, and Cushing's diseases).
- Burns.
- Third spacing (any disease that results in formation of significant volumes of effusion).

RISK FACTORS

Caused by another condition; as such it has no specific risk factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiating Similar Signs

Hypovolemic shock is differentiated from other causes of circulatory shock when inadequate circulating volume results in decreased cardiac output in the face of normal or increased cardiac function and normal or increased systemic vascular resistance.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Mature neutrophilia and lymphopenia secondary to stress.
- Hematocrit, total protein, and platelet count are variable (may be decreased with hemorrhage).

Biochemistry Panel

- Hyperglycemia secondary to stress.
- Total protein and albumin are variable (decreased with hemorrhage and increased in fluid loss).
- Elevated hepatocellular enzyme activity (ALT, AST).
- Electrolyte derangements are variable (more likely in fluid loss).
- Elevated anion gap (accumulation of lactic and renal acids).
- Azotemia due to decreased glomerular filtration rate.

Urinalysis

- Urine specific gravity may be increased; however, acute tubular injury secondary to renal hypoxia may result in isosthenuria.

OTHER LABORATORY TESTS

- Coagulation testing is indicated in critically ill patients and those with evidence of significant hemorrhage.
- Blood gas analysis may reveal metabolic acidosis and evidence of increased oxygen extraction by tissues (a widened arteriovenous oxygen difference and/or a decreased venous oxygen concentration in a patient that is not hypoxic or anemic).
- Hyperlactatemia reflects decreased clearance and increased production of lactate.

IMAGING

- Thoracic radiography may reveal microcardia and pulmonary vascular under-perfusion.
- Radiographic or ultrasonographic findings of pleural or abdominal effusion warrant timely sampling and evaluation of the fluid.

DIAGNOSTIC PROCEDURES

- Thoracocentesis, abdominocentesis, and pericardiocentesis when indicated may provide insight into underlying etiology.

PATHOLOGIC FINDINGS

Abnormalities consistent with various underlying etiologies. Other abnormalities consistent with tissue hypoxia.

TREATMENT

APPROPRIATE HEALTH CARE

- Emergency inpatient intensive care management.
- Resuscitation goals:
 - Maximize blood oxygen content by ensuring adequacy of ventilation and oxygen saturation of blood and correct anemia
 - Restore blood flow and control of further loss
 - Fluid therapy.
 - Traditional endpoints of resuscitation, including restoration of normal vital signs (mentation, capillary refill time, heart rate, peripheral pulse quality, and rectal temperature), blood pressure, and urine output remain the standard of care. However, it has been documented that critically ill patients have evidence of ongoing tissue hypoxia despite normalization of these parameters, suggestive of occult oxygen debt and the presence of compensated shock.
 - There is evidence that normalization of vital signs, blood lactate, base deficit, and oxygen transport indices such as cardiac index, oxygen delivery, oxygen consumption, and mixed venous oxygen and central venous oxygen saturation in concert are more sensitive markers for adequacy of tissue perfusion than any of these variables alone.
 - Until stronger support exists for preferential selection of one endpoint over the others, utilization of as many of these markers as are available on any given patient seems advisable.

NURSING CARE

- Maximize blood oxygen content:
 - Assess and stabilize the airway and breathing as

SHOCK, HYPOVOLEMIC

(CONTINUED)

necessary. • Administer high-flow supplemental oxygen and provide ventilatory support as needed. • Significant anemia (PCV < 25–30%) in a hypovolemic patient is concerning and should be corrected.

- Control further blood or fluid loss:
- External bleeding is frequently controlled with direct pressure; internal bleeding may require surgical intervention
- Control of fluid loss other than hemorrhage, centers on control of symptoms (e.g., antiemetics) and correction of the underlying disorder.
- Fluid resuscitation: ◦ Once IV or IO access is obtained, initial fluid resuscitation is performed with an isotonic crystalloid such as lactated Ringer's solution, normal saline, Plasmalyte-A, and Normosol-R (30 mL/kg, dog; 20 mL/kg, cat over 15 minutes). If the patient is not significantly dehydrated, addition of 7.5% hypertonic saline (4 mL/kg over 15 minutes) may expedite the resuscitation. ◦ After the initial bolus the patient's response is assessed. If vital signs and other resuscitation parameters return to normal, the patient must continue to be monitored to ensure stability. If vital signs and other resuscitation parameters transiently improve or if little or no improvement is seen, another crystalloid bolus should be infused and colloids such as hydroxyethylstarch (dose variable, dependent on type) or appropriate blood products (10–20 mL/kg) considered
- This process is repeated until the patient's resuscitation parameters normalize. When bolusing fluids to correct perfusion deficits, the clinician must monitor not only for response to therapy, but also for potential complications
- While fluid boluses are used to correct perfusion deficits, hydration deficits must be corrected more slowly. After perfusion has been normalized, the patient is reassessed and fluid therapy targeted to correct hydration deficits over 12–24 hours.

ACTIVITY

Minimize patient exertion.

DIET

Withhold oral intake until shock is resolved.

CLIENT EDUCATION

Warn of the danger of imminent cardiac arrest and discuss a "code status" in advance whenever possible.

SURGICAL CONSIDERATIONS

Identify and repair the source of fluid loss (most common in hemorrhage-induced).

MEDICATIONS

DRUG(S) OF CHOICE

- For patients with refractory hypovolemic shock it is important to rule in or out ongoing

losses (especially in the hemorrhage-induced category) and to administer blood products as needed. • If adequate circulating volume is assured and the patient is still demonstrating clinical signs of shock (not very common in patients with hypovolemic shock), consider:

- A pressor such as dopamine (5–20 µg/kg/minute), norepinephrine (0.05–2 µg/kg/minute), or vasopressin (0.5–2 mU/kg/minute). These can be used for vasopressor support in both dogs and cats. Monitor for tachyarrhythmia and excessive peripheral vasoconstriction
- A positive inotrope such as dobutamine (2–20 µg/kg/minute) may be beneficial in patients with decreased contractility or myocardial depression. Monitor for tachyarrhythmia. While dobutamine can generally be used safely in dogs, seizures have been observed in some cats at doses exceeding 5 µg/kg/minute.

FOLLOW-UP

PATIENT MONITORING

- Serial assessment of perfusion: ◦ Physical exam including mentation, mucous membrane color, capillary refill time, pulse quality, muscle strength, temperature, and heart rate.
- Hemodynamic monitoring to include arterial blood pressure (frequently reveals a disproportionately low diastolic pressure), and in a subset of patients central venous pressure (decreased jugular and central venous pressure due to hypovolemia and decreased preload; catheter also allows for measurement of central venous oxygen saturation), cardiac output and tissue oxygenation.
- Laboratory data including serum lactate and base deficit.
- Serial assessment of respiratory rate and effort, and pulmonary auscultation is required to optimize therapy.
- Urine output as an indicator of glomerular filtration rate and renal blood flow.
- Electrocardiography may aid in the characterization of arrhythmias.
- A minimum of daily packed cell volume (PCV), serum total protein, blood glucose, blood gas, serum electrolytes, hepatocellular enzymes, blood urea nitrogen, and serum creatinine to monitor effects of systemic tissue hypoxia and to guide clinical management.
- Patients with hemorrhage-induced hypovolemic shock should have PCV and total protein assessed more frequently.
- Daily measurement of COP may help guide fluid therapy.

PREVENTION/AVOIDANCE

Prevention strategies aimed at the various underlying etiologies.

POSSIBLE COMPLICATIONS

- Dilutional coagulopathy and low colloid oncotic pressure (COP) can occur in patients receiving very large resuscitation volumes (more than 1–2 blood volumes). This is due to dilution of clotting factors and proteins respectively, but is rare within the first hour of resuscitation. Coagulation times should be used to guide the administration of fresh frozen plasma. Low COP is most common and effectively addressed with the administration of artificial colloid solutions.
- Volume overload with clinical signs of pulmonary and/or peripheral edema.
- Anemia and thrombocytopenia.
- Acid-base disturbances.
- Multiple organ dysfunction.
- Cardiac arrest.

EXPECTED COURSE AND PROGNOSIS

Dependent on underlying etiology and ability to institute appropriate therapy.

BASICS

DEFINITION

Sepsis-induced hypotension that persists despite adequate intravascular volume and cardiac output, and is attributable to low systemic vascular resistance.

PATHOPHYSIOLOGY

- In sepsis, infectious agents trigger large-scale activation of monocytes, macrophages, and neutrophils that then interact with endothelial cells inducing a generalized inflammatory response.
- In the subset of septic patients described as having septic shock, the elaborate interaction of inflammatory cells and mediators decreases systemic vascular resistance and provokes maldistribution of blood flow (distributive effect). They also increase capillary permeability such that fluid shifts out of the intravascular space. To compensate for diminishing circulating volume, catecholamines increase cardiac output and myocardial contractility. In the face of severe arterial vasodilation, cardiac output is not sufficient to maintain oxygen delivery to tissues.
- Decreased oxygen delivery is compounded by the presence of interstitial edema and microvascular sludging. In due course, tissue hypoxia leads to organ failure and death.

SYSTEMS AFFECTED

- Cardiovascular**—increased cardiac output, arterial vasodilation, and maldistribution of blood flow with hypotension predominates; however, myocardial dysfunction secondary to circulating factors can be an important variable.
- Endocrine**—may manifest as hyperglycemia and insulin resistance or as insufficient production of either corticosteroids or vasopressin.
- Gastrointestinal**—mucosal necrosis, hemorrhage, and bacterial translocation.
- Hemic**—microvascular thrombosis as well as hyper- and hypocoagulopathy.
- Hepatobiliary**—hepatocellular enzyme leakage, cholestasis, reduced clearance of bacteria, and abnormal synthetic function.
- Nervous**—altered mental status.
- Renal**—ischemic tubular damage, oliguria, and development of acute kidney injury.
- Respiratory**—enhanced microvascular permeability results in interstitial and alveolar edema; hypercoagulopathy may result in pulmonary thromboembolism.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Unknown

SIGNALMENT

- Dogs and cats
- Any breed, age, or sex

SIGNS

Historical Findings

Recent infection, injury, serious illness, surgery, or immunosuppression.

Physical Examination Findings

- Dogs may display a hyperdynamic form that is typified by altered mental status, weakness, hypotension, tachycardia, tachypnea, hyperemia, fast CRT, bounding pulse quality, and fever. Cats rarely demonstrate hyperdynamic signs.
- Patients with the hypodynamic form are more likely to exhibit altered mental status, weakness, hypotension, bradycardia, tachypnea, pale mucous membranes, prolonged CRT, weak pulse quality, and hypothermia.

CAUSES

- Septic peritonitis—gastrointestinal tract rupture, penetrating abdominal wound, infected urinary tract rupture.
- Respiratory and pleural space—pneumonia, pyothorax.
- Skin or soft tissue infections—infected wounds, foreign bodies.
- Urinary tract—pyelonephritis.
- Reproductive—prostatitis, pyometra.
- Cardiovascular—bacterial endocarditis.
- Musculoskeletal—septic arthritis, osteomyelitis.
- Iatrogenic sources of infection—catheters, implants, surgical sites.
- Central nervous system—meningitis, encephalitis.

RISK FACTORS

- Extremes of age
- Concurrent diseases such as diabetes mellitus, hyperadrenocorticism, and malignancy
- Immunosuppression
- Surgery, trauma, and burns
- Prior antibiotic therapy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of distributive shock include drug or toxin reaction, anaphylaxis, and adrenal insufficiency.
- Hypovolemic shock.
- Cardiogenic shock.
- Heatstroke.

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilia or neutropenia, left-shift, and toxic change
- Lymphopenia
- Thrombocytopenia
- Hematocrit and blood glucose are variable
- Hypoalbuminemia
- Elevated bilirubin and liver enzymes
- Electrolyte derangements
- Azotemia
- Isosthenuria and variably active urine sediment

OTHER LABORATORY TESTS

- Prolongation of the activated partial thromboplastin and prothrombin times, increased D-dimers and fibrin degradation products, and decreased levels of antithrombin and protein C.
- Blood gas analysis may reveal hypoxemia and acid-base disturbances.
- Serum lactate elevation.
- Cytology, gram stain, and culture and

sensitivity on samples obtained from potential sites of infection may reveal etiologic organisms.

- Culture and sensitivity of urine and blood may be useful especially when the source of the sepsis is unknown.
- Low COP.
- ACTH stimulation test in patients not responding to standard therapy.

IMAGING

- Thoracic radiographs may reveal a septic focus or cause for respiratory dysfunction.
- Echocardiography may document a vegetative valvular lesion and/or characterize the adequacy of cardiac function.
- Abdominal ultrasonography may detect a septic focus.

DIAGNOSTIC PROCEDURES

Thoracocentesis, abdominocentesis, tissue aspirates, and arthrocentesis when indicated may provide insight into underlying etiology.

PATHOLOGIC FINDINGS

Abnormalities consistent with various underlying etiologies. Other abnormalities consistent with inflammation and tissue hypoxia.

TREATMENT

APPROPRIATE HEALTH CARE

- Emergency inpatient intensive care management.
- Resuscitation goals:
 - Maximize blood oxygen content by ensuring adequacy of ventilation and oxygen saturation of blood and correct anemia
 - Restore blood flow
 - Fluid therapy.
 - Traditional endpoints of resuscitation, including restoration of normal vital signs (mentation, CRT, heart rate, peripheral pulse quality, and rectal temperature), BP, and urine output remain the standard of care. However, it has been documented that critically ill patients have evidence of ongoing tissue hypoxia despite normalization of these parameters, suggestive of occult oxygen debt and presence of compensated shock. There is evidence that normalization of vital signs, blood lactate, base deficit, and oxygen transport indices are more sensitive markers for adequacy of tissue perfusion than any of these variables alone.
 - Until stronger support exists for preferential selection of one endpoint over the others, utilization of as many of these markers as are available on any given patient seems advisable.
- Identify and treat source of infection (antimicrobial therapy, surgery, or both).
- Maintain adequate organ function (guided by cardiovascular and laboratory monitoring).

NURSING CARE

- Maximize blood oxygen content:
 - Assess and stabilize the airway and breathing as necessary
 - Administer high-flow supplemental oxygen and provide ventilatory support as needed
 - Significant anemia (PCV < 25%) should be corrected.
 - Most septic

SHOCK, SEPTIC

(CONTINUED)

patients are hypovolemic and require initial fluid resuscitation with an isotonic crystalloid such as lactated Ringer's solution, normal saline, Plasmalyte-A, and Normosol-R (30 mL/kg, dog; 20 mL/kg, cat over 15 minutes). If the patient is not significantly dehydrated, addition of 7.5% hypertonic saline (4 mL/kg over 15 minutes) may expedite the resuscitation. • After the initial bolus the patient's response is assessed. If vital signs and other resuscitation parameters return to normal, the patient must continue to be monitored to ensure stability. If vital signs and other resuscitation parameters transiently improve or if little or no improvement is seen, another crystalloid bolus should be infused and colloids such as HES (dose variable, dependent on type) considered. • HES will help maintain adequate COP and may reduce the amount of crystalloid required to achieve effective resuscitation. HES at high doses may exacerbate coagulopathy. • Blood products should be administered based on patient need. Packed red blood cells are administered to anemic patients to improve oxygen carrying capacity. Plasma products are used to correct coagulation deficits and concentrated albumin products are most effective raising COP. • This process is repeated until the patient's resuscitation parameters normalize. • Septic patients that have received large volumes of fluids may achieve an adequate circulating volume without normalization of BP and other perfusion parameters. It is important to recognize that continued aggressive fluid therapy in these patients will result in volume overload and that vasopressors and or positive inotropes are indicated. Monitor closely since infusion of large volumes may precipitate pulmonary edema in patients with capillary leak or low COP.

ACTIVITY

Minimize patient exertion.

DIET

Withhold oral intake until shock is resolved.

CLIENT EDUCATION

Warn of the danger of imminent cardiac arrest and discuss a "code status" in advance whenever possible.

SURGICAL CONSIDERATIONS

Identify and remove the source of sepsis (e.g., septic peritonitis, abscess, pyothorax, pyometra, and soft tissue wounds).

MEDICATIONS

DRUG(S) OF CHOICE

- Once adequate circulating volume has been achieved, improvement in systemic BP and other clinical resuscitation parameters may

require the use of one or more vasopressors and or positive inotropic agents: • Dopamine (5–20 µg/kg/minute), norepinephrine (0.05–2 µg/kg/minute), and vasopressin (0.5–2 mU/kg/minute) can be used for vasopressor support (dogs and cats). Monitor for tachyarrhythmia and excessive peripheral vasoconstriction. • Dobutamine (2–20 µg/kg/minute) is primarily used as a positive inotrope in the subset of canine septic shock patients with decreased contractility or myocardial depression. Monitor for tachyarrhythmia. While dobutamine can be used safely in many feline patients, seizures have been observed in some cats at doses exceeding 5 µg/kg/minute. • It is essential that intravenous, empiric, broad-spectrum antibiotic therapy be instituted early in septic patients; the spectrum should be narrowed when culture results become available. Empiric selection is based on the patient's underlying immune status, the suspected source and organism(s) responsible, specific antibiotic properties (tissue penetration, cidal versus static activity), and considerations for resistance (previous antibiotic use, hospital- or community-acquired infection). • It is not unreasonable to empirically treat patients that are not responding adequately to standard therapy with 0.75–1.0 mg/kg q6h intravenous hydrocortisone after undergoing a standard ACTH stimulation test. Therapy should be continued in patients in whom relative adrenal insufficiency (hypoadrenocorticism) is documented.

FOLLOW-UP

PATIENT MONITORING

• Serial assessment of perfusion to optimize titration of fluids and vasoactive therapy: • Exam—mentation, mucous membrane color, CRT, pulse quality, muscle strength, temperature, and heart rate. • Hemodynamic monitoring—BP (frequently reveals a disproportionately low diastolic pressure), CVP (decreased due to hypovolemia and decreased preload; also allows for measurement of central venous oxygen saturation), and cardiac output. • Laboratory data—serum lactate and base deficit. • Serial assessment of respiratory rate and effort, and pulmonary auscultation. • Urine output as an indicator of glomerular filtration rate and renal blood flow. • Continuous ECG to

detect arrhythmia. • Blood gas analysis and pulse oximetry to follow tissue oxygenation, ventilation, and acid-base balance. • A minimum of daily packed cell volume, serum total protein, COP, blood glucose, serum electrolytes, hepatocellular enzymes, blood urea nitrogen, and serum creatinine to monitor effects of systemic tissue hypoxia.

PREVENTION/AVOIDANCE

- Timely and effective treatment of wounds.
- Appropriate use of antimicrobial therapy.

POSSIBLE COMPLICATIONS

- Volume overload • Pulmonary edema
- Vasculitis and peripheral edema
- Hypoglycemia • Anemia and thrombocytopenia • Coagulopathy
- Multiple organ dysfunction (cardiac, respiratory, renal, hepatic, gastrointestinal, pancreatic, adrenal, and brain) • Cardiac arrest

EXPECTED COURSE AND PROGNOSIS

Dependent on underlying etiology and ability to institute appropriate therapy.

SHOULDER JOINT, LIGAMENT, AND TENDON CONDITIONS

BASICS

DEFINITION

Make up the majority of causes for lameness in the canine shoulder joint, excluding osteochondritis dissecans lesions.

PATHOPHYSIOLOGY

Bicipital Tenosynovitis

- Strain injury to the tendon of the biceps brachii. • Mechanism of injury—direct trauma; indirect trauma (more common).
- Pathologic changes—from partial disruption of the tendon to chronic inflammatory changes, including dystrophic calcification. • Proliferation of the fibrous connective tissue and adhesions between the tendon and the sheath—limit motion; cause pain.

Fibrotic Contracture of the Infraspinatus Muscle

- Primary muscle-tendon disorder—not a neuropathy. • Fibrous tissue replaces normal muscle. • Loss of elasticity and function.
- Degeneration and atrophy of affected muscle. • Partial muscle disruption—likely caused by repetitive strain injuries.

Other

- Rupture of the biceps brachii tendon of origin—strain injury or disruption of the tendinous fibers at or near the junction with the supraglenoid tubercle of the scapula.
- Mineralization of the supraspinatus tendon; granular deposits between the fibers of the tendon; unknown cause; probably repetitive strain injury. • Avulsion or fracture of the insertion of the supraspinatus tendon—bone is avulsed from the greater tubercle of the proximal humerus. • Strain injury to other muscles/tendons in the region.

SYSTEMS AFFECTED

Musculoskeletal

INCIDENCE/PREVALENCE

Common cause of forelimb lameness

SIGNALMENT

Species

Dog

Breed Predilections

Medium- to large-breed dogs

Mean Age and Range

- Skeletally mature dogs ≥ 1 year of age
- Usually 3–7 years of age

SIGNS

Historical Findings

- Bicipital tenosynovitis—onset usually insidious; often of several months in duration; may be a traumatic incident as the inciting cause; subtle, intermittent lameness that worsens with exercise. • Rupture of the biceps brachii tendon of origin—similar to bicipital tenosynovitis; may have acute onset due to a

known traumatic event; usually subtle, chronic lameness that worsens with exercise.

- Mineralization of the supraspinatus tendon—onset usually insidious; chronic lameness that worsens with activity.
- Avulsion/fracture of the supraspinatus tendon—similar to mineralization of supraspinatus tendon. • Fibrotic contracture of the infraspinatus muscle—usually sudden onset of lameness during a period of outdoor exercise (e.g., hunting); shoulder lameness and tenderness gradually disappears within 2 weeks; condition results in chronic, persistent lameness 3–4 weeks later, which is not particularly painful but has characteristic gait and limb carriage.

Physical Examination Findings

- Bicipital tenosynovitis—short and limited swing phase of gait owing to pain on extension and flexion of the shoulder; pain inconsistently demonstrated on manipulation of shoulder; *pain most evident by applying deep digital pressure over the tendon in the intertubercular groove region while simultaneously flexing the shoulder and extending the elbow.* • Rupture of the biceps brachii tendon—similar. • Mineralization of the supraspinatus tendon—similar; manipulations often do not produce pain; may palpate firm swelling over the greater tubercle. • Avulsion or fracture of the supraspinatus tendon—similar to mineralization of the supraspinatus tendon.
- Fibrotic contracture of the infraspinatus muscle—usually not painful on manipulation; not possible to internally rotate (pronate) the shoulder joint; when forced, the caudal aspect of the scapula elevates off the trunk, when standing—elbow adducted; paw abducted and outwardly rotated; when patient is walking—lower limb swings in a lateral arc (circumduction) as the paw is advanced; marked atrophy of the infraspinatus muscle on palpation.

CAUSES

- Indirect or direct trauma—likely
- Repetitive strain injury (indirect trauma)—most common

RISK FACTORS

- Overexertion and/or fatigue • Poor conditioning before performing athletic activities • Obesity

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Luxation or subluxation of the shoulder joint—history of trauma with an acute onset of lameness; often severe lameness with marked pain on manipulation of the shoulder joint. • Osteosarcoma of the proximal humerus—progressive lameness with varying degrees of pain on manipulation of the

shoulder; may note swelling and tenderness of the proximal humerus. • Brachial plexus nerve sheath tumor—slow, insidious, progressive lameness over a period of months; marked atrophy of the muscles with chronic disease; may feel a firm mass deep in the axillary region that is painful to digital pressure.

IMAGING

Radiology

- Required for differentiation. • Craniocaudal and mediolateral views necessary for all patients.

Bicipital Tenosynovitis

- Radiographs generally normal in recent injuries. • Mediolateral view (chronic disease)—may see bony reaction on the supraglenoid tubercle, dystrophic calcification of the bicipital tendon, sclerosis of the floor of the intertubercular groove, and osteophytes in the intertubercular groove.

Ruptured Origin of the Biceps Brachii Tendon

Chronic disease—may see bony, irregular reaction on the supraglenoid tubercle.

Mineralization of the Supraspinatus Tendon

- Mediolateral view—calcified foci in tendon cranial and immediately medial to the greater tubercle of the proximal humerus.

- Tangential or skyline view of the intertubercular region of the proximal humerus—eliminates superimposition; allows distinction from calcification of the biceps brachii tendon. • Often bilateral radiographically but rarely produces bilateral lameness.

Avulsion/Fracture of the Supraspinatus Tendon

- Similar to mineralization of the supraspinatus tendon. • Avulsion fragment—may be seen as a defect in the greater tubercle of the humerus; generally not as radiographically dense as that identified with mineralization of the supraspinatus tendon.

Fibrotic Contracture of the Infraspinatus Muscle

Radiographically normal.

Ultrasonography and MRI

- May help identify muscle injuries, bicipital tenosynovitis, and rupture of the biceps brachii tendon of origin. • Useful for determining the location of calcific densities near the intertubercular groove.

DIAGNOSTIC PROCEDURES

- Joint tap and analysis of synovial fluid—identify intra-articular disease; fluid should be straw-colored with normal to decreased viscosity; cytologic evaluation: < 10,000 nucleated cells/ μL (> 90% are mononuclear cells). • Arthroscopic exploration of the shoulder joint—diagnose bicipital tenosynovitis and rupture of the biceps brachii tendon of origin; confirm lack of intra-articular disease.

SHOULDER JOINT, LIGAMENT, AND TENDON CONDITIONS (CONTINUED)

PATHOLOGIC FINDINGS

- Bicipital tenosynovitis—mineralization of the biceps tendon; osteophytosis of the intertubercular groove; proliferative synovitis; and fibrous adhesions between the biceps tendon and its synovial sheath; histologically, synovial proliferation, edema, fibrosis, dystrophic mineralization, and lymphocytic-plasmacytic infiltration of the tendon and synovium.
- Ruptured origin of the biceps brachii tendon—partial to complete rupture of the biceps tendon at its insertion on the supraglenoid tubercle, proliferative synovitis, and fibrous adhesions between the biceps tendon and its synovial sheath; histologically, synovial proliferation, edema, fibrosis, and occasional dystrophic mineralization.
- Mineralization of the supraspinatus tendon—tendon often looks normal, but longitudinal incision reveals numerous pockets of mineralized debris within the fibers; histologically, chondromucinous stromal degeneration of the tendon with multiple foci of dystrophic mineralization.
- Avulsion of the supraspinatus tendon insertion—often looks normal, but longitudinal incision reveals bone fragment(s) surrounded by a fibrous tissue capsule; usually see a corresponding bony defect in the greater tubercle.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—early diagnosis.
- Inpatient—chronic, severe disease requires surgical intervention.
- Bicipital tenosynovitis—50–75% success with medical treatment; requires surgery with evidence of chronic changes and failure of medical management.
- Ruptured origin of the biceps brachii tendon generally requires surgery.
- Mineralization of the supraspinatus tendon—may be an incidental finding; requires surgery after excluding other causes of lameness and medical treatment.
- Avulsion or fracture of the supraspinatus tendon—often requires surgery because of persistent bone fragment irritation of the tendon.
- Fibrotic contracture of the infraspinatus muscle—requires surgery.

S

NURSING CARE

- Cryotherapy (ice packing)—immediately post-surgery; helps reduce inflammation and swelling at the surgery site; performed 5–10 minutes every 8 hours for 3–5 days.
- Regional massage and range-of-motion exercises—improve flexibility; decrease muscle atrophy.

ACTIVITY

- Medical treatment—requires strict confinement for 4–6 weeks; activity; premature return to normal likely exacerbates signs and induces a chronic state.

- Post-surgery—depends on procedure performed.

DIET

Weight control—decrease the load applied to the painful joint.

SURGICAL CONSIDERATIONS

- Bicipital tenosynovitis—recommended with poor response to medical treatment and chronic disease; goal: eliminate movement of the biceps tendon within the inflamed synovial sheath by performing a tenodesis or, more commonly, release of the bicipital tendon; either arthroscopic, or open, or percutaneous (\pm ultrasound guidance) tendon release.
- Rupture of the biceps brachii tendon of origin—reattach tendon to the proximal lateral aspect of the humerus with a screw and spiked washer or pass the tendon through a bone tunnel and suture it to the supraspinatus tendon.
- Mineralization of the supraspinatus tendon—longitudinally incise the tendon; remove the calcium deposits.
- Avulsion or fracture of the supraspinatus tendon—remove the bone fragment(s).
- Fibrotic contracture of the infraspinatus muscle—tenotomy and excision of part of the tendon of insertion; often feel a distinct pop after excision of the last adhesion, which allows complete range of motion of the shoulder joint.

MEDICATIONS

DRUG(S) OF CHOICE

Bicipital Tenosynovitis

- Intra-articular injection of a corticosteroid—initial treatment of choice.
- Systemic treatment (NSAIDs or steroids)—not as effective.
- Do not inject into a septic joint; perform complete synovial fluid analysis if any doubt.
- Prednisolone acetate 20–40 mg, depending on size.
- Lameness markedly improved but not eliminated—give a second injection in 3–6 weeks.
- Incomplete resolution—recommend surgery.

NSAIDs and Analgesics

- May be used for symptomatic treatment; minimize pain, decrease inflammation.
- Deracoxib (3–4 mg/kg PO q24h, chewable).
- Carprofen (2.2 mg/kg PO q12h or q24h).
- Etodolac (10–15 mg/kg PO q24h).
- Meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h—liquid).
- Tepoxalin (load 20 mg/kg, then 10 mg/kg PO q24h).

CONTRAINDICATIONS

- Avoid prolonged use of corticosteroids because of the potential side effects and articular cartilage damage associated with long-term use.
- Direct injection of a corticosteroid into the biceps tendon—may promote further tendon disruption and eventual rupture.

PRECAUTIONS

NSAIDs—gastrointestinal irritation may preclude use.

ALTERNATIVE DRUG(S)

Chondroprotective drugs (e.g., polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate)—may help limit associated cartilage damage and degeneration.

FOLLOW-UP

PATIENT MONITORING

Most patients require a minimum of 1–2 months of rehabilitation after treatment.

EXPECTED COURSE AND PROGNOSIS

- Medically managed bicipital tenosynovitis—often successful after one or two treatments (50–75% of cases) with no chronic changes.
- Surgically treated bicipital tenosynovitis—good to excellent results (90% of cases); recovery to full function may take 2–8 months.
- Surgically treated release or tenodesis of the bicipital brachii tendon—good to excellent prognosis; > 85% of patients show improved return to function.
- Surgically treated mineralization of the supraspinatus tendon—good to excellent prognosis; recurrence possible but uncommon.
- Surgically treated avulsion or fracture of the supraspinatus tendon—good to excellent prognosis; recurrence possible but uncommon.
- Surgically treated fibrotic contracture of the infraspinatus muscle—good to excellent prognosis; patients uniformly return to normal limb function.

MISCELLANEOUS

ABBREVIATIONS

- MRI = magnetic resonance imaging
- NSAID = nonsteroidal anti-inflammatory drug

SICK SINUS SYNDROME

BASICS

DEFINITION

A disorder of impulse formation within, and conduction out of, the sinus node; dysfunction of subsidiary pacemakers and other segments of the cardiac conduction system frequently coexist with the sinus node dysfunction.

ECG Features

- Arrhythmias noted with SSS include any or all of the following: inappropriate sinus bradycardia, sinus pauses (representing sinus arrest or sinoatrial exit block), slow ectopic atrial rhythm, or alternating periods of sinus bradyarrhythmias and SVT (Figure 1).
- Paroxysms of SVT may alternate with prolonged periods of sinus node inertia and often AV nodal inertia as well, producing tachycardia-bradycardia syndrome, a variant of SSS.
- P waves and QRS complexes are usually normal.

- P waves may be abnormal or absent with slow atrial ectopic rhythm or junctional escape rhythm.

PATHOPHYSIOLOGY

- ECG manifestations may precede development of clinical signs.
- Clinical signs usually result from the failure of subsidiary pacemakers to generate escape rhythms when sinus node dysfunction occurs.
- The common clinical manifestations reflect transient decreases in organ perfusion, particularly reduced cerebral and skeletal muscle perfusion.
- Rarely, congestive heart failure develops.

SYSTEMS AFFECTED

- Cardiovascular.
- Nervous, musculoskeletal, and renal systems may be secondarily affected because of hypoperfusion.

GENETICS

- May be heritable in miniature schnauzers and West Highland white terriers.
- Doberman pinschers and boxers can have syncope associated with long sinus pauses, suggestive of sick sinus syndrome.

SIGNALMENT**Species**

Dog

Breed Predilections

- Miniature schnauzer (may be heritable).
- Noted commonly in cocker spaniel, dachshund, and West Highland white terrier.

Mean Age and Range

Most dogs > 6 years old

Predominant Sex

Female

SIGNS**Historical Findings**

- Clinical signs vary from asymptomatic to weakness, syncope, collapse, and/or seizures.
- Sudden death is infrequent.

Physical Examination Findings

- Heart rate may be abnormally rapid or abnormally slow.
- Pauses may be noted.
- Some patients appear normal.

CAUSES

- Idiopathic
- Familial in miniature schnauzers

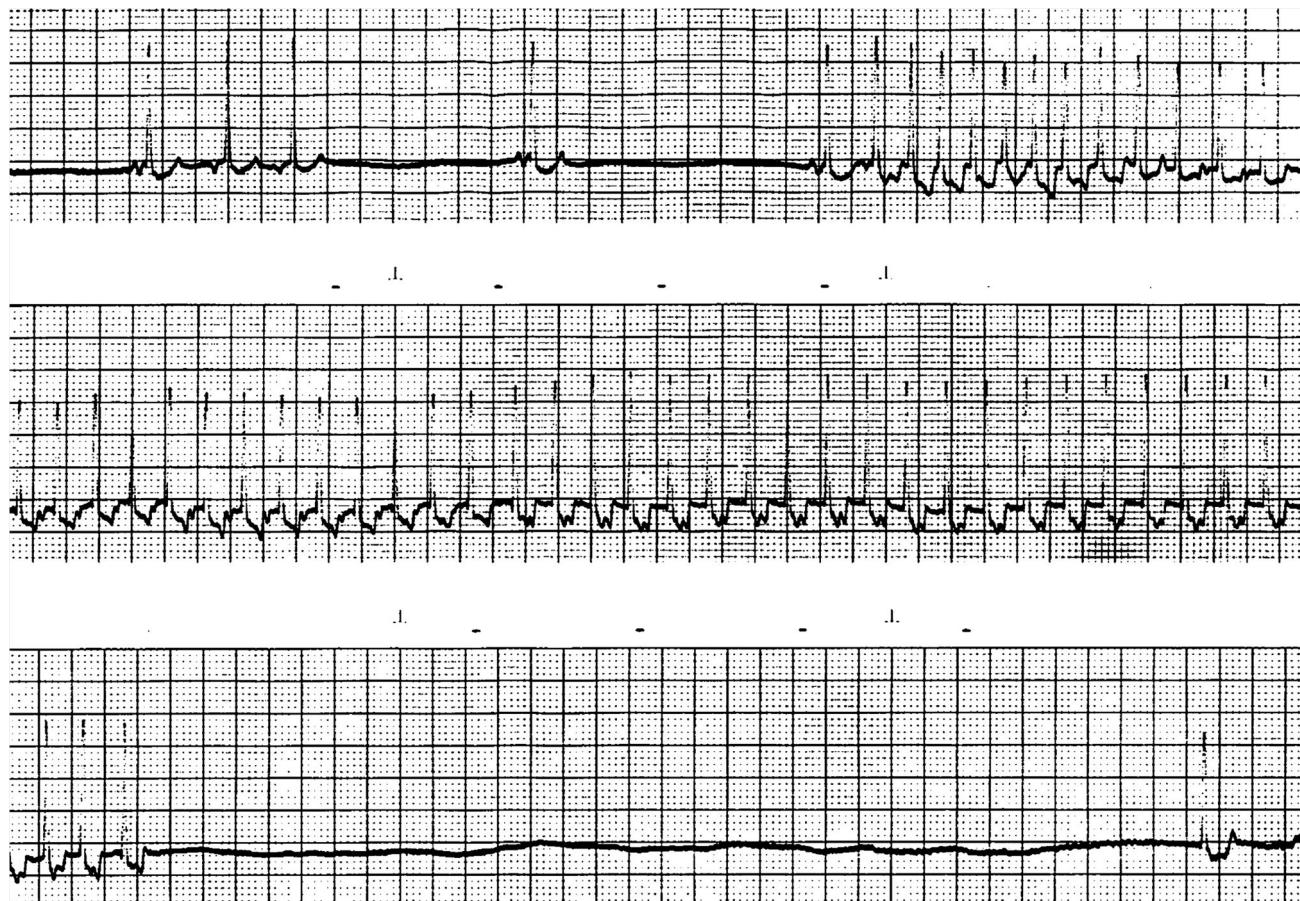

Figure 1.

A continuous lead II rhythm strip (25 mm/s) recorded from a dog with sick sinus syndrome showing an ectopic atrial rhythm interrupted by several short pauses. The third pause initiates a paroxysm of supraventricular tachycardia (250 beats/min) followed by asystole (6.6 s) terminated by a junctional escape complex.

SICK SINUS SYNDROME

(CONTINUED)

- Metastatic disease
- Ischemic disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Healthy dogs may exhibit sinus bradycardia (rate as low as 30 beats/minute) and sinus pauses (as long as 3.5 seconds) normally during sleep.
- Bradycardia and sinus arrest due to normal or enhanced vagal tone.
- Drug-induced (digitalis, α -adrenergic antagonists, α_2 -adrenergic agonists, calcium channel antagonists, cimetidine, opioids).
- Seizures or syncope due to non-cardiac disease.
- Atrial standstill secondary to hyperkalemia or atrial disease.
- Weakness due to neurologic, musculoskeletal, or metabolic diseases.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

IMAGING

Breeds predisposed to SSS are also predisposed to degenerative valvular disease; echocardiography is used to confirm presence of significant valvular disease when heart murmur is present.

DIAGNOSTIC PROCEDURES

- Atropine response testing—indicated in dogs with sinus bradycardia, sinus arrest, and sinoatrial exit block. Administer atropine (0.04 mg/kg IM), and evaluate the ECG 20–30 minutes later. A normal (positive) response is > 50% increase in heart rate with abolishment of pauses; dogs with SSS generally have no response or an incomplete response to atropine.
- Electrophysiologic testing of sinus node recovery time and sinoatrial conduction time.
- 24-hour ambulatory ECG (Holter) or event recording to correlate clinical signs with arrhythmia.

PATHOLOGIC FINDINGS

Vary with cause

TREATMENT

APPROPRIATE HEALTH CARE

- Hospitalization rarely necessary except for electrophysiologic testing or pacemaker implantation.
- Do not treat asymptomatic animals.

ACTIVITY

Avoid vigorous exercise and stressful situations

DIET

Modifications unnecessary

CLIENT EDUCATION

Owner should be aware that medical management is often ineffective.

SURGICAL CONSIDERATIONS

- Permanent artificial pacemaker necessary for dogs failing to respond to medical treatment and those exhibiting unacceptable medication side effects.
- Permanent artificial pacemaker usually required for dogs with bradycardia-tachycardia syndrome.
- Transvenous placement of a pacing lead in the right atrium or auricle may successfully abolish the sinus pauses.

MEDICATIONS DRUG(S)

- Do not treat asymptomatic animals.
- Symptomatic dogs are grouped into those showing primarily bradycardia, sinus arrest, and/or sinoatrial exit block and those with supraventricular tachycardia followed by sinus arrest.
- Atropine-responsive symptomatic dogs with bradycardia or sinus arrest—anticholinergic agents (propantheline: small dogs, 3.75–7.5 mg PO q8–12h; medium dogs, 15 mg PO q8h; large dogs, 30 mg PO q8h; hyoscyamine: 3–6 µg/kg q8h).
- Dogs with bradycardia and sinus arrest—may try theophylline (Theo-Dur, 20 mg/kg PO q12h), terbutaline (0.2 mg/kg PO q8–12h), or hydralazine (1–2 mg/kg PO q8–12h) if anticholinergic drugs are ineffective (avoid hydralazine if patient is hypotensive).
- Dogs with bradycardia-tachycardia whose clinical signs are due to tachycardia or tachycardia-induced sinus arrest—can give digoxin (5 µg/kg PO q12h) or atenolol (0.5–1 mg/kg PO q12–24h) in attempt to suppress the SVT (monitor closely for exacerbation of bradycardia).
- Therapy for tachycardias can only be considered, once pacing is established to avoid worsening of bradyarrhythmias.

CONTRAINDICATIONS

Avoid drugs that may worsen sinus node dysfunction (e.g., β -adrenergic antagonists, calcium channel blocking agents, phenothiazines, class I and III antiarrhythmic agents, opioids, cimetidine, α_2 -adrenergic agonists).

PRECAUTIONS

- Attempts to manage bradycardia-tachycardia syndrome medically without prior pacemaker implantation carry significant risk because drugs used to control SVT may worsen the bradyarrhythmias, and vice versa.
- Adverse effects of anticholinergic medication (constipation, difficulty voiding,

keratoconjunctivitis sicca, emesis, anxiety) occur commonly.

FOLLOW-UP

PATIENT MONITORING

- ECG in asymptomatic patients—to detect progression of disease.
- ECG in patients treated medically or with pacemaker implantation.

POSSIBLE COMPLICATIONS

- Rarely, reduced cerebral or renal perfusion results in chronic renal dysfunction or CNS damage.
- Presence of significant valvular disease has implications for type of permanent pacing mode selected.

EXPECTED COURSE AND PROGNOSIS

- Good, following pacemaker implantation in animals without congestive heart failure.
- Medical management—often ineffective; initial beneficial effects often not sustained.

MISCELLANEOUS

SYNONYMS

- Bradycardia-tachycardia syndrome
- Sinus node dysfunction
- Tachycardia-bradycardia syndrome

SINUS ARREST AND SINOATRIAL BLOCK

BASICS

DEFINITION

- Sinus arrest—a disorder of impulse formation caused by slowing or cessation of spontaneous sinus nodal automaticity; failure of the SA node to initiate an impulse at the expected time. P-P interval does not equal a multiple of basic P-P interval.
- Sinoatrial block—a disorder of impulse conduction; an impulse formed within the sinus node fails to depolarize the atria or does so with delay; most commonly the basic rhythmicity of the sinus node is not disturbed and the duration of the pause is a multiple of the basic P-P interval. Classified into first-, second-, and third-degree SA block (similar to degrees of AV block). Difficult to diagnose first- and third-degree SA block from ECG. Second-degree SA block most common: Mobitz type I (Wenckebach) SA block—P-P interval progressively shortens prior to a pause; duration of pause is less than two P-P cycles; Mobitz type II SA block—duration of pause occurring after a sinus beat is exact multiple (two, three, or four times normal) of basic P-P interval.

ECG Features

- A normal P wave exists for each QRS complex with a pause equal to or greater than twice the normal P-P interval; rhythm is regularly irregular or irregular with pauses (Figure 1).
- Junctional or ventricular escape beats—occurs if pauses significantly prolonged. Subsidiary pacemaker takes over rhythm with escape beats normally from AV junctional tissue or Purkinje fibers; intermittent absence of P waves noted or P waves may be negative and precede, be superimposed on or follow the QRS complexes.
- Surface ECG cannot differentiate sinus arrest from block in the dog because of normal R-R interval variation (sinus arrhythmia).

PATHOPHYSIOLOGY

- Sympathetic and parasympathetic influences can alter spontaneous sinus node depolarization; vagal stimulation of acetylcholine, which binds to SA nodal receptor sites, can slow automaticity of the sinus node by reducing the slope of phase 4 depolarization; sympathetic stimulation releases norepinephrine that binds to β_1 receptors on the SA node, enhancing spontaneous SA nodal discharge rate.
- Post-drive inhibition phenomenon occurs when sinus arrest follows a run of ectopic beats. The sinus node requires a warming-up period until the usual rate of automaticity is reestablished.
- Intrinsic disease of the sinus node may affect the balance between the parasympathetic and sympathetic efferent traffic to the SA node and its spontaneous discharge rate.
- Duration of sinus arrest may be long and possibly irreversible when the sinus node is suppressed by an ectopic tachycardia, particularly with severe underlying heart disease. Persistent sinus arrest not due to any drug often indicates SSS.

SYSTEMS AFFECTED

Cardiovascular—clinical signs of weakness or syncope may appear if sinus arrest or block causes sufficiently long periods (generally 5 seconds or longer) of ventricular asystole with no escape beats initiated by latent pacemakers.

GENETICS

- Seen in purebred pugs with hereditary stenosis of the bundle of His.
- Seen in female miniature schnauzers predisposed to SSS. Is the most common arrhythmia in miniature schnauzers with SSS.
- Congenitally deaf Dalmatian coach hounds often have abnormal SA node and multiple atrial arteries. May be a genetic component to the cause of SSS in those breeds predisposed (see below).

INCIDENCE/PREVALENCE

- Normal incidental finding in brachycephalic breeds of dogs in which inspiration causes a reflex increase in vagal tone.

- Common in dog breeds predisposed to SSS.
- Uncommon in cats.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dogs and cats

Breed Predilections

- Brachycephalic breeds.
- Breeds predisposed to SSS (e.g., miniature schnauzers, dachshunds, cocker spaniels, pugs, boxers and West Highland white terriers).

Mean Age and Range

If associated with SSS, generally middle-aged to older animal

Predominant Sex

If associated with SSS, older females

SIGNS

General Comments

Generally no clinical significance by itself if terminated by sinus node depolarization, or latent pacemakers promptly escape to prevent ventricular asystole.

Historical Findings

- Usually none.
- Signs of low cardiac output (e.g., weakness and syncope) may occur with failure of the SA node to fire on time if no lower pacemaker focus takes over the rhythm.
- Sudden death is possible should prolonged periods of ventricular asystole occur.

Physical Examination Findings

- May be normal.
- Heart sounds following a pause may be louder because the ventricles had longer to fill and eject a larger amount of blood.
- Extremely slow heart rate if arrest or block is prolonged or frequent.
- With significant pathologic cardiac disease—may be findings consistent with poor cardiac output (e.g., prolonged perfusion time, pale mucous membranes, weak femoral pulses).

S

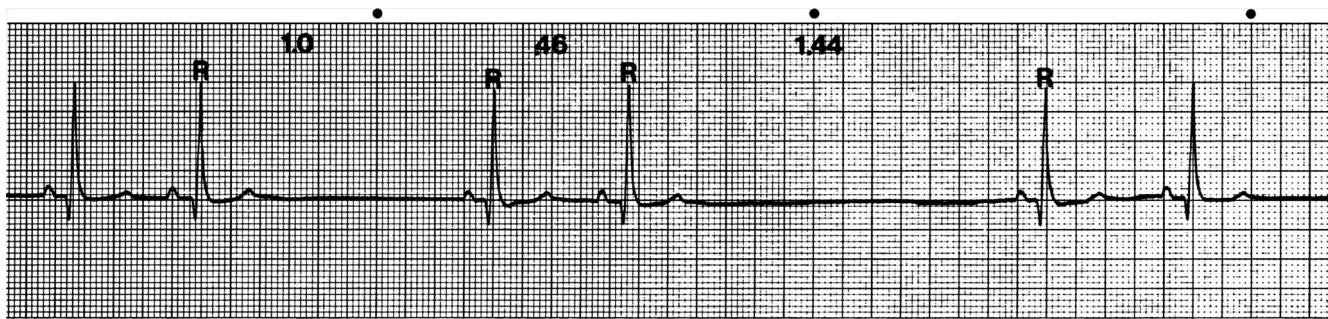

Figure 1.

Intermittent sinus arrest in a brachycephalic breed with an upper respiratory disorder. The pauses (1 and 1.44 seconds) are greater than twice the normal P-P interval (0.46). (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

SINUS ARREST AND SINOATRIAL BLOCK

(CONTINUED)

CAUSES

Physiologic

- Vagal stimulation secondary to coughing, pharyngeal irritation
- Ocular or carotid sinus pressure
- Surgical manipulation

Pathologic

- Degenerative heart disease (fibrosis)
- Dilatory heart disease
- Acute myocarditis
- Neoplastic heart disease
- SSS
- Irritation of vagus nerve secondary to thoracic or cervical neoplasia
- Electrolyte imbalance
- Drug toxicity (e.g., digoxin)

RISK FACTORS

- Certain drugs, including digitalis, quinidine, propranolol, xylazine, acepromazine, hydromorphone
- Respiratory tract disease
- Vagal maneuvers

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Marked sinus arrhythmia and sinus bradycardia.
- Not always possible to differentiate sinus arrest from SA block without direct recordings of sinus node discharge; pauses that are precise multiples of the dominant beat interval suggest sinus block.

CBC/BIOCHEMISTRY/URINALYSIS

Serum electrolyte abnormalities, especially hyperkalemia (serum K⁺ > 5.7 mEq/L).

OTHER LABORATORY TESTS

N/A

IMAGING

- Thoracic radiographs if neoplastic or cardiac disease suspected.
- Cardiac ultrasound if structural or neoplastic heart disease suspected.

DIAGNOSTIC PROCEDURES

- Provocative atropine response test to assess sinus node function. Administer 0.04 mg/kg IV atropine IM; evaluate ECG lead II rhythm strip 30 minutes later for response or administer 0.04 mg/kg atropine IV followed by ECG in 10 minutes. Resolution of the arrhythmia suggests high vagal tone as the underlying cause.
- Ambulatory monitoring may reveal prolonged periods of failure of impulses from the SA node if signs of weakness or syncope.
- In humans, a period of sinus arrest following right carotid massage that lasts longer than 3 seconds suggests inappropriate sinus responsiveness.
- Electrophysiologic studies of sinus node.
- Serum digoxin concentration, if applicable; trough level recommended (just before next

dose or at least 8 hours post pill); therapeutic serum concentrations are typically 0.5–1.5 ng/mL.

PATHOLOGIC FINDINGS

Histologic study of the SA node may reveal necrosis, fibrosis, and/or degenerative changes.

TREATMENT

APPROPRIATE HEALTH CARE

Asymptomatic sinus arrest or block does not require therapy. If clinical signs, therapeutic approach depends on cause, underlying cardiac status, and severity of symptoms. Any indicated treatment may be outpatient unless pacemaker implantation is necessary, which necessitates hospital management.

NURSING CARE

Correct any electrolyte abnormalities.

ACTIVITY

Unrestricted unless signs of weakness, syncope, or CHF develop.

CLIENT EDUCATION

An artificial pacemaker may be necessary when patient is symptomatic and non-responsive to medical management.

SURGICAL CONSIDERATIONS

Implantation of an artificial demand pacemaker in animals with clinical signs non-responsive to therapy.

MEDICATIONS

DRUG(S) OF CHOICE

- Only if patient is symptomatic, consider atropine (0.04 mg/kg IV, IM), glycopyrrolate (5–10 µg/kg IV, IM), or isoproterenol (10 µg/kg IM, SC q6h or dilute 1 mg in 500 mL of 5% dextrose or Ringer's solution, and infuse IV at 0.04–0.08 µg/kg/minute).
- If responsive to injectable anticholinergic drugs (e.g., atropine)—can prescribe parasympatholytic drug such as oral propantheline bromide (0.25–0.5 mg/kg q8–12h) or hyoscyamine (3–6 µg/kg q8h) for at-home management. Sympathomimetic agents including methylxanthine theophylline (10 mg/kg extended release formulation q12h) or terbutaline (0.14 mg/kg q8–12h PO in dogs and 0.1–0.2 mg/kg q12h in cats) could be considered for oral therapy.

CONTRAINDICATIONS

If patient is symptomatic secondary to prolonged pauses, discontinue any drugs that may be causative (e.g., digitalis, beta-blockers, calcium channel blockers).

PRECAUTIONS

Avoid drugs that depress SA node function.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

If medical therapy does not resolve signs, consider pacemaker implantation.

FOLLOW-UP

PATIENT MONITORING

When indicated, periodic serial ECG evaluation to assess therapeutic efficacy and possible progression to a more serious dysrhythmia.

POSSIBLE COMPLICATIONS

If associated with primary cardiac disease, CHF may develop and necessitate appropriate therapies.

EXPECTED COURSE AND PROGNOSIS

If cause is SSS, symptomatic patient may respond well to medical intervention; if poorly responsive, permanent pacemaker implantation would improve prognosis.

Author Deborah J. Hadlock

Consulting Editors Larry P. Tilley and Francis W.K. Smith, Jr.

SINUS ARRHYTHMIA

BASICS

DEFINITION

- Normal sinus impulse formation characterized by a phasic variation in sinus cycle length. An irregular R-R interval is present that has more than 10% variation in sinus cycle length (or variability of 0.12 seconds [dog], 0.10 seconds [cat], or more exists between successive P waves).
- Two basic forms exist—respiratory sinus arrhythmia (RSA): P-P interval cyclically shortens during inspiration due primarily to reflex inhibition of vagal tone and lengthens during expiration; non-respiratory sinus arrhythmia: phasic variation in P-P interval unrelated to the respiratory cycle.

ECG Features

- Other than the irregular rhythm, all other criteria for sinus rhythm are present.
- Normal heart rate.
- Positive P wave in leads, I, II, III, and aVF, unless a wandering pacemaker is present, where the P waves may be positive, diphasic, or negative temporarily.
- A P wave is present for every QRS complex.
- A QRS complex is present for every P wave.
- PR interval is relatively constant.

PATHOPHYSIOLOGY

Sinus node discharge rate depends on the two opposing influences of the autonomic nervous system. Vagal stimulation decreases spontaneous sinus nodal discharge rate and predominates over sympathetic stimulation. Negative intrathoracic pressure occurring with inspiration causes decreased pressure on the vagus nerves. Feedback from the cardioregulatory and vasomotor centers in the medulla produces cardiac acceleration by decreasing vagal restraint on the sinus node; the opposite occurs during exhalation. The genesis of sinus arrhythmia also depends on reflexes involving pulmonary stretch receptors (Hering-Breuer reflex), pressure-volume sensory receptors in the heart (Bainbridge—atrial stretch stimulates receptors in the atrial wall causing vagal inhibition and increase in heart rate, baroreceptor—receptors in the carotid sinus and aortic arch elicit inverse changes in heart rate with acute changes in arterial blood pressure), blood vessels, and chemical factors of the blood.

SYSTEMS AFFECTED

Cardiovascular—generally no hemodynamic consequence, but marked SA may produce a long enough sinus pause to produce syncope if not accompanied by an escape rhythm.

GENETICS

N/A

INCIDENCE/PREVALENCE

Most frequent form of arrhythmia in the dog

SIGNALMENT

Species

- Respiratory SA frequent normal finding in dogs.
- While common in cats asleep and in home environment, in a clinical setting sympathetic dominance occurs and RSA is rare without underlying pathology.

Breed Predilections

- Brachycephalic breeds predisposed.
- Dogs—bulldogs, Lhasa Apsos, Pekingese, pugs, Shar-Peis, Shih Tzus, boxers.
- Cats—Persians, Himalayans.

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

General Comments

- Uncommon, but weakness may develop if pauses between beats are excessively long; syncope can occur when a marked sinus arrhythmia and sinus bradycardia develop.
- In general, symptoms more common in non-respiratory than in respiratory form.

Historical Findings

- Respiratory SA—none.
- Non-respiratory SA—may be findings related to underlying disease.

Physical Examination Findings

- May be normal.
- Irregular rhythm on auscultation.
- May be findings related to specific disease accentuating vagal tone (e.g., stertor and stridor in a patient with brachycephalic airway syndrome).

CAUSES

- Normal cyclic change in vagal tone associated with respiration in the dog; heart rate increases with inspiration and decreases with expiration.
- Underlying conditions that increase vagal tone—high intracranial pressure, gastrointestinal disease, respiratory disease, cerebral disorders, digitalis toxicity, organophosphates.
- Carotid sinus massage or ocular pressure (vagal maneuver) may accentuate.

RISK FACTORS

- Brachycephalic conformation
- Digoxin therapy
- Any disease that increases vagal tone

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Auscultation of SA is often confusing; ECG helps differentiate normal SA from true pathologic arrhythmia.

- Wandering sinus pacemaker frequently associated and a variant of sinus arrhythmia. Site of impulse formation shifts within the sinoatrial node or to an atrial focus or AV node, changing the configuration of the P wave.

- Important to differentiate normal SA from pathologic arrhythmias including atrial premature complexes, SSS, slow atrial fibrillation, and AV dissociation.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Cats with chronic respiratory disease may be positive for feline leukemia or feline immunodeficiency virus.

IMAGING

Radiographs, CT, MRI of head and neck to assess for abnormal anatomic conformation that might predispose to airway problems.

DIAGNOSTIC PROCEDURES

- Pharyngoscopy/laryngoscopy if upper airway disease suspected.
- Atropine challenge test (administer atropine 0.04 mg/kg IM followed by ECG in 30 minutes or 0.04 mg/kg atropine IV followed by ECG in 10 minutes) if associated with sinus bradycardia and primary dysfunction of sinus node is suspected.

PATHOLOGIC FINDINGS

See specific disease

TREATMENT

APPROPRIATE HEALTH CARE

Generally, specific treatment required only when associated with symptomatic sinus bradycardia; if not related to respiration, underlying cause is treated. If patient is suffering respiratory distress, appropriate inpatient management indicated until patient is stable.

NURSING CARE

None unless associated with underlying disease (see also below).

ACTIVITY

Not restricted unless associated with specific disease (e.g., brachycephalic animals may need to limit exercise, especially in high ambient temperatures).

DIET

Caloric restriction for obese animals with airway compromise.

CLIENT EDUCATION

None unless associated with specific disease.

SURGICAL CONSIDERATIONS

None unless associated with specific disease.

SINUS ARRHYTHMIA

(CONTINUED)

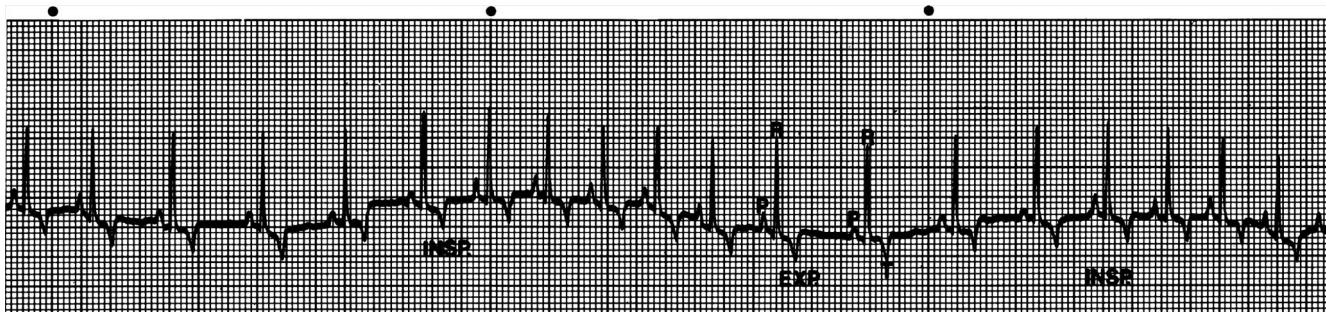

Figure 1.

Respiratory sinus arrhythmia with an average rate of 120/minute (paper speed, 25 mm/second; 6 complexes between 1 set of time lines \times 20). The rate increases during inspiration (INSP) and decreases during expiration (EXP). The fluctuation of the baseline correlates with the movement of the electrodes by the thoracic cavity. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

**MEDICATIONS****DRUG(S) OF CHOICE**

- Generally no therapy indicated; this is a normal rhythm.
- Infectious respiratory diseases require appropriate antibiotic therapy.
- If associated with symptomatic sinus bradycardia or sinus arrest or block, anticholinergics may be indicated—atropine (0.02–0.04 mg/kg IV, IM, SC) or glycopyrrolate 5–10 µg/kg IV, IM, SC).

CONTRAINdications

Discontinue digoxin if toxicity is a problem.

PRECAUTIONS

Avoid atropine in patients with respiratory disease; an adverse effect is drying of secretions.

POSSIBLE INTERACTIONS

**FOLLOW-UP****PATIENT MONITORING**

Only if associated with specific disease.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

N/A

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- SSS
- Brachycephalic airway syndrome
- Asthma
- Chronic obstructive pulmonary disease

AGE-RELATED FACTORS

Generally more pronounced in young adult

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Increased incidence of arrhythmias

SYNOMYS

- Non-respiratory SA = non-phasic SA; sinus irregularity.
- Respiratory SA = phasic SA.
- Ventriculophasic SA—form of non-phasic SA in which atrial cycles containing ventricular complexes are shorter than those in which they are absent. That is, the P-P interval that includes the QRS complex is shorter than the P-P interval without a QRS complex. This can be seen with second-degree AV block, complete AV block or in the

presence of ventricular premature complexes with a full compensatory pause.

SINUS BRADYCARDIA

BASICS

DEFINITION

Sinus rhythm in which impulses arise from the sinoatrial node at slower-than-normal rate for an animal's signalment and activity.

ECG Features

- Dogs—sinus rate < 60 bpm).
- Cats—sinus rate < 110 bpm at home or < 130 bpm at the clinic.
- Rhythm regular, often with a slight variation in R-R interval; may be irregular if bradycardia due to high vagal tone; often coexists with sinus arrhythmia.
- Normal P wave for each QRS complex.
- P-R interval constant.

PATHOPHYSIOLOGY

• Can be an incidental finding in healthy animals or during sleep.

- May represent normal physiologic response to athletic training; may result from enhanced cardiac parasympathetic tone or decreased sympathetic tone as well as from intrinsic changes in the sinus node.
- Automaticity of the heterogeneous sinus node is a very complex phenomenon invoking the calcium and voltage clock mechanisms. More than 16 autonomically influenced currents with the I_f (funny) channel predominating and Ca^{++} release from the sarcoplasmic reticulum are critical in maintaining autonomic balance and changes in heart rate.
- May represent pathophysiologic response due to high vagal tone, change in blood pH, PCO_2 , PO_2 , or serum electrolyte disorders, hypothyroidism, increased intracranial pressure, toxins and certain drugs.
- May be a result of SSS.

SYSTEMS AFFECTED

Cardiovascular—most instances benign arrhythmia and may be beneficial by producing a longer period of diastole and increased ventricular filling time; can be associated with syncope if due to abnormal reflex (neurocardiogenic) or intrinsic disease of sinus node.

GENETICS

Female miniature schnauzer, West Highland white terrier, boxer, cocker spaniel, dachshund, and pug predisposed to SSS with possible underlying heritable component—may cause bradycardia.

INCIDENCE/PREVALENCE

- Common in the dog, less common in cat.
- Interpretation of sinus node rate also depends on environment and type of patient. For example, a sinus rate can be as low as 20 beats/minute in a normal dog that is sleeping.

SIGNALMENT

Species

Dog and cat

Breed Predilections

Bradycardia associated with SSS—miniature schnauzer, cocker spaniel, dachshund, pug, and West Highland white terrier.

Mean Age and Range

- Decreased prevalence with advancing age unless associated with intrinsic disease of SA node.
- SSS typically seen in middle-aged to geriatric patients.

Predominant Sex

With SSS, older female miniature schnauzers

SIGNS

Historical Findings

- Often asymptomatic
- Lethargy
- Weakness
- Exercise intolerance
- Syncope
- Episodic ataxia

Physical Examination Findings

- Pulse rate slow
- Hypothermia may be present
- Poor perfusion
- Syncope
- Decrease level of consciousness

CAUSES

Physiologic

- Athletic conditioning
- Hypothermia
- Intubation with pharyngeal or soft palate tension
- Sleep
- Cushing's response with increased intracranial pressure
- Gastrointestinal distension
- Activation of baroreceptor reflex with increase in systemic BP

Pathophysiologic

- High vagal tone associated with gastrointestinal, respiratory, neurologic, and pharyngeal diseases.
- Reflex-mediated neurocardiogenic (vasovagal)—carotid sinus hyperactivity-situational (micturition, defecation, cough, swallowing).

Pathologic

- High intracranial pressure
- Hyperkalemia
- Hypercalcemia
- Hypocalcemia
- Hypermagnesemia
- Hypoxemia
- Hypothyroidism
- Hypoglycemia
- May precede cardiac arrest
- SSS (rare in the cat)
- Feline dilated cardiomyopathy
- Viral myocarditis
- Sinoatrial block
- In humans, mutations in the I_f channel and drugs which block I_f (such as ivabradine) have been associated with bradycardia.

Pharmacologic

- General anesthesia
- Any negative chronotrope including:
 - Phenothiazines
 - Beta-adrenergic blockers
 - Digitalis glycosides
 - Calcium channel blockers
 - α_2 -adrenergic agonists
 - Sotolol
 - Amiodarone
 - Centrally acting opioids: morphine, hydromorphone, butorphanol, fentanyl

RISK FACTORS

- Any situation or disease that may increase parasympathetic tone
- Oversedation
- Hypoventilation under anesthesia
- Breeds predisposed to SSS

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Persistent and marked SB should raise possibility of SSS.
- Clinical signs may mimic cerebral dysfunction.

CBC/BIOCHEMISTRY/URINALYSIS

- Hyperkalemia, hypercalcemia, hypocalcemia, or hypermagnesemia possible.
- CBC and serum chemistry profile may reveal changes associated with metabolic disease such as renal failure.

OTHER LABORATORY TESTS

- Serum T_4 , free T_4 (FT_4), and TSH assay if hypothyroidism suspected.
- Measure trough serum digoxin concentration, if applicable, 8 hours after last dose or close to next dosing; normal therapeutic serum concentration should be 0.5–1.5 ng/mL.
- Toxicologic screen.

DIAGNOSTIC PROCEDURES

- Provocative atropine response test to assess sinus node function—administer atropine 0.04 mg/kg IV, wait 10–15 minutes, then record ECG or administer same dose IM, wait 30 minutes, then record ECG; persistent sinus tachycardia at > 140 bpm is expected response. Lower doses of atropine have increased tendency to cause initial accentuation of sinus bradycardia and first- or second-degree AV block because of centrally mediated increase in vagal tone.
- 24-hour Holter monitoring or ECG event recorder, an owner triggered device, useful if transient bradycardia is suspected cause for clinical signs.

TREATMENT

APPROPRIATE HEALTH CARE

- Many animals exhibit no clinical signs and require no treatment. In dogs without structural heart disease, heart rates as low as 40–50 bpm generally provide normal cardiac output at rest.
- Therapeutic approaches—vary markedly; depend on the mechanism for SB, the ventricular rate, and severity of clinical signs.
- Inpatient or outpatient management—depends on underlying cause and clinical status of patient.

NURSING CARE

- Provide general supportive therapy including intravenous fluid therapy for hypothermic and hypovolemic patients.
- Discontinue any causative drug.
- Correct any serious electrolyte imbalance with appropriate fluid therapy.

CLIENT EDUCATION

- Discuss importance of complying with daily medical management when treating

SINUS BRADYCARDIA

(CONTINUED)

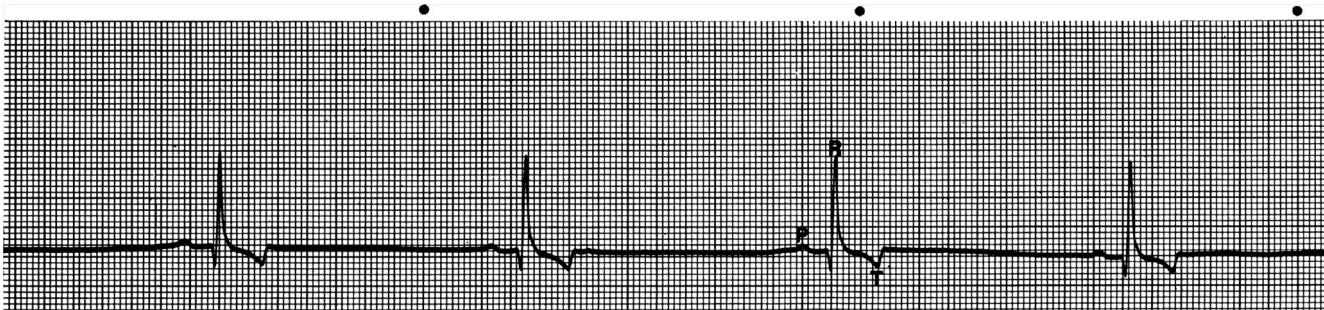

Figure 1.

Sinus bradycardia at a rate of 75 beats/minute in a cat from anesthetic complications during surgery. Note the tall R waves. (Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

underlying disease. • Advise that persistent symptomatic bradycardia may necessitate permanent pacemaker implantation for reliable long-term management.

SURGICAL CONSIDERATIONS

• If progressive bradycardia occurs during anesthesia and is attributed to hypoventilation, immediately discontinue inhalation anesthetics and provide adequate ventilation; atropine is generally ineffective in this situation. • If surgical manipulation triggering vagal reflexes (eye, vagus nerve, larynx) is anticipated, pretreatment with atropine (0.04 mg/kg IM, SC) or glycopyrrolate (5–10 µg/kg IM, SC) may prevent bradycardia. • Severe bradycardia may precipitate cardiopulmonary arrest; identify the causative agent or condition for effective management.

**MEDICATIONS****DRUG(S) OF CHOICE**

• If patient is hypothyroid, supplement with l-thyroxine. • For severe hypocalcemia (< 6 mg/dL) administer 10% calcium gluconate (0.5–1.5 mL/kg IV) slowly over 15–30 minutes; monitor with ECG. • For symptomatic drug-induced bradycardias, disorders causing excessive vagal tone, and initial management of bradycardia associated with SSS, administer atropine (0.04 mg/kg IV) or glycopyrrolate (5–10 µg/kg IV); anticholinergic therapy may be continued short-term using atropine (0.04 mg/kg IM, SC q6–8h) or glycopyrrolate (0.01 mg/kg IM, SC q6–8h). Consider propantheline bromide (0.25–0.5 mg/kg PO q8–12h) or hyoscymamine (3–6 µg/kg PO q8h), methylxanthine theophylline, an adenosine receptor antagonist (extended release formulation 10 mg/kg PO q12h, dogs; 12.5 mg PO q24h in the evening, cats), and/or terbutaline (0.14 mg/kg q8–12h PO, dogs; 0.625–1.25 mg/cat PO, cats) to manage symptomatic bradycardia associated with SA node disease. • For temporary management of symptomatic persistent bradycardia until pacing can be accomplished,

consider continuous IV infusion of isoproterenol (0.04–0.08 µg/kg/min IV). However, if temporary pacing is available this is initial procedure of choice.

CONTRAINDICATIONS

• For hypothermia-induced bradycardia with a pulse, rewarming and supportive measures should be mainstay of treatment. Parasympatholytics generally not recommended. • Parasympatholytic agents contraindicated for acidotic, hypercarbic patients under anesthesia (hypoventilation); bradycardia in this setting may protect the myocardium by decreasing oxygen consumption.

PRECAUTIONS

• Close ECG monitoring recommended when administering calcium solutions for treatment of hypocalcemia; if QT interval shortening or bradycardia, stop administration temporarily. • In patients with heart disease, a lower initial dose of l-thyroxine is advised to allow adaptation to higher metabolic rate. • Administer atropine selectively; rapid IV administration may predispose to ventricular arrhythmias by altering autonomic balance. • Caution when administering parasympatholytic agent to dogs with suspect SSS—could result in a tachycardia that overdrive suppress escape rhythms with potential consequence of asystole.

ALTERNATIVE DRUG(S)

• Bradycardia associated with structural heart disease is most reliably treated by permanent pacemaker implantation. • Glycopyrrolate may have longer vagal blocking effect and cause less frequent ventricular ectopic beats than atropine.

**FOLLOW-UP****PATIENT MONITORING**

• Assess total T₄ 6 hours post pill. • Addison's disease—assess electrolytes every 3–4 months after patient is stable. • ECG check of pacemaker function and pacing rate is

recommended during each follow-up examination.

PREVENTION/AVOIDANCE

• Maintain normal PaO₂ under anesthesia with proper ventilation; monitor with pulse oximetry or blood gases. • Avoid hypothermia intraoperatively.

EXPECTED COURSE AND PROGNOSIS

• Signs, if present, should resolve with correction of causative metabolic or endocrine problem. • Treatment of symptomatic SB with a permanent pacemaker generally offers a good prognosis for rhythm control.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

• Sick sinus syndrome • Heart block • Sinus arrhythmia

PREGNANCY/FERTILITY/BREEDING

Post-parturient hypocalcemia usually develops 1–4 weeks postpartum, but can occur at term, prepartum, or late lactation.

SEE ALSO

- Digoxin Toxicity • Eclampsia
- Hypercalcemia • Hyperkalemia
- Hypermagnesemia • Hypocalcemia
- Hypothermia • Hypothyroidism
- Organophosphate and Carbamate Toxicosis
- Sick Sinus Syndrome

ABBREVIATIONS

- AV = atrioventricular • ECG = electrocardiogram • SA = sinoatrial • SB = sinus bradycardia • SSS = sick sinus syndrome • T₄ = thyroxine • T₃ = triiodothyronine • TSH = thyroid stimulating hormone

SINUS TACHYCARDIA

BASICS

DEFINITION

Disturbance of sinus impulse formation; acceleration of the sinoatrial node beyond its normal discharge rate (Figure 1).

ECG Features

- Dogs—HR > 160 bpm (toy breeds HR > 180 bpm; giant breeds HR > 140 bpm; puppies HR > 220 bpm). • Cats—HR > 180 bpm; (kittens HR > 240 bpm). ECG shows a rapid regular rhythm with possible slight variation in R-R interval. • P wave of sinus origin for each QRS complex with constant P-R interval. • P waves may be partially or completely fused with preceding T waves. • Generally has a gradual onset and termination.

PATHOPHYSIOLOGY

- Accelerated phase 4 diastolic depolarization of sinus nodal cells (as a result of voltage and calcium-dependent mechanisms) generally responsible for ST. • Enhanced adrenergic effect or cholinergic inhibition results in high rate of sinus impulse formation; changes in heart rate usually involve a reciprocal action of the parasympathetic and sympathetic divisions of the autonomic nervous system.

SYSTEMS AFFECTED

Cardiovascular—cardiac output = heart rate × stroke volume. Changes in heart rate affect preload, afterload, and contractility, which determine stroke volume; severe tachycardia can compromise cardiac output. Rapid rates shorten diastolic filling time, and particularly in diseased hearts, the increased heart rate can fail to compensate for decreased stroke volume, resulting in decreased cardiac output and coronary blood flow. • Chronic tachycardias can cause cardiac dilation (tachycardiomyopathy) which often resolves with control of the tachycardia.

GENETICS

N/A

INCIDENCE/PREVALENCE

- Most common benign arrhythmia in the dog and cat. • Most common rhythm disturbance in the postoperative patient.

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dog and cat

Breed Predilections

None

SIGNS

General Comments

Often no clinical signs because ST is almost always a consequence of a variety of physiologic or pathophysiologic stresses.

Historical Findings

In general, ST itself does not produce any symptoms. • If associated with primary cardiac disease, weakness, exercise intolerance, or syncope may be reported. • If associated with other medical conditions, signs may be seen specific to the disease present.

Physical Examination Findings

- High HR • May otherwise be normal if not associated with a pathologic condition. • Pale mucous membranes if associated with anemia or CHF. • Fever may be present. • Signs of CHF (e.g., dyspnea, cough, cyanosis, ascites) if associated with primary cardiac disease.

CAUSES

Physiologic

- Exercise • Pain • Restraint • Excitement
- Any hyperadrenergic state

Pathologic

- Fever • CHF • Chronic lung disease
- Shock • Pericardial effusion • Anemia
- Pain • Infection • Hypoxia • Pulmonary thromboembolism • Hypotension
- Hypovolemia • Functional pheochromocytoma • Hyperthyroidism
- Pericarditis • Pneumothorax
- Hypoglycemia • Vestibulosympathetic hypovolemia

Pharmacologic

- Atropine • Epinephrine • Ketamine
- Telazol • Quinidine • Xanthine bronchodilators • β -agonists

RISK FACTORS

- Thyroid medications • Primary cardiac diseases • Inflammation • Pregnancy
- Anesthesia • Certain toxins (*Amanita muscaria*, scorpion venom, black widow spider venom), plants (Jimson weed, mandrake), and drugs (antihistamines, tricyclic antidepressants)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Must differentiate from supraventricular tachycardia including atrial tachycardia, atrial flutter with 2:1 AV block, and AV junctional tachycardia; as sinus rate increases, the P wave appears closer to the T wave of the previous beat. At very rapid rates, it becomes difficult to distinguish this condition from other pathologic SVT. Gradual slowing of the rate is more suggestive of ST.

CBC/BIOCHEMISTRY/URINALYSIS

- Low PCV if patient is anemic.
- Leukocytosis with left shift if inflammation or infection is causative.

OTHER LABORATORY TESTS

- High serum T_4 or free T_4 concentration (cats) if secondary to hyperthyroidism. • T_3 suppression test, TRH response test, or thyroid scintigraphy if T_4 values are normal and hyperthyroidism is suspected. • Plasma catecholamines (24-hour urine sample collection for catecholamine assay and their metabolites, low sensitivity) in diagnosis of pheochromocytoma; provocative testing to induce hypertension with histamine and glucagon or hypotension with phenolamine may be useful but is not practical. • 24-hour Holter monitoring. • Cardiac electrophysiologic studies. • Consider plasma

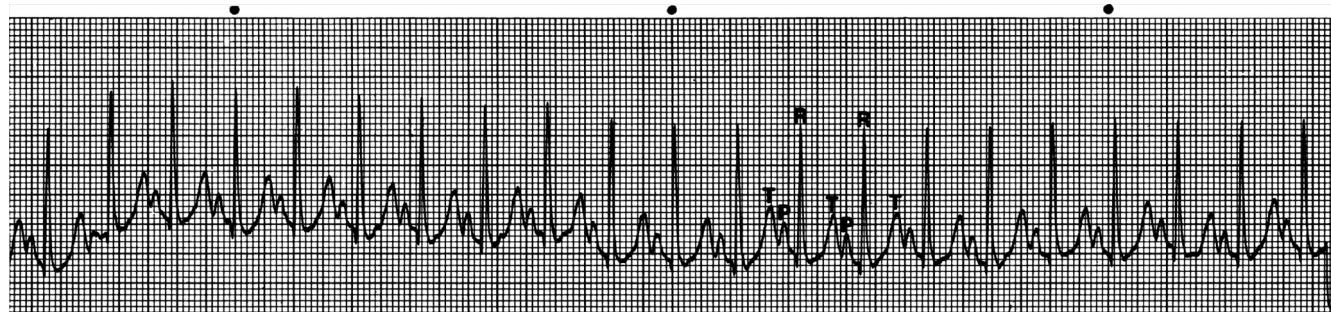

Figure 1.

Sinus tachycardia at a rate of 272 bpm/minute in a dog in shock. The rhythm is sinus because the P waves are normal, the P-R relationship is normal, and the rhythm is regular. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

SINUS TACHYCARDIA

(CONTINUED)

NT-proBNP assay if evaluating for cardiac disease.

IMAGING

- Thoracic radiographs and echocardiography to evaluate for evidence of primary cardiac disease
- Thyroid scan to evaluate for hyperthyroidism.
- Abdominal ultrasound and angiography to evaluate for adrenal mass.
- CT and MRI as well as functional imaging modalities very sensitive for detecting adrenal masses.

DIAGNOSTIC PROCEDURES

- Consider non-pharmacologic vagal maneuver to differentiate from other supraventricular tachyarrhythmias; carotid sinus or ocular pressure may terminate ectopic SVT. With ST, vagal maneuvers produce gradual, transient slowing of the HR if any. Less commonly, varying degrees of AV block (usually first-degree or Wenckebach) may occur transiently. ECG monitoring is recommended during these vagal maneuvers.
- A precordial thump may be used to differentiate ST from other SVT. ST will not be affected, whereas the SVT may stop for at least 1 or 2 beats.
- Serial arterial blood pressure measurement may document hypertension in patients with hyperthyroidism, pheochromocytoma, or renal disease.
- Pharmacologic cardioversion with IV diltiazem at 0.25 mg/kg administered over 2 minutes. If no response, can be repeated in 15 minutes.

PATHOLOGIC FINDINGS

- None if associated with physiologic or pharmacologic cause.
- Pathologic findings depend on the primary disease process.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Identify and correct underlying disorders whenever possible.
- Whether inpatient or outpatient depends on clinical status of patient and primary disease, if any (e.g., if CHF, treat as outpatient unless animal is dyspneic or severely hypotensive).

NURSING CARE

Depends on whether associated with a specific disease.

ACTIVITY

Exercise restriction recommended if symptomatic cardiac disease.

DIET

Sodium restriction generally advised with hypertension and CHF.

CLIENT EDUCATION

Discuss importance of managing any primary disease appropriately, with medical or surgical intervention.

SURGICAL CONSIDERATIONS

- Thyroidectomy—treatment option for hyperthyroidism (cats).
- Tumor removal is the definitive treatment for patients with pheochromocytoma.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Establish underlying cause and treat appropriately; specific antiarrhythmic therapy is generally limited to patients in CHF or those with secondary cardiac disease due to hyperthyroidism or hypertension.
- Dogs—if CHF is the cause, administer pimobendan along with appropriate diuretic therapy and angiotensin converting enzyme inhibitor. Digoxin may be indicated in some cases such as CHF with atrial fibrillation. If ST persists despite above management, consider adding a calcium channel blocker (e.g., diltiazem at 0.5–2.5 mg/kg PO q8h) or a beta-blocker (e.g., atenolol 0.25–1 mg/kg q12h, sotalol 1–2 mg/kg q12h PO) ONLY after congestion is controlled.
- Cats—if ST is associated with hyperthyroidism without CHF, a beta-blocker (e.g., atenolol 0.25–1 mg/kg PO q12–24h) may lower the HR. Consider digoxin (0.01875–0.03125 mg per average-size cat, equal to 1/8–1/4 of a 0.125 mg tablet—tablet preferred) if chronic hyperthyroidism with CHF or for treatment of primary dilated cardiomyopathy. If ST associated with hypertrophic cardiomyopathy, administer atenolol 6.25–12.5 mg/cat PO q12h or diltiazem (1.75–2.4 mg/kg PO q8h).

CONTRAINdications

Avoid drugs such as atropine or catecholamines (epinephrine) that may further increase the HR.

PRECAUTIONS

- Beta-blockers can potentially worsen signs of congestion and lower cardiac output in patients with systolic dysfunction
- Suppression of ST may be catastrophic if occurring as natural compensatory response to maintain cardiac output in a systemically ill patient.

POSSIBLE INTERACTIONS

See manufacturer's insert for specific drug.

ALTERNATIVE DRUG(S)

- If associated with pericardial effusion, avoid drug therapy and perform pericardiocentesis.
- If associated with a certain drug (e.g., hydralazine, bronchodilators), discontinue the medication or adjust the dose.
- If associated with hypovolemia, replace fluid volume.

**FOLLOW-UP****PATIENT MONITORING**

Depends on specific disease—for CHF, serial ECG, thoracic radiographs, BUN, creatinine, and serum electrolytes; for hyperthyroidism, serial serum T_4 , CBC, and biochemistry.

PREVENTION/AVOIDANCE

Minimize stress, exercise, and dietary sodium, if heart disease.

POSSIBLE COMPLICATIONS

- Weakness or syncope if associated with low cardiac output.
- Development of CHF if persistent ST associated with heart disease.

EXPECTED COURSE AND PROGNOSIS

- ST usually resolves with correction of the underlying cause.
- Poor despite treatment if ST is associated with CHF.
- Favorable for remission of ST when hyperthyroidism is controlled medically, surgically, or by radioactive iodine.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

See list of pathologic and physiologic causes.

PREGNANCY/FERTILITY/BREEDING

- Increase in cardiac output in late pregnancy (third trimester) largely due to an accelerated HR.

SYNOMYS

- Inappropriate sinus tachycardia
- Postural tachycardia syndrome

SEE ALSO

SJÖGREN-LIKE SYNDROME

BASICS

OVERVIEW

- A systemic auto-immune disease characterized by keratoconjunctivitis sicca, xerostomia, and lymphoplasmacytic adenitis.
- Underlying mechanism unknown; however, auto-antibodies directed against glandular tissues have been identified.
- Associated with other auto-immune or immune-mediated diseases, such as rheumatoid arthritis and pemphigus.

SIGNALMENT

- Higher incidence in several canine breeds—English bulldogs, West Highland white terriers, and miniature schnauzers.
- Chronic disease of adult dogs.
- Cats unaffected.

SIGNS

Historical Findings

- Adult onset
- Conjunctivitis and keratitis
- Keratitis sicca most prominent clinical feature

Physical Examination Findings

- Blepharospasm
- Conjunctival hyperemia
- Corneal lesions (opacity to ulceration)
- Gingivitis
- Stomatitis

CAUSES & RISK FACTORS

- Possible genetic predisposition in breeds with high incidence.
- Develops concurrently with other immune-mediated and auto-immune diseases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of keratoconjunctivitis sicca—canine distemper, trauma, and drug toxicities.

- Keratoconjunctivitis sicca associated with other immune-mediated diseases—atopy, lymphocytic thyroiditis, polymyositis, systemic lupus erythematosus, rheumatoid arthritis, and pemphigoid diseases.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

- Hypergammaglobulinemia revealed by serum protein electrophoresis.
- Positive antinuclear antibody test.
- Positive lupus erythematosus cell test.
- Positive rheumatoid factor test.
- Positive indirect fluorescent antibody test for auto-antibodies.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Schirmer tear test (0–5 mm/min)

PATHOLOGIC FINDINGS

- Histopathologic changes in salivary glands—lymphoplasmacytic adenitis
- Conjunctival biopsy—reveals conjunctivitis

TREATMENT

- Directed at controlling keratoconjunctivitis sicca.
- Any concurrent disease must be medically managed.
- May include administration of anti-inflammatory or immunosuppressive drugs.
- Surgical management of keratoconjunctivitis sicca indicated in animals that fail to respond to medical treatment.

MEDICATIONS

DRUG(S)

- Topical tear preparations.
- Appropriate topical antibiotics for secondary bacterial infection.

- Immunosuppressive or anti-inflammatory drugs.

- For more aggressive medical treatment and surgical intervention, see Keratoconjunctivitis Sicca.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Use of topical steroids in patients with acute keratoconjunctivitis sicca may cause corneal ulceration and is, therefore, not recommended.

FOLLOW-UP

- Reexamine patients weekly until keratoconjunctivitis sicca controlled.
- Additional monitoring may be indicated to manage underlying or concurrent disease.
- Immunosuppressive drugs—monitor patients every other week for possible side effects.
- Prognosis variable and depends on existence of concurrent disease.

MISCELLANEOUS

Skin Fragility Syndrome, Feline

BASICS

OVERVIEW

- A disorder of multifactorial causes characterized by extremely fragile skin.
- Tends to occur in old cats that may have concurrent hyperadrenocorticism, diabetes mellitus, excessive use of megestrol acetate or other progesterone compounds, or as a paraneoplastic syndrome.
- A small number of cats have no biochemical alterations.

SYSTEMS AFFECTED

- Skin/Exocrine
- Endocrine/Metabolic

SIGNALMENT

- Naturally occurring disease tends to be recognized in old cats.
- Iatrogenic cases have no age predilection.
- No breed or sex predilection.

SIGNS

Historical Findings

- Gradual onset of clinical signs.
- Progressive alopecia (not always present).
- Often associated with weight loss, lusterless coat, poor appetite, and lack of energy.

Physical Examination Findings

- Skin becomes markedly thin and tears with normal handling.
- Skin rarely bleeds upon tearing.
- Multiple lacerations (both old and new) may be noted on close examination.
- Partial to complete alopecia of the truncal region may be noted.
- Sometimes associated with "rat tail," pinnal folding, pot-belly appearance.

CAUSES & RISK FACTORS

- Hyperadrenocorticism—pituitary or adrenal dependent.
- Iatrogenic—secondary to excessive corticosteroid or progesterone drug administration.
- Diabetes mellitus—rare, unless associated with hyperadrenocorticism.
- Possibly idiopathic or paraneoplastic syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cutaneous asthenia.
- Feline paraneoplastic syndrome—pancreatic neoplasia, hepatic lipidosis, cholangiocarcinoma.

CBC/BIOCHEMISTRY/URINALYSIS

- Little diagnostic significance in most cases.
- Approximately 80% of cats with hyperadrenocorticism have concurrent diabetes mellitus (hyperglycemia, glucosuria).

OTHER LABORATORY TESTS

- ACTH-stimulation test—70% of cats with hyperadrenocorticism have an exaggerated response.
- LDDST—15–20% of normal cats may fail to decrease cortisol levels; typically unsuppressed with hyperadrenocorticism and non-adrenal illness.
- HDDST—normal cats show decreases in cortisol concentrations; typically decreased with non-adrenal illnesses; considered by many clinicians to be the best screening test for hyperadrenocorticism; unreliable for discriminating between adrenal tumors and pituitary-dependent causes of hyperadrenocorticism, because both conditions fail to show suppression.
- Endogenous ACTH levels—normal range for most labs is 20–100 pg/mL.

IMAGING

- Abdominal ultrasonography—adrenal masses are often small until end-stage disease.
- CT and MRI—small pituitary tumors may be difficult to visualize; MRI may be more successful.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Histopathology—suggestive, not diagnostic; epidermis and dermis are thin; attenuated collagen fibers are evident.

TREATMENT

- Underlying metabolic disease should be ruled-out.
- Many patients are debilitated and require supportive care.
- Surgical correction of the lacerations—difficult because the tissue cannot withstand pressure from sutures.
- Protect skin—clothing, reduce activities that can traumatize the skin, remove sharp edges from the environment, prevent damage from interaction with other animals.
- Discontinue exogenous corticosteroids if administered.
- Hyperadrenocorticism—adrenalectomy is the preferred treatment.
- Cobalt-60 radiation therapy—variable success in the treatment of pituitary tumors.

MEDICATIONS

DRUG(S)

- Medical management—may be useful for preparing patient for surgery and for minimizing postoperative complications (e.g., infections and poor wound healing).
- No known effective medical therapy for feline hyperadrenocorticism.
- o,p'-DDD (mitotane) 12.5–50 mg/kg PO q12h; response has been equivocal; side effects include anorexia, vomiting, and diarrhea.
- Ketoconazole (Nizoral) 10–15 mg/kg PO q12h; variable response; gastrointestinal disturbances, depression, fever, jaundice, and neurological signs commonly seen in cats.
- Metapyrone 65 mg/kg PO q12h; clinical improvement noted more often with this drug than the others.

CONTRAINdications/POSSIBLE INTERACTIONS

Hyperadrenocorticism—closely monitor diabetic cats; adjust insulin to prevent hypoglycemia when the cortisol levels fall.

FOLLOW-UP

Patients are often quite debilitated, making any form of treatment risky; close monitoring is required in all cases.

MISCELLANEOUS

ABBREVIATIONS

- ACTH = adrenocorticotropic hormone
- CT = computed tomography
- HDDST = high-dose dexamethasone-suppression test
- LDDST = low-dose dexamethasone-suppression test
- MRI = magnetic resonance imaging
- o,p'-DDD = 1,1-(o,p'-dichlorodiphenyl)-2,2-dichloroethane

SMALL INTESTINAL DYSBIOSIS

BASICS

DEFINITION

• Small intestinal dysbiosis (SID) is a clinical syndrome caused by an alteration of the small intestinal microbiota. • Previously, a variety of different terms have been used to describe small intestinal dysbiosis: ◦ Small intestinal bacterial overgrowth (SIBO) has been defined as $> 10^4$ anaerobic and/or $> 10^5$ total bacterial colony-forming units (cfu)/mL in duodenal juice from dogs. However, these criteria are now controversial. ◦ Antibiotic-responsive diarrhea (ARD) has been used by several authors to describe patients that have diarrhea that responds to antibiotic therapy. Neither the type of bacteria nor the type of antibiotic that is effective has been defined for ARD. ◦ Tylosin responsive diarrhea (TRD) has been described by a group of clinicians in Finland. The term was coined based on the fact that several dogs with chronic diarrhea failed to respond to a variety of antibiotics or corticosteroids, but did respond to treatment with tylosin. • Currently, there is no consensus on the quantitative makeup of the gastrointestinal microbiota in healthy dogs or cats. • It should be emphasized that SID differs from colonization of the alimentary tract by known pathogenic bacteria (e.g., *Salmonella* spp., *Campylobacter jejuni*, enterotoxigenic *Clostridium perfringens*, enterotoxic *E. coli*, or others).

PATHOPHYSIOLOGY

• Bacteria are constantly ingested with food and/or saliva. • Host protective mechanisms prevent overgrowth of pathogenic or potentially pathogenic bacteria through gastric acid secretion, intestinal motility (peristalsis), secretion of antimicrobial substances in bile and pancreatic juice, and local enteric IgA production. • The ileocolic valve is a physiologic barrier between the large bowel, which is populated by large numbers of bacteria, and the less populated small bowel. • When these natural defense mechanisms fail and excessive numbers of certain bacterial species persist in the upper small intestine, they may cause pathology, even though they are not considered obligate pathogens. • Anaerobic bacteria (e.g., *Bacteroides* spp. and *Clostridium* spp.) have been considered to more likely cause pathology than many aerobic bacteria.

SYSTEMS AFFECTED

• Gastrointestinal—normal absorptive function is disrupted, resulting in loose stool and weight loss. • Hepatobiliary—the portal vein carries bacterial toxins and other substances to the liver, which may lead to hepatic changes.

GENETICS

- No genetic basis for SID has been identified. However, recent studies would suggest that histiocytic ulcerative colitis should be considered a type of dysbiosis of the large intestine. Since the majority of cases have been described in the boxer, genetic factors that predispose dogs of this breed to this type of dysbiosis are likely. • Certain canine breeds (e.g., German shepherd, Chinese Shar-Pei, and beagle dog) appear to be at an increased risk for SID.

INCIDENCE/PREVALENCE

Unknown

SIGNALMENT

Species

Dog and cat

Breed Predilections

Subjectively, German shepherd dog, Chinese Shar-Pei, and beagle appear to have an increased incidence.

Mean Age and Range

- Unknown. • Can be diagnosed in dogs and cats of any age (age range: < 1 year to > 8 years).

SIGNS

General Comments

Alterations in the gut microbiota can cause clinical signs of small intestinal disease, such as loose stool or diarrhea, weight loss, and/or others.

Historical Findings

- Chronic loose stools or diarrhea (small bowel or large bowel type diarrhea)—common. • Weight loss, despite a reasonable appetite—common. • Borborygmus and flatulence—common. • Vomiting—occasional/variable. • Clinical signs of the underlying disease process may be seen in cases of secondary SID. • Clinical signs may wax and wane or be continuous.

Physical Examination Findings

Unremarkable or evidence of weight loss and decreased body condition.

CAUSES

- Primary SID is probably uncommon, but a definitive cause of SID often remains undiagnosed and thus many dogs are diagnosed with idiopathic SID. • Secondary SID (more common): ◦ Altered small intestinal anatomy— inherited or acquired (e.g., congenital blind loop, partial obstructions, neoplasia, foreign body, intussusception, stricture, adhesion, or diverticulum). ◦ Altered intestinal motility—hypothyroidism, autonomic neuropathies. ◦ Exocrine pancreatic insufficiency (EPI)—approximately 70% of dogs with EPI have concurrent SID. ◦ Hypochlorhydria or achlorhydria—spontaneous or iatrogenic (e.g., proton-pump inhibitor treatment). ◦ Altered immune system-immunodeficiency,

decreased mucosal defense, and preexisting intestinal disease.

RISK FACTORS

Intestinal diseases that affect local defense mechanisms (e.g., inflammatory bowel disease [IBD], adverse food reactions, parasite infestation, others).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Secondary gastrointestinal disease (e.g., hepatic failure, renal failure, EPI, chronic pancreatitis, hypothyroidism, hypoadrenocorticism). • Primary gastrointestinal disease (i.e., infectious, inflammatory, neoplastic, mechanical, toxic, or other).

CBC/BIOCHEMISTRY/URINALYSIS

- Usually unremarkable.
- Hypoalbuminemia—an uncommon finding; when present, it suggests particularly severe intestinal disease and warrants an aggressive diagnostic and therapeutic approach.

IMAGING

Not useful for the diagnosis of primary SID. However, may reveal findings indicative of an underlying cause.

DIAGNOSTIC TESTS

Serum Cobalamin and Folate Concentrations

- Serum folate concentration may be increased—many bacterial species synthesize folate and an increased abundance of folate-producing bacterial species will lead to an overabundance of folic acid in the small intestine. • Serum cobalamin concentration may be decreased—many bacterial species compete with the host for dietary cobalamin. • The finding of an increased serum folate concentration and a decreased serum cobalamin concentration is suggestive, but not specific for SID in dogs. In addition, not all patients with SID show this pattern.
- Serum folate and cobalamin concentration is the only test for SID that is currently routinely available.

Qualitative and Quantitative Bacterial Culture of Small Intestinal Juice

- Aerobic and anaerobic quantitative culture of duodenal fluid has long been considered the “gold standard” for the diagnosis of SIBO in human patients. • Invasive—requires endoscopy or laparoscopy. Not practical and not routinely available. • Recent work would suggest the species of bacteria that comprise the small intestinal microbiota may be more important than bacterial numbers. • No standardized protocols have been established for sampling, handling, and culturing of duodenal juice, leading to high variability in bacterial counts.

SMALL INTESTINAL DYSBIOSIS

(CONTINUED)

Therapeutic Trial

- Treatment of patients with suspected SID with an antibiotic, a prebiotic, or a probiotic.
- Interpreting the results of a therapeutic trial may be difficult as more than one disease (e.g., IBD plus SID, dietary intolerance plus SID) may be present, and lack of a clinical response might lead to the incorrect conclusion that SID is absent; incorrect selection of the treatment that is trialed might also cause failure of a clinical response.

PATHOLOGIC FINDINGS

- No macroscopic findings upon exploratory laparotomy or endoscopy.
- Histopathology of small intestinal mucosal biopsies is typically unremarkable.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient medical management.
- SID can be managed with antibiotics, prebiotics, probiotics, or a combination thereof.
- Antibiotics: see below for medications
- Prebiotics: see below for diet.
- Probiotics: there has been a lot of interest in probiotic use for dogs and cats with chronic diarrhea, although little is known about the efficacy. Currently, because of quality issues with many products, only probiotics from major manufacturers can be recommended.
- Improvement may take a few days to several weeks.

NURSING CARE

- Usually none.
- Supportive care for emaciated or hypoalbuminemic patients

ACTIVITY

Unrestricted

DIET

- Highly digestible diet.
- A diet containing fructooligosaccharides has been shown to be beneficial in dogs with small intestinal dysbiosis.

S

CLIENT EDUCATION

- Some patients show clinical improvement within days.
- Some patients require weeks of therapy before demonstrating improvement—treat for 2–3 weeks before concluding that therapy is ineffective.
- Any concurrent or predisposing diseases (e.g., IBD, EPI, dietary intolerance/allergy, alimentary tract neoplasia, partial obstruction) must also be treated.
- Continuous or repeated treatment is often required.

SURGICAL CONSIDERATIONS

Only indicated for some underlying causes of SID (i.e., partial obstruction, diverticulum, or intestinal mass).

MEDICATIONS

DRUG(S) OF CHOICE

- Broad-spectrum, orally administered antibiotics effective against both aerobic and anaerobic bacteria are preferred.
- Tylosin (10–20 mg/kg PO q12h for 6 weeks) is the primary choice. Tylosin is usually used in a powder formulation that is marketed for use in poultry and pigs. Tylosin is administered in the food because of its bitter taste. It can be used long-term and is very safe and inexpensive. For small dogs and cats the drug should be reformulated into capsules. For larger dogs the dose can be approximated by using a teaspoon and administering the drug in food.
- Metronidazole (10–15 mg/kg PO q12h for 6 weeks) is used commonly in routine practice because of its activity against anaerobic bacteria. Metronidazole may also have immunomodulatory effects. However, metronidazole can have significant side effects.
- Dogs with SID may be cobalamin deficient, and parenteral supplementation of vitamin B₁₂ is indicated (250 µg (cats); 250–1,500 µg (dogs) SC); dose depending on body size; dose regimen is typically one dose weekly for 6 consecutive weeks and one dose a month later; serum cobalamin concentrations should be re-evaluated a month after the last dose to determine the need for continued supplementation).

PRECAUTIONS

- Metronidazole can be associated with gastrointestinal side effects and in rare cases with neurologic side effects.

ALTERNATIVE DRUG(S)

In dogs with EPI and SID, concurrent therapy for SID is only indicated if enzyme replacement alone does not resolve the diarrhea and/or lead to weight gain.

FOLLOW-UP

PATIENT MONITORING

- Body weight and, in hypoproteinemic patients, serum albumin concentrations are the most important parameters; improvement suggests effective therapy.
- Diarrhea should also resolve.
- If diarrhea persists despite improved body weight and/or increased serum albumin concentration, investigation for concurrent intestinal disease is indicated.

EXPECTED COURSE AND PROGNOSIS

Primary SID without complicating factors (e.g., IBD, lymphoma)—prognosis with appropriate therapy is usually good, although relapses can be seen following cessation of antibiotic therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- SID has been suspected as a cause of IBD in some patients.
- Consider the possibility of concurrent EPI.

PREGNANCY/FERTILITY/BREEDING

Avoid oxytetracycline or metronidazole, especially during early pregnancy.

SYNOMYMS

SIBO, ARD, or TRD may be used synonymously by some authors.

SEE ALSO

SMOKE INHALATION

BASICS

OVERVIEW

- Injury occurs as a result of direct heat damage to the upper airway and nasal mucosa. Inhalation of other toxins directly irritates the airway, and particulate matter adheres to the airways and alveoli. Carbon monoxide decreases tissue oxygen delivery by preferentially binding to hemoglobin.
- Extent of damage depends on the degree and duration of exposure and the material that was burning.
- Can have serious lung injury with little cutaneous or oral evidence of burning.
- Lung reaction—initially bronchoconstriction, airway edema, mucus production and airway occlusion; then an inflammatory response, necrotizing tracheobronchitis, and pulmonary fluid accumulation owing to increased capillary permeability.
- Most show progression of lung dysfunction in the initial 2–3 days.
- Superimposed bacterial infections—common cause of morbidity late in the disease.

SIGNALMENT

Dog and cat

SIGNS

- Historical findings consistent with exposure.
- Smoky odor.
- Tachypnea and increased depth of respiration.
- Inspiratory effort suggests upper airway obstruction by edema.
- Postural adaptations to hypoxemia.
- Mucous membranes can be cherry red (from carbon monoxyhemoglobin), pale, or cyanotic.
- Auscultation of wheezes, harsh bronchovesicular sounds, or crackles.
- Cough
- Burned or shriveled whiskers, conjunctival edema, corneal ulcers.
- Neurologic signs can indicate carbon monoxide or cyanide toxicity.
- Cardiac arrhythmias and hypotension can be seen secondary to hypoxemia, smoke and carbon monoxide inhalation, and burn injuries.

CAUSES & RISK FACTORS

Exposure to smoke, usually from being trapped in a burning building.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

- Neutropenia—poor prognostic sign; suggests neutrophil sequestration in the lungs.
- Thrombocytopenia—suggests platelet sequestration or consumption.
- Biochemistry profile—evidence of hypoxic damage to other organ systems can be present.

IMAGING

Thoracic radiographs—establish a baseline; findings vary from normal to a bronchointerstitial or alveolar pattern.

DIAGNOSTIC PROCEDURES

- Bronchoalveolar lavage or tracheal wash for cytology examination and culture—perform for suspected superimposed bacterial tracheobronchitis or pneumonia; results usually reveal an acute suppurative reaction with excessive mucus, neutrophils, and alveolar macrophages; intracellular bacteria indicate concurrent infection.
- Pulse oximetry or arterial blood gases can confirm hypoxemia; of less value with carbon monoxide exposure.
- Bronchoscopy—can demonstrate the severity of airway damage.

TREATMENT

- Initial management—stabilize respiratory function; establish patent airway; severe upper airway edema or obstruction can require intubation or temporary tracheostomy.
- Oxygen—administer immediately to displace carbon monoxide from hemoglobin; use the highest available concentration for 2–4 hours (or longer); after elimination of carbon monoxyhemoglobin, supplement as needed.
- Fluid administration—can be required but should be conservative to minimize pulmonary edema; use of synthetic colloids in animals with hypoproteinemia is controversial but is sometimes necessary for stabilization; cases with extensive dermal burns have high fluid requirements due to considerable loss of fluid and protein.
- Nebulization of saline with coupage—facilitates clearance of respiratory secretions.
- Mechanical ventilation needed in severe cases.
- Nutritional support—maintain body condition and immune status.

MEDICATIONS

DRUG(S)

- Suspected bacterial infection—broad-spectrum antibiotics after bacterial culture has been obtained.
- Bronchodilators—may improve respiratory function if severe bronchoconstriction occurs, especially in cats (e.g., terbutaline 0.01 mg/kg IV, IM, SC). Inhaled beta-agonists can also be beneficial in these patients.
- Single early, anti-inflammatory dose of corticosteroids or aerosolized corticosteroids may decrease airway edema though there is no conclusive evidence of efficacy.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Diuretics—decrease intravascular volume without a major beneficial effect.
- Corticosteroids—use only once and if absolutely necessary; can predispose the patient to bacterial infection.

FOLLOW-UP

PATIENT MONITORING

- Respiratory rate and effort, mucous membrane color, heart rate and pulse quality, lung auscultations, and PCV/TS for 24–72 hours.
- Repeat radiographs in 48 hours—ensure condition is resolving; monitor for bacterial pneumonia.
- Pulse oximetry and arterial blood gas analysis—to monitor hypoxemia and response to therapy.

POSSIBLE COMPLICATIONS

- Bacterial tracheobronchitis or pneumonia.
- Profound, generalized pulmonary inflammatory response or severe systemic inflammatory response syndrome—can develop ARDS. Bronchiectasis can develop secondary to airway injury and impaired mucociliary clearance.
- Severe cases can develop late (3–10 days after exposure) neurologic sequelae (seizures, cerebral edema) secondary to carbon monoxide toxicity.

EXPECTED COURSE AND PROGNOSIS

- Most patients deteriorate during the initial 24–48 hours after smoke exposure then gradually improve, unless bacterial pneumonia or ARDS develops.
- Severe burns or organ injury—poor prognosis.

MISCELLANEOUS

ABBREVIATIONS

- ARDS = acute respiratory distress syndrome
- PCV = packed cell volume

SNAKE VENOM TOXICOSIS—CORAL SNAKES

BASICS

OVERVIEW

- Two clinically important species in North America—*Micruurus fulvius*, eastern coral snake (North Carolina to the north; southern Florida to the south; west of the Mississippi River) and *Micruurus tener*, Texas coral snake (west of Mississippi; in Arkansas, Louisiana, and Texas).
- Family Elapidae—fixed front fangs.
- Color pattern—bands fully encircling the body; red, yellow, and black; distinguished from the harmless tri-colored king snake (*Lampropeltis elapsoides*) by the arrangement of the bands: if yellow (caution) and red (danger) color bands touch, then stay clear; relatively small head; black snout; round pupils.

Bites

- Relatively uncommon due to snake's reclusive behavior and nocturnal habits.
- Often occur on the lip. Snakes remain attached due to chewing action.
- Distinct fang marks may not be obvious.
- Primary cause of death—respiratory collapse.
- Envenomations by *M. tener* seem to be less severe than *M. fulvius*.

SIGNALMENT

Dogs and cats

SIGNS

- Onset of clinical signs may be delayed several hours (up to 18 hours).
- Localized signs generally absent.
- Generalized weakness and ataxia.
- Bulbar paralysis—affecting cranial motor nerves, respiratory tract, and skeletal muscles; acute flaccid quadriplegia.
- Salivation—caused by dysphagia.
- Dyspnea.
- Dysphonias.
- Hyporeflexive spinal reflexes.
- Seizures.
- Urinary incontinence.

CAUSES & RISK FACTORS

- Size of the snake
- Size and duration of bite

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Myasthenia gravis
- Botulism
- Polyradiculoneuritis

- Tick bite paralysis
- Black widow spider bite (*Latrodectus* species)

CBC/BIOCHEMISTRY/URINALYSIS

- Hemolysis—dogs only
- RBC burring
- May note high creatine kinase
- Hemoglobinuria—dogs only

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- First aid—generally avoid; most effective measure is rapid transport to a veterinary facility for antivenin administration; Australian technique for Elapid bites is a pressure wrap of the bitten limb with ace-type bandage to decrease blood flow and venom uptake.
- CAUTION: do not wait for onset of clinical signs to initiate treatment.
- Inpatient—hospitalize for a minimum of 48 hours.
- Monitor CNS and respiratory function closely for 24 hours.
- Specific antivenin is extremely limited for *M. fulvius* envenomations in the USA and typically not accessible for veterinary use. However, protective cross-reactivity occurs with the following antivenins: Coralmyn [Fab₂ equine origin] (Instituto Bioclon, Mexico), Costa Rican coral snake antivenin (Instituto Clodomiro Picado, Costa Rica), and Australian tiger snake *Notechis scutatus* (CSL Limited, Parkville, Victoria, Australia). Expense may be a consideration.
- If antivenin unavailable—provide ventilatory support for several days in a critical care facility.

MEDICATIONS

DRUG(S)

- M. fulvius* reactive antivenin (see "Treatment")—indicated if the history includes recent coral snake interaction; evidence of puncture wounds; clinical signs consistent with coral

snake envenomation; administer 1–2 vials; additional vials may be necessary (technique same as for pit viper antivenin).

- Broad-spectrum antibiotics are not routinely recommended and should only be used if there is indication of infection.
- Neostigmine — may be useful to reverse NM blockade if antivenin not available. Has been used successfully to treat *M. frontalis* envenomation in Brazil.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Corticosteroids—not indicated.
- Observe precautions outlined for pit viper antivenin administration (see Snake Venom Toxicosis—Pit Vipers).

FOLLOW-UP

- Marked clinical signs may last 1–1.5 weeks.
- Full recovery may take months as receptors regenerate.

MISCELLANEOUS

SEE ALSO

SNAKE VENOM TOXICOSIS—PIT VIPERS

BASICS

OVERVIEW

- Pit vipers—*Crotalus* spp. (rattlesnakes), *Sistrurus* spp. (pigmy rattlesnakes and massasauga), and *Agiistrodon* spp. (copperheads and cottonmouth water moccasins); retractable fangs; heat-sensing pit between the nostril and eye; triangle-shaped head.
- Range—throughout the United States (not found in Alaska, Hawaii, Maine).
- Toxicity—considered hemotoxic; several species have subpopulations with lethal neurotoxic components (e.g., Mohave rattlesnake); general ranking of severity: (1) rattlesnakes, (2) moccasins, (3) copperheads.
- Venom—enzymes: hyaluronidase and phospholipase A (cause local tissue injury) and others that interfere with the coagulation cascade (cause major coagulation defects); non-enzymatic polypeptides: affect the cardiovascular and respiratory systems.
- Bite—85% of victims have altered laboratory values and clinically important swelling; severe hypotension from pooling of blood within the splanchnic (dogs) or pulmonary (cats) vessels; fluid loss from the vascular compartment secondary to severe peripheral edema.
- About 20–30% crotalid bites considered “dry bites” with little if any venom deposited and no associated toxicity.

SIGNALMENT

Dogs and cats

SIGNS

General Comments

May be delayed for 8 hours after envenomation.

Historical Findings

- Outdoors, rural setting, indigenous snake.
- Owner saw bite or heard snake.

Physical Examination Findings

- Puncture wounds on head and forelimbs in most animals
- Local tissue swelling and pain surrounding bite site
- Bruising, with possible necrosis and sloughing of bite site tissue
- Ecchymosis and petechiation of tissues and mucous membranes
- Hypotension and shock
- Tachycardia
- Shallow respiration
- Depression, lethargy, and muscle weakness
- Nausea and excessive salivation

CAUSES & RISK FACTORS

Snake-Associated

- Toxic peptide fraction:enzyme fraction ratio—higher in spring and lower in fall (not well documented); high in very young snakes.
- Amount of venom production since last bite.
- Size, fang length, aggressiveness, and motivation of snake.

Victim-Associated

- Bite site—bites to tongue and torso are of major concern.
- Size of victim.
- Elapsed time between bite and initiation of treatment.
- Activity level of victim after the bite—activity increases absorption of venom.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Angioedema secondary to insect envenomation (spider, scorpion, large centipede)
- Blunt trauma
- Penetrating wound
- Animal bite
- Penetration of foreign body
- Draining abscess

CBC/BIOCHEMISTRY/URINALYSIS

- Hemoconcentration
- Bursting of RBCs within first 24 hours
- Thrombocytopenia
- Hypokalemia
- Elevated CK
- Hematuria or myoglobinuria

OTHER LABORATORY TESTS

Clotting tests—reduced platelets and fibrinogen, may note prolonged ACT, PT, and PTT; may note elevated FDPs.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Clinical evaluation of bite for edema, ecchymosis, fang punctures, pain.
- ECG—may detect ventricular arrhythmia, especially in severely depressed patients.

TREATMENT

- Tissue reaction around the bite site—not a reliable indicator of systemic toxicity.
- Bite location—may affect uptake of venom; bites to tongue and torso are of major concern. Distal limb bites may result in significant tissue damage and compromise limb function.

- First aid measures—minimize activity, calm patient, provide analgesia if indicated; transport quickly to a veterinary facility.

- Antivenin is only proven specific treatment (see “Medications”). Expense may be an important factor.

- Intravenous fluids—correct hypotension.
- Repeat coagulation profile after administration of antivenin for comparison to earlier labs. Recurrence of clinical signs or coagulation abnormalities can occur with any antivenin. If initial coagulopathy resolved with antivenin administration, recurrence can occur within the next few days, although rarely as severe as initial. There are no documented cases of clinical bleeding with subsequent coagulopathy; however, the clinician should be aware of the possibility.

MEDICATIONS

DRUG(S)

- Analgesics to reduce pain and stress.
- Antivenin, (VenomVet™—Crotalidae polyvalent, equine origin, Fab2). Injectable solution, no need to reconstitute. Mix each vial of antivenin with 100–150 mL of a crystalloid fluid and administer IV slowly while taking into consideration the patient’s weight and overall fluid load. Infuse over 30 minutes–1 hour. For use in dogs only.
- Antivenin (Crotalidae polyvalent, equine origin, whole IgG)—1 vial mixed with 200 mL crystalloid fluids administered slowly IV with careful monitoring of the inner pinna for onset of hyperemia (indicator of possible allergic reaction), reactions much more common due to extraneous proteins.
- Antivenin (Crofab, polyvalent, ovine Fab₁) has completed clinical trials in dogs and successfully used in cats. Purified antibody fragments provide much less possibility for reactions. Has been submitted for USDA approval in animals. Only approved pit viper antivenin in United States for humans.
- Antivenin (Antivipmyn, polyvalent, equine Fab₂—Instituto Bioclón, Mexico) is in clinical trials for dogs. Purified antibody particles much less possibility for reactions.
- Always flush antivenin vial after initial removal of antivenin, second flush can increase antivenin collection by 30%.
- Allergic reaction—stop antivenin; give diphenhydramine; after 5 minutes, restart antivenin infusion at a slower rate.
- Antibiotics—Infection is rare and antibiotics not recommended unless there is evidence of infection.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- CAUTION: in animals receiving beta-blockers, the onset of anaphylaxis may be

SNAKE VENOM TOXICOSIS—PIT VIPERS

(CONTINUED)

masked; therefore, the condition may be more advanced once recognized and more difficult to treat effectively.

- Corticosteroids—of no value.
- DMSO—enhances uptake and spread of venom.
- Heparin—do not use.
- Rattlesnake vaccine for dogs is currently marketed. Its efficacy is unknown; only anecdotal evidence at this time. Not recommended until peer-reviewed efficacy data available.

**FOLLOW-UP**

- Repeated laboratory analysis—6 hours after admission to hospital.
- Clinical signs—may last 1–1.5 weeks.

**MISCELLANEOUS****ABBREVIATIONS**

- ACT = activated clotting time
- CK = creatine kinase
- DMSO = dimethyl sulfoxide
- ECG = electrocardiogram
- FDP = fibrin degradation products
- PT = prothrombin time
- PTT = partial thromboplastin time
- RBC = red blood cell

SNEEZING, REVERSE SNEEZING, GAGGING

BASICS

DEFINITION

- Sneezing—a normal protective expiratory reflex that serves to expel air and material through the nasal cavity; commonly associated with nasal discharge.
- Reverse sneezing—a normal protective, repetitive inspiratory reflex that serves to remove irritants from the nasopharynx (also termed the aspiration reflex).
- Gagging (also called retching)—a normal protective reflex to clear secretions from the larynx, proximal trachea, pharynx, or esophagus; often misinterpreted as vomiting by owners.

PATHOPHYSIOLOGY

- Irritation of submucosal irritant receptors; various stimuli (infectious, parasitic, irritant, mechanical—especially accumulated secretions) will elicit these reflexes depending on where the irritation is applied.
- Sneezing—nasal mucosal irritation; frequency often diminishes with chronic disease.
- Reverse sneezing—caudodorsal nasopharyngeal mucosal irritation.
- Gagging—cervical tracheal (or laryngeal) mucosal irritation; oropharyngeal and esophageal mucosal irritation may also be involved. May follow a coughing episode as secretions are brought through the larynx or precede coughing due to aspiration into the trachea.

SYSTEMS AFFECTED

- Respiratory—frequently associated with infectious or inflammatory conditions involving the upper respiratory tract.
- Gastrointestinal—gagging may also be caused by swallowing, esophageal, or gastric disorders.

GENETICS

N/A

INCIDENCE/PREVALENCE

These are common, normal reflexes in both dogs and cats in response to mucosal irritation.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

- Any breed dog or cat may be affected.
- These reflexes per se are not associated with any specific age but rather with the conditions that cause them; examples include:
 - Young animals—infestation, cleft palate, primary ciliary dyskinesia.
 - Older animals—nasal tumors, dental disease.
- Acute sneezing in dogs is most often caused by a nasal foreign body, while in cats it is most often associated with acute viral rhinitis.

SIGNS

- Head and mouth position may help owners determine which of these reflexes are present.
- Sneezing typically results in sudden, explosive expiratory effort(s) with the mouth closed and head thrown downward; may result in the animal's nose hitting the ground.
- Reverse sneezing is a sudden, often paroxysmal, noisy, inspiratory effort with the head pulled back, mouth closed, and lips sucked in.
- Gagging is an expiratory effort; typically with the head and neck extended and mouth held open; usually ends with the animal swallowing (with little to nothing expelled).

CAUSES

- Any mucosal irritation or inflammation can elicit these reflexes. The same agent in the nasal cavity might elicit a sneeze, but when placed into the nasopharynx would result in a reverse sneeze. The reflex therefore localizes the site of irritation for further evaluation.
- Common nasal causes of sneezing and reverse sneezing include excess nasal secretions (see Nasal Discharge chapter), foreign body (especially if signs are acute and violent in onset), neoplasia, and parasites; dogs—*Pneumonyssoides*; dogs and cats—*Cuterebra*, *Eucoleus* (*Capillaria*), *Linguatula*.
- Extranasal diseases resulting in reverse sneezing, sneezing (and nasal discharge) as secretions may be forced up into the nasopharynx and the nasal cavities—pneumonia, megaesophagus, chronic vomiting, cricopharyngeal dysphagia, or achalasia.
- Reverse sneezing may be idiopathic, especially in small-breed dogs. In that case, there are no other associated clinical signs.
- Causes of gagging include:
 - Secretions being coughed up from the lower airways and into the larynx or cervical trachea.
 - Pharyngeal/laryngeal dysfunction resulting in airway aspiration due to loss of motor and/or sensory function that normally protects the airway.
 - Vomiting from esophageal and gastrointestinal disease.

RISK FACTORS

- Poorly vaccinated animals may develop nasal infection/inflammation and sneezing (kittens with upper respiratory infections, puppies with canine infectious respiratory disease complex).
- Productive coughing may produce excess secretions that can be propelled into the nasopharynx and lead to reverse sneezing.
- Chronic dental disease can cause rhinitis and either sneezing or reverse sneezing.
- Nasal mites may cause both reverse sneezing and sneezing in dogs (but not cats); in the United States, incidence is inversely proportional to heartworm preventive usage.

- Nasal foreign bodies elicit sneezing and/or reverse sneezing depending on their location; outdoor animals, especially hunting dogs, perhaps more at risk.
- Reverse sneezing is often associated with excitement.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Similar Signs

- Differentiate regular sneezing (occurs on expiration) from reverse sneezing (occurs on inspiration and localizes the site of irritation to the nasopharynx).
- Gagging is often misinterpreted as vomiting.

CBC/BIOCHEMISTRY/URINALYSIS

Results not specific of any particular cause of sneezing, reverse sneezing, or gagging.

OTHER LABORATORY TESTS

These reflexes are secondary to another process that has irritated and stimulated the mucosal surfaces in one or more areas. Diagnostic testing is designed to determine that specific cause.

IMAGING

- Sneezing and reverse sneezing—skull radiographs or CT.
- Gagging—chest radiographs and bronchoscopy may be required to look for excessive lower airway secretions and pneumonia.

DIAGNOSTIC PROCEDURES

- Sneezing and reverse sneezing—anterior and posterior rhinoscopy, periodontal probing.
- Gagging—determine presence or absence of gag reflex, laryngoscopy to determine intrinsic function (use doxapram to stimulate respiration).

PATHOLOGIC FINDINGS

Nonspecific inflammation can be found in the nasal cavity or nasopharynx.

TREATMENT

APPROPRIATE HEALTH CARE

Removal of the inciting mucosal irritation, where/when possible, will result in relief from these reflexes.

NURSING CARE

Outpatient therapy generally indicated, except perhaps following rhinoscopic biopsy.

ACTIVITY

Exercise and activity should be restricted after rhinoscopic biopsies to prevent excessive bleeding.

DIET

N/A

SNEEZING, REVERSE SNEEZING, GAGGING

(CONTINUED)

CLIENT EDUCATION

- Educate clients so they understand these are normal reflexes. Diagnostic testing is required to determine the underlying cause and to allow appropriate treatment.
- Close contact with other animals should be limited until treatment for the underlying cause (if infectious) is completed.
- Episodes of paroxysmal reverse sneezing may be lessened by inducing swallowing (rubbing the throat, giving water) or breath holding (cover nose and mouth).

SURGICAL CONSIDERATIONS

- Depending on the underlying cause, anesthesia for surgery or endoscopy may be needed to remove an abscessed tooth or a foreign body causing sneezing/reverse sneezing.
- Use surgery for laryngeal disease with caution when gagging is prominent due to an increased risk of aspiration pneumonia when concurrent esophageal dysfunction is present.

MEDICATIONS

DRUG(S) OF CHOICE

- There is no drug that specifically suppresses these reflexes; treatment is directed at the underlying irritant.
- Nasal bacterial infections (secondary to foreign body, dental disease, tumor, etc.) are best treated with antibiotics directed against gram-positive bacteria (most common).
- Nasal mites are treated with ivermectin (200–300 µg/kg PO or SC weekly for 3 weeks), selamectin (6–24 mg/kg applied topically every 2 weeks for 3 doses), or milbemycin (in collies and similar breeds at 0.5–1 mg/kg PO weekly for 3 weeks). All dogs in the household should be treated to prevent reinfection.
- When no underlying nasal condition is found to explain sneezing, treatment for nasal mites is recommended. If no improvement is observed, long-term, nonspecific treatment

with doxycycline and piroxicam (0.3 mg/kg PO daily) may be tried.

- Lower airway diseases with excess secretions are treated with antibiotics if bacterial infection is confirmed; gram-negative bacteria are most common.
- For nonspecific airway inflammation use an anti-inflammatory, prednisolone (1–2 mg/kg q12–24h) or piroxicam (0.3 mg/kg PO q24–48h) if no infection is confirmed.
- There is no treatment for gagging secondary to sensory loss in the larynx with recurring aspiration; elevation of food and water bowls is recommended. Altering the consistency of food offered may also be helpful.

CONTRAINdications

- Ivermectin in collies and similar breeds.
- Use of piroxicam concurrently with other NSAIDs or corticosteroids, as well as in patients with renal insufficiency.

PRECAUTIONS

The safety of most recommended drugs has not been established in pregnant animals.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Decongestants (ephedrine, topical vasoconstrictors) or antihistamines may reduce secretions and sneezing in some cases.

FOLLOW-UP

PATIENT MONITORING

Expect reduction in sneezing/reverse sneezing with appropriate therapy.

PREVENTION/AVOIDANCE

Limit access to foreign bodies, provide adequate dental care.

POSSIBLE COMPLICATIONS

If gagging is secondary to laryngeal sensory loss, serious aspiration pneumonia may develop.

EXPECTED COURSE AND PROGNOSIS

- Nasal mites should respond to treatment within 3 weeks.
- Sneezing and reverse sneezing secondary to foreign material resolve quickly after removal of the foreign body.

SOFT TISSUE SARCOMA

BASICS

DEFINITION

- A mesenchymal neoplasm arising in connective tissues.
- Soft tissue sarcomas are a heterogeneous group of different mesenchymal tumors demonstrating similar pathologic features and clinical behavior. Examples of tumors in this group include fibrosarcoma, leiomyosarcoma, peripheral nerve sheath tumor, and myxosarcoma.
- It is important to note that tumors of hematopoietic or lymphoid origin such as hemangiosarcoma are not included within the STS group.
- Benign and malignant histologic STS can arise; this chapter will focus on malignant STS.

PATOPHYSIOLOGY

- Tumors can arise in connective tissues in any anatomic location.
- Locally invasive behavior is typical with tumor extension beyond visible margins.
- Tumors often have low to moderate metastatic potential.

SYSTEMS AFFECTED

- Skin—STS most commonly arise from skin or subcutis.
- Musculoskeletal—STS may arise from muscle, fascial and fibrous tissues.
- Nervous—STS can originate from neurovascular structures.
- Respiratory—STS metastasize hematogenously and can metastasize to the lungs.
- Hemic/Lymph/Immune—lymph nodes are rare sites of metastasis.

GENETICS

There are no specific breed predilections that would suggest genetic predisposition.

INCIDENCE/PREVALENCE

- STS constitute 7% and 15% of skin and subcutaneous tumors in the cat and dog respectively.
- Incidence annually around 17 per 100,000 cats at risk; 35 per 100,000 dogs at risk.

SIGNALMENT

Species

Dog and cat

Breed Predilections

None identified but large-breed dogs have tended to be overrepresented.

Mean Age and Range

- Dogs—middle-aged, range 2–15 years. An exception is rhabdomyosarcoma of the bladder that often arises in younger dogs.
- Cats—middle-aged, range 1.4–18.8 years.

Predominant Sex

No predilection

SIGNS

Historical Findings

- Typically slow-growing, non-painful, fluctuant to firm mass (weeks to months).
- Rapid growth uncommon unless high grade.
- Signs depend on location and local structures affected by tumor presence or invasion.
- Tumors arising in the abdomen may elicit signs due to compression of the GI tract and could include vomiting and/or diarrhea, anorexia, and weight loss. Additionally signs of intestinal obstruction and occasionally perforation can occur with GI leiomyosarcoma.
- Urinary signs of hematuria and dysuria may be seen in young dogs with bladder rhabdomyosarcoma.
- Peripheral nerve sheath tumors affecting the brachial or lumbosacral plexus can cause signs of lameness and pain, muscle atrophy, limb weakness progressing to paralysis.
- Signs of hypoglycemia such as weakness, collapse, and seizures can occur with leiomyoma or leiomyosarcoma.

Physical Examination Findings

- Soft tissue mass that is soft, fluctuant, or firm on palpation.
- Often adhered to underlying tissue.
- Non-painful unless ulcerated or invading into muscles or nerves.

CAUSES

- *Dogs*—STS have been documented following radiation therapy, trauma, orthopedic implants, foreign bodies, and the parasite *Spirocerca lupi*.
- *Cats*—STS have arisen at sites of previous injections including vaccines.

RISK FACTORS

See above under "Causes"

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Abscess
- Cutaneous tumors such as adnexal tumors, basal cell tumors and mast cell tumors
- Fungal infection with granuloma formation

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Hypoglycemia can arise as a paraneoplastic syndrome in dogs with leiomyoma or leiomyosarcoma.

OTHER LABORATORY TESTS

N/A

IMAGING

- Three-view thoracic radiographs are recommended before treatment as the lungs are a common site of metastasis for STS.
- Imaging of the local extent of tumor may be indicated to plan surgery or radiation

treatment if the tumor is adherent to underlying structures. Contrast CT or MRI can be used to determine extent of disease and to optimize treatment planning.

- Abdominal ultrasound may be indicated for diagnosis of intra-abdominal STS and to allow assessment of liver, spleen, and abdominal lymph nodes.

DIAGNOSTIC PROCEDURES

- Fine-needle aspiration and cytology help to rule out other differential diagnoses and may provide tentative diagnosis but a non-diagnostic sample is possible as cells do not always exfoliate well.
- Incisional biopsy and histopathology is essential to confirm diagnosis, determine grade of the tumor, and plan surgical approach.
- Regional lymph node evaluation (cytology or histopathology) is indicated for assessment of enlarged regional lymph nodes and for high-grade tumors to confirm or deny presence of regional metastases.

PATHOLOGIC FINDINGS

Dogs

- Over 20 different histopathologic subtypes of STS exist; histologic distinction between tumor types is not necessary given the similarities in biologic behavior.
- Histologic grading based on differentiation, number of mitotic figures per 10 high power fields and percentage necrosis.
 - Grade I (low grade)
 - Grade II (intermediate grade)
 - Grade III (high grade) representing the most biologically aggressive grade.

Cats

- Some similarities between histopathologic subtypes compared to dogs. Peripheral nerve sheath tumors are rare in cats.
- Vaccine or injection site sarcomas have a more aggressive histologic appearance compared to other sarcomas.

TREATMENT

NURSING CARE

N/A

CLIENT EDUCATION

Early aggressive surgical management of STS is recommended for the best outcomes in both cats and dogs.

SURGICAL CONSIDERATIONS

- Early, aggressive, *en bloc* surgical excision is the treatment of choice. Conventional recommendations are 3 cm margins and 1 fascial plane deep (2 fascial planes deep for feline injection site sarcoma).
- Microscopically, cancer cells extend far beyond gross tumor borders.
- Pseudocapsule composed of compressed cancer cells is common.

SOFT TISSUE SARCOMA

(CONTINUED)

- The tumor should be excised *en bloc*; if it is peeled out, a healthy bed of cancer cells is left behind and can lead to tumor regrowth.
- Submit the entire sample to a pathologist for surgical margin evaluation; applying ink to surgical borders is advised to thoroughly evaluate margins.
- Toe or limb amputation may be necessary with large tumors that may be otherwise unresectable.
- Rib resection or abdominal wall resection may be required for tumors of the trunk.
- The first surgery usually provides the best opportunity for local tumor control.

RADIATION THERAPY

Dogs

Radiation therapy should be considered an option when complete surgical excision is not possible and can be applied on microscopic disease (postoperatively, fractionated) or on gross disease (hypofractionated).

Cats

Given the high rate of recurrence with feline injection site sarcoma following complete surgical resection, fractionated radiation therapy should be considered.

MEDICATIONS

DRUG(S) OF CHOICE

Dogs

- Doxorubicin-based chemotherapy is not consistently reported as beneficial but is often recommended after excision of a high-grade (grade III) tumor.
- Doxorubicin alone (1 mg/kg for small dogs or 30 mg/m² for medium and large dogs, IV, 5 doses q14–21 days).
- Low-dosage (or metronomic) cyclophosphamide chemotherapy (10 mg/m² PO q48h) in combination with piroxicam (0.3 mg/kg PO q24–48h) may help delay local recurrence when the tumor is incompletely resected.

Cats

- Role of postoperative chemotherapy in cats with STS is unclear. Chemotherapy treatment may improve local disease control but has minimal effect on survival in cats following wide surgical excision or RT.
- Doxorubicin alone (1 mg/kg IV q3 weeks for 5 doses).

CONTRAINDICATIONS AND PRECAUTIONS

- Doxorubicin—is cardiotoxic and should be avoided in dogs with underlying cardiac disease as cardiac failure can result. This drug is nephrotoxic in cats and should be avoided in cats with underlying renal disease. This drug is myelosuppressive in both dogs and cats and possesses vesicant properties. Severe local tissue necrosis can occur if extravasation occurs.
- Cyclophosphamide—can result in hemorrhagic cystitis. Monitor for signs of hematuria and pollakuria; discontinue medication if this occurs.

POSSIBLE INTERACTIONS

- Doxorubicin—none
- Cyclophosphamide—none

ALTERNATIVE DRUGS

Analgesic therapy should be administered as needed if pain or discomfort is present.

FOLLOW-UP

PATIENT MONITORING

Patient should be monitored for local regrowth and distant metastases with repeat physical examination and thoracic radiographs every 3 months for the first year, then every 6 months thereafter.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Surgical complications including infection or incisional dehiscence.
- Chemotherapy-related myelotoxicity, cardiotoxicity (dogs) or nephrotoxicity (cats).

EXPECTED COURSE AND PROGNOSIS

- Local recurrence, metastasis, and overall survival time is greatly affected by histologic grade as determined by an anatomic pathologist. Other factors that increase the risk of tumor recurrence are large tumor size at surgery (> 5 cm) and incomplete surgical margins.
- Cure from disease is possible with low and intermediate grade STS with treatment with wide surgical resection or surgery and adjuvant RT with median survival times of over 3 years.
- In many cases when STS are incompletely excised the tumor may recur within a year. Treatment options for dogs and cats following

incomplete tumor excision include staged scar resection to assess for residual tumor (to direct further treatment), wide surgical excision of scar or full-course fractionated RT.

- High-grade tumors carry a more guarded prognosis with a shorter median survival time of 1–2 years.

MISCELLANEOUS

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

While receiving chemotherapy drugs dogs should not be bred.

SYNONYM

Spindle cell tumor of canine soft tissue

ABBREVIATIONS

- CT = computed tomography
- MRI = magnetic resonance imaging
- RT = radiation therapy
- STS = soft tissue sarcoma

SPERMATOCELE/SPERM GRANULOMA

BASICS

OVERVIEW

- Spermatocele—a cystic distension of the efferent ductules or epididymis containing spermatozoa, usually associated with loss of patency of the duct.
- Sperm granuloma—the granulomatous chronic inflammatory reaction that develops when spermatozoa escape from the efferent ductules or epididymal duct into the surrounding tissue; clinically important when bilateral obstruction of the duct system leads to azoospermia.

SIGNALMENT

Dog and cat

SIGNS

- Suspected in azoospermic dog with normal-sized testes.
- Rarely associated with pain, or visible or palpable lesions.

CAUSES & RISK FACTORS

- Trauma causing a break in the epididymal duct—releases sperm antigens into the surrounding tissue.
- Adenomyosis—invasion of the epithelial lining cells of the epididymis into the muscular layers; may be a factor; associated with excess estrogenic stimulation.
- Epithelial hyperplasia of the epididymis—may be a precursor of adenomyosis; not often seen in dogs < 2.5 years old; noted to some degree in 75% of dogs > 7.75 years old; risk increases with age.
- Complication of vasectomy—especially when surgical technique was not meticulous.
- Congenital occlusion of epididymal duct.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Azoospermia (dogs)—testicular degeneration; hypoplasia; retrograde ejaculation; incomplete ejaculation.

- Scrotal signs (e.g., pain and palpable lesions, dogs)—epididymitis; orchitis; scrotal dermatitis.

CBC/BIOCHEMISTRY/URINALYSIS

- Urinalysis (cystocentesis) after ejaculation—rule out retrograde ejaculation.
- CBC and biochemistry profile—usually normal.

OTHER LABORATORY TESTS

- Assay for canine FSH—high concentration associated with degeneration and hypoplasia; normal concentration in azoospermic dogs with normal-sized testicles associated with bilateral blockage of the epididymis or retrograde ejaculation.
- Alkaline phosphatase concentration of seminal plasma—azoospermic samples with AP < 5,000 U/L consistent with bilateral epididymal blockage or incomplete ejaculation; see Infertility, Male—Dogs.

IMAGING

Ultrasonography—useful to differentiate from other conditions causing scrotal enlargement.

DIAGNOSTIC PROCEDURES

Surgical testicular biopsy and excisional biopsy of affected epididymal tissue—allows identification of epididymis; assessment of spermatogenesis; spermatoceles appear as yellow cysts within the epididymis.

PATHOLOGIC FINDINGS

Histologic examination of testicular specimen—complete spermatogenesis in an azoospermic dog indicates blockage.

TREATMENT

- Azoospermic dogs—rarely spontaneously recover.
- Bilateral blockage of the epididymis—probably not treatable except by microsurgical anastomosis of the ductus deferens to the cystic structure or patent segment of the epididymis; few attempts have been made to perform this procedure in dogs.

MEDICATIONS

DRUG(S)

None described in the literature to unblock the duct system

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Unilateral sperm granuloma—fair to guarded for fertility; breeding management will improve fertility; see Breeding, Timing.
- Bilateral sperm granuloma—poor prognosis for fertility.

MISCELLANEOUS

SEE ALSO

- Breeding, Timing
- Infertility, Male—Dogs

ABBREVIATION

- FSH = follicle-stimulating hormone

Consulting Editor Sara K. Lyle

SPERMATOZOAL ABNORMALITIES

BASICS

OVERVIEW

- Teratozoospermia—presence of significant amounts ($\geq 40\%$) of spermatozoal abnormalities in the ejaculate.
- High percentage of spermatozoal abnormalities may cause infertility in dogs.
- Some fertile cats inherently have $\geq 40\%$ spermatozoal abnormalities.
- Spermatozoal abnormalities are sometimes classified into primary and secondary defects; primary defects occur during spermatogenesis, and secondary defects occur during transport and storage within the epididymis, or from inappropriate semen handling.

SIGNALMENT

- Dogs and cats of any age; older dogs and cats most likely to have other age-related conditions affecting sperm quality.
- No breed predilection for dogs or cats; Irish wolfhounds reported to have significantly lower semen quality than dogs of other breeds.

SIGNS

- Infertility after appropriately timed mating to several reproductively proven bitches.
- Spermatozoal abnormalities found during routine breeding soundness evaluation.

CAUSES & RISK FACTORS

Congenital

- Dogs with fucosidosis—lysosomal storage disease caused by a deficiency of the enzyme α -l-fucosidase; acrosomal defects and retention of proximal droplets are common; English springer spaniels—autosomal recessive inheritance pattern.
- Primary ciliary dyskinesia—ultrastructural abnormality of cilia causing absent or abnormal motility of ciliated cells; affected animals are infertile; probably autosomal recessive inheritance.
- Idiopathic—dogs, cats with inherent poor sperm morphology.
- Testicular hypoplasia—tortoiseshell or calico tomcat.
- Inbreeding in domestic cats produces significant reduction in percent morphologically normal cells within one generation.

Acquired

- Conditions disrupting normal testicular thermoregulation—trauma; hematocoele; hydrocele; orchitis; epididymitis; fever; obesity (increased scrotal fat); high environmental temperatures; exercise-induced heat exhaustion.
- Infections of the reproductive tract—prostatitis; brucellosis; orchitis; epididymitis.
- Drugs—anabolic steroids; androgens; estrogens; progestagens; corticosteroids; ketoconazole; amphotericin

B; cimetidine; phytoestrogen (coumestrol); GnRH antagonists (Acyline); intratesticular injections of zinc arginine • Testicular neoplasia • Prolonged sexual abstinence • Overuse • Testicular degeneration

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Excessive numbers of kinked or coiled tails may be iatrogenic artifacts caused by the eosin-nigrosin stain; reexamine the sample under phase contrast microscopy after dilution with formalin phosphate-buffered saline solution.

OTHER LABORATORY TESTS

- Hormonal profile—concentrations of gonadotropin (FSH) and steroid hormones should be determined to rule-out endocrinopathies.
- Azoospermic ejaculates should be examined for the presence of alkaline phosphatase to confirm azoospermia; complete ejaculates have $> 5,000$ U/L of alkaline phosphatase.
- Brucellosis—rapid slide agglutination test—used as a screening test (D-Tec[®] CB, Zoetis; (888)-963-8471); recommend recheck of dogs with positive slide test with agar gel immunodiffusion test (Cornell University Diagnostic Laboratory; (607)253-3900) or bacterial culture of whole blood or lymph node aspirate.

IMAGING

Ultrasonography—to diagnose testicular tumors, orchitis, hydrocele, hematocoele, spermatocele.

DIAGNOSTIC PROCEDURES

- Bright-field microscopic evaluation of dry-mount slide—eosin-nigrosin stain (Society for Theriogenology stain; Lane Manufacturing, Denver, CO) or modified Giemsa stain (Diff-Quik, Baxter Healthcare, Deerfield, IL) is used to stain spermatozoa; recommended to use pre-warmed stain and prepare slides on a heated slide warmer; faster drying decreases the incidence of artifacts such as kinked tails or coiled tails; a minimum of 100 (preferably 200) sperm cells are counted under 1,000X magnification.
- Acrosome staining—acrosomal damage can be evaluated by Coomassie Brilliant blue (Bio-Rad Laboratories, Hercules, CA) staining or Spermac stain (Conception Technologies, San Diego, CA), marketed for human sperm but works very well with dog sperm.
- Phase contrast or differential interference contrast light microscopic evaluation of wet-mount slide—samples diluted with formalin phosphate-buffered saline solution; verify

whether a high percentage of kinked or coiled tails seen on a stained slide is staining artifact.

PATHOLOGIC FINDINGS

- Biopsy—incisional biopsy or testicular fine-needle aspirate to determine status of spermatogenesis.
- Absence of spermatids or spermatocytes—impaired spermatogenesis.
- Neoplasia • Inflammation—peritubular lymphocytic accumulation • Degenerative changes • Hypoplasia

TREATMENT

- There is no specific treatment for spermatozoal abnormalities; if applicable, the underlying disease or condition should be treated accordingly.
- Antibiotics and anti-inflammatory agents for infectious diseases.
- Unilateral orchectomy for unilateral testicular tumors or severe orchitis.
- Sexual rest for edema or hematocoele associated with trauma.
- Frequent semen collection may temporarily improve sperm quality in dogs or cats with idiopathic teratozoospermia.
- Remove the dog or cat from environments that cause extreme heat stress.
- Alter exercise to reduce heat stress.

MEDICATIONS

CONTRAINDICATIONS

- Exogenous hormones—anabolic steroids; estrogens; testosterone; progestagens.
- Glucocorticoids.
- Chemotherapeutic agents.
- Ketoconazole; amphotericin B.
- Cimetidine.

FOLLOW-UP

PATIENT MONITORING

- If an underlying cause is identified and treated, a sperm evaluation should be performed at 30 and 70 days after the condition is resolved.
- In cases due to reversible causes, a complete improvement in sperm morphology does not occur before 70 days (approximate length of a complete spermatogenic cycle).

PREVENTION/AVOIDANCE

- Climate-controlled environment for animals not adapted to high environmental temperatures.
- Avoid heat exhaustion during exercise or grooming.

Author Carlos R.F. Pinto

Consulting Editor Sara K. Lyle

SPIDER VENOM TOXICOSIS—BLACK WIDOW

BASICS

OVERVIEW

- Black widow spider—*Latrodectus* spp. (4 species indigenous to the United States (*L. mactans*, *L. geometricus*, *L. hesperus*, *L. variolus*); females toxic; 2–2.5 cm in length; shiny black; red or orange hourglass mark on the ventral abdomen; immature female brown with red to orange stripes that change into the hourglass shape as she darkens to black and ages.
- Bites—15% may be dry (no venom injected).
- Range—genus found in every state except Alaska; often found around buildings and human habitation.
- Venom—contains α -latrotoxin, a potent neurotoxin; opens cation-selective channels at the presynaptic nerve terminal; causes massive release of acetylcholine and norepinephrine, which causes sustained muscular spasms.

SIGNALMENT

Dogs and cats

SIGNS

Historical Findings

- Usually sudden onset.
- May be delayed several days with mild envenomation.

Physical Examination Findings

Dogs

- Progressive muscle fasciculations.
- Severe pain.
- Cramping of large muscle masses.
- Abdominal rigidity without tenderness.
- Marked restlessness, writhing, and contorted spasms.
- Hypertension and tachycardia anticipated.
- May note bronchorrhea, hypersalivation, hyperesthesia, lymph node tenderness, regional numbness, facial swelling and spasm (referred to as *Latrodectus facies*).
- Rhabdomyolysis possible.

Cats

- Early, marked paralysis.
- Severe pain—manifested by howling and loud vocalizations.
- Excessive salivation and restlessness.

- Vomiting—not unusual to vomit up the spider.
- Diarrhea.
- Muscle tremors and cramping.
- Ataxia and inability to stand—becomes adynamic and atonic.
- Respiratory collapse.
- Death without antivenin.

CAUSES & RISK FACTORS

- Very young or old age—increased risk
- Systemic hypertension—increased risk

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Intervertebral disc disease
- Acute abdomen

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis
- High creatine kinase—with severe muscle spasms
- Albuminuria

OTHER LABORATORY TESTS

Normal hemoccult test

IMAGING

Normal abdominal radiographs

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Inpatient—supportive care
- Monitor respiratory status

MEDICATIONS

DRUG(S)

- Antivenin (Lyovac [*Latrodectus*], equine origin)—1 vial mixed with 100 mL crystalloid solution IV given slowly with monitoring of the inner ear pinna for evidence of hyperemia (indicator of allergic response); dose usually sufficient for response within 30 minutes; with proper use, reactions

are rare. Variable availability. If allergic reaction occurs—stop antivenin; administer diphenhydramine; after 5–10 minutes, restart antivenin at a slower rate.

- New antivenin (Aracmyn—Instituto Bioclon, Mexico) has completed human phase III clinical trials but not yet approved for human use. It is an equine origin Fab₂ product and should be much less likely to trigger an allergic response.
- Studies suggest benzodiazepines are more effective than muscle relaxants for treatment of muscle pain related to black widow spider envenomation.
- Muscle spasms and severe pain are controlled by careful intravenous administration of narcotics or benzodiazepines at lowest effective dosage to avoid respiratory depression; methocarbamol relieves muscle spasms but has no effect on hypertension or respiratory depression.
- Intractable hypertension—sodium nitroprusside.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Intravenous fluids with hypertension

FOLLOW-UP

- Weekly monitoring of the wound site until healed
- Prognosis—uncertain for days; cats, usually fatal without antivenin
- Weakness, fatigue, and insomnia—may persist for months

SPIDER VENOM TOXICOSIS—BROWN RECLUSE

BASICS

OVERVIEW

- Brown recluse family—*Loxosceles* spp. (11 species indigenous to USA); 8–15 mm in body size; legs 2–3 cm long; violin-shaped pattern on cephalothorax with the neck of the fiddle extending caudally; 6 eyes (3 paired diads) as opposed to other spider species with 8 eyes; active at night.
- Distribution—found throughout the Midwest from the Gulf Coast of the United States and up the Mississippi River valley to southern Iowa. Some species are found in eastern southern California, western Arizona, and southern New Mexico.
- Sixty percent of “brown recluse” spider bites in humans are misdiagnosed as they occur in areas with no endemic spider populations. See extensive “Differential Diagnosis” below.
- Bites—usually occur when spider becomes trapped in bedding; induce necrotic arachnidism, an indolent dermatonecrotic lesion mediated by the venom enzyme sphingomyelinase D, direct hemolysis of erythrocytes, platelet aggregation, renal failure, coagulopathy, and death.
- Currently no general consensus on treatment and multiple therapies have been used ranging from antihistamines, corticosteroids, dapsone, hyperbaric oxygen, and surgical excision to antivenom.
- Antivenom currently unavailable in USA (available only in Argentina, Brazil, and Mexico).

SIGNALMENT

Dogs and cats

SIGNS

- Clinical signs are not completely defined in canine and feline envenomations.
- In humans:
 - Local pain and stinging (may last 6–8 hours); followed by pruritus and soreness.
 - Classic target lesion—ischemic area with a dark central eschar on an uneven erythematous background; after 2–5 weeks, central eschar may slough, leaving a deep, non-healing ulcer that usually spares muscle tissue.
 - Less common—hemolytic anemia with hemoglobinuria in the first 24 hours; secondary renal complications.
 - Other possible systemic manifestations within the first 2–3 days after envenomation—fever; chills; rash; weakness; leukocytosis; nausea; arthralgia.
 - Envenomations to fatty areas develop more significant lesions.

CAUSES & RISK FACTORS

Brown recluse spider bite (genus *Loxosceles*)

DIAGNOSIS

- Brown recluse spider bite is frequently misdiagnosed in regions of the country that do not have endemic populations of the spider.
- Epidemiologic history of bite including site of lesion, progression timeline of signs, and visualization of small puncta assist with diagnosis.

DIFFERENTIAL DIAGNOSIS

- Bacterial or mycobacterial infection; MRSA by a large margin in humans
- Decubitus ulcer
- Third-degree burn
- Hemolytic anemia
- Jaundice
- Necrotizing vasculitis
- Thrombocytopenia
- Ehrlichiosis
- RBC parasitism
- Vascular occlusive/venous disease

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia
- Leukocytosis
- Thrombocytopenia
- Hemoglobinuria

OTHER LABORATORY TESTS

- BUN and creatinine.
- Coagulation profile—may reveal prolonged clotting times.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Routine wound care—may need aggressive supportive care.
- Supportive care—may include fluid therapy; presumptive treatment of bacterial superinfection; (rarely) blood transfusion.
- Mild, local envenomation—usually responds to cool compresses as sphingomyelinase D activity is temperature-dependent.
- Necrotic lesions—may need debridement after erythema has subsided.
- Severe envenomation—may require skin grafting after the lesion reaches full maturity.

MEDICATIONS

DRUG(S)

- Antibiotics—prevent secondary infection.
- Hyperbaric oxygen—some evidence indicates that hyperbaric oxygen treatment

may be beneficial for reducing size of the skin lesion.

- Dapsone—mixed results in various studies. 1 mg/kg q8h for 10 days; for dermatonecrotic lesions; leukocyte inhibitor; proposed to minimize inflammatory component of the envenomation; repeat if needed. Efficacy against brown recluse envenomation has not been studied in the dog and cat.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Do not use heat—exacerbates condition.
- Dapsone—may cause hypersensitivity and methemoglobinemia in patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency.
- Early surgical excision may cause larger defect than supportive care alone.
- Antihistamines, colchicine, anticoagulants, topical nitroglycerine, high doses of vitamin C, electric shock, and steroids have been proposed for treatments, but subsequently have been demonstrated to be ineffective.

FOLLOW-UP

Monitor wound site weekly until healed.

MISCELLANEOUS

ABBREVIATIONS

- BUN = blood urea nitrogen
- MRSA = methicillin resistant *Staphylococcus aureus*
- RBC = red blood cell

SPINAL DYSRAPHISM

BASICS

OVERVIEW

- Abnormal spinal cord development along the median plane leading to a variety of structural anomalies—hydromyelia, duplicated or absent central canal, syringomyelia, and aberrations in the dorsal median septum and ventral medial fissure.
- Thoracic and lumbar spinal segments most commonly affected. • Dysraphism suggests an abnormality in closure of the neural tube; the term “myelodysplasia” may be preferable.

SIGNALMENT

Non-progressive

- Dog and cat. • Weimaraner—hereditary.
- Reported in English bulldog, Samoyed, Dalmatian, English setter, golden retriever, rottweiler, Manx cat. • No sex predilection.
- Signs apparent by 3–6 weeks of age—become more obvious as animal matures. In mild cases, may not be presented for examination until several months of age.

Progressive

- Adult Cavalier King Charles spaniels with syringomyelia resulting from occipital bone malformation (Chiari-like malformation; caudal occipital malformation syndrome [COMS]). • Adult Pomeranian with cervical syringomyelia and hydrocephalus. • Adult fox terrier with progressive paresis in the left pelvic limb.

SIGNS

Vary in severity.

Dogs

- Weimaraner—simultaneous flexion and extension of pelvic limbs (bunny hopping); proprioceptive deficits, base wide stance, and crouched pelvic limb posture. • Cavalier King Charles spaniel—neck or head pain; progressive forelimb weakness, paraparesis; imbalance; paroxysmal involuntary flank or neck scratching. • Less common signs include abnormal hair streams in the dorsal cervical area, kinking of the undocked tail, scoliosis, and koiosternia (depression of the sternum).

Cats

Manx cat—pelvic limb paresis or paralysis, urinary and fecal retention.

CAUSES & RISK FACTORS

- Genetic—Weimaraner; homozygous condition lethal; heterozygotes clinically affected. • *In utero* spinal cord damage caused by infection, trauma, and vascular compromise may cause syringomyelia (cavitation of the spinal cord). • Idiopathic in isolated patients. • Syringomyelia may be acquired as result of infection, trauma, or neoplasia. • Manx cat—breeding for absence of tail.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Intervertebral disc disease, myelitis, arachnoid cysts, and neoplasia must be differentiated from progressive causes of syringomyelia.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

IMAGING

- Survey radiographs and myelography—associated vertebral column anomalies and spinal cord compression in some patients.
- Without sophisticated imaging techniques, an antemortem diagnosis may be impossible except in Weimaraner and Manx cat.
- MRI—definitive imaging modality for syringomyelia, attenuation of fourth ventricle, overcrowding of brainstem in caudal fossa, and cerebellar vermal herniation (COMS, Chiari-like malformation); hydrocephalus if evident. • CT—reveal hydrocephalus, if evident, with COMS. • Skull radiographs—occipital bone defect may be demonstrated.

TREATMENT

- Mildly affected animals—may be acceptable pets. • Severely affected animals may benefit from a canine cart; consider euthanasia.
- Surgical considerations—foramen magnum remodeling (with occipital malformation) or ventriculoperitoneal shunt placement; laminectomy, ± syringo-subarachnoid shunting (may reduce pain or improve neurologic signs; sensory disturbances such as scratching infrequently resolve, and recurrence is possible).

MEDICATIONS

DRUG(S)

- Antibiotics—for urinary tract infection. Treat based on culture and sensitivity of urine.
- Corticosteroids—to improve signs in COMS by reducing CSF production and edema formation. Prednisone 0.25–0.5 mg/kg q12h or dexamethasone 0.025–0.05 mg/kg PO q12h; taper to alternate-day prednisone or twice-weekly dexamethasone.
- Carbonic anhydrase inhibitors—may alleviate signs in COMS by decreasing CSF production and allow for a reduction of steroid dosage. Acetazolamide 3.5–7.5 mg/kg q8–12h; methazolamide 5 mg/kg q8–12h or furosemide 5 mg/kg PO, IM, SC q12h.
- Omeprazole—decreases CSF production and may alleviate signs in COMS and allow

for a reduction of steroid dosage. Clinical data on use and effectiveness currently lacking; 0.5–1 mg/kg PO q24h. • Gabapentin—recommended for management of neuropathic pain; 10 mg/kg q8–12h.

- NSAIDs—may help manage neuropathic pain. Meloxicam (Metacam) 0.2 mg/kg once then 0.1 mg/kg q24h in dogs; carprofen (Rimadyl) 2.2 mg/kg PO q12h or 4.4 mg/kg PO q24h in dogs.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Avoid prolonged administration of NSAIDs, or combinations of NSAIDs and steroids because of risks of gastrointestinal ulceration and renal pathology. • Do not use NSAIDs in cats.

FOLLOW-UP

PATIENT MONITORING

- Secondary urinary tract infection—seen in severely affected animals; owing to disorders of micturition. • Avoid decubitus ulcers and urine and fecal scalds by properly caring for recumbent patients.

PREVENTION/AVOIDANCE

- Discourage breeding for absence of tail in Manx cats. • Do not breed Weimaraners that have produced affected puppies because of codominant inheritance.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Congenital vertebral arch (e.g., spina bifida) and vertebral body-disc malformation (e.g., hemivertebra and block vertebra)—alone often does not cause clinical signs.

ABBREVIATIONS

- COMS = caudal occipital malformation syndrome • CSF = cerebrospinal fluid
- CT = computed tomography • MRI = magnetic resonance imaging • NSAID = nonsteroidal anti-inflammatory drug

SPLENIC TORSION

BASICS

OVERVIEW

- May occur as a separate entity or in association with gastric dilatation-volvulus syndrome.
- Acute or chronic.
- Pathophysiology—unknown.
- Systems affected—hemic/lymphatic/immune and cardiovascular.
- Isolated splenic torsion uncommon.

SIGNALMENT

- More common in large-breed, deep-chested dogs, such as German shepherd, standard poodle, and Great Dane.
- No sex predilection.

SIGNS

Historical Findings

- Acute—cardiovascular collapse and abdominal pain.
- Chronic—intermittent anorexia, vomiting, weight loss, and possibly hemoglobinuria.

Physical Examination Findings

- Pale mucous membranes, tachycardia, and other signs of hypoperfusion.
- Palpable abdominal mass (spleen).

CAUSES & RISK FACTORS

- Large-breed and deep-chested dogs.
- Prior stretching of gastrosplenic, phrenicosplenic, and splenocolic ligaments (e.g., prior gastric dilatation and volvulus).
- Historical gastric dilatation.
- Excessive exercise, rolling, and retching may contribute.
- Nervousness and anxiety have been associated with an increased risk of GDV but not of isolated splenic torsion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other splenic disease (e.g., neoplasia and immune-mediated disease).

S

- Acute gastrointestinal disease with abdominal pain.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia
- Thrombocytopenia
- Leukocytosis
- High liver enzyme values
- Hemoglobinuria

OTHER LABORATORY TESTS

Coagulation test—DIC, with prolongation of clotting times and thrombocytopenia.

IMAGING

Abdominal Radiography

- Cranial or midabdominal mass may be seen.
- Spleen may be abnormally located.

Abdominal Ultrasonography

- Splenic congestion/lack of blood flow to spleen.
- Dilated splenic veins.
- Splenic infarction.

DIAGNOSTIC PROCEDURES

ECG—may show ventricular arrhythmias.

PATHOLOGIC FINDINGS

Splenic congestion and infarction.

TREATMENT

- Surgical emergency.
- After adequate cardiovascular stabilization, a splenectomy should be performed without untwisting the splenic pedicle.
- A permanent gastropexy should also be performed because of the association with gastric dilatation-volvulus syndrome.
- A splenic specimen should be submitted for histopathologic examination.
- Fluid support and cardiovascular monitoring indicated after splenectomy.

MEDICATIONS

DRUG(S)

- No specific drugs required.
- Postoperative pain relief advised.

- Heparin (unfractionated or low molecular weight) or plasma transfusion (rarely due to size of patient) may be considered if DIC and coagulopathy are documented.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None

FOLLOW-UP

Surgical correction considered curative.

MISCELLANEOUS

ABBREVIATIONS

- DIC = disseminated intravascular coagulation
- ECG = electrocardiogram
- GDV = gastric dilation and volvulus

Consulting Editor Alan H. Rebar

SPLENOMEGLY

BASICS

DEFINITION

Enlargement of the spleen; characterized as either diffuse or nodular.

PATHOPHYSIOLOGY

- Splenic functions—removal of senescent and abnormal erythrocytes; filtration and phagocytosis of antigenic particles such as microorganisms, degraded cellular material, macromolecules; production of lymphocytes and plasma cells; antibody production, reservoir for erythrocytes and platelets; iron metabolism and storage, hematopoiesis, as required. • Many disorders affect the function of the spleen.

Diffuse Splenomegaly

Four General Pathologic Mechanisms

- Inflammation (splenitis)—associated with infectious agents; classified according to cell type (e.g., suppurative, necrotizing, eosinophilic, lymphoplasmacytic, and granulomatous-pyogranulomatous).
- Lymphoreticular hyperplasia—hyperplasia of mononuclear phagocytes and lymphoid elements (in response to antigens); accelerated erythrocyte destruction. • Congestion—associated with impaired venous drainage.
- Infiltration—involves cellular invasion of the spleen or deposition of abnormal substances.

Nodular

Associated with neoplastic (tumor) or non-neoplastic disorders (infection, hyperplasia/regeneration, or inflammation).

SYSTEMS AFFECTED

Disorders of the spleen also may be associated with changes in the liver.

SIGNALMENT

- Dog and cat; certain conditions maybe more prevalent in specific breeds or sizes of dog.
- Splenic torsion—overrepresented in large, deep-chested breeds (e.g., German shepherd, Great Dane). • Hemangiosarcoma—middle-aged dogs; large breeds; predilection in German shepherd, golden retriever, and Labrador retriever. • Prominent spleen—may be normal in certain breeds (German shepherd, Scottish terrier).

SIGNS

General Comments

- Splenic enlargement—often nonspecific.
- Frequently reflects an underlying disorder rather than primary disease of the spleen.

Historical Findings

- Vomiting, diarrhea, anorexia—can be seen with infiltrative diseases such as lymphoma, mast cell tumor, FIP, lymphoplasmacytic enteritis (cats). • Lethargy, anorexia, vomiting, vague abdominal pain (in acute cases pain can be severe), mild to moderate

abdominal distention in deep-chested large-to giant-breed dogs (Great Dane, German shepherd overrepresented) — associated with splenic torsion (with or without concurrent gastric dilatation volvulus). • Weakness, lethargy, collapse (can be episodic), abdominal distention—can indicate a hemoabdomen secondary to hemangiosarcoma, bleeding/ruptured spleen from other neoplasia (rare) or benign conditions such as a hematoma.

Physical Examination Findings

- Prominent spleen on abdominal palpation or cranial/midabdominal mass; non-palpable spleen does not preclude splenomegaly.
- Dogs—smooth or irregular surface.
- Cats—usually diffuse, uniform enlargement. • Pallor, poor capillary refill time, poor peripheral pulses and tachycardia if splenic hemorrhage or splenic torsion.
- Abdominal distention if massive splenomegaly or splenic rupture (effusion).
- Petechia and ecchymosis if coagulopathy secondary to primary splenic disorder or underlying disease. • Concurrent hepatomegaly, thickened intestines, and/or mesenteric lymphadenopathy imply infiltrative or inflammatory disease.
- Peripheral lymphadenomegaly—suggests lymphoma leukemia. • Cardiac arrhythmias—may indicate clinically significant cardiac abnormality affecting the spleen (congestion) but ventricular arrhythmias also are associated with primary splenic disorders.

CAUSES

Dogs

Inflammation (Splenitis)

- Inflammatory cell type can help prioritize differentials. • Suppurative—penetrating abdominal wound; migrating foreign body; endocarditis; sepsis; infectious complication of splenic torsion. • Necrotizing—usually secondary to torsion or neoplasia; anaerobes; *Salmonella*; acute infectious canine hepatitis. • Eosinophilic—eosinophilic gastroenteritis. • Lymphoplasmacytic—subacute or chronic infectious disorders; infectious canine hepatitis; ehrlichiosis; pyometra; *Brucella*; *Leishmania*; coexistent inflammatory bowel disease. • Granulomatous—histoplasmosis; *Leishmania*. • Pyogranulomatous—blastomycosis; *Mycobacterium*; sporotrichosis.

Hyperplasia

- Infection—chronic bacteremia (bacterial endocarditis; discospondylitis; *Brucella*). • Immune-mediated disease—SLE; hemolytic anemia or thrombocytopenia.

Congestion

- Tranquillizers; barbiturates; portal hypertension; right-sided heart failure; splenic torsion.

Infiltration

- Neoplasia—lymphoma; acute and chronic leukemia; histiocytic sarcoma; multiple

myeloma; systemic mastocytosis; hemangiosarcoma, fibrohistiocytic nodule; metastatic neoplasia. • EMH—immune-mediated hemolytic anemia or thrombocytopenia; chronic anemia; infectious disease; malignancy; SLE. • Amyloidosis.

Cats

Inflammation

- Suppurative—penetrating wound or migrating foreign body; septicemia; salmonellosis. • Necrotizing—salmonellosis.
- Eosinophilic—hypereosinophilic syndrome.
- Lymphoplasmacytic—lymphoplasmacytic enteritis; hemotropic mycoplasmas; pyometra.
- Granulomatous—histoplasmosis; mycobacteriosis. • Pyogranulomatous—FIP, *Mycobacterium*.

Hyperplasia

- Infection—hemotropic mycoplasmosis.
- Immune-mediated—chronic hemolysis, SLE.

Congestion

Portal hypertension, congestive heart failure.

Infiltration

- Neoplasia—mast cell tumor (most common); lymphoma; lymphoproliferative disease; myeloproliferative disease; histiocytic sarcoma; multiple myeloma; hemangiosarcoma (rare). • Non-neoplastic—amyloidosis, EMH.

RISK FACTORS

- Cats—FeLV, FIP • Dogs—breed/age

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other cranial organomegaly or masses

CBC/BIOCHEMISTRY/URINALYSIS

Dogs

- Regenerative anemia secondary to splenic bleeding or hemolytic disease. • Nucleated RBC—may accompany EMH, indicates splenic dysfunction. • Spherocytes—hemolysis, microangiopathic shearing (schistocytes also). • Leukocytosis with a left shift—may indicate infectious or inflammatory conditions, marked regenerative response, or EMH.
- Thrombocytopenia—from increased consumption (DIC or bleeding) secondary to hemangiosarcoma or other neoplasia, increased destruction (immune-mediated), sequestration, or decreased production in the bone marrow. • Hypercalcemia may be associated with neoplasia, especially lymphoma. • Hyperglobulinemia may be associated with neoplasia or *Ehrlichia* infections. • Hemoglobinemia and hyperbilirubinemia—may occur with microangiopathic anemia, splenic torsion, hemangiosarcoma, and immune-mediated anemia with spleen as site of extravascular RBC removal.

SPLENOMEGLY

(CONTINUED)

Cats

- Direct RBC examination for hemoparasites.
- Regenerative anemia and splenomegaly—may indicate hemotropic mycoplasmosis.
- Macrocytosis and nonregenerative anemia—suggests retroviral infection or myeloproliferative disease.
- Eosinophilia—suggests hypereosinophilic syndrome, systemic mastocytosis, or lymphoma.
- Circulating blast cells—suggest myeloproliferative or lymphoproliferative disorder.
- Nucleated RBCs—may accompany EMH and splenic dysfunction.
- Thrombocytopenia—from increased consumption (DIC), increased destruction (immune-mediated), sequestration, or decreased production in the bone marrow.

OTHER LABORATORY TESTS

- FeLV and FIV testing.
- Buffy coat smears—circulating mast cells (may occur with inflammatory disease and neoplasia); blast cells.
- Coagulation panel—DIC commonly seen with hemangiosarcoma (includes prolonged clotting times, hypofibrinogenemia, and increased FDPs; d-dimers not specific for clinical application in differential diagnoses).

IMAGING

Abdominal Radiography

- Confirms or detects splenomegaly.
- Mass effect may appear in the left midcranial abdomen.
- May provide evidence of an underlying cause—concurrent hepatomegaly may indicate infiltrative disease or right-sided heart disease; splenic torsion may occur secondary to gastric dilation or volvulus.
- Effusion—may indicate hemorrhage from splenic rupture (hemangiosarcoma, hematoma) or portal hypertension influencing splenic perfusion. Visualization of the splenic tail along the ventral body wall on lateral radiographs of cats supports the diagnosis of splenomegaly.

Thoracic Radiography

- Three views (right and left lateral and dorsal-ventral views)—screen for metastasis and underlying disease in thoracic cavity and effusion.
- Evaluate sternal lymph nodes—these drain the abdominal cavity, reflecting disorders causing lymphadenomegaly.
- Evaluate for signs of congestive heart failure (size of the cardiac silhouette and pulmonary veins and evidence of pulmonary edema or pleural effusion).

Abdominal Ultrasonography

- Distinguishes between diffuse and nodular parenchymal patterns; nodular abnormalities easily identified.
- Diffuse enlargement with normal parenchyma—may occur with congestion or cellular infiltration.
- Hypoechoogenicity—may occur with splenic torsion, splenic vein thrombosis, lymphoma, or leukemia.
- Complex, mixed echogenic mass—hemangiosarcoma or hematoma.
- Hematomas—variable echogenicity; may

have internal septation and encapsulation and pass through a stage where they resemble target lesions suggesting neoplasia.

- Can identify concurrent abdominal diseases—liver, kidneys, intestines, and lymph nodes.
- Cannot differentiate between benign and malignant splenic disorders.
- Doppler color flow interrogation of splenic vasculature may detect splenic vein thrombi or splenic torsion.

Echocardiography

Evaluation of right atrium for mass lesions—when hemangiosarcoma suspected (based on ultrasonographic appearance and hematology) or to determine if there is cardiac disease causing splenic congestion.

DIAGNOSTIC PROCEDURES

Fine-Needle Aspiration

- Assess coagulation status before any aspiration.
- Procedure—patient in right lateral or dorsal recumbency; use a 23- or 25-gauge, 2.5–3.75 cm (1–1.5 in.) length needle; using ultrasound guidance.
- Non-aspiration method (when negative pressure is NOT applied to the syringe) results in higher yield of nucleated cells relative to the amount of blood than aspiration method.
- Specimens—evaluate cytologically for infectious agents (often found in macrophages); identify predominant inflammatory or infiltrative cell type.
- Neoplastic infiltrates—classified as epithelial, mesenchymal, or discrete (round cell).
- Aspiration of cavitated masses may cause rupture and is not recommended.

Bone Marrow Aspiration

- Indicated with cytopenias before splenectomy (spleen may be supporting hematopoiesis).
- May yield an infectious disorder (e.g., ehrlichiosis, mycosis, toxoplasmosis, leishmaniasis) or hematopoietic neoplasia.

TREATMENT

- Depends on underlying cause; supportive nursing care as needed.
- Important to determine if splenomegaly is appropriate for systemic conditions.
- Treatment and prognosis after splenectomy—based on histopathologic features: hemangiosarcoma may be missed in some tumors owing to regional necrosis with diagnosis rendered of hematoma.

SURGICAL CONSIDERATIONS

Splenectomy

- With anemia or leukopenia—rule out bone marrow aplasia/hypoplasia before surgery; spleen may be the source of hematopoiesis.
- Indicated for splenic torsion, splenic rupture, isolated splenic masses considered likely to be neoplastic, and mast cell infiltration (cats).
- Exploratory laparotomy—permits direct evaluation of all abdominal organs.

MEDICATIONS

DRUG(S)

Depend on underlying disease

FOLLOW-UP

PATIENT MONITORING

Ventricular arrhythmias (dogs)—associated with splenic mass lesions or torsion; may occur before, during, and up to 3 days post-splenectomy; evaluate (auscultation and electrocardiogram) surgical candidates before anesthesia; continuous cardiac monitoring during surgery and postoperatively.

POSSIBLE COMPLICATIONS

- Asplenic patient—increased risk of infection and red cell parasitism.
- Postoperative sepsis—uncommon complication.
- Antibiotics—indicated in asplenic patients receiving immunosuppressive therapy, if any sign of infection apparent.

MISCELLANEOUS

AGE-RELATED FACTORS

Neoplastic causes more likely in geriatric animals.

ZOONOTIC POTENTIAL

A variety of infectious diseases may involve the spleen.

SEE ALSO

See "Causes"

ABBREVIATIONS

- DIC = disseminated intravascular coagulation
- EMH = extramedullary hematopoiesis
- FDP = fibrin degradation product
- FeLV = feline leukemia virus
- FIP = feline infectious peritonitis
- FIV = feline immunodeficiency virus
- RBC = red blood cell
- SLE = systemic lupus erythematosus

Consulting Editor Sharon A. Center

SPONDYLOYSIS DEFORMANS

BASICS

OVERVIEW

- Degenerative, non-inflammatory condition of the vertebral column characterized by the production of osteophytes along the ventral, lateral, and dorsolateral aspects of the vertebral endplates.
- Most common location—dogs: thoracolumbar spine in the area of the antecervical vertebra and the upper lumbar vertebrae; cats: thoracic vertebrae.

SIGNALMENT

- Dog and cat.
- Dogs—commonly seen in large breeds, especially German shepherd; also boxer, Airedale terrier, and cocker spaniel.
- Occurrence increases with age; 50% of dogs by 6 years and 75% by 9 years; may be evident in young dogs with an inherited predisposition.
- Reported in 68% of asymptomatic domestic cats.
- Females > males.
- Boxers—positive correlation between spondylosis deformans and hip dysplasia; both heritable traits are detectable in predisposed animals by radiographic examination at 1 year.

SIGNS

General Comments

- Patients are typically asymptomatic; lesions of minor clinical importance.
- Pain may follow fracture of bony spurs or bridges.

Historical Findings

- Stiffness
- Restricted motion
- Pain

Physical Examination Findings

Neurologic deficits referable to the spinal cord or nerve root compression are unusual.

CAUSES & RISK FACTORS

- Repeated microtrauma
- Major trauma
- Inherited predisposition
- Acromegaly

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Discospondylitis—differentiated by radiographic evidence of endplate lysis.
- Spinal osteoarthritis—degeneration of articular facet joints.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

N/A

IMAGING

Spinal radiography—initially shows osteophytes as triangular projections several millimeters from the edge of the vertebral body; with progression, osteophytes appear to bridge the intervertebral space; true ankylosis is rare.

DIAGNOSTIC PROCEDURES

MRI, CT, or CT myelography—for unusual cases; demonstrate an atypical dorsal osteophyte compressing the spinal cord or nerve roots or encroaching on critical soft tissue structures.

TREATMENT

- Inform owner that the condition is usually an asymptomatic, incidental finding, and is probably not responsible for the clinical signs.
- Spondylosis—treat as outpatient with strict rest and analgesic, possibly acupuncture.
- Obesity—recommend weight-reduction program.
- Acupuncture—dry needle or electroacupuncture treatment at weekly or biweekly interval and tapered to as-needed basis can be very effective in relief of pain; useful in animals that do not tolerate medication or when clients prefer a natural alternative.

MEDICATIONS

DRUG(S)

Use only when the patient is exhibiting signs.

NSAIDs

- Preferred to steroids in dogs unless the patient has neurologic deficits, because of fewer side effects; administer after feeding.
- Carprofen (Rimadyl) 2.2 mg/kg PO q12h or 4.4 mg/kg PO q24h in dogs.
- Meloxicam (Metacam) 0.2 mg/kg once then 0.1 mg/kg q24h in dogs.
- Deracoxib (Deramaxx) 1–2 mg/kg once/day in dogs.
- Firocoxib (Previcox) 5 mg/kg PO q24h in dogs.
- If GI sensitivity, use in combination with an antacid (famotidine 0.5–1 mg/kg q24h or omeprazole 0.5–1 mg/kg q24h) or a gastrointestinal protector (misoprostol at 3–5 µg/kg PO q6–8h or sucralfate 0.5–1 g q8h) to reduce the possibility of gastrointestinal ulceration.

Non-NSAID Analgesics

- Use may enable reduction of dose or frequency of anti-inflammatory medications.
- Tramadol 2–5 mg/kg q8–12h PO in dogs or 1–4 mg/kg q12h in cats.
- Gabapentin 10 mg/kg q8–12h PO in dogs or cats.
- Buprenorphine 0.01–0.03 mg/kg PO q8h in cats.
- Acetaminophen 5 mg/kg q12h PO in dogs.

Corticosteroids

- Only use in patients with neurologic deficits.
- Prednisone 0.25–0.5 mg/kg PO q12h; or dexamethasone 0.025–0.05 mg/kg PO q12h; taper to alternate-day prednisone or twice-weekly dexamethasone.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Acetaminophen and NSAIDs—do not use in cats.
- Avoid prolonged administration of NSAIDs, or combinations of NSAIDs and either acetaminophen or steroids because of risks of gastrointestinal ulceration and renal pathology.

FOLLOW-UP

PATIENT MONITORING

- Gradually return the animal to normal activity after signs have subsided for several weeks.
- Relapse can occur with strenuous activity.
- With prolonged use of analgesic medications, periodic biochemistry testing is warranted.

PREVENTION/AVOIDANCE

Boxers—given genetic correlation between spondylosis deformans and hip dysplasia and possibility of early detection, selectively breed to decrease both traits.

MISCELLANEOUS

ABBREVIATIONS

- CT = computed tomography
- GI = gastrointestinal
- MRI = magnetic resonance imaging
- NSAID = nonsteroidal anti-inflammatory drug

SPOROTRICHOSIS

BASICS

OVERVIEW

- Zoonotic fungal disease affecting the integument, lymphatics, or generalized.
- Caused by inoculation of the ubiquitous dimorphic fungus *Sporothrix schenckii* into subcutaneous tissue.

SIGNALMENT

Dog and cat

SIGNS

- Dogs—cutaneous form: numerous nodules that may drain or crust. • Cats—cutaneous form: lesions appear initially as wounds or abscesses mimicking wounds associated with fighting. • Cutaneolymphatic form—usually an extension of the cutaneous form through the lymphatics, resulting in the formation of new nodules and draining tracts or crusts; lymphadenopathy is common. • Disseminated form.

CAUSES & RISK FACTORS

- Dogs—hunting dogs from puncture wounds associated with thorns or splinters.
- Cats—intact male outdoor cats. • Animals exposed to soil rich in decaying organic debris.
- Exposure to infected animals or clinically healthy cats sharing a household with an affected cat. • Immunosuppressive disease.

DIAGNOSIS

Caution: this is a zoonotic disease and proper precautions should be taken to prevent exposure; the absence of a break in the skin does not protect against the disease.

DIFFERENTIAL DIAGNOSIS

- Infectious—bacterial (deep) and fungal diseases presenting with nodules and draining tracts (e.g., cryptococcosis, blastomycosis, feline leprosy, histoplasmosis) • Neoplasia
- Granulomas caused by infectious organisms and foreign bodies • Parasites—*Demodex*, *Pelodera*, *Leishmania*

CBC/BIOCHEMISTRY/URINALYSIS

None unless associated with generalized disease

OTHER LABORATORY TESTS

- Cultures of affected tissue is preferred; swabs culture may be adequate
- **Caution:** this is a zoonotic disease; laboratory personnel must be warned of the potential differential diagnosis; cultures should not be attempted until other differential diagnoses have been eliminated.
- Serologic testing and PCR assays are available.

DIAGNOSTIC PROCEDURES

- Cytology of exudates—cigar- to round-shaped yeast found intracellularly or free in the exudates, accompanied with pyogranulomatous inflammation.
- Biopsy—organisms usually numerous, especially in cats; fungal stains (PAS or GMS) may aid in the diagnosis; the absence of demonstrable organisms in tissues from dogs does not preclude diagnosis.

TREATMENT

- The zoonotic nature of sporotrichosis should be considered when treating an animal with this disease. • Outpatient therapy may be a consideration but increases the potential for human exposure.

MEDICATIONS

DRUG(S)

Supersaturated Solution of Potassium Iodide

Historical treatment—but seldom used due to the safety and efficacy of other therapies.

Ketoconazole and Itraconazole

- Dogs—ketoconazole: 5–15 mg/kg PO q12h until 1 month after clinical resolution or for a minimum of 2 months; resolution should occur within approximately 3 months; side effects are relatively mild with anorexia being the most common; itraconazole: capsular form 5–10 mg/kg q12–24h for a minimum of 2 months; fewer side effects are noted at the lower dose of 5 mg/kg q24h; often better tolerated than ketoconazole; acute hepatopathy and vasculitis have been reported (see Dermatophytosis); terbinafine: 30–40 mg/kg PO q24h for 30 days beyond clinical cure may also be effective.
- Disseminated disease—combination of amphotericin B and itraconazole is recommended; terbinafine may also be effective.
- Cats—itraconazole 15 mg/kg PO q24h or divided q12h for a minimum of 1 month beyond clinical cure; treatment of choice for cats (efficacy and fewer side effects); itraconazole oral suspension (containing cyclodextrin) 1.5–5.0 mg/kg q24h; compounded formulation of itraconazole is not recommended due to potentially inconsistent absorption; oral suspension is best administered on an empty stomach to improve absorption. Alternative: ketoconazole 5–10 mg/kg PO q12–24h for 1–2 months beyond clinical cure; gastrointestinal

disturbances more commonly seen in cats as are other side effects such as depression, fever, jaundice, and neurological signs.

FOLLOW-UP

PATIENT MONITORING

Reevaluation, including assessment of liver enzymes, recommended every 2–4 weeks.

PREVENTION/AVOIDANCE

Determine the source of the original infection, if possible, to prevent repeat infections.

EXPECTED COURSE AND PROGNOSIS

- Failure of response to therapy should not be unexpected. • Fluconazole and terbinafine remain relatively untested but may show promise for treatment.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- **Caution:** this is a zoonotic disease. • Client education is of paramount importance.
- Absence of a break in the skin does not protect against the disease. • Reports of zoonotic transmission from bites and scratches from rodents, parrots, cats, dogs, horses, and armadillos. • Clinically healthy cats sharing a household with an infected cat may be a source of infection.

ABBREVIATIONS

- GMS = Gomori's methamine silver (stain)
- PAS = periodic acid-Schiff (stain) • SSKI = supersaturated potassium iodide

SQUAMOUS CELL CARCINOMA, DIGIT

BASICS

OVERVIEW

- Locally invasive malignant tumor usually arising from subungual epithelium.
- Cats—metastasis to one or multiple digits from primary pulmonary site reported.
- Dogs—most common digital tumor (~50%); up to 25% metastatic rate, up to 22% multiple digits affected (multicentric disease).
- Forelimb more commonly affected than hind limb.
- Organ systems: skin/endocrine, musculoskeletal.

SIGNALMENT

- Dog and rarely cat.
- Median age—dogs and cats 10 years; reported in dogs as young as 3 years old.
- No sex predilection in dogs; in a small study of cats, females were more common.
- Large breeds (> 75%) and black/dark-coated dogs (> 90%) predisposed; breeds include standard poodle, Labrador retriever, giant schnauzer, rottweiler, dachshund, flat-coated retriever, and possibly Beauceron, Briard, and miniature poodle.

SIGNS

- Swollen digit or digital mass which fails to heal.
- Lameness.
- Ulceration.
- Fractured or missing nail.
- Multiple digits affected in up to 22% of dogs; may present in one digit and develop additional tumors later—may be multicentric or metastatic disease.
- Multiple digits commonly seen in cats (30%); usually part of a metastatic process from a primary pulmonary carcinoma.
- Regional lymphadenomegaly of the sentinel draining lymph node (uncommon at time of diagnosis).
- Cough or respiratory signs consistent with either metastatic pulmonary disease (uncommon at diagnosis) or primary pulmonary neoplasia (cats).

CAUSES & RISK FACTORS

Risk factors—(dogs) hereditary; dark skin pigmentation

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Nailbed infection (paronychia)
- Trauma
- Other tumors—(dog) melanoma; soft tissue sarcomas; mast cell tumor; osteosarcoma
- Other tumors—(cat) fibrosarcoma, adenocarcinoma, osteosarcoma
- Benign lesions—epithelial inclusion cyst, keratoacanthoma

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

IMAGING

- Thoracic radiography—three views are important to rule out metastatic disease (develops in up to 25% of dogs) and rule out a primary pulmonary carcinoma (cats).
- Limb radiography—lysis of the third phalanx of the affected digit in 80% of patients with potential secondary extension proximally to phalanx 2 and 1.
- Abdominal ultrasonography—for hind limb lesions, evaluate intra-abdominal lymph nodes for presence of metastatic disease.

DIAGNOSTIC PROCEDURES

- Cytology—diagnostic utility limited if there is severe inflammation or secondary infection (common), or the tumor is well differentiated.
- Wedge biopsy of lesion—required to confirm diagnosis via histopathology.
- Cytology and/or biopsy of regional lymph nodes—indicated to assess metastatic disease.

TREATMENT

- Amputation of the affected digit at the level of the metacarpal or metatarsal phalangeal joint.
- In cats with a primary pulmonary tumor, amputation of a single affected digit may provide local palliative care; in cats with multiple affected digits due to metastases, surgical intervention might not be a durable option because digits from multiple limbs are generally affected.
- Palliative radiation could be considered for single digits if metastatic disease present or in the setting of multicentric/multiple digits affected in dogs or cats.
- Analgesics for pain control and antibiotics for secondary bacterial infections may be indicated.
- Benefit of chemotherapy has not been established; however in patients with advanced stage of disease chemotherapy useful for squamous cell carcinoma of other sites could be considered.

MEDICATIONS

DRUG(S)

Piroxicam (dogs) 0.3 mg/kg PO q24h for analgesia; (cats) no established dosages; however, 0.3 mg/kg PO q48h has been used anecdotally.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None

FOLLOW-UP

PATIENT MONITORING

- Recheck with physical examination, thoracic radiographs, lymph node evaluation, ± abdominal ultrasound at 1–2 months, then every 3 months after treatment (complete surgical excision).

EXPECTED COURSE AND PROGNOSIS

- Complete surgical excision of the primary lesion and no evidence of metastasis—additional treatment may not be required.
- Survival time following complete surgical excision depends upon location of the tumor on the digit—SCC originating from subungual epithelium: 95% 1-year and 74% 2-year survival; SCC originating in other parts of the digit: 60% 1-year and 44% 2-year survival.
- In one study 1- and 2-year survival was 50% and 18%, respectively, while in two other studies, only 20–45% of dogs died of SCC (multicentric or metastatic) and the median survival time was not reached.
- Development of multicentric disease (multiple affected digits) in dogs appears more common than lymph node or pulmonary metastasis.
- Surgery to amputate affected digit, regardless of presence of metastases, provides positive impact on survival in the dog.
- Histologic grading does not appear predictive of development of multicentric or metastatic disease in dogs.
- Prognosis for cats is poor with median survival times of 2–3 months and metastatic rates of approximately 25%; survival times are similar in cats with primary and metastatic squamous cell carcinoma.

MISCELLANEOUS

ABBREVIATION

SCC = squamous cell carcinoma

SQUAMOUS CELL CARCINOMA, EAR

BASICS

OVERVIEW

- Malignant tumor of squamous epithelium occurring on the pinna, external ear, and/or middle ear (less common). • Pinna—most common location in cats; tumors of the pinna in dogs are rarely squamous cell carcinoma.
- Organ system: Skin/Endocrine.

SIGNALMENT

- Cat and dog. • Tumors of the pinna—common in cats with light pigmentation, average 12 years. • Ear canal tumors—seen in older dogs and cats. • No sex predilection.
- Cocker spaniels overrepresented for benign and malignant ear canal tumors in one study.

SIGNS

- Tumors of the pinna: ° Slowly developing lesions of the edge of the pinna
- Precancerous stage—crusty eczematous lesions (actinic dermatitis) ° Cancerous phase—proliferation and/or ulceration progresses ° Multiple cutaneous lesions (about 10–15% of cats) occur in haired skin, unrelated to sunlight exposure (multicentric squamous cell carcinoma *in situ* or MSCCIS).
- Tumors of the ear canal: ° Usually unilateral
- Usually arise from the external ear canal
- Mass lesion (raised, ulcerated, broad-based)
- Malodorous aural discharge ° Pruritis ° Pain
- Vestibular signs/Horner's syndrome (facial nerve paralysis, head tilt, circling) in ~10% of dogs; more common in cats with ear canal tumors ° Difficulty opening jaw ° Cervical lymphadenomegaly (retropharyngeal, mandibular).

CAUSES & RISK FACTORS

- Pinna—chronic sunlight (UVB) exposure in cats with white fur and light skin pigmentation. • Ear canal—chronic inflammation may be a risk factor.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pinna (cats)—lesions caused by trauma, vasculitis or cryoglobulinemia. • Pinna (dogs)—mast cell tumor, histiocytoma, trauma, sebaceous gland tumor. • Ear canal/middle ear (cat)—inflammatory/nasopharyngeal polyp (middle ear), most external ear tumors are malignant (ceruminous gland adenocarcinoma, other).
- Ear canal/middle ear (dog)—chronic otitis, 60% of external ear canal tumors are malignant (ceruminous gland adenoma or adenocarcinoma, papilloma), nasopharyngeal polyps rare.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

Thorough examination and cytology and/or biopsy of regional lymph nodes (mandibular, retropharyngeal) to evaluate for regional metastasis (rare for pinnal lesions).

IMAGING

- Thoracic radiography—three views needed to evaluate for pulmonary metastasis (rare with pinnal lesions). • Skull radiography—limited usefulness but may identify soft tissue structures and bony lysis of the bulla with ear canal/middle ear tumors.
- Computed tomography—ideal for evaluation of soft tissue and bone involvement prior to planning surgical resection of tumors involving the ear canal; 57–67% locally invasive into surrounding tissues.

DIAGNOSTIC PROCEDURES

- Cytology may confirm diagnosis; however, ulceration, inflammation, and secondary infection may limit diagnostic utility.
- Biopsy of pinna or aural mass to confirm diagnosis via histopathology; video otoscopy may aid in visualization of mass lesion and biopsy.

PATHOLOGIC FINDINGS

Distinguished microscopically by characteristic groups of epithelial cells and keratinizing cells forming keratin pearls.

TREATMENT

- Pinna: ° Appropriate surgical excision may require pinnectomy and possibly vertical ear canal ablation; must remove lesion with margin of normal tissue.
- Alternatives include photodynamic therapy (less predictable; multiple treatments may be required), cryosurgery (for small, superficial lesions), strontium plesiotherapy (superficial radiation therapy), electrochemotherapy with bleomycin, or curettage/diathermy.
- Ear canal/middle ear: ° Total ear canal ablation and bulla osteotomy (TECA-BO) is usually needed to achieve complete excision; lateral ear canal resection rarely achieves adequate control.
- Anecdotally radiation therapy may be used for palliation of nonresectable tumors or postoperatively for microscopic disease.

MEDICATIONS

DRUG(S)

- Pinna (cat): ° Imiquimod 5% cream—apply topically q24h ° Etretinate 0.75–1 mg/kg PO q24h; used successfully to prevent progression of precancerous lesions; may not be

commercially available ° Acitretin (1 mg/kg PO q24h) can be used in place of etretinate ° Vitamin E 400–600 IU PO q12h; may be beneficial to prevent or delay progression of precancerous lesions. • Ear canal tumors:

- Systemic chemotherapy—benefit not yet established; anecdotal benefit.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Women who are pregnant or planning to become pregnant should not handle acitretin.

FOLLOW-UP

PATIENT MONITORING

- Pinna—recheck with physical examination at 1 month, then every 3 months after treatment (complete surgical excision).
- Ear canal—recheck with physical examination, thoracic radiographs, lymph node evaluation, and possible computed tomography every 3 months after treatment.

PREVENTION/AVOIDANCE

- Limit sun exposure, especially between 10 a.m. and 3 p.m.
- Yearly tattoos on nonpigmented areas may be helpful.

EXPECTED COURSE AND PROGNOSIS

- Pinna—prognosis good with complete surgical excision; survival > 1.5 years with complete pinnectomy.
- Ear canal tumors locally invasive (57–67%) and recur locally despite surgery; prognosis is guarded.
- Dogs—median survival 5.3 months with bulla involvement compared to > 58 months without.
- Cats—median survival 3.8 months; worse prognosis with bulla involvement; median survival 1.5 months with neurologic signs.

Author Jackie M. Wypij

Consulting Editor Timothy M. Fan

SQUAMOUS CELL CARCINOMA, GINGIVA

BASICS

OVERVIEW

- Malignant tumor of squamous epithelium.
- Rapid progression, locally invasive, highly bone-invasive (77%). • Most common oral malignancy in cats; one of most common oral malignancies in dogs. • Metastasis—approximately 10–20% metastasis in dogs and cats with potential involvement of draining lymph nodes (most common) and lung parenchyma.

SIGNALMENT

- Mean age (dogs and cats)—10.5 years (range, 3–15 years)
- More common in medium- and large-breed dogs

SIGNS

Historical Findings

- Mass
- Excessive salivation
- Dysphagia
- Halitosis
- Bloody oral discharge
- Weight loss
- Decreased appetite
- Poor grooming (cats)

Physical Examination Findings

- Erythematous, ulcerated, fleshy lesion
- Rostral mandible is most common site
- Loose teeth
- Facial swelling or deformity
- Exophthalmos
- Pain on opening jaw

CAUSES & RISK FACTORS

Potential risk factors in cats include flea collars, canned food, tuna, and tobacco smoke.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other oral malignancy—fibrosarcoma in cats; melanoma, fibrosarcoma, osteosarcoma in dogs
- Epulis
- Tooth root abscess
- Benign growth or polyp
- Gingival hyperplasia
- Eosinophilic granuloma complex

IMAGING

- Skull radiography—evaluate bone involvement deep to the mass; requires 40–50% bone destruction before evident radiographically.
- Dental radiography—more sensitive in evaluating local disease than skull radiography; best with mandibular masses.
- Computed tomography (CT scan)—ideal method to evaluate soft tissue extension, bone invasion, and assess regional lymph nodes prior to surgical planning.
- Thoracic radiography—three views to detect pulmonary metastasis (eventually develop in up to 36% of dogs, rare in cats).

DIAGNOSTIC PROCEDURES

- Cytologic evaluation of lesion—fine-needle aspirate samples often non-diagnostic; obtain impression smear from an incisional biopsy specimen (wedge); ulceration, inflammation, and secondary infection may limit diagnostic

utility.

- Large, deep tissue biopsy (down to bone)—required to differentiate from other oral malignancies via histopathology.

- Cytology and/or biopsy of regional lymph nodes (mandibular, retropharyngeal) to evaluate regionally metastatic disease (10–20% dogs and cats).

TREATMENT

DOGS

- Radical surgical excision required (e.g., hemimandibulectomy or partial maxillectomy); usually well tolerated; margins of at least 2 cm necessary.
- Radiation therapy—effective for long-term control; curative-intent treatment used alone or in combination with surgery or chemotherapy.
- Chemotherapy—alone or in combination with other treatment modalities, toceranib phosphate (Palladia) exerts single-agent activity in a substantial fraction (75%) of dogs treated.
- Piroxicam may have some antineoplastic effects.
- Cryosurgery—indicated for small lesions with no bone involvement.
- Photodynamic therapy—adjunct to surgery may be effective for local control of small tumors.
- Analgesics for pain control and antibiotics for secondary bacterial infections may be indicated.

CATS

- Surgery—most tumors are nonresectable; small rostral lesions may be excised with wide 2–3 cm margins (hemimandibulectomy); cats do not tolerate aggressive oral surgery as well as dogs.
- Palliative treatments include coarse-fraction radiation therapy (< 50% response).
- Metastasis less of a concern as most cats succumb to local disease progression.
- Bisphosphonates—used to palliate bone pain.
- Analgesics for pain control and antibiotics for secondary bacterial infections may be indicated.

MEDICATIONS

DRUG(S)

- Toceranib phosphate (Palladia) treatment of dogs at 2.75–3.25 mg/kg every other day.
- Cisplatin (dogs only) 60–70 mg/m² IV once every 3–4 weeks for four treatments; provides marked palliation of clinical signs; response depends on severity of the localized or metastatic lesion; must use saline diuresis (18.3 mL/kg/h IV over 6 hours; give cisplatin after 4 hours); pretreat with an antiemetic.
- Carboplatin—dogs, 250–300 mg/m² every 3 weeks IV; cats, 180–250 mg/m² every 3–4 weeks for 4–5 treatments.
- Mitoxantrone (cats) 5–6 mg/m² every 3 weeks IV for 4–5 treatments.
- Piroxicam (dogs) 0.3 mg/kg PO daily; may be useful to

induce partial remission in some patients; dosages in cats have not been well established; however, 0.3 mg/kg PO q48h has been used anecdotally.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Cisplatin—never use in cats.
- Do not administer cisplatin with NSAIDs due to nephrotoxicity.

FOLLOW-UP

PATIENT MONITORING

Recheck with thorough physical examination, lymph node evaluation, and three-view thoracic radiographs at 1–2 months, then every 3 months after treatment.

POSSIBLE COMPLICATIONS

Postoperative complications—tumor recurrence, ptalism, mandibular drift leading to malocclusion, difficulty prehending food, inability to groom.

EXPECTED COURSE AND PROGNOSIS

Dogs

- Negative prognostic factors—caudal or maxillary location, > 2 cm diameter, older age, incomplete excision.
- Surgical excision—median survival 15–16 months, 34 months combined with radiation therapy; mandibulectomy better outcome than maxillectomy.
- Photodynamic therapy—adjunct to surgery; median survival 17 months in 8 dogs that responded.
- Combination carboplatin and piroxicam with or without surgery—median survival time of > 18 months (7 dogs).
- Piroxicam—17% response rate with a median progression-free interval of 3.5–6 months.

Cats

- Surgical excision—median survival 1 year for resectable tumors (rare).
- Palliative radiation—median survival 2–5.8 months, up to 10 months with complete remission.
- In a small study of stereotactic radiation therapy, females had better outcome than males.

SQUAMOUS CELL CARCINOMA, LUNG

BASICS

OVERVIEW

- Rare primary tumor of bronchial epithelium with squamous metaplasia.
- High metastatic potential with involvement of regional lymph nodes, pleural surface (carcinomatosis), and pulmonary parenchyma and less commonly distant organs including digits in cats.
- Organ system: respiratory.

SIGNALMENT

- Dog and cat.
- Older animals, mean age—dogs, 11 years; cats, 12 years.
- Persian cats may be overrepresented for pulmonary carcinomas, but not necessarily of squamous histology.

SIGNS

Historical Findings

- Incidental finding
- Harsh, non-productive cough
- Dyspnea
- Lethargy or exercise intolerance
- Cachexia and weight loss
- Lameness and pain associated with digit metastasis or hypertrophic osteopathy

Physical Examination Findings

- Tachypnea
- Wheeze
- Abnormal lung sounds
- Hemoptysis
- Hypertrophic osteopathy
- Single or multiple digital lesions (metastasis) in cats
- Neuromyopathy (such as megaesophagus) and paraplegia (rare)

CAUSES & RISK FACTORS

- Urban environment and second-hand smoke suspected but have not shown definitive correlation in multiple studies.
- Dogs trained to smoke cigarettes may develop lung cancer.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other primary lung neoplasia (e.g., cats: adenocarcinoma, bronchoalveolar carcinoma, adenosquamous carcinoma; dogs: adenocarcinoma, bronchoalveolar carcinoma, histiocytic sarcoma, and anaplastic carcinoma). SCC is one of most rare histologic subtypes of carcinoma.
- Metastatic pulmonary neoplasia.
- Bronchogenic cyst.
- Bullae.
- Abscess.
- Fungal granuloma.
- Aspiration pneumonia.

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilic leukocytosis
- Hypercalcemia (rare)

IMAGING

- Thoracic radiography:
 - Three views; most often in caudal lung lobes
 - Most commonly identify a solitary mass with well-circumscribed margins
 - May identify tracheobronchial lymphadenomegaly or pulmonary metastatic lesions
 - May displace/compress trachea or mainstem

bronchi with airway obstruction and peripheral atelectasis

- May identify pleural effusion
- Computed tomography (CT scan):
- Ideal for evaluating surgical resectability
- Solitary, well-circumscribed, bronchocentric mass with internal air bronchograms
- More accurate than radiographs in detecting pulmonary and lymph node metastasis
- Mild to moderate heterogeneous contrast enhancement
- Limb radiography:
- Rarely, single or multiple digit metastases are identified in cats as bone lysis in the distal phalanx
- Rarely, hypertrophic osteopathy exemplified with periosteal bone proliferation

DIAGNOSTIC PROCEDURES

- Cytology via transthoracic fine-needle aspiration of peripheral lesions; ultrasound or CT guidance may aid in obtaining adequate samples.
- Cytology samples obtained via endoscopic bronchial brushing often non-diagnostic; may be useful for centrally located lesions.
- Cytologic analysis of pleural effusion or intrathoracic lymph node aspirates may be helpful if primary lesion is not amenable to aspiration.
- Tissue biopsy is necessary for definitive diagnosis and may be obtained via keyhole biopsy, thoracoscopy, or thoracotomy.
- Bronchoalveolar lavage and transtracheal wash are rarely diagnostic.
- Potential life-threatening complications of aspiration/biopsy procedures include pneumothorax, hemothorax, pleural effusion, infection, and rarely iatrogenic tumor seeding.

TREATMENT

- Surgery (thoracotomy and lung lobectomy)—wide and complete resection of affected lung lobe affords best opportunity for long-term control; biopsy lymph nodes even if they appear normal; lymph node extirpation is ideal but frequently difficult.
- In select cases, thorascopic surgery may be considered.
- Chemotherapy—potentially beneficial in adjuvant or palliative setting, intracavitary chemotherapy may be useful for carcinomatosis and pleural effusion.
- Palliative medications may include nonsteroidal anti-inflammatories/analgesics, cough suppressants, and antibiotic therapy for secondary bacterial infections.

MEDICATIONS

DRUG(S)

- Cisplatin—(dogs only) 60 mg/m² IV every 3 or 4 weeks for 4 treatments; nephrotoxic, so must use with saline diuresis (18.3 mL/kg/h); antiemetic also required.
- Doxorubicin—dogs > 10 kg, 30 mg/m² IV; dogs < 10 kg and cats, 1 mg/kg once every 2–3 weeks for 5 treatments; has provided marked palliation.

- Carboplatin—dogs, 250–300 mg/m² IV every 3 weeks; cats, 180–250 mg/m² IV every 3–4 weeks for four to five treatments.
- Mitoxantrone (pleural effusion)—dogs and cats, 5–6 mg/m² every 3 weeks; can give intracavitary and/or IV for four to five treatments.
- Vinorelbine—dogs, 15 mg/m² weekly for 4 weeks then every other week for four additional treatments; may be effective for pulmonary carcinomas.

CONTRAINdications/POSSIBLE INTERACTIONS

- Cisplatin—never use in cats.
- Do not administer cisplatin with NSAIDs; severe renal toxicity reported in dogs.

FOLLOW-UP

PATIENT MONITORING

After complete excision, consider chemotherapy options; recheck with three-view thoracic radiographs and/or CT scan in 1–2 months, then every 3 months.

EXPECTED COURSE AND PROGNOSIS

- Survival if untreated or with evidence of metastatic disease—usually < 3 months.
- Median survival with complete excision of primary tumor and no metastasis (dogs and cats)→ 300 days.
- Median survival with incomplete surgical excision of primary tumor or the presence of lung/lymph node metastasis (dogs and cats) < 75 days.
- Median long-term survival of cats with pulmonary carcinomas treated with surgery is 64–115 days.
- Negative prognostic factors (all lung tumors): large size, central location, metastasis, pleural effusion, high histologic grade, poorly differentiated, or respiratory signs at diagnosis.

MISCELLANEOUS

SQUAMOUS CELL CARCINOMA, NASAL AND PARANASAL SINUSES

BASICS

OVERVIEW

- Local invasion of neoplastic squamous epithelium from the nasal cavity and/or paranasal sinuses.
- Slowly progressive (months) and commonly bilateral.
- Low metastatic rate.
- Prevalence—15–17% of nasal neoplasia in cats and dogs.

SIGNALMENT

- More common in dog than in cat.
- Dogs—median age, 9–10 years (range, 3–16 years), male predilection; cats—median 10–2 years, male predilection.
- Dogs—predilection for sinonasal tumors in medium and large breeds.

SIGNS

Historical Findings

- Intermittent and progressive unilateral to bilateral epistaxis and/or mucopurulent nasal discharge
- Epiphora
- Sneezing
- Halitosis
- Anorexia
- Dyspnea
- Seizures secondary to cranial invasion (in up to 35% of dogs)

Physical Examination Findings

- Nasal discharge (epistaxis, mucopurulent, serosanguinous, and/or sanguinous)
- Facial deformity
- Stridor
- Ocular abnormalities: epiphora, decreased retropulsion, elevated third eyelid, exophthalmus
- Pain on nasal or paranasal sinus palpation
- Obstructed nasal airflow

CAUSES & RISK FACTORS

- Unknown.
- Doliccephalic breed, urban environment, and tobacco smoke exposure speculated to be risk factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other intranasal malignant neoplasia—adenocarcinoma, undifferentiated carcinoma, lymphoma (cats), sarcomas (dogs)
- Tooth root abscess
- Viral infection—cats
- Cryptococcosis—cats
- Aspergillosis; other fungal infection
- Foreign body
- Trauma
- Oronasal fistula
- Coagulopathy
- Hypertension
- Bacterial sinusitis—uncommon
- Lymphocytic-plasmacytic rhinitis
- Inflammatory polyps (cats)
- Parasites

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal; may have anemia if chronic and/or severe epistaxis.

OTHER LABORATORY TESTS

If epistaxis, evaluate coagulation profile and blood pressure to rule out hypertension and coagulopathy prior to intranasal biopsy.

IMAGING

- Skull radiography—asymmetrical osteolysis of caudal turbinates; superimposition of soft tissue mass; fluid density in the frontal sinuses; loss of teeth; displacement of midline structures; involvement of hard palate.
- Thoracic radiography—detect pulmonary metastasis (uncommon).
- Computed tomography (CT scan) or MRI (magnetic resonance imaging)—recommended imaging modalities for the identification of soft-tissue density mass, loss of turbinate detail, soft tissue/fluid opacity in sinus; best method for assessing tumor invasiveness, including bony invasion, invasion of cribriform plate or orbit.

DIAGNOSTIC PROCEDURES

- Rhinoscopy—mass effect, may be obscured by exudates.
- Diagnostic utility of cytology obtained by aspiration or squash preparation may be limited by inflammation or secondary infection.
- Deep tissue biopsy with histopathology—necessary for definitive diagnosis; methods include nasal hydropulsion, transnostril blind biopsy with forceps or bone curette, fiber-optic guided biopsy, percutaneous biopsy of facial deformities; biopsy via dental extraction site, rhinotomy.
- Precautions must be taken to minimize risk of penetrating the cribriform plate.
- Cytology and/or biopsy of regional lymph nodes—detect metastatic disease (up to 10% at diagnosis).

TREATMENT

- Surgery alone does not improve outcome in most studies; exenteration and radiation therapy may provide benefit.
- Definitive radiotherapy—with or without surgery; best clinical control in dogs and cats.
- Coarse-fraction radiation therapy also beneficial in dogs and cats for palliation.
- Adjunctive chemotherapy or single-agent toceranib phosphate (Palladia)—responses in dogs reported; recommended for nonresectable mass, palliation of clinical signs, metastasis, and as an adjuvant to radiation therapy.
- Analgesics for pain control.
- Anecdotally, nasal hydropulsion may be used for palliation of clinical signs.

MEDICATIONS

DRUG(S)

- Cisplatin (dogs only) 60–70 mg/m² IV once every 3 weeks for four treatments; nephrotoxic, use saline diuresis (18.3 mL/kg/h IV over 6 hours; give cisplatin after 4 hours); administer antiemetic prior to chemotherapy.
- Carboplatin—dogs, 250–300 mg/m² IV every 3 weeks; cats, 180–250 mg/m² IV every 3–4 weeks for 4 or

5 treatments.

- Mitoxantrone (dogs) 5–6 mg/m² IV every 3 weeks for 4 or 5 treatments.
- Toceranib phosphate (dogs) 2.75–3.25 mg/kg PO q48h long term.

CONTRAINdications/POSSIBLE INTERACTIONS

- Cisplatin—never use in cats.
- Do not administer cisplatin with NSAIDs due to nephrotoxicity.

FOLLOW-UP

PATIENT MONITORING

Recheck with physical examination, thoracic radiographs, lymph node evaluation, ± CT scan every 3 months after treatment or when signs recur.

POSSIBLE COMPLICATIONS

Acute or late side effects from radiation therapy (e.g., ocular cataracts or keratoconjunctivitis sicca, osteomyelitis/osteonecrosis, oronasal fistula).

EXPECTED COURSE AND PROGNOSIS

- Untreated carcinomas (all types)—median survival 3 months; epistaxis carries a worse prognosis.
- Definitive radiotherapy (all carcinomas)—median survival ~12–18 months (dogs and cats); 2-year survival 30–48% (dogs); 1-year survival 44% (cats).
- Coarse-fraction radiation therapy (all tumor types)—improved clinical signs in ~90% of dogs; median survival 4.8–10 months; median survival 10–12 months (cats).
- Surgical exenteration and radiation therapy (all tumor types)—survival ~4 years (dogs).
- SCC reported to have worse prognosis than other nasal tumors; median survival times of 6–9.4 months with radiation therapy; median survival time of 2 months in 8 dogs (with or without therapy); other studies do not demonstrate a difference with histologic subtype.
- Local recurrence with extension to the brain—common; brain involvement is a poor prognostic sign.
- Re-irradiation may be feasible.

SQUAMOUS CELL CARCINOMA, NASAL PLANUM

BASICS

OVERVIEW

- Malignant tumor of squamous epithelial cells of the nasal planum.
- Locally invasive and rarely metastasizes.
- Organ systems: skin/exocrine, respiratory.

SIGNALMENT

- Common in cat; rare in dog.
- Mean age—cats, 8.5–12.1 years; dogs, 9–10 years.
- More likely to develop in animals with a lightly pigmented nose (cats).
- No reported sex or breed predilection in cats.
- Dogs—overrepresentation of males and Labrador retrievers in one study.

SIGNS

- Cats—slowly progressive lesion; may begin as superficial crusting and scabbing, progress to carcinoma *in situ*, and develop into superficial and then invasive erosive carcinoma; other cutaneous sites may be affected (cats—multicentric squamous cell carcinoma *in situ*).
- Dogs—sneezing; epistaxis; swelling and ulceration of planum, proliferative lesion.
- Cervical lymphadenomegaly—occasionally in dogs, rare in cats.

CAUSES & RISK FACTORS

- Exposure to ultraviolet light (UVB)
- Absence of protective pigment (cats)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infection/abscess
- Trauma
- Allergic dermatitis
- Other dermatitis
- Eosinophilic granuloma complex (cats)
- Immune-mediated disease
- Cutaneous lymphoma
- Mast cell tumor

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

S

OTHER LABORATORY TESTS

Cytologic examination and/or biopsy of regional lymph nodes should be performed to identify metastasis (rare in cats, occasionally in dogs).

IMAGING

- Thoracic radiography—three views to evaluate for metastasis (rare).
- Computerized tomography (CT scan)—evaluate soft tissue extension and bone invasion prior to surgical planning, essential for canine tumors in which extensive underlying structures are often involved.

DIAGNOSTIC PROCEDURES

- Cytologic examination—fine-needle aspirate of primary lesion may confirm diagnosis; however, ulceration, inflammation, and secondary infection may limit diagnostic utility.
- Biopsy and histopathology—a deep wedge or punch biopsy is often needed to definitively diagnose squamous cell carcinoma. Multiple samples recommended as lesion may have a spectrum of actinic changes ranging from squamous metaplasia to invasive carcinoma.

PATHOLOGIC FINDINGS

- Lesions—may vary in appearance depending on stage of disease in cats; typically ulcerative in cats; more likely proliferative in dogs.
- Histopathologic—characterized by irregular masses or cords of epidermal cells that proliferate downward into the dermis.
- Keratin formation, horn pearls, desmosomes, mitotic figures, and cellular atypia—frequent.

TREATMENT

- Superficial tumors—surgery, cryosurgery, irradiation (strontium-90 plesiotherapy), photodynamic therapy, electrochemotherapy with bleomycin, or curettage/diathermy.
- Invasive tumors—require radical surgical excision and adjunctive external beam radiotherapy (cats); dogs not as responsive to radiotherapy.
- Immediate postoperative nutritional support may be required, especially for cats.
- Analgesics for pain control and antibiotics for secondary bacterial infections may be indicated.

MEDICATIONS

DRUG(S)

- Etretinate 0.75–1 mg/kg PO q24h; synthetic retinoid; may be useful for early precancerous lesions; not commercially available in the United States or Canada.
- Acitretin (1 mg/kg PO q24h) can be used in place of etretinate.
- Imiquimod 5% cream for nasal planum lesions associated with MSCCIS—apply topically to affected lesions q24–48h; most cats respond but develop new lesions in other sites; these lesions often subsequently respond to topical therapy.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Women who are pregnant or planning to become pregnant should not handle acitretin.

FOLLOW-UP

PATIENT MONITORING

- Physical examination—at 1 month, then every 3 months after treatment.
- Biopsy—any new suspicious lesion.

PREVENTION/AVOIDANCE

- Limit sun exposure, especially between 10 a.m. and 3 p.m.
- Tattoos on nonpigmented areas may be helpful.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—good for small, non-invasive tumors; guarded for invasive tumors.
- Survival with radiotherapy alone (cats)—mean, 17.7 months; 1 year, 61.5% with 81.8% recurrence.
- Surgery (cats, noseectomy)—median survival > 22 months.
- Strontium-90 plesiotherapy (cats, superficial)—98% response rate; median progression-free interval of 4.5 years; median survival > 8 years.
- Photodynamic therapy (cats, superficial)—96% response rate; often need multiple treatments; does not appear as effective as other therapies long term.
- Electrochemotherapy with bleomycin (pilot study)—81% complete remission, risk of recurrence, well tolerated.
- Curettage and diathermy (pilot study)—excellent response, risk of recurrence.
- Dogs (superficial tumors)—surgery alone may be curative.
- Dogs (invasive tumors)—in one study of 8 dogs, average survival time was 5.4 months; in another study of 17 dogs treated with surgery and/or radiation therapy, 70% of tumors recurred with a median survival time of 3–6 months.

SQUAMOUS CELL CARCINOMA, SKIN

BASICS

DEFINITION

- Malignant tumor of squamous epithelium.
- Multicentric squamous cell carcinoma *in situ* (MSSCIS)—also called Bowen's-like disease or Bowenoid carcinoma *in situ* (cats).

PATHOPHYSIOLOGY

- Local disease may progress from carcinoma *in situ* to invasive carcinoma.
- Metastasis is uncommon; most common sites are regional lymph nodes and lungs.
- ~10% MSSCIS, ~90% actinic (solar-induced).

SYSTEMS AFFECTED

Skin/Exocrine—skin and metastatic sites

GENETICS

Unknown

INCIDENCE/PREVALENCE

Represents 9–25% of all skin tumors in cats and 4–18% in dogs.

GEOGRAPHIC DISTRIBUTION

Solar-induced (actinic) SCC is more prevalent in sunny climates and high altitudes (increased ultraviolet UVB exposure).

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Cats—none reported; patients often have light or unpigmented skin; Siamese cats are underrepresented for solar-induced SCC likely due to their protective pigment.
- Dogs—Scottish terrier, Pekingese, boxer, poodle, Norwegian elkhound, Dalmatian, beagles, whippet, and white English bull terrier may be predisposed.

Mean Age and Range

- Dogs—8 years.
- Cats—9 years (2–16) for actinic form; 10 years (7–17) for MSSCIS.

Predominant Sex

None

SIGNS

Historical Findings

- Crusts, ulcer, or mass that may have been present for months and unresponsive to conservative treatment with topical antibiotic or anti-inflammatory therapies.
- MSSCIS (cats)—skin becomes pigmented; ulcer forms in the center; followed by a painful scabby lesion that may expand peripherally.
- Lips, nose, and pinna involvement—may start out as a shallow crusting lesion that progresses to a deep ulcer.
- Facial skin involvement (cats).

Physical Examination Findings

- Proliferative or erosive skin lesions; erosive lesions are most common in the cat.

- Cats—most common sites for solar-induced lesions are the nasal planum, eyelids, lips, and pinna.

- MSSCIS may occur in any site, unrelated to sun exposure or skin pigmentation; may note 2 to > 30 lesions on the head, digits, neck, thorax, shoulders, and ventral abdomen; hair in the lesion epilates easily; crusts cling to the epilated hair shaft.
- Dogs—most commonly affects toes, scrotum, nose, legs, and anus.

CAUSES

- Ultraviolet irradiation (UVB, actinic form).
- Recent studies show an association with papillomaviruses in feline SCC in approximately 50% of samples tested; dogs have also been shown to have papillomavirus-positive SCC.

RISK FACTORS

- Prolonged exposure to ultraviolet light (UVB).
- Light or nonpigmented skin.
- Previous thermal injury—burn scar.
- Risk factors for MSSCIS in cats are undetermined but may be associated with immunosuppression.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infection/abscess
- Dermatophytosis
- Trauma
- Allergic dermatitis
- Other dermatitis
- Eosinophilic granuloma complex
- Immune-mediated disease
- Cutaneous lymphoma
- Mast cell tumor

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

OTHER LABORATORY TESTS

- Cytologic examination—fine-needle aspirate of primary lesion may confirm diagnosis; however, ulceration, inflammation, and secondary infection may limit diagnostic utility.
- Cytologic examination of lymph nodes should be performed to identify presence of regional metastasis.

IMAGING

- Thoracic radiography—three views may detect lung metastasis (rare).
- Abdominal radiography or ultrasonography—evaluate and monitor sublumbar lymph nodes if skin disease involves the caudal half of the patient.

DIAGNOSTIC PROCEDURES

Biopsy and histopathology—a deep wedge or punch biopsy is often needed to definitively diagnose cutaneous SCC. Multiple samples

recommended as actinic form may encompass spectrum from actinic changes to carcinoma.

PATHOLOGIC FINDINGS

Gross

- Ulcerative tumors—most common; may appear shallow and crusted and progress to deep craters.
- Proliferative tumors—may have a cauliflower-like appearance; may ulcerate and bleed easily.
- MSSCIS—multiple painful ulcers that scab over and expand peripherally to reach more than 4 cm in diameter.

Histopathologic

- Cords or irregular masses of epidermal cells infiltrating into the dermis and subcutis.
- Large numbers of horn (keratin) pearls in well-differentiated tumors.
- Desmosomes and mitotic figures common.
- MSSCIS—dysplastic, highly ordered keratinocytes proliferate, replacing normal epidermis, but do not penetrate the basement membrane into the surrounding dermis.

TREATMENT

APPROPRIATE HEALTH CARE

- Superficial tumors suspected to be solar-induced—wide surgical excision may be locally curative; other treatment options include cryosurgery, photodynamic therapy, or irradiation (strontium plesiotherapy).
- Invasive tumors—require aggressive surgical excision; photodynamic therapy and strontium-90 plesiotherapy have little efficacy; external-beam radiation therapy has shown effectiveness postoperatively or alone for nonresectable tumors.
- MSSCIS may be treated with curative-intent surgery for local control; however, most cats develop new lesions in other sites; therefore treatment with immune-modulating drugs (imiquimod) may be most effective for multicentric disease.
- Topical synthetic retinoids—may be useful for early solar-induced superficial lesions.
- External beam radiotherapy—recommended for inoperable tumors or as adjunct to surgery.
- Adjunctive chemotherapy—recommended with incomplete surgical excision, non-resectable mass, and metastasis; cisplatin (dogs only), carboplatin, and mitoxantrone—reported to induce partial and complete remission.
- Electrochemotherapy (bleomycin) and curettage with diathermy show promise in pilot studies but not routinely available in clinical practice.

NURSING CARE

- Consider the use of analgesics as needed.
- Secondary skin infections may benefit from antibiotic therapy.

SQUAMOUS CELL CARCINOMA, SKIN

(CONTINUED)

- Interventional parenteral nutrition (feeding tube)—with nasal planum resection.

ACTIVITY

- Dictated by the location of the tumor and the type of treatment.
- Generally limit until sutures are removed, if surgery has been done.

DIET

Normal

CLIENT EDUCATION

- Inform client about the benefit of early diagnosis and treatment.
- Discuss risk factors associated with the development of the tumor (ultraviolet light exposure).
- Most cats (75%) with MSCCIS will develop new lesions in other sites.

SURGICAL CONSIDERATIONS

Wide surgical excision—treatment of choice for invasive and solar-induced tumors; skin flaps and body wall reconstruction sometimes required. Lower eyelid often easier to reconstruct than upper eyelid.

MEDICATIONS

DRUG(S) OF CHOICE

- Imiquimod 5% cream for MSCCIS—apply topically to affected lesions q24–48h; most cats respond but develop new lesions in other sites; these lesions often subsequently respond to topical therapy.
- Systemic chemotherapy anecdotally useful. Cisplatin—dogs only, 60 mg/m² IV every 3 or 4 weeks for four treatments; nephrotoxic, so must use with saline diuresis (18.3 mL/kg/h IV over 6 hours; give cisplatin after 4 hours); pretreat with an antiemetic.
- Carboplatin—dogs, 300 mg/m² IV every 3 weeks; cats, 200–250 mg/m² IV every 3–4 weeks for 4 or 5 treatments.
- Mitoxantrone—dogs and cats, 5–6 mg/m² IV every 3 weeks for 4 or 5 treatments.

CONTRAINDICATIONS

Cisplatin—do not use in cats, causes severe hydrothorax, pulmonary edema, and death; do not use in dogs with concurrent renal disease, potentially nephrotoxic; do not use in conjunction with NSAIDs.

PRECAUTIONS

- Chemotherapeutics—follow published guidelines and protocols for safe use; be familiar with potential side effects; may be toxic, seek advice from a medical oncologist before treatment if you are unfamiliar with cytotoxic drugs.
- Imiquimod—approximately 25% of cats develop local erythema; < 10% of cats develop elevated liver enzymes, neutropenia, or gastrointestinal upset; most cats develop new lesions which subsequently respond to imiquimod treatment.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

Topical synthetic retinoids (e.g., tretinoin)—may be useful for early solar-induced superficial lesions; may be irritating to skin.

FOLLOW-UP

PATIENT MONITORING

- Routine CBC and serum chemistry panel should be evaluated during medical therapy with chemotherapy or imiquimod cream.
- Physical examination at 1 month after resolution of tumor, then every 3 months after treatment or if the owner thinks the tumor is recurring.
- Thoracic radiography and lymph node evaluation at each 3-month recheck examination; abdominal radiography or ultrasound if the lesion is on the caudal portion of the patient.

PREVENTION/AVOIDANCE

- Limit sun exposure, especially between the hours of 10 a.m. and 3 p.m.
- Tattoos on nonpigmented areas may be helpful.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Prognosis—good with superficial lesions that receive appropriate treatment; guarded with invasive lesions, advanced stage of disease, or recurrent lesions.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Squamous Cell Carcinoma, Ear
- Squamous Cell Carcinoma, Nasal Planum

SYNONYM

MSCCIS—also called Bowen's-like disease or Bowenoid carcinoma *in situ* (cats).

ABBREVIATIONS

- MSCCIS = multicentric squamous cell carcinoma *in situ*
- NSAID = nonsteroidal anti-inflammatory drug
- SCC = squamous cell carcinoma

SQUAMOUS CELL CARCINOMA, TONGUE

BASICS

OVERVIEW

- Malignant tumor of squamous epithelium.
- Rare tumor that occurs more commonly in cats than in dogs. • Usually grows rapidly.
- Cats—most common lingual neoplasia, usually located at the ventral base of the tongue at the frenulum; most often progresses locally prior to clinical evidence of metastasis.
- Dogs—one of most common malignant lingual neoplasia (25–32%); variably metastatic by way of lymphatic vessels to regional lymph nodes and lungs (0–43%).
- Organ system: gastrointestinal.

SIGNALMENT

- Cats—middle-aged or old (> 7 years).
- Dogs—average 10–11 years; females more commonly affected; large breeds more commonly affected especially poodle, Labrador retriever, Samoyed.

SIGNS

Historical Findings

- Excessive salivation • Halitosis • Dysphagia or difficulty prehending food • Oral bleeding
- Decreased appetite • Weight loss • Poor grooming (cats)

Physical Examination Findings

- Incidental finding • Tongue mass—variable appearance, often nodular and ulcerated
- Facial swelling or deformity
- Intramandibular swelling (cats) • Cervical lymphadenomegaly—occasionally

CAUSES & RISK FACTORS

Potential increased risk of feline oral squamous cell carcinoma associated with flea collars, canned food (particularly tuna), and possibly exposure to tobacco smoke.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other lingual malignancy (melanoma, sarcoma, mast cell tumor, granular cell tumor)
- Trauma • Ulcerative glossitis • Benign lesion (papilloma) • Infection/abscess

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

IMAGING

- Advanced imaging with computed tomography or magnetic resonance imaging provides greatest information regarding extent of disease. • Thoracic radiography—three views required to evaluate lungs for metastasis (usually nodular), more common in dogs.

DIAGNOSTIC PROCEDURES

- Cytology—aspire or impression smear from incisional biopsy specimen (wedge); may yield diagnosis; however, ulceration, inflammation, and secondary infection may limit diagnostic utility. • Deep wedge tissue biopsy—necessary for definitive diagnosis.
- Cytology and/or lymph node biopsy to evaluate for regional metastasis; more common in dogs.

TREATMENT

- Surgical—generally inoperable in cats; aggressive excision warranted in dogs; function of the tongue after recuperation is usually acceptable in dogs, but will require changes in husbandry practices. • Post-surgical care (e.g., esophagostomy) by owner often required. • Partial glossectomy—may be performed on the rostral half (mobile tongue) or longitudinal half of the tongue (40–60% removed); ~35–50% of patients have incomplete surgical margins. • Subtotal glossectomy may be considered in select cases.
- Other surgical methods (e.g., electrocautery and cryosurgery) do not offer any additional advantage to conventional excision.
- Response to radiotherapy—poor (< 7 weeks); may be used adjunctively on microscopic disease postoperatively.
- Systemic therapies—chemotherapy agents or toceranib phosphate effective in oral squamous cell carcinoma might exert anticancer activities for lingual squamous cell carcinoma. • Piroxicam may have antineoplastic activity in some patients.
- Supportive/palliative medications for analgesia and antibiotics for secondary bacterial infections should be considered.

MEDICATIONS

DRUG(S)

- Piroxicam (dog) 0.3 mg/kg PO q24h; dosages have not been established for cats; however, 0.3 mg/kg PO q48h has been used anecdotally.
- Carboplatin—dogs, 250–300 mg/m² IV every 3 weeks; cats, 180–250 mg/m² IV every 3–4 weeks for 4 or 5 treatments. Toceranib phosphate (Palladia) in dogs give 2.75–3.25 mg/kg q48h.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Chemotherapy may be toxic; seek advice from a medical oncologist before initiating treatment if you are unfamiliar with cytotoxic drugs.

FOLLOW-UP

PATIENT MONITORING

After complete surgical resection, recheck at 1–2 months and then every 3 months with physical examination and evaluation for metastasis.

POSSIBLE COMPLICATIONS

Possible complications postoperatively—long-term difficulty prehending food, local recurrence.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—poor, owing to extensive local disease (cat) and local recurrence (28% for all lingual tumors) and moderate rate of metastasis (dog). • After surgical excision (subtotal glossectomy, dogs)—median survival 216 days, < 25% survive 1 year.
- Negative prognostic factors (dogs): caudal location, incomplete excision, recurrence, larger size (> 2 cm); histologic grade (grade I tumors median survival 16 months compared with grade II–III tumors, median survival 3–4 months), metastatic disease.
- Piroxicam—17% response rate in oral squamous cell carcinoma with a median progression-free interval of 3.5–6 months; one partial response in 3 dogs with lingual squamous cell carcinoma. • Prognosis in cats similar to other oral sites of squamous cell carcinoma; median survival ~3 months with palliative radiation/chemotherapy.

MISCELLANEOUS

Author Jackie M. Wypij

Consulting Editor Timothy M. Fan

SQUAMOUS CELL CARCINOMA, TONSIL

BASICS

OVERVIEW

- Rapid and progressive local invasion of neoplastic squamous epithelium arising from the tonsillar fossa into tonsillar lymphoid tissue.
- More common in dogs than cats; comprises 9% of canine oral tumors.
- Highly invasive locally into soft tissues.
- Early metastasis; considered systemic at diagnosis as 70–90% eventually metastasize regardless of local control (lymph nodes, lungs, other distant organs).
- Commonly unilateral; may be bilateral.
- Organ system: gastrointestinal.

SIGNALMENT

- Median age 10–12 years (range, 2.5–17 years) dog and cat
- No known breed or sex predilection

SIGNS

Historical Findings

- Cough
- Excessive salivation
- Halitosis
- Dysphagia
- Oral bleeding
- Increased respiratory noise (stridor)
- Weight loss
- Decreased appetite
- Lethargy

Physical Examination Findings

- Abnormally large tonsil (oral mass)
- Cervical lymphadenomegaly possible
- Pain on opening jaw

CAUSES & RISK FACTORS

Exact cause unknown; however, ten times more common in animals living in an urban environment versus those in a rural environment.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lymphoma (generally associated with lymphadenomegaly and bilateral disease)
- Abscess
- Metastatic neoplasm (oral melanoma, sarcoma)
- Tonsillitis
- Tonsillar crypt foreign body
- Salivary gland tumor
- Thyroid carcinoma
- Mast cell tumor

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

IMAGING

- Thoracic radiography—three-view to detect lung metastasis; 5–20% positive for metastasis at presentation; 60–85% metastasis at death.
- Computed tomography (CT scan)—evaluate local extension of primary tumor as well as mandibular and retropharyngeal lymph node involvement; recommended prior to surgical or radiation therapy planning.
- Abdominal ultrasonography—evaluate abdominal organs; in dogs 20% disseminated metastasis to multiple organs at death.

DIAGNOSTIC PROCEDURES

- Cytologic evaluation of lesion—fine-needle aspirate samples often non-diagnostic; obtain impression smear from an incisional biopsy specimen (wedge); ulceration, inflammation, and secondary infection may limit diagnostic utility.
- Large, deep tissue biopsy with histopathology—required to sufficiently differentiate from other oral malignancies.
- Cytology and/or biopsy of regional lymph nodes (mandibular, retropharyngeal) to evaluate for regional metastatic disease; in dogs 20–55% metastasis at diagnosis, 75% metastasis at death.

TREATMENT

- Surgery—most are inoperable; aggressive excision may be warranted in patients with airway obstruction; tonsillectomy, when done, should be bilateral.
- Postoperative care (e.g., esophagostomy or gastrostomy tube) by owner is often required.
- Other surgical methods (e.g., electrocautery and cryosurgery)—no advantage over conventional excision.
- Regional radiation therapy is effective for local control and palliation of clinical signs.
- Chemotherapy—anecdotal reports of cisplatin, carboplatin, doxorubicin being used with limited success.
- Piroxicam or toceranib phosphate (Palladia) may have antineoplastic effects in some dogs.
- Analgesics for pain control and antibiotics for secondary bacterial infections may be indicated.

MEDICATIONS

DRUG(S)

- Cisplatin (dogs) 60–70 mg/m² IV once every 3–4 weeks for 4 treatments; provides marked palliation of clinical signs; nephrotoxic—must use with saline diuresis (18.3 mL/kg/h IV over 6 hours; give cisplatin after 4 hours); pretreat with an antiemetic.
- Carboplatin—dogs, 250–300 mg/m² IV every 3 weeks; cats, 180–250 mg/m² IV every 3–4 weeks for 4 or 5 treatments.
- Piroxicam (dogs) 0.3 mg/kg PO q24h; toceranib phosphate (Palladia) 2.75–3.25 mg/kg q48h.
- Doxorubicin—dogs > 10 kg, 30 mg/m² IV; dogs < 10 kg and cats, 1 mg/kg once every 2–3 weeks for 5 treatments.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Cisplatin—never use in cats.
- Do not administer cisplatin with NSAIDs due to nephrotoxicity.

FOLLOW-UP

PATIENT MONITORING

Most patients euthanized within months for local progression or metastasis; patients with curative-intent therapies should be rechecked with physical examination and evaluation for metastasis at 1–2 months, then every 3 months. Local regrowth may be assessed by serial CT scans.

POSSIBLE COMPLICATIONS

Postoperative complications—tumor recurrence, may need feeding tubes postoperatively, especially cats (long term).

EXPECTED COURSE AND PROGNOSIS

- Prognosis—grave owing to extensive local disease and high rate of recurrence (tongue, pharynx, lymph nodes) and metastasis.
- Minimal information in cats; however, appear to carry a grave prognosis.
- Dogs: overall 11% 1-year survival.
- Untreated (dogs) median survival 2 months vs. treatment, median survival 7–8 months.
- Surgery has limited benefit—median survival 2–4 months (dogs).
- Surgery with radiation therapy or chemotherapy (dogs)—median survival 3–4 months.
- Palliative radiotherapy or chemotherapy (dogs)—75% response rate, 2–9 months median survival.
- Surgery, radiation therapy, and chemotherapy (dogs)—median survival 9–12 months.
- Piroxicam alone—17% response rate for all oral squamous cell carcinoma with a median progression-free interval of 3.5–6 months; 3 of 5 dogs with tonsillar SCC exhibiting a partial remission or stable disease.
- Negative prognostic factors in dogs include anorexia or lethargy at presentation.

STAPHYLOCOCCAL INFECTIONS

BASICS

OVERVIEW

- *Staphylococcus*—gram-positive, facultatively anaerobic, spherical bacteria (cocci); *staphyle* (Greek; “bunch of grapes”) from characteristic microscopic arrangement in clusters; produces a variety of infections characterized by pus formation involving all tissues of the body; can produce toxins (superantigens) that exert profound systemic signs (fever, hypotension, shock, multiorgan failure, death).
- Ubiquitous; live free in environment and as commensal parasites of skin and upper respiratory tract
- Pathogenic and non-pathogenic strains; wide spectrum of virulence, host range, and site specificities; not strictly host- or site-specific.
- Pathogenic strains—possess extracellular toxins and enzymes (e.g., coagulase, staphylokinase, hemolysin, epidermolyticus); staphylocoagulase in more pathogenic strains (e.g., *S. pseudintermedius*, *S. aureus*).

SIGNALMENT

- Dogs and cats.
- Very young—susceptible because of incomplete, developing immunity.
- Old, debilitated—susceptible because of impaired host defenses.
- Immunocompromised—more susceptible.

SIGNS

- Fever.
- Anorexia.
- Pain.
- Pruritus.
- Can affect every organ system.
- Abscesses and infections of the skin, eyes, ears, respiratory system, genitourinary tract, skeleton, and joints—common.
- Dogs—pyoderma; otitis externa; cystitis; prostatitis; pneumonia; abscesses; osteomyelitis; discospondylitis; arthritis; mastitis; bacteremia; endocarditis; wound infections; toxic shock syndrome.
- Cats—abscesses; oral infections; otitis externa; conjunctivitis; metritis; cholangiohepatitis; cystitis; bacteremia.

CAUSES & RISK FACTORS

- Opportunistic pathogens.
- Disease—from disturbance of the natural host-parasite equilibrium when local and general defense mechanisms are significantly lowered (e.g., chronic debilitating diseases).
- Secondary infection—allergies (atopy, food, fleas); endocrinopathies (hypothyroidism, hyperadrenocorticism); parasites (demodicosis); seborrhea.

- Burns or wounds—complications.
- Form biofilms (extracellular polysaccharide networks) of concern for infection of implants and invasive devices (e.g., IV catheters).
- Transmission—airborne organisms; carriers; and direct contact (droplet nuclei).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dermatitis—allergies, seborrhea, parasites, immune-mediated
- Other infectious causes—viruses, bacteria, fungi, *Rickettsia*, protozoa
- Neoplasia
- Immune-mediated diseases

CBC/BIOCHEMISTRY/URINALYSIS

- Normal or high WBCs.
- Biochemistry—may suggest underlying cause (e.g., hypothyroidism, hyperadrenocorticism).
- Urinalysis—pyuria (with or without bacteruria) with cystitis.

OTHER LABORATORY TESTS

- Direct microscopy.
- Gram stain.
- Cytology—neutrophils and cocci singly or in pairs, short chains, or irregular clusters.
- Culture—avoid superficial contamination; collect samples by aspiration, wash, or biopsy; do not overinterpret a positive isolation; organisms can be isolated from normal animals.
- Organisms survive up to 48 hours in clinical specimens when kept cool (4°C; 40°F), particularly on swabs containing a holding medium.
- Antibiotic susceptibility testing.
- PFGE molecular typing.

IMAGING

Radiology—osteolytic and osteoproliferative lesions with osteomyelitis; interstitial or alveolar pulmonary pattern with pneumonia; radiodense uroliths (struvite).

DIAGNOSTIC PROCEDURES

CSF—if meningitis or discospondylitis suspected.

PATHOLOGIC FINDINGS

Characteristic abscess lesion—necrotic tissue, fibrin, and a large number of neutrophils.

TREATMENT

- Properly handle and dispose of contaminated objects.

- Organism resistant to many environmental insults and common disinfectants.
- Topical antibacterial cleaning of wounds and pyoderma—may be beneficial.
- Known or suspected MRS infected animals should be isolated.

MEDICATIONS

DRUG(S)

- Antibiotic resistance—great propensity owing to production of β -lactamase, which inactivates penicillins; may carry plasmids (segments of genetic material that may carry genes for antimicrobial resistance) that can be transferred to other strains of staphylococci or species of bacteria.
- History of previous antimicrobial therapy for staphylococcal infection—culture and antibiotic susceptibility testing indicated.
- Non-penicillinase-producing strains—penicillin G at 10,000–20,000 U/kg IM, SC q12–24h, or penicillin V at 8–30 mg/kg PO q8h.
- Penicillinase-producing strains—use penicillinase-resistant drugs.
- First-generation cephalosporins—rarely resistant; cephalexin at 22 mg/kg PO q8h; cefadroxil at 22 mg/kg PO q8–12h.
- β -lactamase-resistant synthetic penicillins—rarely resistant; oxacillin at 22–40 mg/kg PO q8h; dicloxacillin at 10–25 mg/kg PO q8h; and clavulanic acid-potentiated amoxicillin at 12.5–25 mg/kg PO q8–12h.
- Gentamicin—rarely resistant; 2–4 mg/kg IV, IM, SC q8h.
- Enrofloxacin—rarely resistant; 2.5–5 mg/kg PO, IM q12h.
- Trimethoprim-potentiated sulfonamides—infrequently resistant; 30 mg/kg IV, PO q12h.
- Chloramphenicol—infrequently resistant; 40–50 mg/kg IV, IM, SC, PO q8–12h.
- Penicillin allergy—try cephalosporin, clindamycin, or vancomycin (although strongly discouraged to reserve vancomycin for treatment of serious MRSA infections in humans).
- Methicillin-resistant (*express meC gene* which encodes an altered penicillin-binding protein [PBP-2a]) *Staphylococcus* increasingly isolated from dogs and cats is an emerging problem due to their multidrug resistance phenotype which limits treatment options and challenges infection control measures.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid immunosuppressive drugs.

STAPHYLOCOCCAL INFECTIONS

(CONTINUED)

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

- Possible.
- Most people and pets carry their own pathogenic staphylococcal flora; disease not caused by mere exposure; however, transfer from dogs to humans possible.
- Bite infections contain a mix of aerobes and anaerobes from both the skin of the patient and the mouth of the animal including *Staphylococcus*.
- MRSA can be transmitted between animals and humans, thus pets pose risk of infection to owners and veterinary personnel (and

likewise human MRSA carrier can infect susceptible pet).

- Hand hygiene is an integral part of the prevention of the spread of MRSA between animals and between animals and humans.

ABBREVIATIONS

- CSF = cerebrospinal fluid
- MRS = methicillin-resistant *Staphylococcus pseudintermedius*
- MRSA = methicillin-resistant *Staphylococcus aureus*
- PFGE = pulsed field gel electrophoresis
- WBC = white blood cell

STEROID-RESPONSIVE MENINGITIS-ARTERITIS—DOGS

BASICS

OVERVIEW

- May be acute or protracted.
- Lesions—most impressive in CNS, affecting meninges and meningeal arteries; also vascular changes in the heart, liver, kidney, and gastrointestinal system.
- Genetic factors—may play a role; suspected in beagle colonies and in Nova Scotia duck tolling retrievers.
- Worldwide occurrence.

SIGNALMENT

- Dog. • Beagle, Bernese mountain dog, Nova Scotia duck tolling retriever, and Boxer predisposed; any breed can be affected.
- Mostly young adult dogs of both sexes; age range 5–18 months.

SIGNS

- Classical (acute)—hyperesthesia; cervical rigidity; stiff gait; fever up to 42°C (107.6°F).
- Protracted—neurologic deficits, usually reflecting a spinal cord or multifocal lesion.

CAUSES & RISK FACTORS

- Cause unknown.
- Pathologic findings, laboratory data, and marked response to steroids—suggest an immune-mediated disease related to a dysregulation of IgA production.
- Epidemiologic observations—altered immune response may be triggered by an environmental factor, possibly of infectious nature; genetic predisposition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute—bacterial meningitis; meningeal tumors; discospondylitis.
- Protracted—bacterial meningitis; meningeal tumors (histiocytosis, meningioma, lymphosarcoma); viral encephalitides; granulomatous meningoencephalitis; protozoal infections; other CNS inflammatory lesions of unknown origin.

CBC/BIOCHEMISTRY/URINALYSIS

- Acute—leukocytosis with neutrophilia and left-shift.
- Protracted—CBC non-contributory.

OTHER LABORATORY TESTS

IgA levels (serum and CSF)—usually high; high serum C-reactive protein levels.

IMAGING

Radiographs to exclude discospondylitis, MRI to exclude differential diagnoses.

DIAGNOSTIC PROCEDURES

Cerebrospinal Fluid Analysis

- Acute—mild-to-moderate elevation of protein; moderate-to-marked pleocytosis,

predominantly polymorphonuclear cells.

- Protracted—normal, or mild elevation of protein; mild-to-moderate pleocytosis with mixed cell population, or with a predominance of mononuclear cells.

PATHOLOGIC FINDINGS

Acute

- Marked meningitis with macrophages, plasma cells, lymphocytes, and varying numbers of polymorphonuclear cells mostly in the cervical region.
- Lesions of the meningeal arteries—degenerative with perivascular inflammation.

Protracted

- Marked fibrous thickening and focal mineralization of the leptomeninges.
- Arterial walls—thickened and stenotic from cellular proliferation of the intima and fibrosis.

TREATMENT

- Inpatient—at onset, fluid therapy and ice packs useful for high body temperature.
- After initial treatment, managed as outpatient.
- Regular follow-ups—inform client about side effects of long-term steroid treatment.

MEDICATIONS

DRUG(S)

- Initial signs with mild CSF pleocytosis—NSAIDs; carefully monitor the patient.
- First relapse, or symptoms become worse with marked CSF pleocytosis—start long-term treatment (6 months) with prednisolone (4 mg/kg PO q24h for 1–2 days; then taper slowly); reexamine patient (including CSF collection and blood profile) every 4–6 weeks after initiation of therapy.
- Neurologic examination and CSF become normal, normal serum C-reactive protein levels—reduce steroid dose.
- Persistent pleocytosis—continue same steroid dosage.
- Treatment may be stopped after about 6 months.
- Immunosuppressive drugs if patient does not respond well to prednisolone alone; used in combination.
- Consider gastrointestinal protector to avoid ulcer.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Corticosteroids—high-dose treatment can lead to severe complications; non-life-threatening side effects (polyuria, polydipsia, polyphagia, and weight gain); not tolerated in about 5% of dogs.

FOLLOW-UP

PATIENT MONITORING

Control examinations—every 4–6 weeks; include blood examination and CSF collection; measurement of serum C-reactive protein levels until steroids discontinued.

PREVENTION/AVOIDANCE

Strictly control treatment schedule to prevent frequent relapses.

POSSIBLE COMPLICATIONS

- Subarachnoid bleed—may result in acute tetra- or paraplegia.
- Hypoxic lesions of spinal cord or brain.
- Side effects of immunosuppressive treatment.

EXPECTED COURSE AND PROGNOSIS

- Acute—prognosis relatively good in young dogs with early aggressive therapy.
- Protracted cases with frequent relapses—prognosis guarded; controlled studies note about 60% of dogs are cured after immunosuppressive treatment.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Polyarthritis

AGE-RELATED FACTORS

Old animals do not tolerate long-term steroid treatment well, but condition rare in dogs > 5 years of age.

SYNOMYS

- Aseptic meningitis
- Canine juvenile polyarteritis syndrome
- Corticosteroid-responsive meningomyelitis

ABBREVIATIONS

- CNS = central nervous system
- CSF = cerebrospinal fluid
- CT = computed tomography
- MRI = magnetic resonance imaging
- NSAID = nonsteroidal anti-inflammatory drug

STERTOR AND STRIDOR

BASICS

DEFINITION

- Abnormally loud sounds that result from air passing through a narrowed nasopharynx, pharynx, larynx, or trachea.
- Discontinuous sounds heard without a stethoscope.
- Stertor—low-pitched snoring sound that usually arises from the vibration of flaccid tissue or fluid; usually arises from nasal or pharyngeal airway obstruction.
- Stridor—higher-pitched sounds that result when relatively rigid tissues are vibrated by the passage of air; result of partial or complete obstruction of the larynx or cervical trachea.

PATOPHYSIOLOGY

- Airway obstruction causes turbulence as air travels through a narrowed passage; with worsening obstruction or increasing airflow velocity, the amplitude of the sound increases as the tissue, secretion, or foreign body composing the obstruction vibrates.
- Obstruction sufficient to increase the work of breathing augments respiratory muscle effort and exacerbates turbulence; inflammation and edema of tissues in the region of the obstruction may develop, further reducing the airway lumen and further increasing the work of breathing, creating a vicious cycle.
- Obesity further increases respiratory effort and exacerbates airway obstruction.

SYSTEMS AFFECTED

Respiratory

GENETICS

- Brachycephalic syndrome heritable in many breeds.
- Inherited laryngeal paralysis—identified in Bouvier des Flandres, Rottweilers, Siberian huskies, and Dalmatians.

INCIDENCE/PREVALENCE

Common

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Common in brachycephalic dogs or cats
- Acquired laryngeal paralysis—overrepresented in certain giant breeds (e.g., Saint Bernards and Newfoundlands) and large breeds (e.g., Irish setters, Labrador retrievers, and golden retrievers).

Mean Age and Range

- Affected brachycephalic animals and dogs or cats with inherited laryngeal paralysis are typically younger than 1 year of age when owners detect a problem.

- Acquired laryngeal paralysis typically occurs in older dogs and cats.
- Cats—diagnosed less commonly than are dogs; no obvious age pattern.

Predominant Sex

No sex predilection for any cause, although inherited laryngeal paralysis has a 3:1 male predominance.

SIGNS

- Change or loss of voice.
- Partial obstruction—produces an increase in airway sounds before producing an obvious change in respiratory pattern or gas exchange.
- Owners may indicate that the sound has existed for as long as several years.
- Breath sounds audible from a distance without a stethoscope—suspect narrowing of upper airway.
- Nature of the sound—ranges from abnormally loud to obvious fluttering to high-pitched squeaking, depending on the degree of airway narrowing.
- May note increased respiratory effort and paradoxical respiratory movements (chest wall collapses inward during inspiration and springs outward during expiration) when the effort is extreme; respiratory motions often accompanied by obvious postural changes (e.g., abducted forelimbs, extended head and neck, and open-mouth breathing).

CAUSES

- Brachycephalic airway syndrome (stenotic nares, elongated soft palate, everted laryngeal saccules, laryngeal collapse).
- Laryngeal paralysis—inherited or acquired.
- Laryngeal neoplasia—benign or malignant.
- Granulomatous/inflammatory laryngitis.
- Tracheal collapse, stenosis, obstruction, neoplasia, foreign body.
- Nasopharyngeal polyp, stenosis, foreign body.
- Acromegaly.
- Neuromuscular dysfunction or trauma.
- Anesthesia or sedation—only if predisposing anatomy exists.
- Cystic Rathke cleft.
- Cleft soft palate.
- Aplasia of soft palate.
- Redundant pharyngeal mucosal folds.
- Soft palate mass.
- Edema or inflammation of the palate, pharynx, and larynx (including everted mucosal lining of the laryngeal ventricles)—secondary to coughing, vomiting or regurgitation, turbulent airflow, upper respiratory infection, and hemorrhage.
- Secretions (e.g., pus, mucus, and blood) in the airway lumen—acutely after surgery; a normal conscious animal would cough out or swallow them.

RISK FACTORS

- High ambient temperature or humidity.
- Fever.

- High metabolic rate—as occurs with hyperthyroidism or sepsis.
- Exercise.
- Anxiety or excitement.
- Any respiratory or cardiovascular disease that increases ventilation.
- Turbulence caused by the increased airflow can lead to swelling and worsen the airway obstruction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Systematically auscultate over the nose, pharynx, larynx, and trachea to identify the point of maximal intensity of any abnormal sound and to identify the phase of respiration when it is most obvious.
- Important to identify the anatomic location from which the abnormal sound arises and to seek exacerbating causes (see “Risk Factors”; e.g., a chronic airway obstruction may become manifest when the patient is exposed to extremely high ambient temperatures).
- Must differentiate sounds of pharyngeal, laryngeal, and tracheal narrowing from sounds arising elsewhere in the respiratory system.
- Nasal and tracheal narrowing and severe or extensive narrowing of the bronchi—can cause increased respiratory sounds.
- If the sound persists when the patient opens its mouth, a nasal cause can virtually be ruled out.
- If the owner describes a change in voice, the larynx is the likely abnormal site.

OTHER LABORATORY TESTS

Arterial blood gas occasionally indicated; hypoxia and hypoventilation occur with prolonged severe obstruction.

IMAGING

- Lateral radiographs of the head and neck—may help identify abnormal soft tissues of the airway (e.g., elongated soft palate or a nasal polyp); limited use for identifying laryngeal paralysis, although experienced radiographers can identify abnormally dilated or swollen laryngeal saccules; cartilaginous destruction is suggestive of neoplasia or granulomatous laryngitis; may detect external masses compressing the upper airway.
- Radiography and fluoroscopy—important for assessing the cardiorespiratory system; rule out other or additional causes of respiratory difficulty; such conditions may add to an underlying upper airway obstruction, causing a subclinical condition to become clinical.
- Digital radiology is preferred for best detail.
- Ultrasound can be used to assess laryngeal structure and function, can also be used to document cervical tracheal collapse but air is a poor acoustic window.
- Computed tomography can be used to provide additional anatomic detail.

(CONTINUED)

DIAGNOSTIC PROCEDURES**Pharyngoscopy and Laryngoscopy**

- Definitive diagnostic tests for direct visualization of pharyngeal or laryngeal changes
- Require heavy sedation that preserves laryngeal function
- Remember that the patient's ability to use muscles to open the airway is compromised by anesthesia; veterinarian and clients must determine if they are prepared to carry out surgical remedies if indicated.
- If correctable conditions are not identified and corrected—patient's recovery from anesthesia can be complicated by severe airway obstruction; must be prepared to perform a tracheotomy if airway is obstructed and a definitive surgical remedy cannot be pursued immediately.
- Assess timing and degree of movement of the vocal folds during light anesthesia—evaluate laryngeal paralysis. Use dopram (1 mg/kg IV) to stimulate respiration if needed.
- Normal palate—thin; just barely overlaps the tips of the epiglottis; easily displaced dorsally using the blade of the laryngoscope.
- Overlong soft palate—thick; usually inflamed; may lie 1 cm or more past the tip of the epiglottis.
- Patient should be as stable as possible before undergoing general anesthesia, but do not unduly delay procedure; appropriate surgical treatment is usually the only means of reducing the airway obstruction.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Inpatient management required for surgical treatment.
- Closely monitor effects of sedatives; sedatives can relax the upper airway muscles and worsen the obstruction; be prepared with emergency methods for securing the airway if complete obstruction occurs. Diazepam preferred.
- Extreme airway obstruction—attempt an emergency intubation; if obstruction prevents intubation, emergency tracheotomy or passage of a tracheal catheter to administer oxygen may be the only available means for sustaining life; a tracheal catheter can briefly sustain oxygenation while a more permanent solution is sought.

NURSING CARE

- Treatment requires removal of obstruction, supplemental oxygen is variably helpful.
- Intravenous fluids may be required, particularly if hyperthermia develops from increased work of breathing.

- Active cooling measures (ice packs in axilla and groin region, alcohol on foot pads, chilled IV fluids) helpful in alleviating hyperthermia but not indicated for fever.

ACTIVITY

Keep patient cool, quiet, and calm—anxiety, exertion, and pain lead to increased ventilation, potentially worsening the obstruction.

DIET

- NPO if anesthesia is planned.
- Avoid obesity that worsens respiratory effort.

CLIENT EDUCATION

Inform client that the patient can make the transition from being a noisy breather to having an obstructed airway in a few minutes or even seconds.

SURGICAL CONSIDERATIONS

- Laryngoscopy and bronchoscopy for foreign body retrieval and biopsy of laryngeal region and tracheal lumen. Use of small balloon catheters passed beyond the foreign body prior to expansion may be useful in removing some objects.
- Take particular care when inducing general anesthesia or when using sedatives in any patient with upper airway obstruction.
- Surgery—indicated to obtain a diagnosis through biopsy with histopathology, to manage obstruction while awaiting histopathology results or resolution of inflammation/infection (e.g., tracheotomy), or to resolve disease by excision, correction of obstructive lesion, and removal of foreign bodies.

**MEDICATIONS****DRUG(S)**

- Medical approaches—appropriate only if the underlying cause is infection, edema, inflammation, or hemorrhage; anatomic or neurologic causes are not amenable to medical treatment.
- Steroids—may be indicated if edema or inflammation is thought to be an important contributor; effect with intravenous administration should be apparent in approximately 1 hour. Single dose may be sufficient or a tapering dose might be required. Inflammatory laryngitis often requires higher doses administered over a longer dosing schedule with taper of the dose according to resolution of clinical signs.

PRECAUTIONS

Sedatives, analgesics, and anesthetics—avoid excessive suppression of laryngeal movement

and respiratory suppression to avoid aspiration in animals with laryngeal disease.

**FOLLOW-UP****PATIENT MONITORING**

Respiratory rate and effort need to be closely monitored. When owner chooses to take an apparently stable patient home, or if continual observation is not feasible, inform client that complete obstruction could occur.

PREVENTION/AVOIDANCE

Advise client to avoid exercise, high ambient temperatures, and extreme excitement.

POSSIBLE COMPLICATIONS

Serious complications may occur without therapy to relieve the obstruction; these include airway edema, pulmonary edema (may progress to life-threatening acute lung injury), and hypoxia; may require tracheotomy and/or artificial ventilation.

EXPECTED COURSE AND PROGNOSIS

- Varies with underlying cause.
- Even with surgical treatment, some degree of obstruction may remain for 7–10 days due to swelling.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Peripheral neuropathy often associated with laryngeal paralysis.

STOMATITIS

BASICS

DEFINITION

Inflammation of the mucous lining of any of the structures in the mouth; in clinical use the term should be reserved to describe widespread oral inflammation (beyond gingivitis and periodontitis) that may also extend into submucosal tissues (e.g., marked caudal stomatitis extending into submucosal tissues may be termed "caudal stomatitis").

PATHOPHYSIOLOGY

- Inflammation and other changes may develop in the normal oral mucosa because of the tremendous amount of vasculature in the area and its proximity to the external environment.
- Can also affect behavior due to discomfort and difficulties in eating; ophthalmic conditions due to proximity of some oral structures to ocular structures; and skin if inflammation extends to the peri-oral area.

SIGNALMENT

Species

Dogs and cats

Breed Predilections

- Ulcerative stomatitis in Maltese—higher incidence in males.
- Oral eosinophilic granuloma—most commonly in Siberian husky (may be hereditary).
- Gingival hyperplasia in large breeds (see Gingival Hyperplasia/Enlargement).
- Rapidly progressive periodontitis seen mostly in young adult animals, such as in the greyhound and the shih tzu.
- Localized juvenile periodontitis in the maxillary or mandibular incisor region—especially common in miniature schnauzer.

Mean Age and Range

- Juvenile-onset periodontitis in young cats.
- Periodontal disease associated with calculus is seen most often in old dogs and cats and in susceptible breeds.

Predominant Sex

None

SIGNS

General Comments

A definitive diagnosis of inflammation often cannot be made based on physical examination findings alone.

Physical Examination Findings

- Halitosis.
- Pain.
- Ulcerated lesions.
- Ptyalism.
- Edema.
- Periocular inflammation possible due to proximity to oral cavity.
- Extensive plaque and calculus. Look for lesions on oral buccal and labial surfaces that

are adjacent to teeth with large amounts of calculus.

CAUSES

Anatomic

- Periodontal disease due to overcrowding of teeth
- Lip frenulum attachment
- Tight-lip syndrome in shar-pei

Metabolic

- Uremia and high ammonia levels in saliva
- Vasculitis and xerostomia seen with diabetes mellitus
- Macroglossia and puffy lips as seen with hypoparathyroidism
- Lymphoma can be seen affecting the palate and/or tongue

Immune Mediated

- Pemphigus foliaceus
- Pemphigus vulgaris
- Bullous pemphigoid
- Systemic lupus erythematosus and discoid lupus erythematosus in the dog
- Acute hypersensitivity to drugs
- Caudal stomatitis in cats may have an immune-mediated component

Infectious

- Opportunistic oral flora secondary to oral lesions
- Mycotic stomatitis
- Systemic infections
- Leptospirosis: petechia
- Feline leprosy (mycobacterium): raised plaques
- Calicivirus or herpesvirus infections—cat
- Canine distemper
- Viral papillomatosis—dogs

Trauma

- Irritation from calculus and plaque
- Foreign objects—gum-chewers syndrome
- Electrical cord shock
- Chemical burns
- Lacerations
- Snake bite
- Blows
- Trauma of the palate from base-narrow mandibular canine teeth

Toxic

- Certain plants
- Chemotherapy
- Radiotherapy
- Chemical irritants

RISK FACTORS

- Poor oral health due to gingivitis, plaque, calculus, or periodontitis.
- Stress may be a factor in caudal stomatitis in cats.
- May be environmental factors in some cases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Oral ulcers

- Chronic ulcerative paradental stomatitis (CUPS)
- Idiopathic osteomyelitis
- Lymphoma

CBC/BIOCHEMISTRY/URINALYSIS

Biochemical tests to detect other diseases

OTHER LABORATORY TESTS

- Immunologic testing
- Mycotic cultures
- Virus isolation
- Toxicologic studies
- Serum protein electrophoresis
- Endocrine tests

IMAGING

Radiography to identify osseous or dental abnormalities

DIAGNOSTIC PROCEDURES

Biopsy

TREATMENT

APPROPRIATE HEALTH CARE

- Correct nutritional or hydration deficiencies as needed, on an inpatient or outpatient basis.
- Dental disease or periodontal disease present should be treated.

NURSING CARE

Can place feeding tube if necessary.

ACTIVITY

N/A

DIET

Consider using a hypoallergenic diet to reduce the antigen load that accumulates on the tooth surfaces in plaque. Dietary adjustments may need to be made depending on the patient's ability to eat if painful.

CLIENT EDUCATION

Clients must be aware that this is a multifactorial, often chronic condition that will require constant management, with variable responses from patients.

SURGICAL CONSIDERATIONS

Sometimes most or all teeth must be extracted to resolve stomatitis, especially caudal stomatitis in cats.

MEDICATIONS

DRUG(S) OF CHOICE

- Antimicrobials—broad-spectrum antibiotics; amoxicillin-clavulanate; clindamycin; metronidazole (10 mg/kg PO q12h or 40–50 mg/kg as a loading dose on the first day, followed by 20–25 mg/kg q8h for 7 days or less); doxycycline (5 mg/kg PO loading dose, 2.5 mg/kg PO 12h later, and 2.5 mg/kg PO once daily thereafter); chlorhexidine solution or gel (CHX, VRx Products, Harbor City, CA)—plaque

(CONTINUED)

STOMATITIS

retardant; and Maxi/Guard (Addison Biological, Fayette, MO)—zinc-organic acid solutions and gels to promote tissue healing and retard plaque accumulation.

- Anti-inflammatory drugs—prednisolone or prednisone; for eosinophilic ulcer (2–4.4 mg/kg PO once a day; for chronic cases use 0.5–1 mg/kg PO every other day); for adjunctive therapy of feline plasma cell gingivitis–pharyngitis—may improve inflammation and appetite.
- Immunosuppressive drugs if secondary to autoimmune disease.
- Chemotherapy if secondary to lymphoma.
- Omega interferon (recombinant feline interferon)—submucosal infiltrations: 1–2 MU/buccal cavity, repeated 3 times at 2-week intervals if necessary, or 1 MU/kg SC q48h for 5 injections.

CONTRAINDICATIONS

Immunosuppressive therapy if secondary to infectious disease.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

Evaluate oral cavity periodically to monitor for resolution or recurrence of oral lesions.

PREVENTION/AVOIDANCE

- OraVet (Merial, Atlanta, GA) applied weekly to calculus-free teeth might be helpful

in preventing further inflammation to oral tissues.

- Oral rinses and brushing the teeth with oral medications may be helpful, especially with periodontal disease.

POSSIBLE COMPLICATIONS

Bacteremia from periodontal disease may cause renal, cardiac, hepatic, and pulmonary disease.

EXPECTED COURSE AND PROGNOSIS

Varies with underlying cause.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Periodontitis
- Oropharyngeal inflammation
- Gingivitis
- Alveolar mucositis
- Sublingual mucositis
- Labial/buccal mucositis
- Caudal mucositis
- Palatitis
- Glossitis
- Cheilitis
- Osteomyelitis
- Tonsillitis
- Pharyngitis

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

Dental prophylaxis procedures in pets have caused human infections from aerosolized

bacteria. Safety glasses and a mask are recommended when performing such procedures.

PREGNANCY/FERTILITY/BREEDING

N/A

SYNONYMS

- St. Vincent's stomatitis, an ulceromembranous stomatitis due to *Fusobacterium* spp. and spirochetes
- Trench mouth

STOMATITIS, CAUDAL—CAT

BASICS

OVERVIEW

- Inflammatory response affecting the oral cavity in cats.
- Oral and oropharyngeal inflammation is classified by location as:
 - Gingivitis—inflammation of gingiva.
 - Periodontitis—inflammation of non-gingival periodontal tissues (i.e., the periodontal ligament and alveolar bone).
 - Alveolar mucositis—inflammation of alveolar mucosa (i.e., mucosa overlying the alveolar process and extending from the mucogingival junction without obvious demarcation to the vestibular sulcus and to the floor of the mouth).
 - Sublingual mucositis—inflammation of mucosa on the floor of the mouth.
 - Labial/buccal mucositis—inflammation of lip and cheek mucosa.
 - Caudal mucositis—inflammation of mucosa of the caudal oral cavity, bordered medially by the palatoglossal folds and fauces, dorsally by the hard and soft palate, and rostrally by alveolar and buccal mucosa.
 - Palatitis—inflammation of mucosa or covering the hard and/or soft palate.
 - Glossitis—inflammation of mucosa of the dorsal and/or ventral surface of the tongue.
 - Cheilitis—inflammation of the lip (including the mucocutaneous junction area and skin of the lip).
 - Osteomyelitis—inflammation of jaw bone and bone marrow.
 - Stomatitis—inflammation of the mucous lining of any of the structures in the mouth; in clinical use the term should be reserved to describe widespread oral inflammation (beyond gingivitis and periodontitis) that may also extend into submucosal tissues.
 - Tonsillitis—inflammation of the palatine tonsil.
 - Pharyngitis—inflammation of the pharynx.

SIGNALMENT

- Cats
- Purebred breeds predisposed—Abyssinian, Persian, Himalayan, Burmese, Siamese, and Somali

SIGNS

- Ptyalism.
- Halitosis.
- Dysphagia.
- Anorexia—prefers soft food.
- Weight loss.
- Scruffy hair coat from lack of grooming.
- Erythematous, ulcerative, proliferative lesions affecting the gingiva, glossopalatine arches, tongue, lips, buccal mucosa, and/or hard palate.
- Gingival inflammation commonly completely surrounds the tooth, compared with gingivitis, which usually occurs on the buccal and labial surfaces.
- May extend to the glossopharyngeal arches as well as the palate.

CAUSES & RISK FACTORS

- Cause unknown; bacterial, viral, and immunologic etiologies suspected.

- Significant findings of feline calicivirus.
- Immunosuppression from FeLV or FIV can also lead to poorly responsive infections; most affected cats are negative for FeLV and FIV.

- Refractory cases with extensive proliferative lesion in the caudal oral cavity and pharynx warrant a more guarded prognosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Periodontal disease
- Oral malignancy
- Eosinophilic granuloma complex

CBC/BIOCHEMISTRY/URINALYSIS

- Elevated globulin. Polyclonal gammopathy secondary to antibody production following bacterial invasion into periodontal tissues.
- Leukocytosis and eosinophilia may be present.

IMAGING

Intraoral radiographs to evaluate periodontal disease and tooth resorption.

DIAGNOSTIC PROCEDURES

Biopsy (especially unilateral lesions) to rule out neoplasia—primarily squamous cell carcinoma.

TREATMENT

- Initial therapy for early mucositis involves dental scaling above and below the gingiva and treatment (extraction) for teeth affected with grades 3 and 4 periodontal disease and/or tooth resorption.
- For cases of focal vestibular and alveolar mucositis, extraction of the locally affected teeth in proximity to the lesions usually results in resolution.
- For caudal stomatitis, extraction of the maxillary and mandibular teeth distal to the canines resulted in resolution of inflammation in 60% of cases without further need for medication, 20% of cases required control with medication, and 20% did not resolve in one published study.
- To aid the extractions: create a gingival flap in all quadrants for exposure. After completely elevating all of the roots, use a high-speed drill with water spray to create a trough of bone where the roots were, removing most of the keratinized gingiva, periodontal ligament, and periradicular alveolar bone. Before suturing, “smooth down” the alveolar margin to remove sharp edges with a round or football-shaped diamond bur.
- If patients do not respond to extraction of the teeth distal to the canines, consider a trial of prednisone 2 mg/kg every other day to control the inflammation or, remove all teeth; when extracting the teeth, pay meticulous attention to removing all dental hard tissue; take intraoral radiographs before and after surgery; postoperative application of fluocinonide 0.05% (Lidex Gel) to the gingival margin may help healing.

MEDICATIONS

DRUG(S)

- Medication and other therapies have been used with limited long-term success; lack of permanent response to conventional oral hygiene, antibiotics, anti-inflammatory drugs, and immunosuppressive drugs is typical.
- Medications should not be regarded as the primary method to control oropharyngeal inflammation.
- Antibiotics—clindamycin (5 mg/kg q12h), metronidazole, amoxicillin, ampicillin, enrofloxacin, tetracycline.
- Corticosteroids—prednisone (2 mg/kg initially daily, followed by every other day); methylprednisolone acetate (2 mg/kg q7–30 days) may also help control inflammation.
- Gold salts—Solganal (Schering) 1 mg/kg IM weekly until improvement (up to 4 months), then every 14–35 days.
- Chlorambucil 2 mg/m² orally every other day or 20 mg/m² every other week.
- Bovine lactoferrin (40 mg/kg) applied to the oral mucous membranes.
- Interferon—alpha or omega 30 IU/day 7 days on, 7 days off, indefinitely.
- CO₂ laser to decrease inflamed tissue.
- Cyclosporine—2 mg/kg BID.

MISCELLANEOUS

SYNOMYMS

- Lymphocytic plasmacytic stomatitis
- Stomatitis

ABBREVIATIONS

- FeLV = feline leukemia virus
- FIV = feline immunodeficiency virus

STREPTOCOCCAL INFECTIONS

BASICS

OVERVIEW

- *Streptococcus*—gram-positive, non-motile, facultatively anaerobic spherical bacteria (cocci); grow in pairs or chains; commensal organisms; normal flora of the upper respiratory tract, oropharynx, lower genital tract, and skin; under appropriate conditions, capable of infecting all areas of body; primary infections involve respiratory, circulatory, integumentary, urogenital, or central nervous systems; frequent secondary invader of body tissues.
- Classified by ability to hemolyze RBCs and produce zone on blood agar plates around bacterial colony— α -hemolytic (green zone of partial hemolysis); β -hemolytic (clear zone of hemolysis); γ -hemolytic (no change; non-hemolytic); β -hemolytic usually more pathogenic than α -hemolytic, which is more pathogenic than non-hemolytic strains.
- Hemolytic strains further subdivided by antigenic differences in cell wall carbohydrates—Lancefield serogroups A–H and K–T (e.g., group G *S. canis*); some groups more likely to be associated with disease, depending on species (e.g., group G associated with cats and dogs; group A associated with humans).
- Produce exotoxins—streptolysins (hemolysins), streptokinases, deoxyribonucleases, and hyaluronidases.
- Produce adhesions to bind to extracellular matrix proteins.

SIGNALMENT

- Dogs and cats.
- Very young—more prone to infection because of incomplete, developing immunity; particularly kittens born to primiparous queen.

SIGNS

- Vary with site of infection and host immunocompetence.
- Weakness.
- Coughing.
- Dyspnea.
- Fever.
- Hematemesis.
- Hematuria.
- Lymphadenopathy.
- Pain.
- Dogs—abscesses; septicemia; endometritis; pyometra; vaginitis; mastitis; proctitis; otitis; arthritis; fading puppies; abortion; urinary tract infection; pyelonephritis; pneumonia; endocarditis; meningoencephalitis; necrotizing fasciitis and myositis; streptococcal toxic shock syndrome; wound infections; bitch sterility.
- Cats—abscesses; septicemia; peritonitis; cervical lymphadenitis; pharyngitis; tonsillitis; arthritis; pneumonia; fading kitten; necrotizing fasciitis.

OTHER LABORATORY TESTS

- Age, exposure, and immune response—important for determining disease.
- Virulence—depends on cellular products, surface components, and related substances.
- Opportunistic—wounds, trauma, surgical

procedures, viral infections, or immunosuppressive conditions.

- Co-infection with canine influenza virus (CIV) increases severity of disease.
- FeLV, FIP, immunodeficiency, respiratory viral infections, feline lower urinary tract disease—predisposing conditions.
- Maternal antibodies generally protect puppies and kittens against clinical disease.
- Carrier state occurs.
- Bacterial superantigens suspected as cause of multiple organ involvement in toxic shock syndrome and necrotizing fasciitis and myositis; association with enrofloxacin may be due to enrofloxacin-induced bacteriophages enhancing superantigen expression.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other infectious causes—viruses, bacteria, fungi, *Rickettsia*, protozoa.

CBC/BIOCHEMISTRY/URINALYSIS

- Normal or high WBCs with neutrophilic inflammatory response with a left shift or degenerative left shift.
- Cocci—may be found in circulating neutrophils in overwhelming sepsis.
- Biochemistry—may suggest predisposing conditions.
- Urinalysis—pyuria (with or without bacteruria) with cystitis.

OTHER LABORATORY TESTS

- Direct microscopy.
- Gram stain—of exudates; reveals chains of and single gram-positive cocci.
- Culture—affected tissues; exudate or needle aspirates; confirms diagnosis.
- Antibiotic susceptibility testing.
- PCR.

IMAGING

Radiographs—interstitial or alveolar pulmonary pattern with pneumonia; radiodense uroliths (struvite).

PATHOLOGIC FINDINGS

- Acute inflammation—gross or microscopic abscesses.
- Septicemia—post-mortem reveals omphalophlebitis, peritonitis, hepatitis, pneumonia, and myocarditis.

TREATMENT

- Good nursing care
- Rehydrate
- Drain and flush abscess
- Debride necrotic tissue

MEDICATIONS

DRUG(S)

- Penicillin—first choice; penicillin G at 10,000–20,000 U/kg IM, SC q12–24h, or penicillin V at 8–30 mg/kg PO q8h.

- Ampicillin 20–30 mg/kg IV, IM, SC, PO q8h; alone or in combination with gentamicin at 2–4 mg/kg IV, IM, SC q8h; for group B.
- Erythromycin 10–20 mg/kg IV, SC, PO q8h.
- Clindamycin 11 mg/kg PO q12–24h.
- Prophylactic treatment—all kittens born to primiparous queens indicated for neonatal infections.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid immunosuppressive drugs.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Avoid overcrowding and poor environmental sanitation.
- Prevention in newborns—dipping navel and umbilical cord in 2% tincture of iodine.
- Prevention in colonies—avoid overcrowding; maintain clean feeders; segregate infected animals.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Dogs and cats may show no clinical signs with group A streptococci but may serve as a reservoir for human infection.
- Streptococci isolated from people are usually of human, not animal, origin.
- *S. canis* infections in people reported from dog bites and ulcers or wounds in contact with dogs.

ABBREVIATIONS

- FeLV = feline leukemia virus
- FIP = feline infectious peritonitis
- PCR = polymerase chain reaction
- RBC = red blood cell
- WBC = white blood cell

STRONGYLOIDIASIS

BASICS

OVERVIEW

- Dogs—infection of small intestinal mucosa by *Strongyloides stercoralis*; only female nematodes are parasitic; can cause diarrhea and/or bronchopneumonia.
- Free-living males mate with females in the environment. In infected animals, female worms reproduce by parthenogenesis.
- Cats—natural *S. stercoralis* infection not reported in United States; *S. tumefaciens* uncommon—infection of large intestine causing grossly visible nodules.
- Multiple routes of transmission for infective larvae including skin penetration, ingestion, and transmammary; infective larvae can develop from eggs in GI tract and auto-infect host, resulting in persistent infection.
- Relatively host-specific; potential for transmission to humans.

SIGNALMENT

- Dogs and cats.
- Pups (possibly kittens) due to transmammary transmission of larvae from dam.

SIGNS

- S. stercoralis*—usually asymptomatic, can be severe, especially in young.
- Development of clinical signs follows larval migration pathway from skin penetration to lungs and then to small intestine.
- Debilitated pups or kittens.
- Dermatitis.
- Cough, bronchopneumonia.
- Diarrhea (especially in neonates); may contain blood or mucus; constipation.
- Cats (*S. tumefaciens*) usually asymptomatic; palpable firm colon.

CAUSES & RISK FACTORS

- Transmammary transmission if bitch is infected during late gestation or lactation; no dormant larvae occur in tissues of bitch.
- Infective larvae in environment contaminated with feces penetrate skin, especially under conditions of poor sanitation, high temperatures, and high humidity.
- Increased prevalence in kennels.
- Possible autoinfection due to rapid development of larvae to infective stage within host GI tract.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Multiple other parasite, viral, or bacterial enteric infections and non-infectious causes of diarrhea.

CBC/BIOCHEMISTRY/URINALYSIS

Eosinophilia can occur.

OTHER LABORATORY TESTS

N/A

IMAGING

Nodules of *S. tumefaciens* may be visible by colonoscopy.

DIAGNOSTIC PROCEDURES

- Egg with larva or just larvae may be detected in feces. Eggs are less than 50 μm , which is a good criterion for differentiating them from strongyle eggs which are larger. Detection of first stage larvae with rhabditiform (barbell-shaped) esophagus in fresh feces or third stage larvae with filariform (straight, cylindrical) esophagus and forked tail in incubated feces; repeated fecal examinations may be necessary because larvae are shed irregularly and in low numbers.
- Baermann method most sensitive, other methods include formalin-ethyl acetate.
- S. tumefaciens*—also examine nodules microscopically for adult females, eggs, and larvae.
- Necropsy—microscopic examination of small intestinal mucosal scrapings for adult females (2–2.5 mm \times 35 μm) with long cylindrical esophagus occupying one-third of body length and first-stage larvae (200–250 μm long) with rhabditiform esophagus.

TREATMENT

Usually anthelmintic treatment as outpatient unless intravenous fluid supplementation needed for dehydration.

MEDICATIONS

DRUG(S)

- Anthelmintic use is extra-label.

- Fenbendazole 50 mg/kg PO q24h for 5 days; may need to be repeated.
- Ivermectin 0.2 mg/kg SC or PO as single dose; repeat treatment may be needed; dose is extra-label.
- Adulicide/larvicide (fenbendazole) recommended for infection in neonates to eliminate larvae undergoing lung migration.

CONTRAINdications/POSSible INTERACTIONS

Do not give ivermectin at 0.2 mg/kg to heartworm-positive patients or to ivermectin-sensitive dog breeds, e.g., collies.

FOLLOW-UP

PATIENT MONITORING

Repeat fecal examinations monthly for 6 months after treatment to assure clearance of infection; larval shedding intermittent.

PREVENTION/AVOIDANCE

Kennels—implement thorough daily cleaning, disinfection with 1% bleach, and monthly anthelmintic treatment to eliminate or minimize number of infective larvae present in environment.

MISCELLANEOUS

ZOONOTIC POTENTIAL

S. stercoralis is probably underdiagnosed in humans. Humans can develop dermatologic lesions at the site of skin entry, severe abdominal discomfort, and diarrhea.

ABBREVIATION

- GI = gastrointestinal

Author

Matt Brewer

Consulting Editor Stephen C. Barr

Acknowledgment The author and editors acknowledge the prior contribution of Julie Ann Jarvinen.

BASICS

OVERVIEW

- Stupor—unconscious but arousable with noxious stimuli.
- Coma—unconscious, not arousable with noxious stimuli.

PATHOPHYSIOLOGY

Ascending reticular activating system—network of neurons situated in the core of the brainstem; arousal system for the cerebral cortex; any severe pathologic change (anatomic or metabolic) that causes interruption can lead to depression, stupor, or coma.

SYSTEMS AFFECTED

- Nervous
- Cardiovascular
- Neuromuscular
- Ophthalmic
- Respiratory

SIGNALMENT

- Dog and cat
- No breed, age, or sex predilection

SIGNS

Historical Findings

- Possibility of trauma or unsupervised roaming.
- Past medical problems of significance—diabetes mellitus and insulin therapy; hypoglycemia; cardiovascular problems; hypoxic episodes; renal failure; liver failure; neoplasia.
- Patient's environment—possible heatstroke; hypothermia; drowning; exposure to drugs, including owner's medications narcotics, and toxins (e.g., ethylene glycol, lead, anticoagulants).
- Onset may be acute or slowly progressive, depending on underlying cause.

Physical Examination Findings

- Look for evidence of external or internal trauma.
- Severe hypothermia or hyperthermia.
- Evidence of hypoxia or cyanosis, ecchymosis or petechiation, or cardiac or respiratory insufficiency—warrants investigation for metabolic causes.
- Palpate for evidence of neoplasia.
- Retinal hemorrhages or distended vessels—hypertension.
- Papilledema—cerebral edema.
- Retinal detachment—infectious, neoplastic, or hypertensive causes.
- Chorioretinitis—infectious causes (distemper, FeLV-related diseases, toxoplasmosis, cryptococcosis, or coronavirus).
- Sustained bradycardia (with normal serum potassium)—midbrain, pontine, or medullary lesion.

Neurologic Examination Findings

- Differentiate cerebrum-diencephalon lesion from brainstem lesion (better vs. worse prognosis).
- Determine level of consciousness and if patient arousable.
- Pupillary light reflexes—small responsive pupils: cerebral or diencephalic lesion; dilated unresponsive pupils (unilateral or bilateral) or fixed in midposition: midbrain or severe

medullary lesions.

- Oculocephalic reflex (when cervical manipulation possible)—loss of physiologic vestibular nystagmus: brainstem involvement.
- Respiratory patterns—Cheyne-Stokes respiration: severe, diffuse cerebral or diencephalic lesion; hyperventilation: midbrain lesion; ataxic or apneustic breathing: pons or medulla lesion.
- Cranial nerves—no deficits with lesion of cerebrum-diencephalon; deficits of cranial nerve III: midbrain lesion; deficits of cranial nerves V–XII: pons and medulla lesions.
- Postural changes—decerebrate rigidity: midbrain lesion.

CAUSES

- Drugs—narcotics; anesthetics; depressants; ivermectin
- Anatomic—hydrocephalus.
- Metabolic—severe hypoglycemia; hyperglycemia; hyperosmolar syndromes; hypernatremia; hyponatremia; hepatic encephalopathy; hypoxemia; hypercarbia; hypothermia; hyperthermia; hypotension; coagulopathies; renal failure; lysosomal storage disease, severe hypothyroidism
- Nutritional—hypoglycemia; thiamin deficiency
- Neoplastic (primary)—meningioma; astrocytoma; gliomas; choroid plexus papilloma; pituitary adenoma; others
- Metastatic—hemangiosarcoma; lymphoma; mammary carcinoma; others
- Inflammatory non-infectious—granulomatous meningoencephalomyelitis
- Infectious—bacterial; viral (distemper, FCoV); parasitic (aberrant larva migrants); protozoal (neosporosis, toxoplasmosis); fungal (cryptococcosis, blastomycosis, histoplasmosis, coccidioidomycosis, actinomycosis); tick-borne diseases
- Idiopathic—epilepsy (post-status epilepticus)
- Immune-mediated—vasculitis and thrombocytopenia leading to hemorrhage
- Traumatic
- Toxins—ethylene glycol; lead; rodenticide anticoagulants; others
- Vascular—hemorrhage (bleeding disorders, hypertension); infarction (feline ischemic encephalopathy, microfilaria, or migrating adult heartworm)

RISK FACTORS

- Diabetes mellitus—insulin therapy
- Hepatic failure
- Insulinoma
- Severe heat or cold exposure without protection
- Free-roaming animals—trauma
- Young and unvaccinated animals
- Hypertension

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute onset—most commonly caused by toxins, drugs, trauma, or vascular accidents
- Slow progression of neurologic signs without systemic abnormalities—suggests primary neurologic disorders of inflammatory, neoplastic, or anatomic causes
- Bilateral

diffuse cortical signs—metabolic diseases, toxins, systemic infection, drugs, and nutritional causes

- Brainstem signs—trauma, inflammation, neoplasia, vascular accidents, or commonly from progression of cerebral disease causing tentorial herniation

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Lead toxicity—may show nucleated red blood cells or basophilic stippling
- Severe infection—inflammatory hemogram
- Severe anemia—suggests hypoxemia

Biochemistry

May see hypoglycemia, hyperglycemia, hypernatremia, azotemia, hyperosmolarity, and other metabolic derangements

Urinalysis

- Diabetes mellitus—glycosuria
- Renal failure—isosthenuria, granular casts
- Immune-mediated disease or severe infection—proteinuria
- Hepatic encephalopathy—ammonium biurate crystals
- Ethylene glycol toxicity—calcium oxalate or hippurate crystals

OTHER LABORATORY TESTS

- Serum ethylene glycol level and osmolar gap—acute onset.
- Serum ammonia concentrations and preprandial and postprandial bile acids—high levels indicate hepatic encephalopathy.
- Serum and CSF titers—suspected infectious disease.
- Arterial blood gases—evidence of hypoxemia; severe pH changes; hypo- and hyper-carbia.
- Coagulogram—including PT, PTT, fibrinogen, fibrin degradation product, d-dimer, platelet count, antithrombin, and buccal bleeding time; suspected intracranial bleeding or thrombosis.
- Serologic testing—FeLV, FIV, FCoV, protozoal and heartworm disease.
- Serum toxicity levels (e.g., lead, macrolide).
- Thyroid panel.

IMAGING

- Survey radiographs (chest and abdomen)—evidence of heavy metal, organ enlargement, infiltration, or neoplasia.
- Skull radiographs—fractures in trauma cases, masses.
- CT—excellent for detecting acute hemorrhage within calvaria; depressed fractures; penetrating foreign bodies.
- MRI with contrast—demonstrates cerebral edema, hemorrhage, mass, infiltrative diseases.

DIAGNOSTIC PROCEDURES

- CSF—cytology, protein and immunoglobulin concentrations, and titers for infectious diseases; perform only when no evidence of trauma, increased intracranial pressure, coagulopathies, or metabolic disease.
- Brainstem auditory-evoked response—determine brainstem function.
- ECG—determine cardiac dysfunction; abnormalities may contribute to stupor or coma or may be caused by brain disease.
- EEG—detect nonclinical seizure activity that can prolong stupor and coma.

STUPOR AND COMA

(CONTINUED)

PATHOLOGIC FINDINGS

Cerebral edema; hemorrhage; infarct; ischemia; inflammation; neoplasia; herniation; laceration; contusion; hematomas; skull fracture; necrosis and apoptosis.

TREATMENT

POOR PERFUSION

- Small volume fluid resuscitation technique; a combination of hydroxyethyl starch with balanced isotonic crystalloids. • Use peripheral veins, leaving the jugular vein blood flow unobstructed; shifting blood volume into the jugular veins is an important compensatory mechanism during high ICP.
- Maintain systolic BP > 90 mmHg; avoid hypertension. • Hydration—maintain with a balanced electrolyte crystalloid solution.
- The head and neck should be leveled with the body or elevated to a 20° angle. • Oxygen supplementation—avoid a cough or sneeze reflex during intubation or nasal cannula placement; administer lidocaine (dogs, 1–2 mg/kg IV) before intubation to blunt the gag and cough reflex. • PaO₂ must be > 50 mmHg to maintain cerebral blood flow auto-regulation in normal tissue.

VENTILATION

- PaCO₂—maintain between 35–45 mmHg.

REDUCE INCREASE IN ICP

- Prevent thrashing, seizures, or any other form of uncontrolled motor activity that can elevate ICP; diazepam infusion (0.5–1 mg/kg/h), midazolam (0.2–0.4 mg/kg), or propofol (3–6 mg/kg IV titrated to effect; then 0.1–0.6 mg/kg/min CRI); levetiracetam 20 mg/kg IV/IM/rectal q8h if seizure activity. • Ensure systolic BP > 90 mmHg. • 7% hypertonic saline (2–4 mL/kg IV); can reduce fluid volume needed to reach resuscitation endpoints; combine with colloid. • Furosemide 0.75 mg/kg IV; may decrease CSF production; used in patients with congestive heart failure, volume overload, hyperosmolar diseases, or anuric renal failure; use before mannitol. • Mannitol 0.1–0.5 g/kg IV bolus repeated at 2-hour intervals 3 or 4 times in dogs, and 2 or 3 times in cats; repeated doses must be given on time; improves brain blood flow and lowers ICP. • Hyperventilation (PaCO₂ 32–35 mmHg) for 48 hours using mechanical ventilation; requires intensive monitoring. • Ventriculostomy for drainage of CSF if critical elevation of ICP nonresponsive to medical treatment.

- Consider surgical decompression and exploration—if cerebral dysfunction is progressing to midbrain signs with a history of trauma or bleeding (tentorial herniation); high ICP not responsive to medical therapy (if monitoring instrumentation available);

depressed skull fracture fragments; penetrating foreign body; requires intensive monitoring.

NURSING CARE

- Prevent secondary complications of recumbency—eye lubrication; aseptic technique with catheters; turning. • Prevent urine/fecal scalding. • Careful nasogastric tube feeding for early trickle flow feeding; cisapride (0.5 mg/kg PO q8–12h) and metoclopramide (1–2 mg/kg/day) may promote GI motility.

MEDICATIONS

DRUG(S) OF CHOICE

Underlying Disease

- Glucocorticosteroids—inflammatory, immune-mediated and space-occupying intracranial abnormalities. • Lactulose enemas, flumazenil (0.02 mg/kg IV) and fluid support—hepatic encephalopathy. • Fluid diuresis, dialysis—renal failure. • Rehydration and insulin—diabetes mellitus with hyperosmolarity; lower glucose slowly.
- Glucose supplementation—hypoglycemia.
- Support intravascular volume; cool—hyperthermia. • Support intravascular volume; warm to ≥ 98°F—hypothermia.
- Gastric lavage and instillation of activated charcoal with a cathartic—toxin ingestion.
- Specific toxins may require specific therapeutics (e.g. ethylene glycol treated with ethanol and peritoneal/hemo dialysis).
- Antibiotics—use agents that cross the blood-brain barrier for suspected bacterial infections (e.g., trimethoprim-sulfa, clindamycin, doxycycline, and metronidazole). • Adjust crystalloid fluid selection to correct electrolyte disorders.
- Thiamin (cat, 5–50 mg; dog, 1–20 mg IV)—possible thiamin deficiency.

CONTRAINDICATIONS

N/A

PRECAUTIONS

- Avoid hypo- and hypertension, hypo- and hyperglycemia. • Avoid intravascular volume overload.

FOLLOW-UP

PATIENT MONITORING

- Serial neurologic examinations—detect deterioration that warrants aggressive therapeutic intervention. • BP—keep fluid therapy adequate for perfusion while avoiding hypertension. • Blood gases—assess need for oxygen supplementation or ventilation; monitor PCO₂ when hyperventilating.
- Blood glucose—ensure adequate level to

maintain brain functions while avoiding hyperosmolality. • ECG—detect arrhythmias that may affect perfusion, oxygenation, and cerebral blood flow. • ICP—detect marked elevations; track success of therapeutics.

- Electrolytes—detect hypernatremia and hypokalemia.

PREVENTION/AVOIDANCE

- Keep pets confined or leashed. • Prevent exposure to toxins or in-home medications.
- Routine healthcare program to minimize infectious and metabolic disease complications.

POSSIBLE COMPLICATIONS

- Residual neurologic deficits and seizures.
- Complications consistent with underlying disease.

EXPECTED COURSE AND PROGNOSIS

- Pathology of brainstem worse than pathology of cerebral cortex. • Glasgow Coma Score can provide prognostic information.

MISCELLANEOUS

ABBREVIATIONS

- BP = blood pressure • CSF = cerebrospinal fluid • CT = computed tomography
- ECG = electrocardiogram • EEG = electroencephalogram • FeLV = feline leukemia virus • FCoV = feline coronavirus
- FIV = feline immunodeficiency virus
- ICP = intracranial pressure • MRI = magnetic resonance imaging • PaCO₂ = partial pressure of carbon dioxide in arterial blood • PaO₂ = partial pressure of arterial oxygen • PT = prothrombin time • PTT = partial thromboplastin time

SUBARACHNOID CYSTS (ARACHNOID DIVERTICULUM)

BASICS

DEFINITION

Subarachnoid cysts refer to dilation of the subarachnoid space causing compression of the underlying spinal cord. The use of the term "cyst" is misleading, as most do not have a defined cyst wall with an epithelial lining and the term subarachnoid diverticulum is frequently used.

PATHOPHYSIOLOGY

- There are several proposed etiologies of subarachnoid cysts.
- Any disease process that causes arachnoiditis has the potential to cause adhesions that result in the formation of one-way valves through which CSF flows, but cannot return, thus producing a "cyst."

SYSTEMS AFFECTED

Nervous—spinal cord and brain (quadrigeminal cistern)

GENETICS

Certain breeds appear to be predisposed (e.g., pug, rottweiler for spinal cord, Pekingese, Shih Tzu for brain), but there is no data confirming heritability or a mode of inheritance.

INCIDENCE/PREVALENCE

No specific data

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Spinal: pug, rottweiler, French bulldog
- Brain: small brachycephalic breeds

Mean Age and Range

Dogs < 3 years, range 2.5 months–13 years

Predominant Sex

Male > female

SIGNS

Historical Findings

Spinal

- Owners report a slowly progressive ataxia and paresis involving all or just the pelvic limbs.
- Fecal incontinence—common early sign of thoracolumbar cysts, with urinary incontinence developing shortly after.
- Owners do not usually report that the pet is in pain. In a study of 122 cases, 19% of the dogs had pain.
- There may be prior history of traumatic spinal cord injury.

Brain

- Cerebellar signs
- Seizures

Physical Examination Findings

Usually normal, although possible secondary consequences of the myelopathy include abrasions of the dorsal aspect of the toes, wearing of the nails, and urinary tract infections.

Neurologic Examination Findings

Spinal

- Neurologic signs reflect lesion localization—hindlimb involvement for thoracolumbar cysts and all limbs for cervical cysts.
- Ataxia frequently characterized by hypermetria.
- Paresis.
- Proprioceptive placing deficits.
- Fecal and/or urinary incontinence; urine retention (due to defective voiding).
- Spinal reflexes may be reduced if the lesion is at the brachial or lumbosacral intumescence but otherwise are normal or increased.
- Spinal pain is rarely elicited.

Brain

- Quadrigeminal cysts are frequently an incidental finding. However, extremely large cysts can produce compression of the cerebellum and brainstem.
- Signs of cerebellar disease—hypermetria, intention tremor, wide based stance.
- Signs of brainstem compression—tetraparesis, head tilt.
- Seizures (the relationship between the cyst and the presence of seizures is unclear).

CAUSES

- Several proposed etiologies.
- Congenital malformation of the arachnoid mater (dilated septum posticum; in young dogs).
- Secondary to traumatic injury to the arachnoid, causing adhesions and development of one-way valves for CSF flow.
- Secondary to chronic microtrauma to the arachnoid, causing adhesions and development of one-way valves for CSF flow. This mechanism has been proposed for pugs with caudal thoracic subarachnoid cysts. Affected dogs have hypoplasia of their articular facets leading to chronic instability.

RISK FACTORS

- Traumatic spinal cord injury that damages the arachnoid mater.
- Hypoplastic articular facets associated with subarachnoid cysts in certain dog breeds (pugs).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Distinctive features—slowly progressive, nonpainful paresis and ataxia with a hypermetric gait, and presence of fecal and/or urinary incontinence in an animal that is still ambulatory.
- Any cause of focal myelopathy could cause the same neurologic presentation.
- Intervertebral disc herniation.
- Neoplasia.
- Trauma.
- Inflammatory or infectious myelitis.
- Congenital vertebral/spinal malformation.
- Intraspinal vascular malformation.

CBC/BIOCHEMISTRY/URINALYSIS

Urinalysis may show evidence of urinary tract infection (pyuria, hematuria, proteinuria, and bacteriuria).

OTHER LABORATORY TESTS

Aerobic urine culture if evidence of urinary tract infection.

IMAGING

- Thoracic radiography—in older patients to rule-out metastatic neoplasia.
- Spinal radiography—should be performed in all patients; typically unremarkable in patients with subarachnoid cysts. However, some patients may have evidence of spinal fractures, and occasionally there is evidence of a vertebral malformation (articular facet hypoplasia, spina bifida, hemivertebra, or block vertebra) co-localizing with the neurologic signs.
- Myelography—focal dilation of the subarachnoid space most commonly located dorsally but sometimes located ventrally; the dilation may be multilobed.
- CT myelography—further delineates the dilated subarachnoid space in transverse section; without intrathecal contrast, will not demonstrate the lesion.
- MRI—dilation of the subarachnoid space in sagittal and transverse section on T2-weighted images. T2-HASTE images provide even more definition of the CSF accumulation. The presence of active arachnoiditis can be detected on pre- and post-contrast T1-weighted images.

DIAGNOSTIC PROCEDURES

CSF—to rule out a primary inflammatory process; may show mild inflammation as secondary consequence of the subarachnoid cyst.

PATHOLOGIC FINDINGS

- At surgery, adhesions may be evident in the subarachnoid space. Occasionally a thin cyst wall is apparent (this is unusual).
- Histopathology of excised arachnoid—may show fibrosis or mild inflammation.
- Histopathology of the spinal cord shows chronic compressive injury—loss of gray and white matter, Wallerian degeneration, demyelination.

TREATMENT

APPROPRIATE HEALTH CARE

- Patients with mild signs can be managed medically; surgery recommended for young dogs with moderate, progressive signs.
- Non-ambulatory patients should be hospitalized for diagnostic workup and possible surgical decompression as soon as possible.

NURSING CARE

- Patients that have incomplete micturition should have their bladders manually expressed three to four times a day. If this is not possible, their bladders should be catheterized in a sterile fashion once to twice a day.

SUBARACHNOID CYSTS (ARACHNOID DIVERTICULUM)

(CONTINUED)

- Appropriate maintenance fluids should be administered in the immediate postoperative period.
- Postoperative pain should be assessed regularly (q6h) and treated as needed with opiates and nonsteroidal anti-inflammatory drugs.
- Surgical incisions should be ice packed for 5–10 minutes three times a day for 24 hours after surgery and then should be hot packed for a similar period for an additional 2–5 days.
- Rehabilitation is important; a patient-specific rehabilitation program should be developed to include gait training and improvement of strength.

ACTIVITY

- Paretic and ataxic patients need to be restricted to non-slip, flat surfaces to avoid falling.
- Exercise should be restricted to walking on a leash to avoid falling, but controlled exercise is important in maintaining muscle strength and joint integrity.
- Postoperatively, patients need to be restricted to a small, well-padded space (crate) to ensure that they do not fall while the laminectomy site is healing. Limited controlled exercise should be performed during this period.

CLIENT EDUCATION

- Clients need to be educated on the implications of a chronic compressive myelopathy; permanent damage to the spinal cord has already occurred and may not be reversible. The primary aim of treatment is to prevent further deterioration, with a hope of also producing a clinical improvement.
- There may be an initial deterioration immediately postoperatively; there is a small chance that this deterioration could be permanent.
- Incontinence, if present, is likely to be permanent.
- The disease may recur in spite of surgical therapy.

SURGICAL CONSIDERATIONS

- Surgical decompression of spinal subarachnoid cysts is recommended in young dogs and can be attempted in older animals.
- Marsupialization of the meninges may reduce the chance of a recurrence.
- Surgical treatment of quadrigeminal cysts is only recommended if there are clear signs of compression of adjacent cerebellum and cerebral cortex. Direct surgical exploration and decompression or shunt placement can be attempted.

MEDICATIONS

DRUG(S) OF CHOICE

- Anti-inflammatory doses of prednisone (0.5 mg/kg orally once to twice a day) may improve signs and reduce inflammation. If there is no improvement, prednisone should be tapered and discontinued.

- Omeprazole may reduce CSF production rate and improve signs. If there is no improvement it should be discontinued.
- Treatment with antiepileptic drugs should be initiated in dogs with more than 1 seizure a month or cluster seizures. Choice of antiepileptic drug depends on a number of patient and client factors. Phenobarbital (starting at 2 mg/kg q12h), zonisamide (starting at 5–10 mg/kg q12h) and levetiracetam (starting at 20 mg/kg q8h) are all appropriate choices for first-line therapy.

CONTRAINDICATIONS

N/A

PRECAUTIONS

Corticosteroids should be used with caution if the patient has urinary tract infection.

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- If response to prednisone is being assessed, the patient's gait and postural reactions should be reassessed in 1–2 weeks. The owner's assessment of continence is also important.
- If there is a positive response to medical management, the patient should be monitored every 8–12 weeks for maintenance of the improvement over the next 6 months and then every 6–12 months. The owner should be instructed to call if deterioration in clinical signs is detected.
- Surgical treatment—patient reassessed at 7–10 days for suture removal, evaluation of incision, and to ensure that there is no deterioration in gait, level of pain, continence; reassessment at 1–3 months and every 6–12 months subsequently. Telephone updates are acceptable if the patient is doing well.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Clients may encounter fecal and urinary incontinence.
- If incontinent, there is a predisposition to urinary tract infections.
- Signs may recur at any time.

EXPECTED COURSE AND PROGNOSIS

Spinal Cysts

- Surgical decompression produces a good long-term outcome (more than 1 year) in approximately 66% of dogs with spinal disease.
- Age at onset of signs and duration of signs are associated with outcome. Dogs less than 3 years of age and with a short duration of signs (less than 4 months) are more likely to have a good long-term outcome.
- There is

no data on the prognosis with medical management, but anecdotally the author can report a good long-term outcome in old dogs with mild signs when treated with prednisone and rehabilitation alone.

Quadrigeminal Cysts

Data on prognosis of quadrigeminal cysts managed medically or surgically is extremely limited but suggests that a positive outcome can be attained with both treatment strategies.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Cervical cysts are more common in dogs < 3 years of age and thoracolumbar cysts are common in old pugs.

PREGNANCY/FERTILITY/BREEDING

N/A

SYNONYMS

Arachnoid diverticula, arachnoid cyst, meningeal or leptomeningeal cyst

SUBINVOLUTION OF PLACENTAL SITES

BASICS

OVERVIEW

- Failure or delay of normal postpartum uterine involution (normally requires 12–15 weeks to complete).
- Failure of eosinophilic masses of collagen at placental sites to slough at 3–4 weeks postpartum.
- Failure of fetal trophoblastic cells to regress (normally occurs within 2 weeks); instead, they invade the maternal deep glandular endometrium and myometrium.
- Cause—unknown; hormonal or uterine basis not suspected based on coexistence of unaffected and subinvolved placental sites in the same uterus.

SIGNALMENT

- Dog only
- Bitch < 3 years most common
- Higher incidence in first litter
- No breed predilections

SIGNS

Historical Findings

- Patient presented > 12 weeks postpartum
- Serosanguineous vulvar discharge beyond 12 weeks postpartum
- Typically no systemic signs; rare occurrence of hypovolemic shock

Physical Examination Findings

- Serosanguineous vulvar discharge
- Firm, spherical structures within uterus on abdominal palpation

CAUSES & RISK FACTORS

- Unknown.
- Hormonal—unlikely, because only some of the placental sites may be involved.
- Uterine disease—unlikely, because of high first litter prevalence.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Metritis—differentiated by vaginal cytology and physical examination.
- Vaginitis—differentiated by vaginal cytology.
- Vaginal neoplasia—differentiated by vaginal cytology and vaginal endoscopy.
- Uterine neoplasia—differentiated by ultrasonography or exploratory laparotomy.
- Cystitis—differentiated by vaginal cytology and urinalysis obtained by cystocentesis.
- Coagulopathy—differentiated by clotting times.
- Trauma.
- Endogenous estrogen stimulation—bitch with an extremely shortened interestrous interval.

- Exogenous estrogen stimulation—oral medication or contact with topical hormone replacement product on human skin, bedding, or clothing.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

- Serology for *Brucella canis* negative
- Progesterone < 2 ng/mL

IMAGING

Uterine ultrasonography—focal uterine wall thickening; possible echogenic fluid in the lumen.

DIAGNOSTIC PROCEDURES

- Vaginal cytologic examination—key for diagnosis; reveals erythrocytes and parabasal epithelial cells; may note pathognomonic trophoblastic cells (polynucleated, heavily vacuolated).
- Guarded anterior vaginal or transcervical uterine culture—if vaginal cytologic examination or hemogram supports a diagnosis of secondary metritis.

PATHOLOGIC FINDINGS

- Gross—sites characterized by a thickened, hemorrhagic area that may be nodular.
- Histopathologic—definitive diagnosis; eosinophilic collagen masses with trophoblasts extending into the myometrium.

TREATMENT

- Usually outpatient.
- Spontaneous remission—occurs in most patients before or at next cycle; medical therapy is generally not warranted.
- Medical—for rare development of anemia, metritis, or peritonitis.
- Severely affected patients—may require blood transfusion (rare).
- Warn owner of the rare possibility of excessive hemorrhage; instruct owner to monitor mucous membrane color.
- Ovariohysterectomy—curative; treatment of choice if future breeding not desired.
- Surgical curettage of subinvolved sites—may also be performed; effectiveness unknown.

MEDICATIONS

DRUG(S)

- Oxytocin generally not successful.
- Ergonovine 0.2 mg/15 kg IM (10–30 µg/kg) once; do not use if uterus friable.
- Small study showed response to megestrol acetate 0.1 mg/kg q24h for 1 week, then 0.05 mg/kg q24h daily for 1 week; 5 of 6

treated bitches were successfully bred, with normal parturition and puerperal periods.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Ecbolics—may cause uterine rupture.
- Progestational drugs—increase the risk of metritis, which may mimic pyometra or induce cystic endometrial hyperplasia.

FOLLOW-UP

PATIENT MONITORING

- Mucous membrane color and amount of discharge.
- Packed cell volume—if anemia is a concern.
- Changes in discharge color or odor and vaginal cytologic examination and culture—diagnose secondary infection.

POSSIBLE COMPLICATIONS

Infection, blood-loss anemia, or uterine rupture—rare

EXPECTED COURSE AND PROGNOSIS

- Spontaneous resolution—the usual outcome in the majority of cases.
- Recurrence—not expected, occurs rarely.
- Prognosis for future reproduction—excellent with spontaneous resolution.

SUBMISSIVE AND EXCITEMENT URINATION—DOGS

BASICS

OVERVIEW

- Excitement and submissive urination occur as distinct behavioral presentations but may overlap in some patients.
- Submissive urination is related to fearful responses—animal perceives potential threat or danger during interaction and displays submissive behavior, including urination, as appeasement gesture to abort potential escalation of aggressive interactions.
- Generally seen in interaction with people; however, submissive urination may occur during interactions with other animals, especially conspecifics.

SIGNALMENT

- Onset as puppy in dogs of either sex; generally < 1 year of age
- Anecdotally higher incidence in some small breeds, e.g. dachshund, cocker spaniel
- Not observed in cats

SIGNS

- Excitement: loss of urine control in situations of high arousal—greeting people, anticipation of activities such as walks or car rides; no actual urination posturing seen—urine is expelled while dog is engaged in activities such as jumping up or play; dog does not necessarily show submissive behaviour.
- Submissive/fear: expelling small amounts of urine during interactions with people or other animals or in frightening situations; partial or full squatting position; dog may lift one hind leg partially for inguinal presentation.
- Dogs may be excited and aroused yet submissive or fearful during greeting—when there are competing motivations this might therefore be described as conflict induced—the approach may be active with tail wagging and crouching/low body posture.

CAUSES & RISK FACTORS

See "Signs"

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Incontinence, ectopic ureter, patent urachus
- Cystitis

- Disorders of urethral competence (which may increase severity or frequency of urination during submissive or excitement urination)

- Disorders causing PU/PD may decrease pet's ability to maintain bladder control.

CBC/BIOCHEMISTRY/URINALYSIS

Indicated only to rule out medical disorders

IMAGING

Indicated only to rule out medical disorders

DIAGNOSTIC PROCEDURES

Indicated only to rule out medical disorders

TREATMENT

Excitement urination

- Avoid arousing situations.
- Do not greet dog when aroused/excited—greet dog away from front door and several minutes after arrival only after dog is calm.
- When entering home, toss treats away to redirect and distract pet; over time can gradually transition to tossing treats closer to person and eventually hand treats to pet when pet sits calmly on cue.
- Avoid high-pitch excited speech around pet; avoid eye contact if it arouses/excites the pet.
- Teach owner to reinforce calm behavior and teach behaviors incompatible with high arousal, e.g. sit or lie down for greetings and before walks.
- Owners should interact with pet in emotionally neutral, low-key manner.

Submissive/fear urination

- Avoid threatening or confrontational interactions; do not lean over pet, do not punish or raise voice with pet; avoid eye contact.
- Avoid deep, loud or high-pitch excited speech while around or interacting with the pet.
- Move slowly and consistently around pet to avoid potential startling or threatening actions.
- Squat down or greet/interact with pet while sitting in chair or on floor with the body turned partially away from the dog.
- Redirection or distraction with food treats or toys; toss treats away to redirect and distract pet; over time can gradually transition to tossing treats closer to person and eventually hand treats to pet when pet sits calmly on cue.

- Teach behaviors incompatible with submissive posturing using positive reinforcement (food treats): pet sitting upright with head and ears up and forward; eye contact.

- Owner should turn and walk away or back away if pet begins to show submissive posturing.

MEDICATIONS

- Medications generally not indicated but could consider: Phenylpropanolamine (12.5–50 mg PO up to q8h) temporarily to increase urethral sphincter tone while behavior modification is taking effect.
- Imipramine (2.2–4.4 mg/kg PO q12h) or clomipramine (1–3 mg/kg PO q12h): increase urinary retention through anticholinergic effects; serotonin and norepinephrine properties can help reduce excitement or fear that contribute to urinating.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Prognosis is good if owners can follow simple behavior modification steps; a number of pets will improve with maturity alone.

SUPERFICIAL NECROLYTIC DERMATITIS

BASICS

OVERVIEW

- Uncommon in dogs; rare in cats.
- Usually a cutaneous marker for advanced liver disease with or without concurrent diabetes mellitus.
- Lesion pathogenesis unclear; keratinocyte degeneration and necrosis possibly due to cutaneous nutritional deprivation; hyperglucagonemia, hypoaminoacidemia, zinc and essential fatty acid deficiencies believed to play a role.

SYSTEMS AFFECTED

- Skin/Exocrine
- Endocrine/Metabolic
- Hepatobiliary

SIGNALMENT

- No breed predilection
- Older dogs

SIGNS

- Skin—lesions often precede clinical evidence of internal disease by weeks or months; erythema, crusts, and erosions/ulcerations affecting the muzzle, mucocutaneous areas of the face, pinna, distal limbs (especially elbows and hocks), feet, perineum, perianal area, and external genitalia.
- Footpads—hyperkeratotic with fissures and ulcerations; pain when walking.
- Pruritus absent to severe.
- Secondary bacterial and/or yeast infection—mainly footpad lesions.
- Feline—alopecia and scaling of the limbs and trunk (two cases); erythema, ulceration, crusting, and alopecia of the limbs and trunk (one case); crusts and hyperkeratosis of paw pads (one case).

CAUSES & RISK FACTORS

- Specific cause unknown.
- Cutaneous nutritional deprivation—probably hypoaminoacidemia and/or deficiencies in essential fatty acids and zinc; due to metabolic abnormalities caused by hyperglucagonemia, liver dysfunction, or a combination.
- Usually associated with advanced liver disease with or without concurrent diabetes mellitus.
- Rarely associated with pancreatic or extrapancreatic glucagon-secreting tumor, ingestion of mycotoxins, or long-term phenobarbital and phenytoin therapies.
- Feline—one case each of pancreatic carcinoma, hepatic carcinoid, hepatopathy, and hepatopathy and intestinal lymphoma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pemphigus foliaceus.
- Systemic lupus erythematosus.
- Zinc-responsive dermatosis.
- Toxic epidermal necrolysis.
- Drug eruption.
- Feline exfoliative skin diseases:

thymoma-associated exfoliative dermatitis and cutaneous epitheliotropic lymphoma. • Distal extremity erythema and footpad hyperkeratosis with fissures/ulcerations: suggestive of this condition in dogs.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia—occasional; normocytic, normochromic, nonregenerative.
- RBC abnormalities—polychromasia, anisocytosis, poikilocytosis, target cells.
- ALP, ALT, and AST—high activity with advanced liver disease.
- Total bilirubin—variably high.
- Albumin—frequently low.
- Biochemistry abnormalities other than hypoalbuminemia are unusual in dogs with glucagon-secreting tumors.
- Most patients eventually develop borderline or frank hyperglycemia.

OTHER LABORATORY TESTS

- Bile acid levels—variably high.
- Liver biopsy—vacuolar hepatopathy with parenchymal collapse and nodular hyperplasia.
- Elevated plasma glucagon levels—present with glucagon-secreting tumors; variable with chronic liver disease.
- Hypoaminoacidemia—common.
- High insulin levels may be noted.
- BSP retention—typically increased.

IMAGING

- Abdominal radiography and ultrasonography—“honeycomb” pattern on liver ultrasound in advanced hepatopathy.
- Usually unremarkable with pancreatic or rarely extrapancreatic glucagon-secreting tumor unless large enough to visualize.

DIAGNOSTIC PROCEDURES

Skin biopsy: sample early lesions; include crusts and avoid eroded/ulcerated lesions.

PATHOLOGIC FINDINGS

- Skin biopsy—diffuse parakeratotic hyperkeratosis with high-level intracellular and intercellular epidermal edema; irregular epidermal hyperplasia and mild-to-severe superficial perivascular dermatitis.
- Chronic lesions—marked parakeratotic hyperkeratosis and epidermal hyperplasia.

TREATMENT

- Usually as outpatients.
- Supportive care for systemic signs.
- Surgical excision of glucagon-secreting tumors—can be curative if no metastasis.
- Most cases caused by chronic irreversible liver disease.
- Oral nutritional support—high-quality protein diet or protein supplement for non-encephalopathic cases; three to six cooked whole eggs or yolks per day.
- Inform clients that this disorder indicates concurrent internal disease.
- Hydrotherapy and shampoos—remove crusts; lessen pruritus and pain.

MEDICATIONS

DRUG(S)

- Specific treatment—attempt to correct the underlying disease if possible.
- Nonspecific therapy—antibiotics and antifungal drugs for secondary skin infections.
- Amino acid hyperalimentation—intravenous administration of a 10% crystalline amino acid solution (e.g., Aminosyn) approx 25 mL/kg, administrated over 6–8 hours and repeated every 7–10 days or as needed for symptom relief. Oral amino acid therapy may be beneficial.
- Octreotide (somatostatin analogue) 2–3.2 µg/kg subcutaneously q6–12h as maintenance therapy for patients with nonresectable glucagon-secreting tumors.
- Glucocorticoids—can improve skin lesions; consider use carefully; encourages development of diabetes mellitus.
- Colchicine (0.03 mg/kg/day) may be beneficial in advanced liver disease.
- Zinc sulfate (10 mg/kg/day), zinc gluconate (5 mg/kg/day), or zinc methionine (2 mg/kg/day)—adjunctive therapy.
- Essential fatty acids—adjunctive therapy.

FOLLOW-UP

POSSIBLE COMPLICATIONS

- Liver failure
- Diabetes mellitus (indicates worse prognosis)
- Secondary bacterial and/or yeast skin infections

EXPECTED COURSE AND PROGNOSIS

- Prognosis poor; survival time reported as 5 months after development of skin lesions.
- Very rare incidence of recovery if hepatic/metabolic insult resolves.

SUPRAVENTRICULAR TACHYCARDIA

BASICS

DEFINITION

Repetitive supraventricular premature depolarizations that originate from a site other than the sinus node, such as the atrial myocardium or atrioventricular nodal tissue.

ECG Features

- Heart rate—rapid, 150–350 bpm in dogs. The lower rate of supraventricular tachycardia depends on the size of the patient. Smaller dogs typically have higher sinus nodal rates than larger dogs.
- Rhythm usually very regular (R-R interval is constant) and may be sustained, but there can be frequent or infrequent short runs of supraventricular tachycardia, so-called paroxysmal SVT.
- Rarely, the rhythm during the tachycardia will be irregular, suggesting abnormal automaticity as the etiology.
- Usually the QRS complexes are typical of normal sinus complexes, narrow with a normal mean electrical axis. In some cases a coexisting bundle branch block or aberrant ventricular conduction makes it difficult, if not impossible, to differentiate an SVT from a ventricular tachycardia by examining the ECG.
- P waves can be normal or abnormal and typically differ in configuration from the sinus P waves. P waves may be buried in the previous T wave and therefore not visualized.
- Atrioventricular conduction is usually normal (1:1), but various levels of functional second-degree AV block may occur at higher atrial rates (2:1, 3:1, 4:1, etc.).

PATOPHYSIOLOGY

- SVT may be primary (idiopathic) or secondary to other cardiac disease, generally those creating atrial enlargement.
- May result from a reentrant mechanism or from abnormal automaticity in an ectopic focus. Reentrant SVT typically produces a very regular rhythm; SVT due to an automatic focus in atrial myocardium can produce an irregular rhythm.
- Most cases in dogs respond to drugs that specifically alter conduction and refractoriness in the AV nodal tissue, suggesting AV nodal reentry as the mechanism.
- Recent electrophysiologic studies revealed that some SVT in dogs is related to a congenital accessory pathway between the atria and ventricles that allows the electrical impulses to travel freely between the atria and ventricles without traversing the AV node and without conduction delay; in these patients, the SVT is caused by reentry through the accessory pathway and the AV node.

SYSTEMS AFFECTED

- Cardiovascular—CHF may develop secondary to progressive myocardial failure associated with a chronically high heart rate (so-called tachycardia-induced myocardial

failure).

- Neuromuscular—syncope or generalized episodic weakness due to reduced cardiac output and oxygen delivery.

SIGNALMENT

Species

Dog and rarely cat

SIGNS

General Comments

- Clinical signs may relate to the underlying cause.
- Dogs with slow SVT or infrequent paroxysmal SVT may exhibit no clinical signs.
- Dogs with fast SVT (heart rate usually > 300 bpm) generally exhibit episodic weakness or syncope.

Historical Findings

- Owners are generally unaware of the arrhythmia.
- Coughing or breathing abnormalities in dogs with CHF.
- Episodic weakness or syncope.

Physical Examination Findings

- Rapid, usually regular heart rhythm.
- However, in dogs with paroxysmal SVT the rhythm may be normal and regular during the physical exam.
- May have evidence of poor peripheral perfusion—pale mucous membranes, a prolonged capillary refill time, and weak pulses.
- May have no signs other than the rapid heart rate.
- Findings may reflect an underlying cardiac condition (e.g., heart murmur).

CAUSES

- Chronic valvular disease
- Cardiomyopathy
- Congenital heart disease
- Cardiac neoplasia
- Systemic disorders
- Ventricular preexcitation
- Electrolyte imbalances
- Digoxin toxicity
- Idiopathic

RISK FACTORS

Heart disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Sinus tachycardia.
- Atrial flutter.
- Atrial fibrillation.
- Ventricular tachycardia (SVT with right bundle branch block or aberrant conduction can look like ventricular tachycardia; resolution of arrhythmia after lidocaine administration usually confirms ventricular tachycardia).

IMAGING

- Echocardiography (including Doppler studies) may help characterize the type and severity of underlying cardiac disorders. Echocardiography is also important for assessing myocardial function in patients with idiopathic SVT.
- When viewed on an echocardiogram during bursts of SVT, the left ventricle has a normal end-systolic diameter and a small end-diastolic diameter, resulting in a decreased shortening fraction because of inadequate filling.
- Usually left or right atrial

enlargement in dogs with SVT secondary to other cardiac disorders.

DIAGNOSTIC PROCEDURES

- Long-term ambulatory (Holter) recording of the ECG may detect paroxysmal SVT in cases of unexplained syncope. This is generally only helpful if syncope is occurring regularly within a 24- to 48-hour period. Holter monitors may also help characterize the rate and frequency of sustained SVT and are useful in evaluating the efficacy of therapy.
- Event (loop) recorders may detect paroxysmal SVT in patients with infrequent episodes of syncope (< q24–48h).
- Sustained SVT must be distinguished from sinus tachycardia because the two arrhythmias have different implications and treatment. A precordial thump may help differentiate sinus tachycardia from SVT when the heart rate is in the 150–250 bpm range; it will usually stop an SVT for at least 1 or 2 beats, while a sinus tachycardia will not slow. A vagal maneuver (e.g., ocular pressure or carotid sinus massage) may break an SVT abruptly but only gradually slows sinus tachycardia.

TREATMENT

APPROPRIATE HEALTH CARE

- Asymptomatic patients can be managed on an outpatient basis; patients with a sustained SVT or signs of congestive heart failure should be hospitalized until stable.
- SVT is a medical emergency in dogs that exhibit weakness and collapse; non-pharmacologic interventions that may break an SVT include vagal maneuvers, precordial thump, and electrical cardioversion.
- Vagal maneuvers are often unsuccessful but may be used initially because of their ease of administration and non-invasive nature.
- Delivering a precordial thump can successfully (> 90% of the time) terminate an SVT in dogs, but this maneuver may break the rhythm for only a brief period. At other times the rhythm remains converted. To perform a precordial thump, the dog is placed on its right side and the left apex beat is located. This region is then “thumped” with a fist while recording the ECG.
- Emergency medical therapy is required in patients in which a precordial thump is unsuccessful (see below).

NURSING CARE

Treat CHF and correct any underlying electrolyte or acid-base disturbances.

ACTIVITY

Restrict until arrhythmia has been controlled.

DIET

Mild to moderate sodium restriction if in CHF.

(CONTINUED)

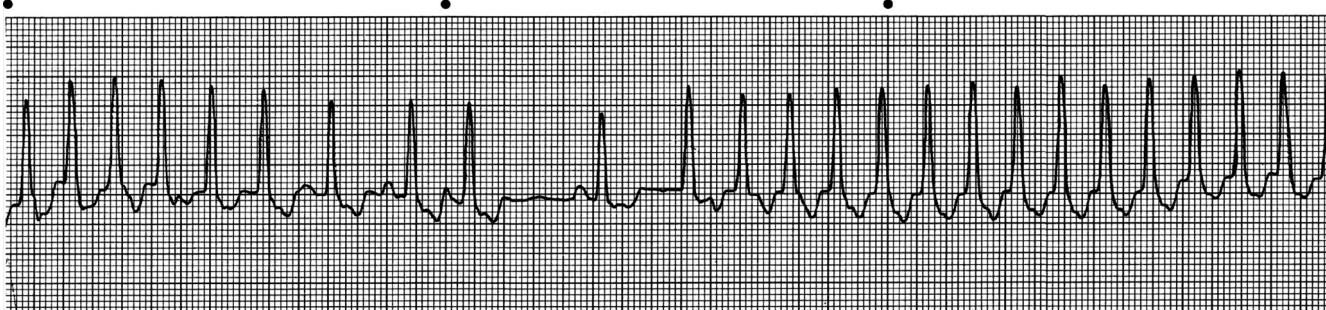

SUPRAVENTRICULAR TACHYCARDIA

Figure 1.

Sinus with an atrial premature complex and paroxysmal supraventricular tachycardia. Abrupt initiation and termination of the tachycardia help distinguish it from sinus tachycardia (lead II, 50 mm/second, 1 cm = 1 mV). (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

CLIENT EDUCATION

Owners should observe patients closely for signs of low cardiac output such as weakness and collapse.

SURGICAL CONSIDERATIONS

Consider transvenous catheter ablation for patients with accessory pathways.

**MEDICATIONS****DRUG(S) OF CHOICE*****Emergency Therapy***

- Administer one of the following drugs:
 - Calcium channel blockers—verapamil (0.05 mg/kg boluses IV over 3–5 minutes up to three times) or diltiazem (0.05–0.25 mg/kg IV over 5–15 minutes).
 - β -adrenergic blockers—esmolol (0.25–0.5 mg/kg slow IV bolus administration followed by a constant-rate infusion of 50–200 μ g/kg/min); moderate-to-severe myocardial failure is a relative contraindication to the administration of these drugs at these doses.
 - Electrical cardioversion or intracardiac electrophysiologic pacing methods may be considered in extreme cases.

Long-Term Therapy

- Digoxin—administer at either a maintenance oral dose or double the maintenance dose for the first day to produce a therapeutic serum concentration more rapidly; contraindicated in patients with accessory pathways.
- β -adrenergic blocker—atenolol (0.2–1 mg/kg PO q12–24h) can be administered as long as the patient does not have underlying moderate-to-severe myocardial failure.
- Diltiazem is the calcium channel blocker of choice for long-term control of SVT. The dosage required to control SVT has not been reported in the dog. Diltiazem is used more frequently to control the ventricular rate in patients with atrial fibrillation at a dosage of 0.5–1.5 mg/kg

PO q8h. In our clinic, we generally start in this dosage range but almost always need to increase the dose to 2–3 mg/kg PO q8h to effect control of SVT.

- Class I antiarrhythmic agents such as quinidine and procainamide can be tried when the aforementioned drugs are ineffective or when the SVT is thought to be due to an automatic, rather than a reentrant, rhythm. SVT caused by an automatic atrial focus may produce an irregular rhythm and may be refractory to conventional drug therapy. When the SVT is due to an accessory pathway, these drugs are more effective.

CONTRAINdications

Avoid use of calcium channel blockers in combination with beta-blockers; clinically significant bradyarrhythmias can develop.

PRECAUTIONS

Calcium channel blockers and β -adrenergic blockers have negative inotropic properties and should be used cautiously in dogs with documented myocardial failure.

ALTERNATIVE DRUG(S)

Emergency treatment—intravenous adenosine (1–12 mg IV rapidly). Adenosine is very expensive and short-lived; propranolol (0.02 mg/kg slow IV boluses up to a total dose of 0.1 mg/kg). Propranolol has a long half-life after IV administration and also has significant β_2 blocking effects and is generally not recommended unless no other alternative is available.

**FOLLOW-UP****PATIENT MONITORING**

Serial ECG or Holter monitoring

POSSIBLE COMPLICATIONS

Syncope and CHF

EXPECTED COURSE AND PROGNOSIS

Most is controlled effectively with medication

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Accessory pathways in some patients

AGE-RELATED FACTORS

In young dogs without evidence of structural heart disease, suspect a reentrant tachycardia involving an accessory pathway.

SYNONYMS

Atrial tachycardia, junctional tachycardia

SEE ALSO

Atrial Fibrillation and Atrial Flutter

ABBREVIATIONS

- AV = atrioventricular
- CHF = congestive heart failure
- ECG = electrocardiogram
- SVT = supraventricular tachycardia

available online**

SYNCOPE

BASICS

DEFINITION

Temporary loss of consciousness and vascular tone associated with loss of postural tone, with spontaneous recovery.

PATHOPHYSIOLOGY

Inadequate cerebral perfusion and delivery of oxygen and metabolic substrates leads to loss of consciousness and motor tone; impaired cerebral perfusion can result from changes in vasomotor tone, cerebral disease, and low cardiac output caused by structural heart disease or arrhythmias.

SYSTEMS AFFECTED

- Cardiovascular
- Nervous

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Sick sinus syndrome—cocker spaniel, miniature schnauzer, pug, dachshund
- Ventricular arrhythmias—boxer, German shepherd

Mean Age and Range

More common in old animals

CAUSES

Cardiac Causes

- Bradyarrhythmias—sinus bradycardia, sinus arrest, second-degree atrioventricular block, complete AV block, atrial standstill.
- Tachyarrhythmias—ventricular tachycardia, supraventricular tachycardia, atrial fibrillation.
- Low cardiac output (non-arrhythmic)—cardiomyopathy, AV valve endocardiosis, subaortic stenosis, pulmonic stenosis, pulmonary hypertension, heartworm disease, pulmonary embolism, cardiac tumor, cardiac tamponade.

Neurologic and Vasomotor Instability

- Vasovagal syncope—emotional stress and excitement may cause heightened sympathetic stimulation, leading to transient tachycardia and hypertension, which is followed by a compensatory rise in vagal tone, leading to excessive vasodilation without a compensatory rise in heart rate and cardiac output; bradycardia often occurs.
- Situational syncope refers to syncope associated with coughing, defecation, urination, and swallowing.
- Carotid sinus hyperactivity may cause hypotension and bradycardia—often the cause of syncope when one pulls on a dog's collar.

Miscellaneous Causes

- Drugs that affect blood pressure and regulation of autonomic tone.
- Hypoglycemia, hypocalcemia, and hyponatremia (rare).

- Hyperviscosity syndromes (e.g., polycythemia and paraproteinemia) cause sludging of blood and impaired cerebral perfusion (rare).

RISK FACTORS

- Heart disease.
- Sick sinus syndrome.
- Drug therapy—vasodilators (e.g., calcium channel blockers, ACE inhibitors, hydralazine, and nitrates), phenothiazines (e.g., acepromazine), antiarrhythmics, and diuretics.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential Signs

- Must differentiate from other altered states of consciousness, including seizures and narcolepsy (a sleep disorder).
- Seizures are often associated with a prodromal and postictal period; syncope occurs without warning, and animal usually has rapid, spontaneous recovery. Unlike syncope, seizure activity is usually associated with tonic clonic muscle activity rather than flaccidity.
- Like syncope, narcolepsy occurs suddenly, results in muscle flaccidity, and resolves spontaneously. Unlike syncope, narcolepsy can last for minutes and can be terminated by loud noises or harsh external stimuli.
- Must differentiate from other causes of collapse such as musculoskeletal disease and neuromuscular disease (e.g., myasthenia gravis), which are not associated with loss of consciousness.

Differential Causes

- Syncope with excitement or stress suggests vasovagal syncope.
- Syncope with coughing, urination, or defecation suggests situational syncope.
- Syncope with exercise suggests low-output states associated with arrhythmias or structural heart disease.
- A murmur supports heart disease but does not confirm cardiac cause for syncope.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal
- Hypoglycemia or electrolyte disturbance in some animals

OTHER LABORATORY TESTS

- If animal is hypoglycemic, measure insulin concentration on same blood sample. Calculate an amended insulin:glucose ratio to rule out insulinoma.
- If animal is hyponatremic or hyperkalemic, consider an ACTH stimulation test.
- If low cardiac output is suspected, rule out occult heartworm disease.

IMAGING

Radiography may detect structural heart disease, evidence of pulmonary embolism or vascular changes supportive of heartworm disease.

Echocardiography

- May detect structural heart disease or pericardial disease that could lower cardiac output.
- Doppler echocardiography may aide in the diagnosis of pulmonary hypertension.
- Computed tomography pulmonary angiography may detect pulmonary embolism.
- Ventilation perfusion scintigraphy may detect pulmonary embolism.

DIAGNOSTIC PROCEDURES

- Have client monitor heart rate during any syncopal episode.
- Electroencephalogram, computed tomography of the head, cerebrospinal fluid tap if CNS origin suspected.

Electrocardiographic Findings

- Post-exercise ECG may reveal intermittent arrhythmia.
- Holter monitoring (24-hour ECG recording) or use of an ECG event (loop) recorder—useful for evaluating arrhythmic causes.
- Carotid sinus massage with ECG and blood pressure monitoring useful in evaluating carotid sensitivity.

TREATMENT

APPROPRIATE HEALTH CARE

- Avoid or discontinue medications likely to precipitate syncope.
- Treat as outpatient unless important heart disease is evident.

CLIENT EDUCATION

- Minimize stimuli that precipitate episodes.
- Low cardiac output—minimize activity.
- Vasovagal—minimize excitement and stress.
- Cough—remove collar.

SURGICAL CONSIDERATIONS

Pacemaker implantation for sick sinus syndrome and advanced AV block and persistent atrial standstill.

MEDICATIONS

DRUG(S) OF CHOICE

Bradyarrhythmias

- Correct metabolic causes.
- Anticholinergics (e.g., atropine, propantheline bromide, hyoscymine sulfate).
- Sympathomimetics (e.g., isoproterenol, bronchodilators).
- Pacemaker implantation in some patients.

(CONTINUED)

SYNCOPE

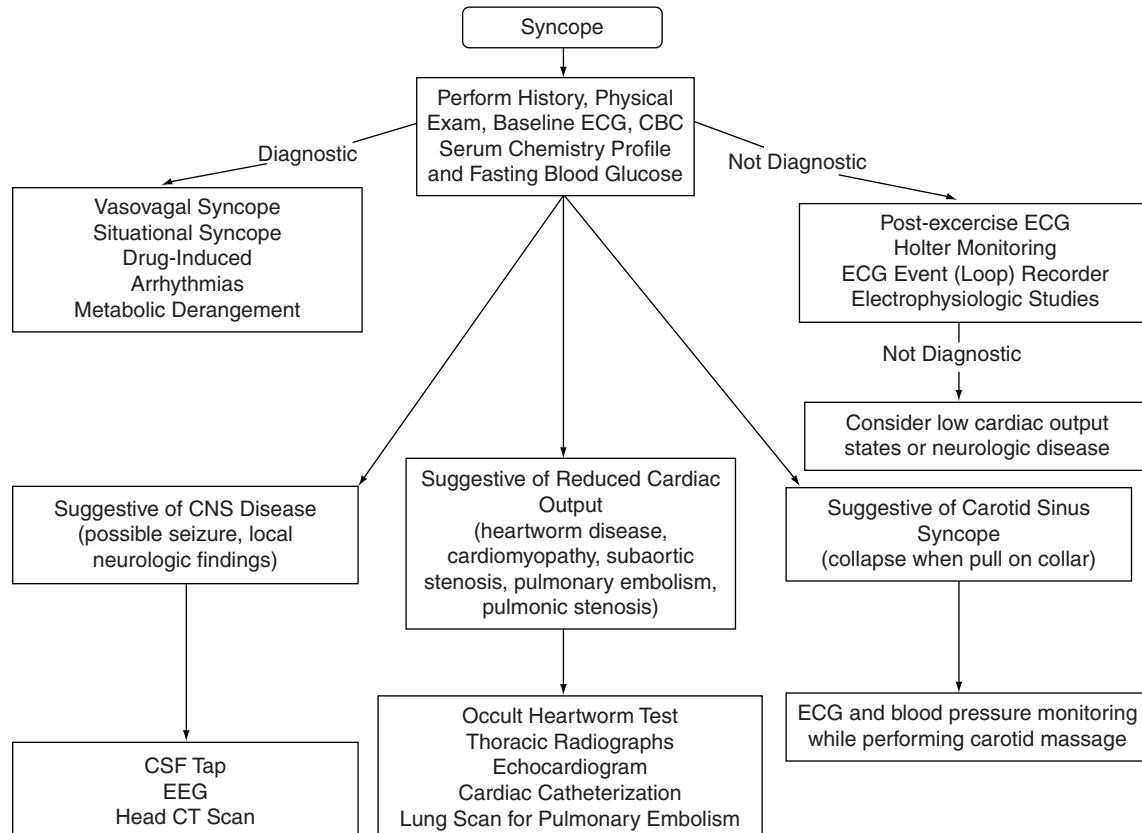

Figure 1.

Algorithm for syncope.

Tachyarrhythmias

- Atrial arrhythmias—administer digoxin, beta-blocker, or diltiazem.
- Ventricular arrhythmias—administer lidocaine, mexiletine, sotalol, or beta-blocker.

Low Cardiac Output

- Institute treatment to improve cardiac output, which varies according to specific cardiac disease.

Vasovagal

- Theophylline or aminophylline—sometimes helpful; mechanism of action in this setting is unclear.
- Beta-blockers (e.g., atenolol, propranolol, and metoprolol) may indirectly prevent vagal stimulation by blocking the initial sympathetic response.
- Anticholinergics may blunt the vagal response.

**FOLLOW-UP****PATIENT MONITORING**

ECG or Holter monitoring to assess efficacy of antiarrhythmic therapy

POSSIBLE COMPLICATIONS

- Death
- Trauma when collapse occurs

EXPECTED COURSE AND PROGNOSIS

Most noncardiac causes are not life-threatening; cardiac causes may be treated, but syncope in patients with cardiac disease may suggest higher mortality risk.

**MISCELLANEOUS****SEE ALSO**

- Myasthenia Gravis
- Narcolepsy and Cataplexy
- Seizures (Convulsions, Status Epilepticus)—Cats
- Seizures (Convulsions, Status Epilepticus)—Dogs

ABBREVIATIONS

S

SYNOVIAL SARCOMA

BASICS

OVERVIEW

- Synovial sarcoma (or synovial cell sarcoma) is a malignant neoplasm arising from type B synoviocytes of the joint capsule or tendon sheath.
- Synovial sarcomas are locally aggressive and have moderate metastatic potential. At diagnosis up to 32% of dogs have metastases with the most common sites being the local lymph node and lungs.
- The disease is seen most commonly in the appendicular skeleton, specifically affecting the elbow, stifle, and shoulder joints. SS must be differentiated via immunohistochemistry from other types of joint tumors, namely histiocytic sarcoma, which has a more aggressive biologic behavior and a worse prognosis.

SIGNALMENT

- Dog—often large-breed dogs of either sex, predisposition of flat-coat and golden retrievers, mean age of 9 years
- Cat—rarely reported

SIGNS

- Slowly progressive lameness
- Palpable mass
- Weight loss
- Anorexia
- Clinical course may be protracted over months to years

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other primary neoplasia (e.g., histiocytic sarcoma, chondrosarcoma, osteosarcoma).
- Metastatic neoplasia.
- Other bone or joint diseases (e.g., osteoarthritis, osteomyelitis).

S

CBC/BIOCHEMISTRY/URINALYSIS

No consistent abnormalities

OTHER LABORATORY TESTS

N/A

IMAGING

- Radiographs of the affected joint often demonstrate both bone and joint involvement with periarticular soft tissue swelling and periosteal reaction or multiple punctate osteolytic changes in adjacent bone.
- Thoracic radiographs should be obtained to screen for metastatic disease.
- Abdominal ultrasonography should be performed to evaluate intra-abdominal lymph nodes in animals with tumors on the pelvic limbs.

DIAGNOSTIC PROCEDURES

- Regional lymph nodes should be palpated and fine-needle aspirates performed.
- Biopsy and immunohistochemistry to differentiate from HS (HS is CD18+).

TREATMENT

Limb amputation; forequarter, coxofemoral disarticulation or hemipelvectomy to minimize risk of local recurrence.

MEDICATIONS

DRUG(S)

- The role of chemotherapy for SS is not known; however, doxorubicin is commonly utilized for the treatment of sarcoma histologies.
- Pain management with analgesic drugs as necessary.

CONTRAINDICATIONS/POSSIBLE

INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Monitor for local recurrence and pulmonary metastatic disease every 2–3 months for the first year, every 6 months thereafter.

EXPECTED COURSE AND PROGNOSIS

- Localized disease at diagnosis—prognosis is excellent. Median survival time > 36 months. Lesser dose of surgery (i.e., marginal excision) is associated with poorer prognosis compared to limb amputation.
- Metastatic disease at diagnosis—poor prognosis with median survival time < 6 months. High-grade tumors (high mitotic rate, high percent tumor necrosis, high nuclear pleomorphism) also confer a worse prognosis.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Do not breed animals that are receiving chemotherapy.

ABBREVIATIONS

- HS = histiocytic sarcoma
- SS = synovial sarcoma

SYRINGOMYELIA AND CHIARI-LIKE MALFORMATION

BASICS

DEFINITION

- CM is characterized by overcrowding of the CCJ and obstruction of CSF channels.
- A consequence is SM where fluid-filled cavities (syringes) develop within the spinal cord.
- The primary clinical sign is pain due to obstruction of the CSF pulse pressure and/or damage to spinal cord dorsal horn and/or axons conveying or modifying nociceptive sensory transmission to the brain.

PATHOPHYSIOLOGY

Chiari-like Malformation

Complex disorder involving skull base shortening and CCJ abnormalities including increased proximity of the atlas to the occiput. There may be increased parenchymal volume, for example CKCS have relatively increased cerebellar volume compared to other breeds. Overcrowding of the cerebellum in the caudal part of the caudal cranial fossa is correlated with the development of SM. Classical CM is characterized by herniation of the hindbrain into the foramen magnum.

Syringomyelia

The most accepted theory of SM pathogenesis is that obstruction to CSF flow in the subarachnoid space results in a mismatch in timing between the arterial and CSF pulse peak pressure. If peak CSF pressure is high when spinal arteriole and perivascular space pressures are low then the perivascular spaces act as a one-way valve drawing in CSF which collects in, then expands and disrupts, the spinal cord central canal and ultimately a syrinx develops.

SYSTEMS AFFECTED

- Nervous
- Ophthalmic

GENETICS

• SM associated CM has moderately high heritability ($H^2 = 0.37$). • Symptomatic SM-associated CM has high heritability ($H^2 = 0.81$). • Two novel genomic regions are strongly associated to CM in the Griffon Bruxellois. One region contains a single gene *Sall-1* which is involved in skull development.

INCIDENCE/PREVALENCE

- In some brachycephalic toy breeds, most notably the CKCS, prevalence of CM approaches 100%.
- SM prevalence increases with age with 25% CKCS affected at 1 y rising to 70% of CKCS > 6 y.
- Studies in the Griffon Bruxellois suggest 42–52% have SM, not always in association with classical CM.
- Prevalence of symptomatic CM and SM is difficult to determine because pain is subjective and difficult to measure directly.
- One study suggested 15.4% prevalence of symptomatic SM in 6 years old CKCS.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Brachycephalic toy-breed dogs and crosses.
- CKCS, King Charles spaniel, Griffon Bruxellois, Affenpinscher, Yorkshire terrier, Maltese, Chihuahua, Pomeranian, Boston terrier, Papillon.
- CM but not SM observed in the Persian cat.

Mean Age and Range

From 6 months old; however, dogs asymptomatic at 6 years old are less likely to ever develop clinical signs.

Predominant Sex

No sex predisposition

SIGNS

General Comments

CM and SM may be asymptomatic. CM alone may cause pain.

Historical Findings

- Pain behavior:
 - Vocalization—often posture-related, e.g., when dog stands, jumps or when picked up
 - Exercise intolerance or unwillingness to exercise
 - Withdrawn
 - Decreased interaction
 - Disrupted sleep
 - Sleeping with unusual head position, e.g., elevated or flexed
 - Allodynia, i.e., signs of discomfort from a non-noxious stimulus, such as touch or wearing a collar
 - Head scratching or rubbing
 - Partial eye closure
 - Signs exacerbated by excitement, exercise, weather conditions, time of day (morning)
- Phantom (reflex) scratching.
- Rhythmic scratch without making purposeful skin contact induced by touch, clothing, walking and excitement.
- Neurobehavioral disorders related to anxiety.

Physical Examination Findings

- Spinal pain.
- Non-contact scratching induced by touch of cervical dermatome corresponding to damaged cervical spinal cord.
- Cervicothoracic scoliosis/torticollis. Gait abnormalities—hypermetria; ataxia; weakness.
- Exotropia—ventrolateral strabismus when gazing to the ipsilateral side.

CAUSES

- SM can develop secondary to any obstruction to CSF channels.
- Degenerative—vertebral canal stenosis due to chronic and often multiple IVDD and facet disease.
- Anomalous—CM, arachnoid cyst/web.
- Neoplastic—mass causing obstruction of CSF channels and/or cerebellar herniation.
- Inflammatory/Infectious—feline infectious peritonitis, granulomatous meningoencephalomyelitis.
- Traumatic—sequel of spinal cord injury and arachnoid adhesions.

RISK FACTORS

Brachycephalism and miniaturization

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Spinal Pain/Weakness/Ataxia

- IVDD—acute onset, persistent localized pain in dogs > 2 y.
- Encephalitides—pain with rapidly progressive neurologic signs.
- Atlantoaxial subluxation—tetraparesis and pain especially on cervical flexion.
- Discospondylitis—fever and neutrophilia at onset; pain constant.

Scratching

Skin disease—in SM, there are no skin lesions.

Abnormal Head Position

Rule out vestibular dysfunction due to inner ear, cranial nerve VIII, or intracranial disease.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

IMAGING

Skull and Cervical Radiographs

Limited value; can suggest changes characteristic of CM (short basicranium, shallow caudal fossa). If wide SM, vertebral canal may be expanded especially at C2. Dynamic cervical images to assess for atlantoaxial subluxation.

Computed tomography

Can confirm cerebellar herniation and assess other bony abnormalities, e.g., atlanto-occipital overlapping. Limited value for assessment SM.

Magnetic Resonance Imaging

- To establish cause and extent of SM, i.e., CM or other causes of CSF obstruction.
- CCJ conformation varies between breeds.
- Classical CM—cerebellum and medulla displaced into the foramen magnum with little or no CSF around neural structures.
- Supraoccipital bone indents the cerebellum, which loses normal rounded shape.
- Cerebellar herniation minimal in some individuals.
- Flexed position increases size of cerebellar herniation.
- Medulla and cranial cervical spine kinked.
- Ventriculomegaly.
- SM—spinal cord fluid-containing cavities.
- Dogs with cervical SM often have more caudal SM; restricting MRI to the cervical region may underestimate severity.
- Maximum syrinx transverse width and asymmetry is strongest predictor of pain, reflex scratching and scoliosis.
- Narrow width symmetrical SM may be asymptomatic.

DIAGNOSTIC PROCEDURES

CSF—to rule out inflammatory diseases; protein may be elevated.

PATHOLOGIC FINDINGS

- Gross—Cerebellar herniation, ventriculomegaly, spinal cord cavitation.
- Histopathologic—in comparison to asymptomatic SM-affected dogs, dogs with history of behavioral signs of pain had asymmetrical syrinx with altered dorsal horn

SYRINGOMYELIA AND CHIARI-LIKE MALFORMATION

(CONTINUED)

structure and altered expression of pain-related neuropeptides, substance P, and calcitonin gene-related peptide.

TREATMENT

APPROPRIATE HEALTH CARE

Medical and surgical treatment options—main treatment objective is pain relief.

NURSING CARE

- Raise food bowls.
- Avoid neck collars and in some cases harnesses.
- Complementary therapy, e.g., acupuncture may be useful.

ACTIVITY

- Exercise to within own limits.
- Inability to exercise associated with higher neuropathic pain score.
- Grooming may not be tolerated and can exacerbate signs.

DIET

Obesity positively correlated with a reduced quality of life but not greater neuropathic pain.

CLIENT EDUCATION

Periodic exacerbations of pain common and dog may require "top-up" medication during this time.

SURGICAL CONSIDERATIONS

- CCD most common surgical procedure—establishing a CSF pathway via the removal of majority of supraoccipital bone and dorsal arch of C1; may be combined with a durotomy, with or without patching with a suitable graft material and with or without cranioplasty. Successful in reducing pain and improving neurologic deficits in ~ 80% cases; ~ 45% cases have satisfactory quality of life 2 y postoperatively. SM persists postoperatively.
- Clinical improvement probably attributable to improvement in CSF flow; most cases require additional medical management.
- Atlantoaxial stability should be assessed prior to CCD.

MEDICATIONS

DRUG(S) OF CHOICE

Non-neuropathic Pain

- NSAIDs—at data sheet dosage.
- Drugs that reduce CSF pressure—proton pump inhibitors (omeprazole 0.5–1.5 mg/kg q24h); or H₂ receptor antagonists (cimetidine 5–10 mg/kg q8h); or diuretics (furosemide 1–2 mg/kg q12h; acetazolamide 4–8 mg/kg q 9–12h).

Neuropathic Pain/MRI Evidence Spinal Dorsal Horn Damage

- First-line adjuvant analgesics—gabapentin 10–20 mg/kg q12h/q8h or pregabalin at 5 mg/kg q12h.
- Second-line (add-on) adjuvant analgesics—amitriptyline 0.25–2 mg/kg q12–24h (titrate up to effective

dose) or tramadol 2–5 mg/kg q8h or amantadine 3–5 mg/kg q24h.

Gait Abnormalities

- Drugs that reduce CSF pressure (as above).
- Corticosteroids—lowest possible dose that controls signs, starting with 0.5 mg/kg prednisolone or methylprednisolone daily; withdraw NSAIDs.

CONTRAINDICATIONS

Amitriptyline should not be combined with drugs metabolized by cytochrome P450 2D6, e.g., cimetidine.

PRECAUTIONS

- Furosemide may activate renin-angiotensin-aldosterone system which might be deleterious in dogs predisposed to MVD.
- Long-term acetazolamide or corticosteroids not recommended due to potential adverse effects.

POSSIBLE INTERACTIONS

CM/SM does not increase risk of anesthesia unless there is associated syringobulbia (syrinx in brainstem).

FOLLOW-UP

PATIENT MONITORING

- Periodic review of pain management and neurologic status.
- Serial MRI may be useful.
- Periodic CBC/biochemistry if receiving medication.

PREVENTION/AVOIDANCE

Purchase from a breeder that has health screening and can provide appropriate health certificates.

POSSIBLE COMPLICATIONS

Dogs with higher neuropathic pain scores are more likely to have anxiety-related behavior disorders which can have a negative impact on the owner-perceived quality of life of a dog.

EXPECTED COURSE AND PROGNOSIS

- Approximately three-quarters of CKCS with CM and/or SM-associated neuropathic pain deteriorate when managed medically. However, many dogs maintain an acceptable quality of life.
- 15–20% dogs are euthanized because of severe neuropathic pain.
- Early surgical intervention may improve prognosis; however, robust studies evaluating this hypothesis have not been performed.
- Surgery does not necessarily improve long-term prognosis as 25–47% of the operated dogs have recurrence or deterioration of the clinical signs within 0.2–3 y of surgery.

MISCELLANEOUS

ASSOCIATED CONDITIONS

CKCS with CM and SM have a high prevalence of MVD, pancreatic disorders including pancreatitis, biliary tree

calcification, epilepsy, myoclonus, fly-catching behavioral disorder, otitis media with effusion, deafness, macrothrombocytopenia, keratoconjunctivitis sicca, idiopathic facial nerve paresis, idiopathic vestibular disease.

AGE-RELATED FACTORS

Older brachycephalic toy breeds are more likely to have other comorbidities such as MVD.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

- Breeding stock of breeds predisposed to CM and/or SM should be MRI screened and official Health Schemes exist in many countries, for example the British Veterinary Association/Kennel Club CMSM Health Scheme.
- Breeding recommendations based on SM status and ages are available.

SYNOMYMS

- Caudal occipital malformation syndrome
- Occipital hypoplasia • Syringohydromyelia

TAPEWORMS (CESTODIASIS)

BASICS

OVERVIEW

- Infection of dog and cat small intestine with adult tapeworms, including species of *Taenia* (especially *T. pisiformis* of dogs and *T. taeniaformis* of cats), *Dipylidium caninum*, *Echinococcus* spp., and *Mesocestoides*.
- Infection acquired by ingestion of intermediate host containing tapeworm larvae. *Taenia*, *Echinococcus*, and *Mesocestoides* acquired by predation on rabbits, rodents, birds, etc. *Dipylidium caninum* acquired by ingestion of adult fleas (or lice).
- Adult tapeworms cause no apparent harm to host other than perianal pruritus.
- PLC—occurs when dogs become accidental intermediate hosts caused by peritoneal infection with *Mesocestoides* larvae, is potentially fatal.
- Mesocestoides* adults and larvae can multiply asexually within host.

SIGNALMENT

Dog and cat

SIGNS

- Motile or dried, white to cream-colored, single proglottids or chains of proglottids of *Taenia* and *Dipylidium* visible on perineum or in feces; *Mesocestoides* proglottids smaller, more numerous, and resemble sesame seeds; *Echinococcus* proglottids too small to see.
- Dragging or rubbing anus on ground because of perianal pruritus.
- PLC—abdominal distension (ascites), anorexia, lethargy.

CAUSES & RISK FACTORS

- Taenia*, *Echinococcus*, *Mesocestoides*—eating viscera of intermediate hosts such as birds, reptiles, rabbits, rodents, sheep.
- Dipylidium* infections—eating fleas (or lice).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Adult tapeworms—anal sac impaction
- PLC—other causes of ascites

CBC/BIOCHEMISTRY/URINALYSIS

PLC—leukocytosis, hypoalbuminemia

OTHER LABORATORY TESTS

N/A

IMAGING

PLC—abdominal ultrasonography and radiography

DIAGNOSTIC PROCEDURES

- Fecal flotation to detect eggs; false negatives occur if eggs have not been released from proglottids.
- Crush minced segments between two glass slides to release eggs, add

drop of water, and examine microscopically for eggs.

- *Dipylidium*—press adhesive cellophane tape to perianal skin to collect egg packets, then apply tape to microscope slide; packets contain multiple eggs; individual eggs in packets are $\sim 50 \mu\text{m}$ in diameter, pale yellow, and contain a hexacanth embryo with three pairs of hooks.
- *Taenia*, *Echinococcus*—individual eggs (not in packets); spherical, brown, $\sim 30-35 \mu\text{m}$ in diameter; contain hexacanth embryo.
- *Mesocestoides*—individual eggs (not in packets) oval, thin-shelled; contain hexacanth embryo.
- PLC—abdominocentesis or laparotomy to obtain peritoneal fluid; detect larvae in peritoneal fluid by microscopy or PCR-RFLP.

TREATMENT

- Outpatient anthelmintic treatment for intestinal infection with adult tapeworms.
- Discuss need for flea (or louse) control to prevent recurrence of *Dipylidium*.
- PLC—in addition to anthelmintic treatment, may require peritoneal lavage or surgery to remove ascites fluid and larvae.

MEDICATIONS

DRUG(S)

Taenia

- Fenbendazole 50 mg/kg PO q24h for 3 days for adult *Taenia* in dogs.
- Praziquantel 2.5–7.5 mg/kg PO, SC, or IM.
- Praziquantel/pyrantel pamoate—label dose for cats.
- Praziquantel/pyrantel pamoate/febantel—label dose in dogs; for *Taenia*, *Echinococcus*, *Mesocestoides* (extra-label) and *Dipylidium*.
- Epsiprantel 5.5 mg/kg PO for dogs, 2.8 mg/kg PO cats, for *Taenia*, *Dipylidium*.
- Emodepside (3 mg/kg)/praziquantel (12 mg/kg), topically once in cats for *Taenia*, *Dipylidium*.
- Canine PLC—praziquantel, 5 mg/kg SC repeated in 2 weeks may be curative; fenbendazole, 50–100 mg/kg PO q24h for 4–8 weeks (extra-label); provides clinical remission but often not curative.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

Do not use praziquantel or epsiprantel for puppies or kittens < 4 weeks old.

FOLLOW-UP

PATIENT MONITORING

- For infection with adult tapeworms, post-treatment examination for tapeworm

segments and/or eggs; incomplete removal of adult *Mesocestoides* can result in repopulation of intestine by asexual multiplication.

- For PLC—ultrasonography and/or abdominocentesis to detect recurrence; larvae difficult to eliminate and can repopulate peritoneal cavity by asexual multiplication.

PREVENTION/AVOIDANCE

- Implement flea (or louse) control to prevent recurrence of *Dipylidium* infection.
- Prevent hunting and scavenging to prevent ingestion of vertebrate intermediate hosts to prevent recurrence of infection (*Taenia*, *Echinococcus* or *Mesocestoides*).

EXPECTED COURSE AND PROGNOSIS

- Anthelmintic treatment will eliminate adult *Taenia*, *Echinococcus*, and *Dipylidium*, but reinfection often occurs.
- Incomplete removal of adult *Mesocestoides* by anthelmintic treatment can result in recurrence of infection in the absence of reinfection as a result of asexual multiplication by adults.
- Treatment of PLC provides clinical remission but often is not curative.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Children may be at risk for *Dipylidium* infection by ingestion of adult fleas; in children, tapeworm segments have been mistaken for pinworms (*Enterobius*).
- Ingestion of *Echinococcus* eggs can cause hydatid disease in humans.
- Taenia* and *Echinococcus* shed identical eggs. Strict sanitation should be practiced when taeniid eggs are observed due to the risk of hydatid disease.
- Human infection with adult *Mesocestoides* can occur; infection is not acquired from dogs or cats but by ingestion of vertebrate intermediate hosts.

ABBREVIATIONS

- PCR-RFLP = polymerase chain reaction restriction fragment length polymorphism
- PLC = peritoneal larval cestodiasis

TAURINE DEFICIENCY

BASICS

OVERVIEW

• Taurine is an essential amino acid in cats; they must conjugate bile acids with taurine and cannot synthesize enough to cope with this obligatory loss, so deficient diets cause taurine deficiency in cats. All cat food manufacturers add taurine to their diets. Taurine is not essential in dogs and so most canine diets do not contain added taurine. However, some "cardiac" canine diets, especially those containing lamb and rice, have taurine added to them. • Taurine is found throughout the body, with highest concentrations in excitable tissues (e.g., myocardium, central nervous system, and retina), where its exact function is unknown. Taurine is actively concentrated in myocardial cells by a membrane pump that is influenced by catecholamines. • Taurine deficiency results in retinal degeneration and primary myocardial failure (i.e., dilated cardiomyopathy [DCM]), which has been identified in domestic cats, foxes, and some dogs. In each, the myocardial failure is usually fully or partially reversible with dietary taurine supplementation. • Mice devoid of the protein that transports taurine into cells develop DCM. Poor myocardial function is due to myocardial atrophy rather than abnormal cellular contractile function.

SIGNALMENT

• Cats—DCM due to taurine deficiency is currently rare because taurine is added to most cat foods. • Dogs—American cocker spaniels with DCM are almost uniformly taurine-deficient. Some giant-breed dogs (Newfoundlands) with DCM, especially those on a lamb and rice diet, have been taurine-deficient. Some mixed-breed dogs with DCM or breeds that uncommonly get DCM but with DCM have a low plasma taurine concentration.

SIGNS

See Cardiomyopathy, Dilated—Cats and Cardiomyopathy, Dilated—Dogs.

CAUSES & RISK FACTORS

• Cats fed home-cooked diets (e.g., vegetarian, boiled meat, or cooked chicken diets) are at risk; rarely, a commercial diet will cause taurine deficiency in cats. • Dogs—breed predisposition (American cocker spaniels, unusual breed with DCM, mixed breed), breed size (e.g., Newfoundlands), diet, and cystinuria are risk factors. Rarely, a common breed (e.g., Doberman pinscher) with DCM will be taurine deficient. Taurine deficiency might be a problem in certain lines of Portuguese water dogs fed certain diets.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Idiopathic dilated cardiomyopathy or myocardial failure due to another cause; see Cardiomyopathy, Dilated—Cats and Cardiomyopathy, Dilated—Dogs.

CBC/BIOCHEMISTRY/URINALYSIS

Cystinuria in some dogs

OTHER LABORATORY TESTS

- Place a heparinized blood sample on ice, and centrifuge within 30 minutes. Do not allow clotting because platelets are rich in taurine. Avoid hemolysis. A plasma taurine concentration < 40–60 nmol/mL is too low in dogs and cats. A whole-blood concentration < 200 nmol/mL is too low.
- Prolonged fasting in cats can produce a low plasma concentration; the whole blood concentration stays within the normal range longer.

IMAGING

DCM is usually diagnosed by identifying an increase in end-systolic diameter, along with a compensatory smaller increase in end-diastolic diameter and a consequent reduction in shortening fraction on an echocardiogram.

DIAGNOSTIC PROCEDURES

Examine any taurine-deficient patient for central retinal degeneration.

TREATMENT

• Use conventional heart failure therapy and pimobendan (0.25 mg/kg PO q12h) until supplementation has caused significant echocardiographic improvement; drug therapy can usually be discontinued after 3–6 months of taurine supplementation as long as there has been a substantial echocardiographic improvement in left ventricular function. • Most cats in heart failure do better if they are sent home. • There is no known benefit to taurine supplementation in a dog or cat with any other form of cardiac disease.

MEDICATIONS

DRUG(S)

• Supplement taurine (cats, 250 mg PO q12h; dogs, 250–1,000 mg PO q12h), usually for life. • Taurine supplements—obtain from a health food store. • Carnitine supplementation (1 g PO q12h) is also recommended for American cocker spaniels, especially if they do not respond to taurine supplementation alone.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

No adverse effects of taurine supplementation; excess taurine is eliminated in the urine.

FOLLOW-UP

Routine examinations for a heart failure patient; repeat echocardiogram in 3–6 months to document improvement. If there is substantial improvement, continue taurine supplementation but discontinue heart failure drugs.

MISCELLANEOUS

ABBREVIATION

• DCM = dilated cardiomyopathy

TEMPOROMANDIBULAR JOINT DISORDERS

BASICS

OVERVIEW

- Disorders of the TMJ lead to an alteration of the normal function of the masticatory system as the mobility and function of the joint are compromised.
- Genetic, traumatic, degenerative, or idiopathic causes may result in pain, occlusal dysfunction, joint laxity, chronic arthritis, or open-mouth locking.

SIGNALMENT

- Dog and cat. • No breed, sex, or age predisposition in most TMJ disorders.
- Open-mouth mandibular locking—basset hounds; Irish setters. • There may be a genetic predisposition in certain breeds (e.g., basset hounds) to develop TMJ disorders.

SIGNS

General Comments

- Difficulty opening mouth. • Difficulty closing mouth. • Laxity or excessive lateral movement of the mandible. • Pain and/or crepitus when masticating, yawning, and/or vocalizing.

Specific

- TMJ luxation/subluxation—history of trauma or mouth locked open; radiographic evidence of luxation. • Open-mouth mandibular locking—coronoid process of the mandible “slips” lateral to the ventral surface of the zygomatic arch and is locked in that position; large bulge palpated on affected side of face. • Traumatic injury—evidence of trauma; mouth dropped open; mobility of mandible (may have multiple fractures); radiographs indicate fracture. • Osteoarthritis/chronic post-traumatic changes—crepitus and pain when eating or if mandible is forced to move; radiographs may show osseous reaction indicative of arthritic changes.

CAUSES & RISK FACTORS

- Patients at a higher risk to experience injuries—young; free roaming. • Trauma may cause fractures or a luxation resulting in immediate problems, as well as future degenerative problems.
- Mandibular neuropraxia—carrying heavy objects by mouth. • MMM—adult; large breed (e.g., German shepherds).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Craniomandibular osteopathy. • Primary or secondary hyperparathyroidism. • Mandibular neuropraxia—stretching of the nerve branches (motor) of the masticatory muscles; usually caused by carrying heavy objects in the mouth; mandible hangs open but can be easily closed manually. • MMM—auto-immune disease of

type 2M myofibers of masticatory muscles supplied by trigeminal nerve with necrosis, phagocytosis, and fibrosis; trismus progresses to total inability to open jaws.

CBC/BIOCHEMISTRY/URINALYSIS

Findings are expected to be within normal limits.

OTHER LABORATORY TESTS

- Serum autoantibodies to type 2M myosin—to rule out MMM. • Cytology of fluid aspirated from TMJ—may be beneficial in diagnosis of a polyarthropathy in which the articular surfaces of the joint are inflamed.

IMAGING

- Skull radiography—essential to perform proper radiographic technique to visualize the TMJ. • MRI—gold standard for imaging the TMJ.

DIAGNOSTIC PROCEDURES

- Usually none. • Muscle biopsy—rule out MMM.

TREATMENT

- Definitive treatment is aimed at eliminating or altering the etiologic factor responsible for the disorder, as well as correcting the problem.
- TMJ luxation—traumatic: luxation often occurs in a rostral direction; in acute cases, place a “dowel” (pencil) across the mouth between the carnassial teeth; gently close the rostral portion of the mouth with a gentle “push” to reduce the luxation (push caudally for a rostral luxation); chronic luxation may not reduce and may require surgery.
- Open-mouth mandibular locking—immediate attention; sedate animal, open the mouth further and apply gentle pressure on the bulging coronoid process to allow it to slip back under the zygomatic arch; surgical management: excise ventral portion of the zygomatic arch and/or a dorsal portion of the coronoid process to relieve future locking.
- Injury or fracture at TMJ—depends on extent of damage; fixation is difficult; condylectomy sometimes necessary.
- Chronic osteoarthritis or ankylosis—if severe, condylectomy may be needed.
- “Dropped jaw” (trigeminal [mandibular] neuropraxia)—conservative treatment: rest, anti-inflammatory drugs. • MMM—immunosuppressant medications; possible forcible, gradual opening of mouth.

MEDICATIONS

DRUG(S) OF CHOICE

- Analgesics—for painful disorders.
- Anti-inflammatory drugs—for postoperative pain and chronic inflammation.

- Muscle relaxants—help prevent increased muscle activity due to chronic pain response.

FOLLOW-UP

PATIENT MONITORING

Each case should be carefully followed because of the progressive changes that may occur in the TMJ, especially after traumatic injury.

PREVENTION/AVOIDANCE

Avoid situations that allow for trauma (pets running loose).

POSSIBLE COMPLICATIONS

In many cases after surgical treatment involving TMJ disorders, arthritis may develop later.

EXPECTED COURSE AND PROGNOSIS

Depends on the disorder afflicting the TMJ and the degree to which it is affected.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Condition is typically unaffected by pregnancy. However, if medical treatment is considered, agents such as corticosteroids should not be used in pregnant patients.

SEE ALSO

Maxillary and Mandibular Fractures

ABBREVIATIONS

- MMM = masticatory muscle myositis
- MRI = magnetic resonance imaging
- TMJ = temporomandibular joint

TESTICULAR DEGENERATION AND HYPOPLASIA

BASICS

OVERVIEW

- Degeneration—histologic changes in the testes after puberty; may be differentiated from hypoplasia by the increased thickness of the basement membrane in the degenerated testis.
- Hypoplasia—a variety of histologic lesions thought to be congenital (although often not obvious until after puberty) or heritable.

SIGNALMENT

- Dog and cat. • Dog—any age or breed; hypoplasia, generally young; degeneration, generally old. • Tortoiseshell cat—may be fertile; usually linked with sex chromosome abnormalities (see Sexual Development Disorders).

SIGNS

- Infertility. • Reduced testicular size and loss of normal turgidity. • Oligospermia (low numbers of spermatozoa in the ejaculate) or azoospermia (no spermatozoa in the ejaculate).
- Hypoplasia (dogs)—rarely any physical signs other than small testes. • Degeneration (dogs)—any previous scrotal or testicular lesion can be related.

CAUSES & RISK FACTORS

Degeneration

- Heat. • Irradiation. • Metals—lead salts; cadmium; organic mercurial compounds.
- Nitrogen-containing and halogenated compounds. • Other toxins. • Orchitis—*infectious* (such as brucellosis) or non-infectious (auto-immune). • Steroid hormones—estrogen: secreted by a Sertoli cell tumor or exogenous exposure. • Other hormonal abnormalities—hypothyroidism; hypocortisolism; hyperadrenocorticism.
- Increasing age—6.3% of beagles maintained to 7.75 years had incomplete spermatogenesis.
- Arterial sclerosis. • Some chemotherapeutic agents—cimetidine; ketoconazole; nitrofurans; flutamide. • Incisional testicular biopsies.
- Any previous scrotal or testicular lesion may be related. • Epididymal occlusion.

Hypoplasia

- Klinefelter (XXY) syndrome.
- Hypogonadotropic hypogonadism—may be acquired from traumatic or neoplastic lesion of the pituitary. • XX sex reversal—disorder of sexual development with the absence of SRY region (dogs).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Degeneration—old, azoospermic, or severely oligospermic previously fertile dogs with small testes. • Hypoplasia—young,

azoospermic, never-fertile dogs with small testes. • Spermatocoele. • Sperm granuloma. • Orchitis. • Neoplasia. • Ejaculatory failure—retrograde ejaculation; incomplete ejaculation.

OTHER LABORATORY TESTS

- Canine FSH assay—differentiate from blockage (spermatocoele); high concentration indicates incomplete spermatogenesis associated with hypoplasia or degeneration.
- Alkaline phosphatase concentration of seminal plasma—rule-out incomplete ejaculation; samples with AP < 5,000 U/L consistent with incomplete ejaculation or bilateral epididymal blockage.

IMAGING

Ultrasonography—testicular size; homogenous echogenicity of the parenchyma

DIAGNOSTIC PROCEDURES

- Semen evaluation—primary diagnostic procedure; dog: always obtained by use of an artificial vagina or collection cone; cat: obtained by electroejaculation, when available; collect two ejaculates on separate days or 1 hour apart; establish azoospermia or oligospermia. • Testicular biopsy (for azoospermia)—fine-needle: identify long spermatids and spermatozoa; Tru-Cut (tissue plug): most complete histopathologic diagnosis; fix tissue for sectioning in Bouin's or Zenker's fixative. • Karyotype—identify extra X chromosome or other numerical or structural chromosome anomaly.

PATHOLOGIC FINDINGS

- Normal spermatogenesis—indicates blockage in azoospermic dogs. • Basement membrane thickness—differentiates hypoplasia from degeneration.

TREATMENT

- Degeneration linked to adenohypophysis, adrenal gland, thyroid gland, or other metabolic disruption—goal is to correct the underlying cause. • No specific diagnosis—may try gonadotropin hormones; rare anecdotal reports of success.

MEDICATIONS

DRUG(S)

- Although no controlled studies validate an increase in spermatozoal output and fertility with the use of GnRH or gonadotropins, both drugs have been used in many species; most likely to cause improvement with cases of hypogonadotropic hypogonadism, which is rare in domestic animals. • hCG 500 IU SC two times/week. • GnRH 1 µg/kg SC with or with hCG (1,600 IU IM).

FOLLOW-UP

PATIENT MONITORING

Suspected testicular degeneration (dogs)—a repeat semen analysis performed at least 70 days after correcting any identified underlying cause is needed before reversibility can be assessed.

EXPECTED COURSE AND PROGNOSIS

- Hypoplasia (dogs)—prognosis for fertility poor. • Degeneration (dogs)—prognosis for fertility depends on the cause, site, and extent of injury; usually guarded to poor.

BASICS

OVERVIEW

- *Clostridium tetani*—an obligate anaerobic spore-forming Gram-positive rod found in soil and as part of the normal bacterial flora of the intestinal tract of mammals with a predilection for contaminated necrotic anaerobic wounds (puncture, surgery, lacerations, burns, frostbite, open fractures, abrasions).
- Germinating spores—in wounds, produce potent exotoxin tetanospasmin (tetanus toxin); resistant to disinfectants and to the effects of environmental exposure.

SIGNALMENT

- Dogs—occasionally (usually localized tetanus)
- Cats—rarely

SIGNS

Historical Findings

- Appear a few days to a few months after spores enter wound (fracture surgery and puncture).
- Wound—often necrotic; but may have healed over and may not be observed by owner.

Physical Examination Findings

The most common *initial* clinical signs in affected dogs are ocular and facial abnormalities.

Localized

- Mild rigidity of muscles or leg nearest the site of spore inoculation (wound).
- Stiffness of (hind) limbs; stilted gait; mild weakness and incoordination.
- Can resolve spontaneously—reflects partial immunity to tetanospasmin.
- Can be prodromal to generalized disease—when enough toxin gains access to CNS.

Progressive/Generalized

- Tail—stretches out; progressive tetany of muscles to point of sawhorse appearance.
- Convulsions (clonic)—limbs; whole body (opisthotonus); pain during contractions.
- Difficulty breathing—dyspnea.
- Difficulty opening jaws—lockjaw trismus.
- Difficulty eating—dysphagia.
- Eyes—lids retract (*visus sardonicus*); third eyelid prolapses when head is touched; eyeballs recede into orbit (*enophthalmos*).
- Wrinkled forehead.
- Erect ears.
- Grinning appearance—commissure of lips retracted.
- Salivation.
- Fever, painful urination (dysuria), and constipation—may be seen.
- Tetanic muscle spasms—from stimulation (sudden movement, sound, touch).

- Death—during spasm of laryngeal and respiratory muscles (fatal acute asphyxia).

CAUSES & RISK FACTORS

- Unattended wounds (e.g., punctures, surgical, compound bone fractures)—portal of entry for spores.
- Outdoor activities provide opportunities for trauma/exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Intoxications mimicking tetanus—lead and strychnine poisoning.
- The dystonic reaction to neuroleptic drugs (atropine, acepromazine).
- Rabies.
- Meningitis-encephalitis.
- Immune-mediated polymyositis.
- Spinal trauma.
- Hypocalcemia.
- Look for: foot injury/trauma (footpad, nails, interdigital), foreign bodies in conjunction with puncture wounds.

CBC/BIOCHEMISTRY/URINALYSIS

- Initial leukopenia; switch to moderate leukocytosis; then gradual return to normal range.
- AST and CPK—some increase; result of muscle damage during later stages of disease.
- Urinalysis—essentially normal; high myoglobin from muscles damaged by constant excitation.

OTHER LABORATORY TESTS

- Serology—antitetanus antibody often undetectable in serum.
- Culture—wounds; usually unrewarding to culture for *C. tetani*; must use true anaerobic transport medium (do not refrigerate).
- Serum—to detect toxin (by mouse neutralization).
- CSF and blood cultures for bacterial pathogens of meningitis

TREATMENT

- Inpatient—good supportive and constant nursing care important; prolonged period (3–4 weeks).
- Feeding—patients often have difficulty in prehending food unless helped; pay particular attention to what consistency of food the patient easily ingests; placement of a gastrostomy tube may be necessary; force feeding or feeding with a stomach tube may exacerbate tetanic state, so not advised.
- Hydration—maintain with oral water; if inadequate give a balanced intravenous fluid.
- Keep patient in darkened quiet area; do not disturb.

- Keep patient on soft bedding; prevent decubital ulcers.

- Airway and ventilation—assess; may be necessary to perform endotracheal intubation; tracheostomy may be necessary later.

MEDICATIONS

DRUG(S)

Sedation

- To control reflex spasms and convulsions.
- Phenothiazines—drugs of choice; chlorpromazine; with or without barbiturates (e.g., phenobarbital).
- Heart rate—may drop when phenothiazines are used in combination; if < 60 beats/minute reverse the bradycardia with glycopyrrolate.
- Diazepam—alternative to Phenobarbital.

Tetanus Antitoxin

- First test for hypersensitivity reaction.
- Human tetanus immunoglobulin—administer 500–3,000 U IM at multiple sites, especially proximal to wound; or use equine tetanus antitoxin (10,000 U IV).
- Administer adsorbed tetanus toxoid intramuscularly.

Antibiotics

- Have no effect against toxin already bound to nerves.
- Metronidazole: dog, 15 mg/kg q12h, or 12 mg/kg q8h PO; cat, 10–25 mg/kg q24h PO.
- Penicillin—administer systemically and locally into the wound; 20,000 IU/kg q12h for 5 days; use crystalline penicillin on the first day and procaine penicillin thereafter.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Avoid glucocorticoids and atropine.
- Avoid narcotics—depress respiratory center.

FOLLOW-UP

PATIENT MONITORING

- Prevent decubital ulcers and peripheral nerve palsies—cautiously move stabilized patient.
- Monitor blood pressure and ECG.
- Bronchopneumonia possible.
- Constipation possible.

PREVENTION/AVOIDANCE

- Vaccinate—tetanus toxoid.
- Prevent skin wound trauma—clear runs and yards of wire, glass, etc.
- Wound management—early and thorough irrigation with hydrogen peroxide; debridement draining, especially in known tetanus-prone wounds.

TETANUS

(CONTINUED)

- Penicillin—administer for minimum of 3 days for all deep contaminated wounds.

EXPECTED COURSE AND PROGNOSIS

- Younger dogs with tetanus may be more likely to develop severe clinical signs.
- The prognosis for survival in dogs with tetanus is good if abnormalities in heart rate or blood pressure values do not develop.
- Prognosis—depends on number of factors; the more toxin bound to nerves, the poorer the prognosis; improve by removing source of additional toxin (debriding and cleaning wound); the closer the wound is to the head, the poorer the prognosis; the shorter the interval between injury and first tetanic spasm, the poorer the prognosis.

- Course of recovery—slow; requires rehabilitation to regain full use of limbs; most recover in 1 week; some have a course of 3–4 weeks; unattended disease can be fatal if the disease progresses to generalized disease (versus the typical localized tetanus that affects only a limb).

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

None, but tetanus spores ubiquitous in environment.

ABBREVIATIONS

- AST = aspartate aminotransferase
- CNS = central nervous system
- CPK = creatine phosphokinase
- CSF = cerebrospinal fluid
- ECG = electrocardiogram

TETRALOGY OF FALLOT

BASICS

OVERVIEW

- A congenital cardiac malformation that consists of a VSD, pulmonic stenosis, an overriding aorta, and right ventricular hypertrophy (Figure 1). The VSD is usually large, with an area that equals or exceeds that of the open aortic valve. The essential developmental abnormality is probably a cranial deviation of a component of the infundibular septum; the other defects are secondary.
- Hemodynamics are determined primarily by the size of the VSD and the severity of right ventricular outflow tract obstruction. A large VSD allows equilibration of left and right ventricular pressures, with shunt direction determined by the relationship between peripheral vascular resistance and the resistance to right ventricular ejection. Severe right ventricular outflow tract obstruction results in a right-to-left shunt with cyanosis and compensatory erythrocytosis as prominent clinical features.
- An uncommon congenital defect, but the most common congenital cardiac malformation that causes cyanosis in dogs and cats.

SIGNALMENT

- Dog and cat—uncommon in both
- English bulldog and Keeshond predisposed

SIGNS

Historical Findings

- Weakness • Syncope • Shortness of breath

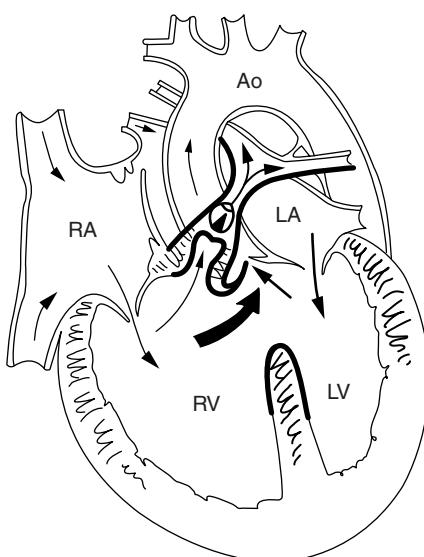

Figure 1.

Classic tetralogy of Fallot. RA = right atrium, LA = left atrium, RV = right ventricle, LV = left ventricle, AO = aorta. (From: Roberts W. Adult Congenital Heart Disease. Philadelphia: F.A. Davis Co., 1987, with permission.)

Physical Examination Findings

- A systolic ejection murmur at the left heart base, caused by right ventricular outflow tract obstruction in most patients; some with hyperviscosity and severe pulmonary stenosis do not have murmurs.
- Cyanosis—in most patients; degree of cyanosis depends on the direction and volume of shunt. If right ventricular outflow tract obstruction is mild, the direction of the shunt may be left to right; in this case, cyanosis is absent and the pathophysiology is that of an isolated VSD.
- Arterial pulses usually normal.
- Congestive heart failure occurs rarely, possibly because the right ventricle can unload into the left ventricle, preventing the development of suprasystemic right ventricular pressures.

CAUSES & RISK FACTORS

Congenital; a continuum of conotruncal defects that includes tetralogy of Fallot is inherited in Keeshonden; the mode of transmission is likely oligogenic. Genetic factors are probably etiologically important in the naturally occurring disorder.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pulmonic stenosis, aortic stenosis, ventricular septal defect, and atrial septal defect can all cause left basilar ejection murmurs.
- Patients with severe pulmonic stenosis and a right-to-left atrial-level shunt may have similar findings on physical examination.
- Other anatomic right-to-left shunts (PDA or VSD with high pulmonary vascular resistance) do not typically cause murmurs; differential cyanosis (cranial mucous membranes are pink; caudal mucous membranes are cyanotic) is observed if a PDA shunts right to left.

CBC/BIOCHEMISTRY/URINALYSIS

- Compensatory erythrocytosis if the shunt is right to left.

IMAGING

Thoracic Radiographic Findings

- Variable degree of right ventricular enlargement.
- Ascending aorta may be prominent.
- Pulmonary vessels are small.

Echocardiographic Findings

- Right ventricular hypertrophy.
- Large VSD visualized directly.
- Overriding of the VSD by the aorta.
- Narrow infundibulum and/or abnormal pulmonic valve.
- Doppler evidence of pulmonic stenosis.
- Contrast echocardiography typically delineates a right-to-left shunt.

Angiocardiography

- Reveals VSD, right ventricular hypertrophy, pulmonic stenosis, and direction of shunt.
- Non-selective angiography may confirm the diagnosis in patients that weigh less than approximately 10 kg.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

Right ventricular hypertrophy pattern in most dogs and cats.

Oximetry

Used to confirm peripheral desaturation of hemoglobin.

TREATMENT

- Most can be treated as outpatients.
- Exercise restriction recommended.
- Treat erythrocytosis by periodic phlebotomy to maintain a PCV of 62–68%.
- Palliative surgical procedures that enhance pulmonary blood flow have been performed.
- Definitive surgical correction requires cardiopulmonary bypass.

MEDICATIONS

DRUG(S)

Non-selective β -adrenergic antagonists such as propranolol may be palliative; they act as negative inotropes, thereby limiting dynamic right ventricular outflow tract obstruction, and also prevent the physiologic drop in peripheral vascular resistance that occurs during exercise. These hemodynamic effects serve to limit right-to-left shunting. Propranolol may also favorably affect the oxyhemoglobin dissociation curve.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Vasodilators contraindicated

FOLLOW-UP

- Monitor PCV every 1–3 months.
- Breeding affected animals is not advisable.
- Bacterial endocarditis, neurologic complications associated with erythrocytosis, arrhythmias, and sudden death are potential sequelae.
- Prognosis is poor; most patients with clinical signs live < 1 year, although survivals > 3 years have been documented.

MISCELLANEOUS

ABBREVIATIONS

- PDA = patent ductus arteriosus
- VSD = ventricular septal defect

Author Jonathan A. Abbott

Consulting Editors Larry P. Tilley and Francis W.K. Smith, Jr.

THIRD EYELID PROTRUSION

BASICS

DEFINITION

Abnormal protrusion (elevation) of the third eyelid.

PATOPHYSIOLOGY

- Dogs—movement of the third eyelid is passive.
- Cats—partial sympathetic nervous control of the third eyelid.
- Elevated third eyelid results from a space-occupying mass in the orbit pushing the third eyelid forward, enophthalmos, sympathetic denervation, or a painful eye.

SYSTEMS AFFECTED

- Nervous—autonomic nervous system
- Ophthalmic—third eyelid(s); orbit; globe

SIGNALMENT

See "Causes"

SIGNS

- May have none.
- May be associated with primary condition—exophthalmos; enophthalmos; blepharospasm; Horner's syndrome.
- Unilateral or bilateral—depending on cause.

CAUSES

Unilateral

Blepharospasm

- Painful ocular condition—corneal ulcer; glaucoma; uveitis; or ocular foreign body.
- May cause the globe to be retracted and secondary third eyelid elevation.

Space-Occupying Orbital Mass

- Often an abscess or neoplasm.
- May displace the third eyelid anteriorly.
- Usually causes exophthalmos.
- Abscess—generally seen in young patients; usually acute onset; painful on palpation.
- Neoplasm—usually seen in old patients; gradual onset; frequently not painful (see Orbital Diseases [Exophthalmos, Enophthalmos, Strabismus]).

Enophthalmos

- Globe—recedes into the orbit, causing third eyelid to appear elevated.
- Unilateral—may be caused by trauma, orbital fat atrophy, and inflammation; may be secondary to orbital neoplasia in cats (see Orbital Diseases).

Microphthalmus or Phthisis Bulbi

- Small globes—cause the third eyelid to appear elevated.
- Microphthalmus—congenital; may be idiopathic; inherited in specific breeds (collie eye anomaly); may result from toxin ingestion (griseofulvin in pregnant cats).
- Phthisis bulbi—occurs with severe damage to the globe (severe uveitis, glaucoma, or trauma); ciliary body fails to produce aqueous humor; diminished; small, fibrotic globe from chronic inflammation.

Other

- Horner's syndrome—clinical signs develop after sympathetic denervation; elevated third eyelid; enophthalmos; ptosis (drooping upper eyelid); miosis (see Horner's Syndrome).
- Neoplasia of the third eyelid—most common: adenocarcinoma of the gland of the third eyelid and squamous cell carcinoma of eyelid.
- Cherry eye—see Prolapsed Gland of the Third Eyelid (Cherry Eye).
- Everted or scrolled cartilage of the third eyelid—seen in Wiemaraners, Great Danes, German shorthaired pointers, and other breeds; the T-shaped cartilage of the third eyelid is rolled away from the surface of the eye instead of conforming to the corneal surface.
- Symblepharon—post-inflammatory adhesions between the third eyelid and cornea or conjunctiva. Common in cats who had ocular surface inflammation before the eyelids opened.

Bilateral

Exophthalmos

- Space-occupying lesions of both orbits.
- Usually caused by inflammatory lesions (e.g., eosinophilic myositis and extraocular muscle polymyositis).

Conformational

- Breed-specific—Doberman pinschers and pointers.
- Deep orbits and prominent third eyelids.
- Not pathologic.
- No treatment needed.

Plasmoma

- Immune-mediated thickening and hyperemia of the leading edge of the third eyelid.
- Seen almost exclusively in German shepherds.
- May be associated with chronic superficial keratitis (pannus).

Other

- Blepharospasm.
- Enophthalmos—caused by dehydration, bilateral orbital fat atrophy secondary to severe cachexia, and chronic masticatory muscle myositis.
- Haw syndrome (cats)—idiopathic bilateral elevation of the third eyelids; all other aspects of the ophthalmic examination are normal; usually resolves in 3–4 weeks without treatment.
- Dysautonomia (Key-Gaskell syndrome)—bilateral elevated third eyelids; dilated non-responsive pupils; KCS; dry mucosal surfaces; anorexia; lethargy; regurgitation; megaesophagus; bradycardia; megacolon; distended bladder (see Dysautonomia).
- Tranquilizers—many (e.g., acepromazine) cause bilateral third eyelid elevation.
- Fatigue—may cause transient third eyelid elevation, especially in dogs prone to ectropion.

RISK FACTORS

Depends on cause

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Most common causes of acute onset of unilateral condition—ocular pain (e.g., corneal ulcer and uveitis); orbital inflammation (e.g., orbital abscess and cellulitis).
- Middle-aged or older patient with unilateral, non-painful condition—third eyelid or orbital neoplasm likely.
- All patients—must rule out a small eye (microphthalmus or phthisis bulbi) and Horner's syndrome.
- Likely causes of bilateral condition—systemic illness (e.g., dehydration, cachexia, and dysautonomia); associated with conformational abnormalities.
- Prolapsed gland of the third eyelid—medial aspect of the third eyelid swollen; the third eyelid itself usually normal.

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis and a left shift—with orbital inflammatory processes.
- Blood work—generally unrewarding in differentiating causes.

OTHER LABORATORY TESTS

Dysautonomia—confirmed by measuring urine and plasma catecholamine concentrations and pharmacologic testing of the autonomic nervous system.

IMAGING

- Thoracic radiography—all patients with Horner's syndrome to rule out intrathoracic cause of sympathetic denervation; patients with suspected neoplasia to evaluate for metastatic disease.
- Orbital ultrasound—recommended to help localize suspected orbital mass and define its nature (e.g., solid or cystic).
- CT or MRI—further define suspected or known orbital mass.
- Skull radiographs—rarely show signs of orbital disease unless the lesion is very large and destructive.

DIAGNOSTIC PROCEDURES

- Thorough ophthalmic examination.
- Slit-lamp biomicroscope or some other source of magnification—recommended to localize any potential ocular abnormality.
- All patients with unilateral condition—examine both surfaces of the third eyelid and the conjunctival cul-de-sac carefully for a foreign body or symblepharon.
- Pharmacologic testing—localize lesion(s) with Horner's syndrome (see Horner's Syndrome).
- Exploratory surgery and biopsy—may be only means to make a definitive diagnosis for a suspected orbital or third eyelid mass.

(CONTINUED)

THIRD EYELID PROTRUSION**Cytology**

- For suspected mass lesions—orbital mass or mass of the third eyelid; fine-needle aspirate; may help make the diagnosis.
- Unguided fine-needle aspiration—attempt only if the mass is anterior to the equator of the eye.
- Ultrasonography-guided fine-needle aspiration—for masses posterior to the eye; help avoid delicate retrobulbar structures.
- Third eyelid scrapings (German shepherds with suspected plasmoma)—reveal plasma cells and lymphocytes.

**TREATMENT**

- Depends on cause.
- Painful condition—remove the cause of the irritation (e.g., foreign body); treat the primary ocular condition.
- Orbital cellulitis and abscess—generally respond well to drainage and systemically administered antibiotics.
- Orbital neoplasms—usually require wide surgical excision via an orbital exenteration; may require adjunct therapeutic modalities (e.g., radiotherapy or chemotherapy) if excision is incomplete.
- Microphtalmic eyes—usually none required; remove the globes if painful or subject to recurrent conjunctivitis.
- Blind traumatized eyes—enucleate to prevent formation of intraocular sarcomas (cats).
- Horner's syndrome—treat cause, if known (~50% of dogs and cats); otherwise will usually resolve without treatment in 4–12 weeks.
- Surgical removal of the entire third eyelid—indicated for third eyelid neoplasia; may require adjunct therapeutic modalities (e.g., radiotherapy or chemotherapy) if the surgical margins are not free of neoplasm.
- Radiotherapy around the eye—may result in severe keratitis, dry eye, and cataracts; discuss enucleation with the client before initiating treatment if eye will be in the field.
- Orbital exenteration—may be warranted if the mass extends into the orbit.

- Plasmomas—usually controlled with topically applied medications; not cured; inform client that some form of treatment will likely be needed for the life of the patient; topical corticosteroids (0.1% dexamethasone or 1% prednisolone acetate; q6h initially, reduced to q24h when the lesion appears resolved); topical 1% cyclosporine in oil (q12h) also effective.
- Haw syndrome—usually resolves in 3–4 weeks without treatment.
- See Dysautonomia.

**MEDICATIONS****DRUG(S) OF CHOICE**

See "Treatment"

CONTRAINDICATIONS

Topical corticosteroids—never use with a corneal ulcer.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

**FOLLOW-UP****PATIENT MONITORING**

Malignant neoplasm—take thoracic radiographs every 3–6 months to monitor for metastatic disease.

POSSIBLE COMPLICATIONS

- Neoplasm—extension to or infection of adjacent orbital structures (e.g., eye, orbit, orbital sinuses, and cranial cavity) possible; metastasis to distant sites (usually thorax or liver) possible (approximately 90% are malignant).
- Vision loss—from the lesion itself; from the elevation; from treatment (e.g., radiotherapy and exenteration).

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

- Middle-aged to older patients—at risk for neoplastic diseases of the third eyelid and orbit.
- Young patients—at risk for congenital abnormalities; affected by inflammatory conditions of the third eyelid more frequently than are old animals.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

N/A

SYNONYMS

T

THROMBOCYTOPATHIES

BASICS

OVERVIEW

- Acquired or hereditary defects that can affect any of the main functions of platelets, including procoagulant activity. Defects are divided in 2 categories: intrinsic and extrinsic (e.g., vWD).
- Affected animals typically have normal platelet counts but have spontaneous or excessive bleeding; mucosal bleeding is the most common sign.
- Thrombocytopenic animals with concurrent thrombocytopathia will bleed more excessively than expected for the platelet count.

SIGNALMENT

- Acquired defects are the most common thrombocytopathias seen in companion animals. They occur in all breeds and at all ages.
- Hereditary platelet function defects may be diagnosed at all ages but may first appear in young animals when excessive bleeding occurs with loss of deciduous teeth.
- Hereditary defects are rare disorders that have been described in the following breeds/species:
 - Type I Glanzmann thrombasthenia—otter hound and Great Pyrenees
 - Storage pool disease—Chediak-Higashi syndrome—Persian cat; delta-granule—American cocker spaniel; cyclic hematopoiesis—grey collie
 - Thrombocytopathia (CalDAG-GEFI deficiency)—basset hound, spitz, and Landseer
 - Scott syndrome—German shepherd
 - P2Y12 (ADP) receptor mutation—Greater Swiss mountain dog

SIGNS

- Often mild spontaneous muco-cutaneous bleeding, such as epistaxis, petechiation, and gingival bleeding.
- Prolonged bleeding in some animals during or following diagnostic or surgical procedures.
- In Scott syndrome, postoperative hemorrhage is the most common sign.

CAUSES & RISK FACTORS

Acquired—Drugs

- NSAIDs (e.g., aspirin) inhibit platelet function by preventing the formation of thromboxane A₂. This effect is less pronounced to absent with more selective cyclooxygenase-2 antagonists (e.g., meloxicam, deracoxib).
- Potentiated sulfonamides and hydroxyethyl starch solutions suppress platelet function in dogs.

• Penicillins, tetracyclines, anesthetic/sedative agents, and antihistamines cause thrombocytopenia and/or platelet function defects in humans—however, effects have not been documented in dogs and cats.

Secondary to Systemic Disease

Disseminated intravascular coagulopathy, uremia, anemia, liver disease (cholestasis and acquired or inherited shunts), ehrlichiosis, leishmaniasis, immune-mediated thrombocytopenia, heart disease, and neoplastic disorders (both hematopoietic and non-hematopoietic neoplasms).

Hereditary

- von Willebrand disease—a deficiency (type I and III) or qualitative defect (type II) of von Willebrand factor.
- Basset hound, spitz, and Landseer hereditary thrombocytopathia—signal transduction defects due to CalDAG-GEFI mutations.
- Otter hound and Great Pyrenees with type I Glanzmann thrombasthenia—platelet defect caused by a mutation in glycoprotein IIb-IIIa (integrin $\alpha_{IIb}\beta_3$) receptor on the platelet surface.
- Storage pool disease: Chediak-Higashi syndrome and deficiency in delta-granule storage pool of ADP—aggregation defect caused by lack of adenine nucleotides.
- Scott syndrome in German shepherd—platelet procoagulant deficiency (failure to externalize phosphatidyl-serine on the platelet surface and inability of the platelets to support effective assembly of coagulation complexes).
- P2Y12 (ADP) receptor mutation in Greater Swiss mountain dog.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia, if bleeding is severe; regenerative or nonregenerative.
- Platelet counts typically normal in dogs with inherited thrombocytopathies, but low counts with bizarre and giant platelets seen in some.
- Biochemical profile—no specific changes.

OTHER LABORATORY TESTS

- Platelet function analyzer-100 and vWF by immune assay—in animals suspected of vWD.
 - Platelet function testing—in specialized laboratories. The most common tests are platelet aggregation and flow cytometry.
 - Coagulation tests (thromboelastography, PT, and APTT)—to eliminate coagulopathy as a cause of hemorrhage; APTT may be prolonged in some animals with von Willebrand disease.
 - Genetic testing of carrier animals.

DIAGNOSTIC PROCEDURES

Mucosal bleeding time—to confirm platelet function defect; normal buccal mucosal bleeding time measured using a spring-loaded lancet that makes an incision 5 mm long by 1 mm deep (Triplett, Helena Laboratories, Beaumont, TX) is less than 4–5 minutes in dogs and less than 2–3 minutes in cats.

TREATMENT

- Transfusion—20 mL/kg (minimum 10 mL/kg) platelet-rich plasma or fresh frozen plasma (contains platelet particles) or 1 unit/10 kg (minimum 1 unit/30 kg) platelet concentrate or cryoprecipitate depending on condition.
- Whole blood or packed red cell transfusion to correct anemia (should be reserved for animals with hematocrit below 15% or clinical compromise due to anemia).
- In animals with acquired platelet function disorders, treat the underlying disease process or withdraw the offending agent.
- Elective surgical procedures should be avoided or accompanied by appropriate transfusion products.
- Avoid over-generous fluid therapy.
- Restrict activity during a bleeding episode.

MEDICATIONS

DRUG(S)

- Desmopressin acetate (DDAVP) (1 μ g/kg SC or IV diluted in 20 mL saline administered over 10 minutes) to dogs with von Willebrand disease during a bleeding episode (if effective, effect lasts 2–3 hours).
- Desmopressin (3 μ g/kg SC) improves bleeding time in dogs with thrombocytopathia due to aspirin and liver disease. It is beneficial in many thrombocytopathies in humans, so consider using in dogs with other thrombocytopathias.
- Give desmopressin to donor 30 minutes before collection of blood for transfusion to dogs with von Willebrand disease or thrombocytopathia.

FOLLOW-UP

- Take special precautions when performing surgical procedures on these animals.
- Make owner aware that animals with hereditary platelet function defects may have recurring bleeding episodes, but fatal episodes are uncommon.

(CONTINUED)

THROMBOCYTOPATHIES

- If a hereditary defect is identified, do not use the animal for breeding.

THROMBOCYTOPENIA

BASICS

DEFINITION

Platelet count below the lower limit of reference interval, which varies with the method of platelet counting. Grade of thrombocytopenia—Grade 1: $100,000/\mu\text{L}$ to lower limit of reference range; Grade 2: $50,000$ – $99,000/\mu\text{L}$; Grade 3: $25,000$ – $49,000/\mu\text{L}$; Grade 4: $< 25,000/\mu\text{L}$.

PATHOPHYSIOLOGY

- Platelets are produced by bone marrow megakaryocytes and released into the blood, where they normally circulate 5–10 days.
- Thrombocytopenia is caused by one or more of decreased production; increased sequestration, utilization, destruction of platelets. • Thrombocytopenia may cause spontaneous or excessive hemorrhage.

SYSTEMS AFFECTED

- Hemorrhage may occur into any organ system. • Clinical hemorrhage—most commonly recognized in the skin/exocrine and gastrointestinal systems, followed by the renal/urologic and respiratory systems; less commonly recognized in the ophthalmic, nervous, and reproductive systems.

INCIDENCE/PREVALENCE

- Thrombocytopenia is a common hematologic abnormality. • Severe hemorrhage due to thrombocytopenia is uncommon (dogs) or rare (cats) in general practice.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Hereditary asymptomatic thrombocytopenia with macroplatelets in Cavalier King Charles spaniel. • Hereditary asymptomatic mild thrombocytopenia in greyhound and Polish ogar dog.

SIGNS

General Comments

- Grade 1 thrombocytopenia—no increased risk of hemorrhage. • Grade 2—increased surgical hemorrhage may occur. • Grade 3—microscopic spontaneous hemorrhage may occur. • Grade 4—mild, moderate, and severe risk of spontaneous clinical hemorrhage at platelet counts of $< 25,000/\mu\text{L}$, $< 10,000/\mu\text{L}$, and $< 5,000/\mu\text{L}$, respectively.
- These figures are guidelines only because of variation in methods of platelet counting and imprecision of low platelet counts.
- Concurrent platelet function defect, von Willebrand disease, coagulopathy, vasculitis, or sepsis increases risk of hemorrhage. • Dogs with IMT have a lower risk of hemorrhage for a given platelet count. • Cats have a lower risk of hemorrhage than dogs.

Historical Findings

- Spontaneous or excessive mucous membrane, cutaneous, gastrointestinal, nasal, urinary and ocular bleeding. • Lethargy and collapse (hemorrhagic anemia). • Dyspnea and coughing (respiratory tract hemorrhage).
- Neurologic signs (CNS bleeding). • Clinical signs of the primary disease.

Physical Examination Findings

- Petechiae and ecchymoses • Persistent bleeding from wounds and venipuncture sites
- Melena, hematochezia, hematemesis
- Hematuria • Ocular hemorrhages
- Splenomegaly, hepatomegaly • Pale mucous membranes • Weakness • Dyspnea, hemoptysis • Heart murmur • Neurologic signs • Excessive bleeding in estrus • Clinical signs of the primary disease

CAUSES

- Decreased production—hereditary; bone marrow neoplasia; Sertoli cell tumor; infectious agents; immune-mediated; drugs; irradiation. Thrombocytopenia varies from mild to severe and may be an isolated hematologic abnormality or a feature of pancytopenia. • Increased sequestration—splenomegaly; severe thrombocytopenia is uncommon. • Increased utilization—DIC; local thrombosis (e.g., portal vein); vasculitis; severe thrombocytopenia is uncommon.
- Increased destruction—primary IMT or IMT secondary to neoplasia, infectious agents, aseptic inflammation, drugs. Most common cause of severe thrombocytopenia in dogs. • Increased loss—hemorrhage due to vitamin K antagonist poisoning may result in mild to moderate thrombocytopenia; hemorrhage due to major trauma may result in mild to severe thrombocytopenia after volume resuscitation.

RISK FACTORS

- Potentially any infection—most commonly associated with thrombocytopenia: FeLV; FIV; distemper; parvoviruses; *Ehrlichia* spp.; *Anaplasma* spp.; Rocky Mountain spotted fever; leptospirosis; *Borrelia burgdorferi*; bacterial sepsis; histoplasmosis; *Cytauxzoon felis*; *Babesia* spp.; *Rangelia* spp.; *Hepatozoon canis*, *Leishmania* spp.; *Theileria* spp. heartworm, *Angiostrongylus vasorum*, and aberrant larva migrans. • Potentially any non-infectious inflammation, e.g., vasculitis.
- Potentially any neoplasm—most commonly identified include hemangiosarcoma, thyroid carcinoma, lymphoma, histiocytic sarcoma and acute leukemias. • Large-field radiation therapy and cytotoxic drug therapy—predictable myelosuppression; lomustine causes a cumulative thrombocytopenia.
- Potentially any drug—drugs with known risk for unpredictable myelosuppression or IMT include estrogen, gold compounds, phenylbutazone, phenobarbital (dogs); chloramphenicol, griseofulvin, propylthiouracil, methimazole and carbimazole (cats); drugs with reported idiosyncratic reactions causing myelosuppression include cephalosporins and albendazole (dogs, cats), fenbendazole, sulfonamides, ACE inhibitors (dogs), and ribavirin. • Vaccination within 1 month—for IMT. • Toxins and venoms—zinc, autumn crocus (myelosuppression); mycotoxins, xylitol (acute hepatic injury—DIC); snake bite. • Hyperthermia—DIC.

carbamazole (cats); drugs with reported idiosyncratic reactions causing myelosuppression include cephalosporins and albendazole (dogs, cats), fenbendazole, sulfonamides, ACE inhibitors (dogs), and ribavirin. • Vaccination within 1 month—for IMT. • Toxins and venoms—zinc, autumn crocus (myelosuppression); mycotoxins, xylitol (acute hepatic injury—DIC); snake bite. • Hyperthermia—DIC.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Measurement error due to platelet clumping—most likely with traumatic venipuncture and in cats. EDTA-induced platelet clumping may occur in dogs (rare).
- Clerical error. • Local hemorrhage—rule out trauma, gastrointestinal ulceration, primary intranasal, urinary, and reproductive tract disorders. • von Willebrand disease—petechiae, ecchymoses, and ocular hemorrhages unusual. • Coagulopathy—petechiae, gastrointestinal hemorrhage, and epistaxis unusual; subcutaneous swellings, swollen joints, hemothorax, and hemoabdomen may be present.

CBC/BIOCHEMISTRY/URINALYSIS

- Confirm thrombocytopenia reported by a hematology analyzer by examination of a blood smear; examine feather edge for platelet clumps; estimate platelet count from red cell monolayer where about 50% of cells are touching; each platelet-per-oil immersion field represents $15,000$ – $25,000/\mu\text{L}$. • Mean platelet volume and platelet distribution width are inversely related to platelet count and usually do not assist in differentiating causes of thrombocytopenia. Platelet morphology changes are nonspecific.
- Plateletcrit (analogous to hematocrit)—best method to diagnose pathologic thrombocytopenia in a Cavalier King Charles spaniel. • Regenerative anemia—rule out hemorrhage or IMHA concurrent with IMT.
- Neutrophilia and left shift—rule out sepsis, non-septic inflammation, and nonspecific stimulation of granulopoiesis.
- Eosinophilia—rule out heartworm and other helminth infections. • Concurrent non-regenerative anemia and neutropenia—thrombocytopenia probably due to decreased production. • Schistocytes—DIC.
- Organisms in blood cells. • Abnormalities on a biochemistry profile and urinalysis reflect primary disease.

OTHER LABORATORY TESTS

- von Willebrand factor antigen. • PT, APTT, ACT—prolonged times increase likelihood of DIC; normal PT rules out vitamin K antagonism. • Fibrinogen degradation products and D-dimer—positive result increases likelihood of DIC or local

(CONTINUED)

thrombosis. • Cultures of abnormal organs, blood, and urine for bacterial or fungal sepsis. • Serologic and PCR tests for infectious organisms. • Fecal floatation and Baermann tests for parasitic larvae. • Antiplatelet/antimegakaryocyte antibody tests—negative results help rule out IMT. • Coombs' test—positive result increases likelihood of concurrent IMHA. • Antinuclear antibody test—positive result increases likelihood of SLE. • Flow cytometry for immature reticulated platelets (analogous to reticulocyte count).

IMAGING

Identify splenomegaly, hepatomegaly, neoplasms, infection, and internal bleeding.

DIAGNOSTIC PROCEDURES

Bone marrow biopsy—rule out reduced platelet production: neoplasia in bone marrow, histoplasmosis, maturation arrest, marrow aplasia, myelofibrosis, and marrow necrosis; no specific finding that rules in or out immune-mediated megakaryocytic hypoplasia; low diagnostic yield if the only hematologic abnormalities are thrombocytopenia causing bleeding and regenerative anemia (likely IMT). Not contraindicated in severe thrombocytopenia.

PATHOLOGIC FINDINGS

Internal bleeding; other findings reflect primary disease.

TREATMENT

APPROPRIATE HEALTH CARE

- Treatment of primary disorder. • Platelet transfusion—20 mL/kg (minimum 10 mL/kg) fresh whole blood, platelet-rich plasma, or fresh frozen plasma (contains platelet particles), or 1 unit/10 kg (minimum 1 unit/30 kg) platelet concentrate (fresh, room-temperature stored, cryopreserved, and lyophilized) or cryoprecipitate (where 1 canine unit refers to product derived from a 450 mL unit of whole blood); transfuse if critical hemorrhage is noted and consider prophylactic transfusion if platelet count < 5,000–10,000/ μ L; transfusions may be needed q1–3d if severe thrombocytopenia persists; most useful when thrombocytopenia is due to reduced production or loss and rapid resolution is anticipated; less useful in splenomegaly and DIC and least useful in IMT. • Whole blood or packed red cell transfusion to correct anemia—bleeding due to thrombocytopenia is worse in the presence of anemia. • Do not drain hematomas unless necessary (e.g., tracheal compression).

NURSING CARE

- Minimize IM and SC injections. Apply extended pressure after IV injection/catheterization and invasive procedures. Avoid

jugular venipuncture. • Avoid overexuberant fluid therapy.

ACTIVITY

Restrict activity with moderate-to-severe thrombocytopenia.

DIET

Avoid hard foods with severe thrombocytopenia (gingival bleeding).

SURGICAL CONSIDERATIONS

Extensive perioperative transfusion may be needed.

MEDICATIONS

DRUG(S) OF CHOICE

- See specific chapters for diseases causing thrombocytopenia. • Acepromazine has negligible effects on platelet function in dogs and cats and may be used to sedate animals to reduce risk of hemorrhage associated with excessive activity.

CONTRAINdications

NSAIDs that interfere with platelet function—opioids are preferred for analgesia; if NSAID use required, use selective cyclooxygenase-2 inhibitors (e.g., deracoxib).

PRECAUTIONS

- Heparin (used in DIC) may aggravate hemorrhage due to thrombocytopenia.
- Corticosteroid therapy may exacerbate infection and promote gastrointestinal ulceration.

POSSIBLE INTERACTIONS

Corticosteroids are prothrombotic.

ALTERNATIVE DRUG(S)

- Thrombopoietic stimulants: Oprelvekin—50 μ g/kg SC q24h for maximum of 2 weeks (to avoid risk of neutralizing antibody formation); most useful when thrombocytopenia caused by cytotoxic therapy; expensive. Romiplostim, eltrombopa, lithium carbonate—not recommended. • Plasmin inhibitors: aminocaproic acid, tranexamic acid; as for IMT; contraindicated in DIC; Melatonin and 5-methoxytryptamine—as for IMT.

FOLLOW-UP

PATIENT MONITORING

- Amount of bleeding—control of clinical hemorrhage is most important parameter to monitor to judge effectiveness of treatment.
- Serial platelet counts using same method
- Serial coagulation profiles—if DIC suspected.

PREVENTION/AVOIDANCE

Varies with cause.

THROMBOCYTOPENIA

POSSIBLE COMPLICATIONS

- Hemorrhagic shock • Uveitis
- Mild-to-severe neurologic signs (CNS bleeding)

EXPECTED COURSE AND PROGNOSIS

Varies with cause. If underlying cause of severe thrombocytopenia cannot be treated, prognosis poor because of limited ability to provide extensive platelet transfusions.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- If thrombocytopenia is from reduced production, may be concurrent anemia and neutropenia. • IMT may be solitary or associated with other immune-mediated disorders.

AGE-RELATED FACTORS

Varies with cause—e.g., FeLV in younger cats, IMT in middle-aged dogs, neoplasia in older dogs.

ZOONOTIC POTENTIAL

Thrombocytopenia may be due to a zoonotic infection (e.g., leptospirosis).

THROMBOCYTOPENIA, PRIMARY IMMUNE-MEDIATED

BASICS

DEFINITION

- Immune-mediated destruction of platelets with no identifiable cause.
- In secondary IMT, infectious diseases, neoplasia, vaccination, or drugs trigger the production of antibodies.

PATHOPHYSIOLOGY

- Antiplatelet auto-antibodies result in premature platelet destruction by macrophages mainly in the spleen by a Type II (antibody-dependent cytotoxicity) mechanism.
- In secondary IMT, platelet-bound antibodies can be antibodies bound to platelet antigens altered during course of disease or antibodies bound to foreign antigens or immune complexes.
- Auto-antibodies can be directed against megakaryocytes, thereby impeding marrow responsiveness.
- Antibody-mediated impairment of platelet function possible.
- Cause of immune dysregulation and auto-antibody production is unknown.

SYSTEMS AFFECTED

- CNS
- GI Tract
- Ophthalmic
- Respiratory
- Skin
- Urinary

GENETICS

Auto-immunity is frequently recognized in particular dog breeds and is often familial, suggesting a strong genetic influence.

PREVALENCE

Approximately 6% of canine and 3% of feline thrombocytopenia cases.

SIGNALMENT

Species

- Dog
- Rare (or rarely diagnosed) in cat

Breed and Familial Predilections

Cocker spaniel, poodle, Old English sheepdog, Irish setter; any breed can be affected.

Mean Age and Range

- Mostly middle-aged dogs
- Reported age range in dogs: 0.3–15 years (mean 5); in cats: 0.7–12 years (mean 6)

Predominant Sex

Female dogs, spayed or intact, are predisposed.

SIGNS

Historical Findings

- Dogs often presented due to acute onset (surface) hemorrhage.
- Chronic blood loss due to IMT is very rare.
- Sometimes lethargy, weakness, inappetence.
- Cats presented due to lethargy, inappetence, (surface) hemorrhage.
- Asymptomatic cases can be detected on (routine) health checks or presurgical screens.
- Specific questions: drug/travel history, vaccination history (vaccination within the last 4 weeks might indicate vaccine reaction).

Physical Examination Findings

- Mainly surface bleeding.
- Mucosal and cutaneous petechiae/ecchymoses.
- Gingival bleeding.
- Melena, hematemesis, hematochezia.
- Epistaxis.
- Ocular hemorrhage.
- Hematuria.
- Sometimes hematomas.
- Prolonged hemorrhage after trauma or venipuncture.
- Mucous membrane pallor due to blood loss anemia, hemorrhagic shock.
- Neurologic signs (rare) due to CNS bleeding.
- Fever, mild lymphadenomegaly unusual.
- Sometimes enlarged spleen palpable.

DIAGNOSIS

- Is based on
- Usually severe thrombocytopenia
- Positive platelet-bound antibody test (if available)
- Response to immunosuppressive therapy
- Careful exclusion of underlying diseases or potential triggers.

DIFFERENTIAL DIAGNOSIS

- Measurement error due to platelet clumping; especially in cats low platelet counts often incorrect (due to tendency to aggregate/large size).
- Decreased production:
 - Infectious diseases; vaccination within the last weeks; drugs/toxins; irradiation; primary bone marrow disorders; immune-mediated response against megakaryocytes; inherited macrothrombocytopenia of Cavalier King Charles spaniels.
 - Either isolated thrombocytopenia or pancytopenia.
- Thrombocytopenia can be severe dependent on underlying disease.
- Increased sequestration in an enlarged spleen:
 - E.g., inflammatory disorders, neoplasias; splenic torsion.
 - Thrombocytopenia mild to moderate unless other mechanisms contribute (e.g., secondary IMT, DIC).
 - Increased utilization or consumption:
 - DIC; local thrombosis; vasculitis/vascular damage with or without DIC.
 - Severe hemorrhage: may result in mild to moderate thrombocytopenia after volume resuscitation.
 - Increased destruction (most common cause of severe thrombocytopenia):
 - Primary IMT.
 - Secondary IMT due to infectious diseases (anaplasmosis, ehrlichiosis, Rocky Mountain spotted fever, bartonellosis, babesiosis, leishmaniasis, dirofilariosis, angiostrongylus infection, bacterial infections; FeLV, FIV, FIP, distemper, infectious hepatitis); sterile inflammation (in cats fat tissue necrosis, etc.); neoplastic diseases (lymphoma, leukemia, hemangiosarcoma, etc.); drugs/toxins (vaccines, sulfonamides, cephalosporins, phenobarbital, NSAID); blood transfusions; SLE.

CBC/BIOCHEMISTRY/URINALYSIS

- Thrombocytopenia often severe (< 30–40,000/ μ L), high risk of spontaneous bleeding; dogs and cats may be asymptomatic.

- Blood smear examination: to confirm low platelet count; to identify potential causes for secondary IMT; e.g., morulae, babesia, schistocytes, spherocytes, blast cells; anemia due to blood loss/concurrent IMHA possible.
- Leukogram can be normal; mild to moderate leukocytosis in one-third of the dogs (due to stress/inflammation), rarely leukopenia. Sometimes monocytosis, neutrophilia with/without left shift, lymphopenia, eosinophilia, eosinopenia.
- Concurrent neutropenia may indicate primary marrow disease or infectious disease.
- Coagulation testing generally normal; if abnormal consider secondary IMT, DIC and further tests.
- Chemistry results unspecific for IMT. Sometimes mildly increased liver enzymes, rarely hyperbilirubinemia due to hematoma resorption; hypoproteinemia/hypoalbuminemia due to blood loss. Hyperglobulinemia may indicate underlying disease (e.g., ehrlichiosis, leishmaniasis, FIP).
- Microscopic or macroscopic hematuria.

OTHER LABORATORY TESTS

- No gold standard immunodiagnostic test for IMT widely available. No test can distinguish between primary and secondary IMT; pIMT is a diagnosis of exclusion.
- Direct tests to detect platelet-bound antibodies have been evaluated. Flow cytometric assays performed in specialized laboratories appear to have a good sensitivity and specificity.
- Adjunct immunodiagnostic testing such as Coombs' test or antinuclear antibody titer if IMHA or SLE is suspected.
- Select other tests to exclude the above-listed differentials for thrombocytopenia (serology and/or PCR testing for infectious diseases; microbiology of urine and blood; etc.).

IMAGING

- Often diffuse splenomegaly, rarely hepatomegaly.
- Radiography and ultrasonography to exclude other causes of thrombocytopenia (e.g., splenic mass) or internal bleeding.

DIAGNOSTIC PROCEDURES

- Bone marrow evaluation not indicated if diagnosis seems straightforward and there is response to therapy within several days; indicated if concurrent neutropenia or nonregenerative anemia, atypical nucleated cells, or treatment failure.
- Number of megakaryocytes often increased, megakaryocytic hypoplasia is rare.
- Fine-needle aspiration of enlarged lymph nodes possible; no organs shall be aspirated due to high risk of severe bleeding. (Otherwise platelet products have to be available.)

TREATMENT

APPROPRIATE HEALTH CARE

- Uncomplicated cases with low bleeding risk and good owner compliance may be treated as

(CONTINUED)

THROMBOCYTOPENIA, PRIMARY IMMUNE-MEDIATED

outpatients. • Patients with severe thrombocytopenia have very high risk of bleeding and warrant strict refinement (e.g., cage rest). • Transfusion of platelet products: 10–20 mL/kg fresh whole blood, 1 unit of whole blood–derived platelet-rich plasma (ca. 8×10^{10} platelets) per 10 kg (minimum 1 unit/30 kg) in cases with critical hemorrhage. Platelets may be destroyed rapidly, but protect against catastrophic hemorrhage until specific therapy is beneficial. • Packed red blood cells or (preferably) fresh whole blood to correct blood loss anemia. • Management of hypovolemia with crystalloid solutions (colloids may impair platelet function).

NURSING CARE

- No IM and SC injections. Apply extended pressure after IV injections and invasive procedures (e.g., lymph node aspiration). Avoid cystocentesis and jugular venipuncture. Bone marrow aspiration is safe.
- Intensive nursing care in patients with moderate to severe hemorrhage, hypovolemia, CNS signs, etc.
- Avoid hard foods.

SURGICAL CONSIDERATIONS

- High risk of bleeding in dogs with severe thrombocytopenia.
- May need extensive peri- and intraoperative (platelet) transfusions.
- Splenectomy is a (controversial) option for refractory cases not responding to medical therapy.

MEDICATIONS

DRUG(S)

- Corticosteroids: methyl prednisolone 10 mg/kg IV once; prednisolone (dogs 1–1.5 mg/kg q12h, cats 1.5–2 mg/kg q12h initially); dexamethasone rarely used (0.1–0.5 mg/kg q24h). • Consider antibiotics (potential of underlying occult infection; predisposition to infection from immunoderegulation); doxycycline if tick-borne disease is not excluded.
- GI protectants (sucralfate and/or proton pump inhibitors) to prevent or treat GI ulceration.
- Other immunosuppressive agents when prednisolone fails, only controls the disease at persistently high doses, causes unacceptable side effects, and for the long-term control of refractory/relapsing cases. Most of these agents not effective in the acute management; few controlled studies available.
- Acute management—dogs: vincristine (0.02 mg/kg IV, once) or hIg (0.5 g/kg IV over 6–8h, once) in combination with prednisolone led to a more rapid increase in platelet counts compared to prednisolone alone; mycophenolate mofetil (7–10 mg/kg q12h)

(onset of action unknown; successful as first-line single agent in 5 dogs); cats: hIg. • Other immunosuppressive drugs for long-term control (initial dosages)—dogs, cyclosporine (5 mg/kg q12h), mycophenolate mofetil, azathioprine (initially 2 mg/kg q24h), leflunomide (3–4 mg/kg q24h), in combination with prednisolone; cats, chlorambucil (0.1–0.2 mg/kg q24h), mycophenolate mofetil. • Once the platelet count is in the normal range, the initial prednisolone dose will be tapered by approximately one-fourth to one-fifth every 2 weeks, finally switching to alternate-day therapy. Taper slowly over approximately 6 months if no relapse occurs.

PRECAUTIONS

- Discontinue any unnecessary medications (may have induced secondary IMT).
- Corticosteroids: GI ulceration; iatrogenic hyperadrenocorticism.
- Immunosuppression: predisposes to opportunistic infections.
- Cytotoxic medications: bone marrow suppression.
- Dose tapering too rapidly after remission may predispose to recurrence. Relapses are more difficult to control.

FOLLOW-UP

PATIENT MONITORING

- Hematocrit measurements 2–3 times daily in cases with severe hemorrhage (risk of life-threatening (GI) blood loss).
- Measure platelet count daily until $> 50,000/\mu\text{L}$; then every few days until platelet counts normalize. Then every 1–3 weeks during the period of drug dose tapering.
- CBC and biochemistry every 2–4 weeks.
- Microbiological urinalysis every 4–6 weeks due to risk of secondary infections (especially in females).

PREVENTION/AVOIDANCE

- Use vaccines judiciously. Role in recurrence is uncertain.
- Minimize stress that may initiate recurrence.

POSSIBLE COMPLICATIONS

- Excessive bleeding can be fatal; spontaneous death, e.g., due to CNS, pericardial bleeding.
- Side effects of medications (GI ulceration, Cushing habitus, opportunistic infections, bone marrow suppression).

EXPECTED COURSE AND PROGNOSIS

- Platelet counts will usually increase $> 50,000/\mu\text{L}$ a few days after starting treatment (after 1–15, median 5 days in 24 of 25 dogs).
- Vincristine or hIg in addition to prednisolone led to a more rapid increase to $50,000/\mu\text{L}$ (median 2.5–4 days).
- Few dogs never achieve normal platelet counts.

- Failure to respond to therapy should prompt reconsideration of the diagnosis.
- 5 of 19 dogs (26%) relapsed after 19–286, median 66 days; causes for relapse were dose reduction of prednisolone, lack of owner compliance.
- If relapses occur a second immunosuppressive drug should be added, a more gradual tapering is advised, leaving the animal on an alternating daily regimen possibly for the rest of its life.
- Survival to discharge in recent studies: 84–97%;
- prognosis is more favorable with intensive therapy including blood/platelet products if needed.
- Mortality rate in cats is 15% (2/13).

MISCELLANEOUS

ASSOCIATED CONDITIONS

Approximately one-third of dogs with primary IMT also have IMHA (Evans syndrome).

SYNOMYMS

- Auto-immune thrombocytopenia
- Idiopathic/auto-immune thrombocytopenic purpura

BASICS

OVERVIEW

Thunderstorm phobia is a disorder in which there is persistent and exaggerated fear of storms or the stimuli associated with storms. Fears of noises other than thunder also occur, such as fireworks or gunshots. Pathophysiology involves physiologic, emotional, and behavioral components.

SYSTEMS AFFECTED

- Behavioral—avoidance or escape attempts.
- Cardiovascular—tachycardia.
- Endocrine/Metabolic—increased cortisol levels, stress-induced hyperglycemia.
- GI—inappetence, gastrointestinal upset.
- Musculoskeletal—self-induced trauma resulting.
- Nervous—adrenergic/noradrenergic overstimulation.
- Respiratory—tachypnea.
- Skin—displacement grooming.

SIGNALMENT

• Occurs in dogs and cats, but dogs more often presented for treatment. Cats with noise aversion might present with redirected aggression.

- No association with sex or neuter status.
- Any breed can be affected. In one study, thunderstorm phobias were most prevalent in herding breeds.
- Dogs may begin exhibiting signs as puppies but may not be presented until adulthood.

SIGNS

Historical Findings

• One or more of the following occurs during storms, or when the pet is exposed to the eliciting noise: panting, pacing, trembling, remaining near owner, hiding, salivating, destructiveness, vocalization, self-inflicted trauma, and inappropriate elimination.

• Stimuli that can elicit fear during storms include rain, lightning, thunder, wind, and possibly static electricity and changes in barometric pressure.

Physical Examination Findings

Unremarkable, except if self-inflicted or escape-related injuries.

CAUSES & RISK FACTORS

May include combinations of the following:

- Lack of exposure to storms or noises early in development.
- Unintentional reinforcement by owner.
- Highly aversive experience, such as exposure to a violent storm.
- Genetic predisposition for emotional reactivity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Conditions causing similar behavioral responses include separation anxiety, barrier frustration, and other phobias.

- Underlying medical conditions including pain, GI, endocrine or dermatologic should be ruled out.

CBC/BIOCHEMISTRY/URINALYSIS

Results should be within normal ranges.

OTHER LABORATORY TESTS

Tests for thyroid or adrenal disease may be indicated.

IMAGING

Radiographs to help identify sources of pain.

DIAGNOSTIC PROCEDURES

Skin biopsies if a primary dermatologic condition is suspected.

TREATMENT

ENVIRONMENT

Avoid crate confinement if risk of injury.

BEHAVIOR MODIFICATION

- Neither punish nor attempt to comfort the animal during noise exposures or storms.
- Desensitization involves exposure to a recorded stimulus at a volume that does not elicit fear. The volume is gradually increased only if the animal remains relaxed.
- Counter-conditioning involves teaching a response (sit, relax) that is incompatible with the fear response. Food rewards are often used to facilitate learning.
- Audio recordings of noises or storms are commercially available.
- Improper use of these exercises can worsen the condition.
- Exercises will be ineffective if the animal does not react to recorded thunderstorm sounds.

MEDICATIONS

DRUG(S) OF CHOICE

- Use of medications is considered extra-label.
- Azapirones, TCAs, and SSRIs require 2–4 weeks for effect and must be given daily during storm season to control anxiety. They can be used in combination with fast-acting medications.

Medications for Acute, Short-Term Control of Anxiety or Adjunctive Use Benzodiazepines

- Alprazolam—dogs, 0.02–0.1 mg/kg PO q4–12h prn
- Clonazepam—dogs, 0.05–0.25 mg/kg q12h prn
- Diazepam—dogs, 0.5–1 mg/kg PO q4–12h prn
- Lorazepam—dogs, 0.02–0.2 mg/kg PO q8–24h prn

Alpha-2 Adrenergic Agonists

- Clonidine—dogs, 0.01–0.05 mg/kg PO q6–24h prn

Serotonin-2 Antagonists, Reuptake Inhibitors

- Trazodone—dogs, 2–10 mg/kg PO q12–24h

Azapirones

- Buspirone—dogs, 0.5–2.0 mg/kg PO q8–12h; cats, 2.5–7.5 mg/cat PO q12h

GABA Agonists

- Gabapentin—dogs, 10–20 mg/kg PO q12h; cats, 5–10 mg/kg PO q12h

Medications Used Daily Year Round or Throughout Thunderstorm Season

Selective Serotonin Reuptake Inhibitors

- Fluoxetine—dogs, 1–2 mg/kg PO q24h; cats, 0.5–1 mg/kg PO q24h
- Paroxetine—dogs, 1 mg/kg PO q24h; cats, 0.5–1 mg/kg PO q24h
- Side effects: inappetence and irritability

Tricyclic Antidepressants

- Clomipramine—dogs, 2 mg/kg PO q12h; cats, 2.5–5 mg/cat PO q24h
- Side effects: sedation, GI and anticholinergic effects, and cardiac conduction disturbances.

Phenothiazine Tranquilizers

- Acepromazine—dog 0.1–1 mg/kg PO q6–8h
- Poor anti-anxiety properties
- Use *only* if further sedation needed to prevent injury.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Use benzodiazepines with caution in cats and aggressive dogs—disinhibition of aggression possible.
- Avoid using TCAs and phenothiazines in breeding males, patients with seizure disorders, cardiac disease, diabetes mellitus, glaucoma, or thyroid disease.
- Decrease dose or avoid use of these medications in geriatric patients and patients with impaired hepatic or renal function.
- TCAs, SSRIs, SARIs, and phenothiazines should never be combined with monoamine oxidase inhibitors.

FOLLOW-UP

PATIENT MONITORING

With medication use, CBC and biochemistry profiles should be monitored periodically.

PREVENTION/AVOIDANCE

- Puppies and kittens should be exposed to a variety of stimuli under benign conditions.
- Ignore mild signs of anxiety during storms to avoid reinforcing these behaviors.

POSSIBLE COMPLICATIONS

Severe injuries and property damage

EXPECTED COURSE AND PROGNOSIS

Prognosis depends on severity, duration, and the ability to prevent injuries. The condition can progress if left untreated.

MISCELLANEOUS

ABBREVIATIONS

- GI = gastrointestinal
- SARI = serotonin-2 antagonist reuptake inhibitor
- SSRI = selective serotonin reuptake inhibitor
- TCA = tricyclic antidepressant

Author Lynne M. Seibert

Consulting Editor Gary M. Landsberg

THYMOMA

BASICS

OVERVIEW

- Originates from thymic epithelium, rarely metastasizes
- Infiltrated with mature lymphocytes
- May be associated with myasthenia gravis
- Classified as invasive or non-invasive

SIGNALMENT

- Rare in dog and cat
- Most common in medium- and large-breed dogs
- Dogs—mean age, 9 years
- Cats—mean age, 10 years

SIGNS

- From physical presence of tumor: coughing, tachypnea, dyspnea.
- Secondary to obstruction of cranial vena cava: swelling of the head, neck, or forelimbs.
- Paraneoplastic syndromes
- Muscle weakness and megaesophagus caused by myasthenia gravis (~ 20%), hypercalcemia ~ 30% (causing PU/PD), polymyositis, skin disease, hypergammaglobulinemia.

CAUSES AND RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lymphoma (main rule out)
- Branchial cyst
- Ectopic thyroid carcinoma
- Chemodectoma
- Various subtypes of sarcoma
- Mesothelioma
- Non-neoplastic granuloma, abscess, or cyst

CBC/BIOCHEMISTRY/URINALYSIS

Lymphocytosis—occasionally

OTHER LABORATORY TESTS

- Antibody titers to acetylcholine receptors to confirm myasthenia gravis.
- Ultrasound-guided fine-needle aspiration and cytology of the mass: characterized by small lymphocytes, occasional mast cells, and possible epithelial population (versus a pure population of lymphoblasts with lymphoma). Thymomas can be cavitated/cystic, whereas lymphoma is homogenous.

- Biopsy may be needed to confirm diagnosis and immunohistochemical stains can be used.

IMAGING

- Thoracic radiography—typically reveals a cranial mediastinal mass with dorsal deviation of the trachea, and may show pleural effusion or megaesophagus.
- CT scan or MRI can be used prior to thoracotomy for surgical planning, though cannot predict ease of resection.

DIAGNOSTIC PROCEDURES

Tensilon test—evaluate for myasthenia gravis in patients with signs of muscle weakness, dysphagia, or regurgitation.

TREATMENT

- Inpatient.
- Surgical excision—treatment of choice, and possible in 70% of cases; thymoma tends to be highly invasive and difficult to resect in dogs and less invasive and easier to remove in cats; use an intercostal approach for small masses and a sternotomy for large masses. Recurrence ~ 17%, median survival time 635 days (compared to 76 days without surgery).
- Dogs with myasthenia gravis and aspiration pneumonia have a poorer prognosis with surgery.
- Radiotherapy—potentially beneficial by reducing the lymphoid component of the mass (> 75% of cases benefit); median survival time 248 days in dogs and 720 days in cats.

MEDICATIONS

DRUG(S)

- Chemotherapy—little information available.
- Prednisone (20 mg/m² PO q48h) and cyclophosphamide (50–100 mg/m² PO q48h)—used in a very limited number of patients, two of which had a partial remission likely associated with lymphodepleting effects.
- Myasthenia gravis—treat with prednisone and anticholinesterase drugs until the tumor can be removed.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Immunosuppressive drugs—do not use to treat myasthenia gravis with aspiration pneumonia.

FOLLOW-UP

- Thoracic radiography—every 3 months; monitor for recurrence.
- Cure—possible if tumor is surgically resectable; greater than 80% alive at 1 year if resectable and no associated megaesophagus; median survival > 1800 days for cats and almost 800 days for dogs. 10–20% recur and may respond favorably to a second surgery.
- Prognosis—poor with nonresectable tumor, though some dogs and cats have prolonged survival despite no therapy, likely a result of the indolent nature of the tumor.
- Patients with high lymphocyte proportion in tumor have a more favorable prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Concurrent non-thymic tumors, polymyositis, and other autoimmune diseases—20–40% of patients.

T

TICK BITE PARALYSIS

BASICS

DEFINITION

Flaccid, lower motor neuron tetraparesis to tetraplegia caused by salivary neurotoxins from certain species of female tick.

PATHOPHYSIOLOGY

- Presynaptic disorder—tick injects salivary neurotoxin that interferes with the depolarization/acetylcholine release from the presynaptic nerve terminal of the neuromuscular junction; this effect is probably associated with an interruption of the calcium flux across axonal membranes.
- Australian *Ixodes holocyclus* tick—neurotoxin (holocyclotoxin) effects are more pronounced at higher temperatures; one adult tick is sufficient to cause neurologic signs, but infestation with *I. holocyclus* larvae or nymphs can also induce signs; holocyclotoxin also interferes with acetylcholine release at the autonomic nerve terminals.
- Signs—5–9 days after initial tick attachment.
- Not all infested animals develop tick paralysis; not all adult female ticks produce the toxin.

SYSTEMS AFFECTED

- Nervous—peripheral nervous system and neuromuscular junction most affected; cranial nerves can become involved, including the vagus and facial nerves with the North American ticks and, in addition, the trigeminal nerves and sympathetic nervous system with the Australian *Ixodes* tick.
- Respiratory—may see paralysis of the intercostal muscles and diaphragm; caudal brainstem respiratory center may be affected (rare with North American ticks; more common with Australian *Ixodes* ticks).

GENETICS

No genetic basis

INCIDENCE/PREVALENCE

- North America—somewhat seasonal (more prevalent in the summer months); in the warmer areas (southern United States) may become a year-round problem.
- Australia—distinctly seasonal, up to 75% of cases occur during southern hemisphere spring season (September–November).
- Overall incidence—low in the United States; higher in Australia.

GEOGRAPHIC DISTRIBUTION

- United States—*Dermacentor variabilis*: wide distribution over the eastern two-thirds of the country, California, and Oregon; *D. andersoni*: from the Cascades to the Rocky Mountains; *Amblyomma americanum*: from Texas and Missouri to the Atlantic Coast; *A. maculatum*: Atlantic and Gulf of Mexico seaboards.

• Australia—*Ixodes holocyclus*: coastal areas of the east; *I. cornuatus*, southern Australia (Tasmania).

- Other—cases with apparent tick paralysis have been described in South Africa (*Rhipicentor nuttalli*), southern Italy (*Rhipicephalus sanguineus*), and Iran (*Ornithodoros laborensis*).

SIGNALMENT

Species

- Australia—dogs and cats
- United States—dogs; cats appear to be resistant

Breed Predilections

None

Mean Age and Range

Any age

Predominant Sex

N/A

SIGNS

Historical Findings

- Patient exposed to ticks (wooded area) approximately 1 week before onset of signs.
- Onset—gradual; starts with weakness in the pelvic limbs, progresses to the thoracic limbs within 12–72 hours.

Neurologic Examination Findings

North American Ticks

- Neurologic signs—rapidly ascending, flaccid generalized lower motor neuron tetraparesis to tetraplegia.
- Patient becomes extremely weak to recumbent in 1–3 days, with hyporeflexia to areflexia and hypotonia to atonia.
- Pain sensation preserved, no hyperesthesia.
- Cranial nerve dysfunction—uncommon; may note facial weakness and reduced jaw tone; sometimes dysphonia and dysphagia early in the course; megaesophagus uncommon.
- Urination and defecation usually normal.
- No cardiovascular effects.
- Respiratory paralysis—uncommon in the United States; may occur if ticks are not removed; death may occur in 1–5 days.

Australian Ticks

- Neurologic signs—much more severe and rapidly progressive; ascending motor weakness can progress to tetraplegia within a few hours.
- Sialosis, depressed gag reflex, dysphonia, megaesophagus, vomiting/regurgitation.
- Sympathetic nervous system—mydriasis and poorly responsive pupils (common in cats); hypertension; tachyarrhythmias; pulmonary edema.
- Urinary bladder dysfunction may be present.
- Caudal medullary respiratory center involvement—progressive reduction in respiratory rate and increased respiratory effort.
- Respiratory muscle paralysis—much more prevalent; dogs and cats progress to dyspnea,

cyanosis, and respiratory paralysis within 1–2 days if not treated.

CAUSES

United States

- *D. variabilis*—common wood tick
- *D. andersoni*—Rocky Mountain wood tick
- *A. americanum*—lone star tick
- *A. maculatum*—Gulf Coast tick

Australia

- *I. holocyclus*—far more potent neurotoxin than that of the North American species.
- *I. cornuatus*—southern paralysis tick, occasionally causes paralysis in southern Australia.

RISK FACTORS

- Environments that harbor ticks.
- Australia—higher risk during spring, and in areas with higher rainfall, containing tree cover and areas of water; higher risk of death if dogs < 6 months old or if a toy-breed dog.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Botulism
- Acute polyneuropathy
- Acute polyradiculoneuritis (coonhound paralysis)
- Distal denervating disease
- Fulminant myasthenia gravis
- Generalized (diffuse) or multifocal myelopathy
- Intoxications (coral snake, black widow spider, lasalocid, blue and green algae)

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

Arterial blood gases—severely affected patients may show hypoventilation and respiratory acidosis (low PaO₂, high PaCO₂, low pH).

IMAGING

Thoracic radiography (*Ixodes* ticks)—megaesophagus, aspiration pneumonia, pulmonary edema

DIAGNOSTIC PROCEDURES

- History of exposure to ticks.
- Thoroughly search for a tick—head, neck, body and limbs, ear canals, mouth, rectum, vagina, prepuce, and in between the digits and footpads; clipping the entire fur may be needed; immediately remove tick.
- In some cases the offending tick may have dropped, a negative finding does not exclude tick paralysis.
- Electrodiagnostics—electromyogram; normal insertional activity without spontaneous myofiber activity; lack of motor unit action potentials; motor nerve stimulation shows a dramatic decrease in

(CONTINUED)

amplitude or a complete absence of compound muscle action potentials; decrease in motor nerve conduction velocities; normal sensory conduction and repetitive nerve stimulation.

PATHOLOGIC FINDINGS

- Pulmonary histopathologic findings in dead/euthanized dogs include diffuse bronchopneumonia, congestion, and alveolar edema.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient—neurologic dysfunction suggesting tick paralysis; hospitalize until either a tick is found and removed or appropriate treatment to kill a hidden tick is performed.
- Remove tick with forceps, applying steady pressure, taking care to remove mouth parts.

NURSING CARE

- Inpatient supportive care—essential until patient begins to show signs of recovery.
- Oxygen cage—hypoventilation ($\text{PaCO}_2 < 45 \text{ mmHg}$) and hypoxia.
- Mechanical ventilation—respiratory failure ($\text{PaCO}_2 > 45 \text{ mmHg}$).
- Intravenous fluid therapy—if patient unable to eat/drink due to dysphagia, vomiting/regurgitation.
- Prevention of aspiration pneumonia—elevated feedings if megaesophagus present.

ACTIVITY

- Keep patient in a quiet environment.
- Ixodes* tick paralysis—keep patient in a cool, air-conditioned area (toxin is temperature-sensitive).

DIET

- Withhold food and water if patient has dysphagia or vomiting/regurgitation.

CLIENT EDUCATION

- Non-*Ixodes* tick—inform client that good nursing care is essential, although the patient's recovery is rapid (within 24–72 hours) after removal of ticks.
- Ixodes* tick—warn client that cranial nerve signs and weakness often continue to worsen for 24–48 hours even after tick removal; inform client that aggressive treatment to neutralize the toxin must be undertaken, and that patient death may ensue even if appropriate therapy is initiated.

MEDICATIONS

DRUG(S) OF CHOICE

- United States—if the tick cannot be found, topically apply a systemic insecticide such as fipronil or, alternatively, dip the patient in an insecticidal bath; often the only treatment needed.
- Australia—in addition to tick removal and use of topical acaricides, treatment often includes the use of commercially available tick antitoxin hyperimmune serum (TAS) to neutralize circulating toxin (0.5–1 mg/kg IV), depending on severity of clinical signs; adverse reactions to TAS administration can be reduced by premedication with atropine; if severe sympathetic signs, use of phenoxybenzamine, an α -adrenergic antagonist (1 mg/kg IV diluted in saline and given slowly over 20 minutes) can be beneficial.

CONTRAINdications

Drugs that interfere with neuromuscular transmission (e.g., tetracycline, aminoglycosides, procaine penicillin).

PRECAUTIONS

Ixodes tick—administer intravenous fluids at a slow rate to avoid further complications of pulmonary edema.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Non-*Ixodes* tick—reassess neurologic status daily after tick removal; should see rapid improvement in muscle strength.
- Ixodes* tick—monitor neurologic status, respiratory and cardiovascular functions intensively even after tick removal, because of the residual effect of neurotoxin.

PREVENTION/AVOIDANCE

- Vigilantly check for ticks up to 5–9 days after exposure.
- Frequent search for ticks in endemic areas during spring/summer months.
- Routine topical application of acaricidal solution/collar, or weekly insecticidal baths.
- Short-term acquired immunity develops after exposure to *Ixodes* neurotoxin.

POSSIBLE COMPLICATIONS

- No long-term complications if the patient survives the acute effects of the toxin.

TICK BITE PARALYSIS

EXPECTED COURSE AND PROGNOSIS

- Non-*Ixodes* tick—prognosis good to excellent if ticks are removed; recovery in 1–3 days.
- Ixodes* tick—prognosis often guarded; recovery prolonged; removal of tick does not always result in improvement; respiratory paralysis main cause of death; death in 1–2 days without treatment; 5% mortality rate reported in affected dogs, fatality rate in affected cats appears lower.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

Although humans can acquire the disease by being bitten by the same ticks (especially in Australia), tick paralysis is not transmitted to humans from affected pets.

T

TICKS AND TICK CONTROL

BASICS

DEFINITION

- Dogs and cats are parasitized by ticks in the families *Ixodidae* and *Argasidae*.
- Arthropod ectoparasites feed only on the blood of their hosts; closely related to scorpions, spiders, and mites.
- Transmit pathogens—protozoa, bacteria, rickettsiae, and viruses.
- May cause toxicosis, hypersensitivity, paralysis, and blood-loss anemia.

PATOPHYSIOLOGY

- Blood-loss anemia—from heavy infestations.
- Damage to the integument—tick mouth parts cut through the host's skin; bites are generally painless; local irritation and infection may occur; tick adaptations exist to suppress the host response and allow ticks to feed for up to 1 week.
- Salivary secretions—neurotoxins may lead to systemic signs (tick paralysis); other pharmacologically active compounds cause impaired hemostasis and immune suppression at the tick-feeding site.
- Pathogens—acquired when ticks feed on infected reservoir hosts (often rodents and small feral mammals); transmitted while feeding on dogs and cats.

TICK BIOLOGY

- Hard ticks—four life stages: egg, larva, nymph, and adult; larvae and nymphs feed to repletion before detaching and molting; as adult female *Ixodid* ticks engorge, they may increase their weight by more than 100-fold; after detachment, females lay thousands of eggs and die; various tick stages may survive over winter, tolerate long starvation, low humidity, as well as water deprivation.
- In some species, organisms disseminate to the ticks' ovaries and transovarial transmission occurs: infected eggs hatch and produce infected larvae; in other species transstadial transmission occurs: immature ticks become infected while feeding on reservoir hosts and maintain infection through the molt from one life stage to the next.
 - Host infection occurs when infections acquired during a previous life stage are transmitted to new hosts when the next stage feeds.
 - Ticks generally acquire hosts by a passive ambush process; when a suitable host brushes against vegetation harboring questing ticks, they transfer to the host.
 - Amblyomma americanum* is unique in that it can be an active hunter and traverse distances of up to 60 feet to attack a suitable host.
 - In a unique symbiotic relationship *Ixodes scapularis* infected with *Anaplasma phagocytophylum* express an antifreeze

glycoprotein gene that enhances survival of the tick in cold weather.

SYSTEMS AFFECTED

- Skin/Exocrine
- Hemic/Lymphatic/Immune
- Musculoskeletal
- Nervous

GEOGRAPHIC DISTRIBUTION

- Strong geographic specificities exist for some tick species and their associated pathogens producing geographic prevalence of associated diseases.
- Ranges of ticks are expanding, therefore the geographic incidence of tick parasitism and infections vectored by them are expanding.
- Emergence of new tick-borne infections and co-infection has been noted and represents a strong trend.
- Expanding incidence of co-infections developing due to co-infected vector ticks or parasitism of hosts by ticks of more than one species.
- Ixodes scapularis* and *I. pacificus*—midwest, northeast, southeast, and south-central United States, and west coast, respectively.
- Rhipicephalus sanguineus*—throughout the continental United States; *R. sanguineus* is unique among hard ticks; it can survive and establish its life cycle inside dwellings and kennels at (low) household humidity (common name “kennel tick”).
- Dermacentor variabilis*—eastern seaboard and west coast.
- Amblyomma americanum*—found throughout the midwest, south-central, southeast, and parts of the northeast United States with strong range expansion.
- Amblyomma maculatum*—gulf coast states with range expansion.

SIGNALMENT

Species

- Dog and cat.
- Cats are efficient at removing ticks, but tick attachment and tick-vector diseases including Lyme disease, anaplasmosis, and cytauxzoonosis have been diagnosed in domestic felines.

SIGNS

- Attached ticks or tick-feeding cavities may be seen on the skin.
- Irritation secondary to bite.
- Petechiation secondary to infectious organisms (*Rickettsia rickettsii* invades vascular endothelium causing necrotizing vasculitis; *Anaplasma platys* causes thrombocytopenia).
- Blood-loss anemia (direct effect); thrombocytopenia, anemia, inclusion bodies in neutrophils, monocytes, RBCs secondary to infectious organisms transmitted.
- Limb/joint abnormalities secondary to infectious organisms (*Borrelia burgdorferi* and other organisms implicated in oligo- and polyarthritis).

- Cardiac—varying degrees of heart block secondary to infectious organisms (*B. burgdorferi*); rare.

- Renal—unique, generally fatal protein-losing nephropathy in dogs infected with *B. burgdorferi* linked to immune complexes associated with antigen and antibody from infection, but not related to vaccine antigen or vaccine-induced antibodies.

- Neurotoxin-induced paralysis, CNS signs develop secondary to infectious organisms (*R. rickettsii*).

- Pyogranulomatous myositis, periosteal reaction, neutrophilia, antigenic stimulation and amyloid deposition in viscera in *Hepatozoon americanum* infection in which the dog serves as the intermediate and reservoir host and the dog ingests the tick (*A. maculatum*) which is the definitive host.
- Weight loss, anemia, lethargy, fever, neutrophilia, hyperglobulinemia and hypoalbuminemia in *Hepatozoon canis* infection in which the dog serves as the intermediate and reservoir host and the dog ingests the tick (*A. americanum*) which is the definitive host.

CAUSES

Ticks—attracted to hosts by warmth, presence of carbon dioxide, physical contact, and host-associated odors.

RISK FACTORS

- Domestic animals—can be in close contact with ticks owing to encroachment of ticks into suburban environments and expansion of suburban environment into surrounding forests, prairies, and coastline areas.
- Travel—risk factor for exposure to ticks outside of a pet's normal environment.
- Risk is expanding as new cycles for maintenance of infectious organisms are emerging (and being discovered); expansion of *B. burgdorferi* in the midatlantic and southeast states may be associated with an emerging enzootic cycle involving *Ixodes affinis* ticks.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

N/A

OTHER LABORATORY TESTS

- Snappy 4Dx—in-office rapid assay for multiple vector-borne infections; detects antibodies (C₆ ELISA) induced by tick-borne infection with *B. burgdorferi*, *E. canis*, *E. ewingii*, *A. phagocytophylum* (formerly *E. equi*) and *A. platys*, as well as the insect-borne *Dirofilaria immitis*.
- Tests are sensitive and specific; *B. burgdorferi* test does not cross-react with vaccine-induced antibodies.

(CONTINUED)

- Abaxis VetScan Canine *Borrelia Burgdorferi* Antibody Test Kit—in-office visual and rapid test for qualitative detection of antibodies to *Borrelia burgdorferi* in canine whole blood, serum or plasma; uses peptides that bind antibodies elicited in response to certain *Borrelia* antigens in an amplified lateral flow sandwich assay; test is highly sensitive and specific, does not cross-react with vaccine-induced antibodies, and is very inexpensive.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient after removal of ticks.
- Removal—as soon as possible to limit time available for pathogen or neurotoxin transmission; grasp ticks close to the skin with fine-pointed tweezers and gently pull free.

NURSING CARE

Wash feeding cavity with soap and water; generally sufficient to prevent local inflammation or secondary infection.

CLIENT EDUCATION

Application of hot matches, petrolatum jelly, or other materials not only fails to cause tick detachment but allows for longer periods of attachment and feeding.

MEDICATIONS

DRUG(S) OF CHOICE

See “Prevention/Avoidance”

FOLLOW-UP

PREVENTION/AVOIDANCE

- Difficult to avoid environments that harbor ticks.
- Tick control does not always equal control of tick-borne diseases; often the goal is the perceived absence of ticks on the host animal (clinical repellence).
- Pets—there may be some period of attachment and tick feeding or live ticks may spend some time crawling on the animal after the ticks have been exposed to lethal levels of an acaricide; immature ticks of some species are very small.
- Tick-borne pathogens—may be transmitted very rapidly (viruses) or require several hours (*R. rickettsii*), less than 1 day (*A. phagocytophilum*), 1–2 days (*B. burgdorferi*), or 2–3 days (*Ehrlichia* species and *B. canis*).
- Ingestion of infected ticks makes tick control problematic for prevention of infection with *Hepatozoon* species.

Insecticides and Acaricides

- In the United States, the EPA licenses pesticides as safe and effective.
- Tick control required year-round in many areas.
- Acaricides meant only for dogs must not be applied to cats.
- Acaricidal collars—Preventic, Seresto, and Scalibor collars; contain rapid tick killers with clinical repellence: amitraz, deltamethrin, and flumethrin, respectively.
- Spot-on treatments (Frontline Top Spot, K9 Advantix, Ovitrol X-Tend spot-on, Activyl, and Vectra 3D)—gained wide use due to safety, ease of application, and owner compliance.
- Disease transmission interruption studies have been published for products containing fipronil, amitraz, and permethrin; rapid killing and clinical repellence are essential to prevent or interrupt tick feeding.
- At 4 weeks after application, efficacy in prevention of transmission of *B. burgdorferi* to dogs was 75–87.5% for fipronil (Frontline Top Spot) and 100% for permethrin (K9 Advantix and Vectra 3D); amitraz (Preventic Collar) was 100% effective at 7 days post-application.

POSSIBLE COMPLICATIONS

Tick-borne diseases or tick paralysis

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Canine babesiosis—vectored by *R. sanguineus*; *B. canis* infects canine RBCs, leading to sludging in capillaries and destruction in the spleen.
- Rocky Mountain spotted fever—vectored by *D. variabilis* and *R. sanguineus*.
- Canine monocytic ehrlichiosis—*E. canis* vectored by *R. sanguineus*; infects mononuclear cells and platelets; *E. chaffeensis* vectored by *A. americanum* infects mononuclear cells.
- Cyclic thrombocytopenia—caused by *A. platys*, the only intracellular pathogen of platelets.
- Granulocytic anaplasmosis—caused by *A. phagocytophilum* vectored by *I. scapularis* and *I. pacificus*; infects granulocytes; *E. ewingii* vectored by *A. americanum* also infects granulocytes and causes granulocytic ehrlichiosis.
- Lyme disease—vectored by *I. scapularis* and *I. pacificus*; caused by *B. burgdorferi*; associated with arthritis or syndromes leading to complete heart block, protein-losing nephropathy, and possibly neurologic abnormalities.
- American canine hepatosplenitis—caused by protozoal organism *H. americanum* after the dog ingests an infected *A. maculatum*.

- Canine hepatosplenitis—caused by protozoal organism *H. canis* after the dog ingests an infected *R. sanguineus*.
- Tick paralysis—caused by a neurotoxin; affects acetylcholine synthesis and/or liberation at the neuromuscular junction of the host animal; ascending flaccid paralysis initially affects the pelvic limbs 5–9 days after tick attachment.

VACCINES

- Currently for Lyme disease; two types for dogs: whole-cell, killed bacterin: LymeVax, Duramune Lyme, and Nobivac Lyme, and outer surface protein A (OspA): Recombitek Lyme.
- Safety and efficacy—both types have been demonstrated to be safe. Laboratory studies demonstrate high efficacy but fail to duplicate natural exposure; in an early study (1993) natural exposure study of whole-cell bacterin, incidence of disease was 1% in 1,969 immunized dogs and 4.7% in 4,498 unimmunized control dogs; in later studies (2002 and 2005) natural exposure studies the incidence of infection in dogs immunized with whole-cell bacterin and OspA subunit vaccine was determined to be 5% and 25%, respectively; bacterin had a preventable fraction of 92.2% and subunit OspA vaccine had a preventable fraction of 60.3%.
- Asymptomatic Lyme-positive dogs treated with doxycycline or amoxicillin concurrent with whole-cell bacterin immunization (author's Test, Treat and Vaccinate Protocol) and followed clinically for up to 4 years, no episodes of any forms of Lyme disease were observed (see “Further Reading for an extended list of references on vaccination studies”).

ZOONOTIC POTENTIAL

- Ticks may parasitize wildlife, domestic animals, or humans at different stages in their developmental cycles; infections acquired in early life stages may be transmitted when ticks feed again in the next stage.
- Humans, if parasitized, may be exposed to organisms in infected ticks. *B. burgdorferi*, *A. phagocytophilum*, *R. rickettsia*, and *E. chaffeensis* are also human pathogens.

TOAD VENOM TOXICOSIS

BASICS

OVERVIEW

- Two species of primary concern—Colorado River toad (*Rhinella alvarius*) and marine or cane toad (*R. marina*); marine toad more toxic; both can be fatal.
- Toads—most active during periods of high humidity (the monsoon season of late summer in the desert Southwest for Colorado River toads); most encounters occur during the evening, night, or early morning.
- Toxin—produced from the parotid glands; defensive; rapidly absorbed across the victim's mucous membranes; contains several major components: indole alkyl amines (similar to the street drug LSD), cardiac glycosides, and noncardiac sterols.

SIGNALMENT

Primarily dogs; rarely, ferrets and cats

SIGNS

General Comments

Rapid onset

Historical Findings

- Crying and pawing at the mouth
- Frothing at mouth
- Ataxia or stiff gaited
- Seizures
- Animal found dead with toad in mouth

Physical Examination Findings

- Profuse hypersalivation
- Hyperexcitability with vocalization
- Brick red buccal mucous membranes
- Hyperthermia
- Collapse
- Marked cardiac ventricular arrhythmia—less common with Colorado River toad intoxication
- Cyanosis
- Dyspnea

CAUSES & RISK FACTORS

- Living in indigenous geographic region for toxic species and in close proximity to toads
- Moist, warm, outside environment
- Outdoor animal

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Caustics or other oral irritants

CBC/BIOCHEMISTRY/URINALYSIS

May note hyperkalemia

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Electrocardiogram—may reveal ventricular arrhythmias

TREATMENT

- Marine toad intoxication—medical emergency; death common.
- Decontamination—flush mouth with copious quantities of water for 5–10 minutes.
- Hyperthermia ($> 40.6^{\circ}\text{C}$; 105°F)—provide a cool bath; remove patient from bath once temperature reaches 39.4°C (103°F).
- Maintain airway.
- Rapid evaluation of cardiac function.

MEDICATIONS

DRUG(S)

- Atropine—0.04 mg/kg IM, SC; reduces the amount of salivation; helps prevent aspiration; use with bradycardia, heart block, or other sinoatrial node alterations as a result of the digitalis-like effect of the toxin; not recommended if severe tachycardia present.
- Esmolol or propranolol—esmolol is very short acting and may be used as a test dose. If arrhythmia responds to treatment, propranolol is used because the duration of action is much longer (hours; see “Contraindications/Possible Interactions”); rapid administration may be required to combat tachyarrhythmias; may be repeated in 20 minutes; may need continuous intravenous infusion for persistent arrhythmias.
 - Esmolol 0.05–0.1 mg/kg IV every 5 minutes for a maximum dosage of 0.5 mg/kg.
 - Propranolol 0.02 mg/kg IV slowly as needed up to a maximum dosage of 1 mg/kg.
- Anesthesia with pentobarbital (dogs)—increases tolerance to intoxication.

- Digoxin-specific Fab fragments (Digoxin Immune Fab) have been used successfully to treat toad venom induced cardiotoxic effects.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Cardiac disease or bronchial asthma—patient may not tolerate the use of beta-blockers such as esmolol and propranolol. Use a test dose of esmolol (very short duration of action) and monitor closely before using propranolol (much longer duration of action).
- Anesthetics (e.g., pentobarbital)—may depress function of an already compromised myocardium; use with caution.

FOLLOW-UP

- Continuous electrocardiographic monitoring—recommended until the patient is fully recovered.
- Colorado River toad intoxication—patients usually normal within 30 minutes of onset of treatment; death relatively uncommon if treated; do not underestimate the risk of secondary heatstroke.
- Marine toad intoxication—medical emergency; death common.

T

TOOTH FORMATION/STRUCTURE, ABNORMAL

BASICS

DEFINITION

Variation in Tooth Size

- Macrodontia—crown oversized, root normal
- Microdontia—crown normal shape, but small
- Peg tooth—small, cone-shaped tooth with a single cusp

Variation in Tooth Structure/Shape

- Fusion—two separate tooth buds joined to form an entire single tooth or joined at the roots by cementum and dentin.
- Gemination—developing tooth bud undergoes an incomplete split, resulting in two crowns with a common root canal.
- Dilacerated—distorted or malformed tooth (crown or root)—a general term that may be used for many different presentations.
- Dens-in-dente (tooth within a tooth)—external layers invaginate into internal structures with varying severity.
- Shell teeth—crown present, but little to no root development.
- Amelogenesis imperfecta—hereditary reduction in the amount of developed enamel matrix.

PATHOPHYSIOLOGY

- Stress or stimulus (trauma) at time of development can alter tooth formation.
- Infection, trauma to tooth buds, or traumatic extraction of deciduous teeth during permanent tooth formation can significantly alter the structure.
- Genetic or familial tendencies not known for most conditions.
- Dog/cat.

SIGNALMENT

Clinical Features

- See “Definition.”
- Fusion—fused crown will be larger than a single tooth. There will be a reduced number of teeth (two counted as one).
- Gemination tooth—actual number of teeth will be unaltered, but one tooth will be larger, with duplication of part of the crown (and possibly roots radiographically). “Siamese twin.”
- Dilacerated teeth.
 - Any variation in structure or form—extra root, curved root.

- Each tooth must be evaluated for integrity of the pulp system, as any disruption in the continuity of the crown and roots may result in exposure of the pulp to the external environment.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Trauma to tooth structures
- Developmental abnormalities

DIAGNOSTICS

- Complete oral examination.
- Intraoral radiographs.
- With any abnormal structure (dilaceration), pulpal integrity and the potential for crowding must be evaluated.
- Appropriate preoperative diagnostics when indicated prior to procedure.

TREATMENT

- Abnormal development of mandibular first molars in small-breed dogs.
- Dilaceration is more common, sometimes described as dens-in-dente.
- As one of the first permanent teeth to form, there may be a mechanical challenge (lack of space) in small dogs that impedes proper crown-root development.
- Invagination of the enamel and/or cementum at the neck of the tooth, often with some degree of gingival recession.

RADIOGRAPHIC SIGNS

- Discontinuity between crowns and roots
- Possible pulp exposure and pulp stones
- Roots are convergent with wide canals (non-vital pulp)
- Periapical/root abscession with extensive bone loss

MEDICATIONS

DRUGS

Procedures

- Appropriate antimicrobial and pain management therapy when indicated.

- Appropriate patient monitoring and support during anesthetic procedures.
- Fusion teeth—no treatment is necessary unless the groove between the two teeth and/or crowns extends to the gingival margin or below (nidus for periodontal disease).
- Gemination tooth—if tooth crowding results, extraction may be necessary.
- Dilacerated tooth—if there is pulpal exposure or compromise, extraction is generally necessary.
 - In some cases, endodontic and restorative therapy may allow preservation of the tooth.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Good prognosis on teeth with moderate changes (peg teeth, fusion teeth, gemination tooth).
- Guarded prognosis on dilacerated teeth with pulpal compromise, though extraction typically successful.

Author Heidi B. Lobprise

Consulting Editor Heidi B. Lobprise

BASICS

DEFINITION

- Traumatic tooth injuries may involve fracture of enamel, dentin, and cement or damage to the periodontium.
- May involve the crown and root of the affected tooth.
- Classified as uncomplicated if they do not involve pulpal exposure and complicated if the pulp is exposed by the fracture line.

PATHOPHYSIOLOGY

- Untreated pulpal exposure invariably leads to pulpitis and eventually pulpal necrosis and periapical pathology.
- Pulpitis and pulpal necrosis may also occur with uncomplicated fractures, particularly if the fracture line is close to the pulp chamber, which exposes a large number of wide-diameter dentinal tubules and allows communication between the pulp and the external environment.

SYSTEMS AFFECTED

- Gastrointestinal—oral cavity.
- Infection in the oral cavity may cause systemic complications.

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dogs and cats

Breed Predilections

None

Mean Age and Range

Any age

Predominant Sex

None

SIGNS

Crown Fractures

- Clinical loss of tooth crown substance; may affect enamel only, or enamel and dentin; fracture line may be transverse or oblique.
- Uncomplicated fractures with the fracture line close to the pulp chamber—pale pink pulp is visible through the dentin; gentle exploring will not allow the explorer into the pulp cavity.
- In complicated crown fractures, the pulp chamber is open and readily accessed with an explorer.
- The fresh complicated fracture is associated with hemorrhage from the pulp.
- Older fractures may exhibit a necrotic pulp; clinically the pulp chamber is filled with dark necrotic material, and the tooth is often discolored.

Root Fractures

- May occur at any point along the root surface; often in combination with fracture of the crown, but may occur in isolation.
- Fracture line may be transverse or oblique; segments may remain aligned or be displaced.
- Clinical signs indicating a possible root fracture include pain on closure of the mouth or during open-mouth breathing.
- Abnormal horizontal or vertical mobility of a periodontally sound tooth may raise suspicion of a root fracture.

CAUSES

Generally the result of a traumatic incident (e.g., road traffic accident, blunt blow to the face, chewing on hard objects).

RISK FACTORS

Free-roaming behavior increases risk of trauma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Crown fracture—attrition, abnormal tooth formation.
- Root fracture—luxation; definitive diagnosis of root fractures is by radiography.

CBC/BIOCHEMISTRY/URINALYSIS

Unaffected by tooth fracture.

OTHER LABORATORY TESTS

None

IMAGING

- Radiographs are mandatory.
- Intraoral radiographic technique and dental intraoral film are required.
- Radiographs reveal the full extent of the lesion and allow treatment planning.
- Radiographs are required for adequate performance of endodontic procedures and monitoring treatment outcome.

DIAGNOSTIC PROCEDURES

Transillumination to help determine tooth vitality: shine a bright light through the tooth (otoscope light); a vital tooth should transilluminate well.

PATHOLOGIC FINDINGS

Untreated pulpal exposure invariably leads to pulpitis and eventual pulpal necrosis and periapical pathology.

TREATMENT

APPROPRIATE HEALTH CARE

Depends on extent and severity of trauma to the patient.

NURSING CARE

Depends on extent and severity of trauma to the patient.

ACTIVITY

Restrict as indicated by nature of trauma.

DIET

In the immediate postoperative period (24–72 hours), moistening the patient's dry food may help decrease the chance of traumatizing the suture line. Continue to monitor the site.

CLIENT EDUCATION

A series of treatments may be necessary.

SURGICAL CONSIDERATIONS

Uncomplicated Crown Fractures

Remove sharp edges with a bur and seal the exposed dentin tubules with a suitable liner or restorative material.

Complicated Crown Fractures

All require endodontic therapy if the tooth is to be maintained; extraction is preferable to no treatment at all.

Mature Tooth

- Recent fracture in the mature tooth with the pulp still vital—two options exist, partial pulpectomy and direct pulp capping (vital pulpotomy) followed by restoration or conventional root canal therapy and restoration.
- For partial pulpectomy and direct pulp capping to succeed, the procedure should be carried out within hours of the injury.
- Tell the client at the beginning that the procedure may not be the final treatment—the tooth may require standard root canal treatment later if the pulp becomes necrotic.
- When the pulp is already chronically inflamed or necrotic, standard root canal therapy and restoration are the treatments of choice if the tooth is periodontally sound.

Immature Tooth

- A vital pulp is required for continued root development; as long as the pulp is vital the treatment of choice is partial pulpectomy and direct pulp capping, followed by restoration.
- If the pulp is necrotic, no further root development will occur; necrotic immature teeth need endodontic treatment to be maintained; remove the necrotic tissue and pack the root canal with calcium hydroxide paste; some apexogenesis (physiologic event, continued root development) and apification (closure of the apex, induced by treatment) can be stimulated if this procedure is performed; change the calcium hydroxide every 6 months until the apex is closed when a standard root canal is performed.
- Immature teeth may be present in the mature animal if trauma to the developing teeth caused pulp necrosis; treat such teeth as you would any immature teeth.

Root Fractures

- Treatment of crown and root fractures depends on how far below the gingival margin the fracture line extends.

TOOTH FRACTURE

(CONTINUED)

- If the fracture line does not involve the pulp and does not extend more than 4–5 mm below the gingival margin, restorative dentistry can be performed; if the fracture extends more than 5 mm below the gingival margin and involves the pulp, the tooth should usually be extracted.
- The fracture level determines the choice of treatment for horizontal root fractures; a fracture in the apical region carries a better prognosis than one close to the gingival margin.
- A horizontal fracture of the coronal part of the root usually mandates tooth extraction; the main exception is the lower canine, since jaw stability and strength depend on the canine roots. If the root is periodontally sound it must receive endodontic treatment after removal of the coronal portion.
- Horizontal midroot and apical fractures will heal if the tooth is immobilized; horizontal root fractures can heal by means of a dentino cemental callus, a fibrous union, or an osteofibrous union.
- If the pulp of the coronal fragment becomes necrotic the fracture will not heal; endodontic treatment of the coronal segment is indicated; the apical segment may be left in situ if there is no radiographic evidence of periapical pathology; if radiographic evidence of periapical pathology exists, remove the apical segment.

MEDICATIONS

DRUG(S) OF CHOICE

- A broad-spectrum bacteriocidal antibiotic drug for 5–7 days may be indicated, e.g., when long-standing infection is present.
- Appropriate analgesic regime – usually nonsteroidal anti-inflammatory drug for 3–5 days.

CONTRAINDICATIONS

None

PRECAUTIONS

None

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

None

FOLLOW-UP

PATIENT MONITORING

- Check a partial pulpectomy and direct pulp-capping procedure with postoperative radiographs after 6 and 12 months, or at intervals determined by clinical signs, to detect pulp death and consequent periapical changes indicating the need for root canal treatment.
- Check the outcome of conventional root canal therapy radiographically 6–12 months postoperatively; evidence of periapical pathology at this time indicates the need for further endodontic therapy or extraction of the tooth; further endodontic therapy consists of redoing the root canal therapy, often in conjunction with surgical endodontics.
- Check root fractures radiographically 6–12 months postoperatively.
- Check uncomplicated fractures postoperatively with radiographs at 4–6 months to assess periapical status.

PREVENTION/AVOIDANCE

- Avoid situations in which teeth are likely to be damaged; keep animal from chewing on hard objects such as rocks.
- To avoid complications, institute treatment within hours of injury.

POSSIBLE COMPLICATIONS

- Untreated pulpal exposure invariably leads to pulpitis and eventual pulpal necrosis and periapical pathology.
- Arrested development of immature teeth.

EXPECTED COURSE AND PROGNOSIS

Varies with vitality of the pulp, location of the fracture, and whether the tooth is mature or immature; see "Treatment" section for detailed discussion.

MISCELLANEOUS

ASSOCIATED CONDITIONS

None

AGE-RELATED FACTORS

Treatment of mature and immature teeth differs; see "Treatment."

ZOONOTIC POTENTIAL

TOOTH LUXATION OR AVULSION

BASICS

OVERVIEW

- Luxation of a tooth can be either vertical (i.e., an intrusion or extrusion) or lateral.
- An intrusion occurs when the tooth is pushed apically into the alveolar bone. • An extrusion occurs when the tooth is dislocated vertically partially out of the alveolus.
- Lateral luxation—the affected tooth is tipped in either a labial or a palatal/lingual direction; can occur when trauma pushes the crown in one direction and the root in the opposite direction; always associated with a fracture of the lingual or labial alveolar bone plate that allows the tooth to luxate rather than fracture. • An avulsed tooth has been totally luxated from its alveolus.

SIGNALMENT

Dogs and cats

SIGNS

- Intrusion—tooth appears shorter than normal; no tooth mobility detected.
- Extrusion—tooth appears longer than normal and is mobile both vertically and horizontally. • Lateral luxation—tooth crown is displaced in either a labial or palatal/lingual direction. • Avulsion—intact tooth is totally displaced from its alveolus.

CAUSES & RISK FACTORS

- Luxation/avulsion—usually results from a traumatic incident (e.g., road traffic accident or dog fight). • The trauma causes injury to the periodontium, thus allowing abnormal tooth mobility and malpositioning. • The upper canine tooth is the most commonly luxated/avulsed tooth. • Advanced periodontitis will predispose.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Luxation—root fracture where the coronal segment is displaced • Avulsion—tooth lost due to severe periodontitis

CBC/BIOCHEMISTRY/URINALYSIS

Non-contributory

OTHER LABORATORY TESTS

N/A

IMAGING

General

- Radiographs are mandatory. • Intraoral radiographic technique and dental X-ray film are required.

Radiographic Findings

- Intrusion—narrowing of the periodontal ligament space in the apical region.
- Extrusion—widening of the periodontal ligament, especially in the apical section.
- Lateral luxation—widening and narrowing of the periodontal ligament space and fracture of the alveolar bone plate. • Avulsion—empty but intact alveolus.

TREATMENT

- Replace and fix the tooth in its normal position; bond with acrylic splints and fine ligature wire—an effective method of achieving stabilization and occlusal alignment. • Handle the avulsed tooth only by its crown and rinse gently with sterile saline solution; if severely contaminated, the tooth root can be gently cleaned with sterile gauze swabs moistened with saline. • Be gentle; tooth handling should be kept to a minimum; it is essential not to remove the periodontal ligament from the root; a viable periodontal ligament is necessary for healing.
- Replace the tooth in its bony socket; there is usually no need to remove the blood clot from the alveolus; the tooth is just firmly placed in its bony socket and fixed in that position.
- Contraindications for repositioning a luxated or avulsed tooth are deciduous teeth, severe periodontitis, caries, or resorptive lesion. • The two most important factors determining the result of treatment are the length of time the avulsed tooth has been out of its bony socket and the medium in which the tooth has been stored during this period.
- The sooner an avulsed tooth is reimplanted, the better the prognosis; optimal results are achieved if the tooth is reimplanted within 30 minutes of avulsion; do not let the avulsed tooth dry prior to reimplantation; the best medium for storing an avulsed tooth is saline; if not available, use milk. • Advise clients to place the tooth in either saline or milk and bring the affected animal in for treatment as quickly as possible.
- The appliance for fixation is usually left in place for 4–6 weeks; maintain oral hygiene during this period; a water pick or curved-tip syringe is used to flush debris from between the splint, teeth, and soft tissue; rinsing the oral cavity with chlorhexidine solution is also useful. • The appliances are removed with pliers or high-speed drill; at this stage the tooth should be stable or very slightly mobile; take radiographs; if the tooth is still loose, reimplantation has failed and it should be extracted.

MEDICATIONS

DRUG(S)

- Use of a broad-spectrum bacteriocidal antibiotic is recommended; if oral hygiene is maintained, only a short course is necessary.
- If no oral hygiene measures are possible, antibiotics may be indicated throughout the period of fixation. • Daily rinsing with 0.12% chlorhexidine gluconate solution will diminish the need for prolonged administration of antibiotics. • Appropriate analgesic regime—usually nonsteroidal anti-inflammatory drug for 3–5 days.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None

FOLLOW-UP

- An avulsed tooth invariably develops pulpal necrosis; the tooth must receive endodontic therapy to prevent development of periapical pathology. • Best to perform endodontic therapy when the appliance is removed.
- External root resorption and ankylosis commonly follow reimplantation. • Luxated teeth often suffer pulp necrosis; check at regular intervals. • Signs of pulp pathology (e.g., tooth discoloration or radiographic evidence of periapical pathology) are indications for endodontic treatment.

TOOTH—MISSING

BASICS

OVERVIEW

- Absence of tooth or teeth due to developmental conditions, not to trauma or extraction.
 - Total anodontia—absence of all teeth due to failure in development.
 - Partial anodontia—failure in development of part of the dentition (hypodontia, oligodontia—some teeth missing).
 - Edentulous—“without teeth”—but primarily due to tooth loss (e.g., end-stage periodontal disease).
- In dogs, premolars or distal molars are the most common missing teeth.
- If a deciduous tooth is missing, its permanent successor will probably not develop as well.
- If a permanent tooth is missing, and a deciduous tooth was not exfoliated and is still present, if root structure is still stable, that deciduous tooth might stay functional for a long time; lack of permanent tooth should be documented.

SIGNALMENT

- Any breed, size or gender, but smaller breeds predominate
- Some familial tendencies, breed prevalences

SIGNS

- Tooth not present (crown and root)
- Alveolar bone and gingival margin at site is regular, smooth, even slightly “scalloped” appearance
- No tooth structure present radiographically

CAUSES AND RISK FACTORS

- Dog/cat
- Total and partial anodontia—typically hereditary and may be associated with ectodermal dysplasia (rare).
- Bilateral patterns of missing teeth may be indicative of a genetic or familial tendency, as apposed to a single missing tooth.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Delayed eruption
- Unerupted teeth (see Dentigerous Cyst)
- Invulsed tooth
- Extracted or lost due to periodontal disease or trauma
- Fusion tooth—if two teeth have fused, there will be reduction in the tooth number (see Tooth Formation/Structure—Abnormal)

CBC/BIOCHEMISTRY/URINALYSIS

Typically not affected

OTHER LABORATORY TESTS

N/A

IMAGING

- Intraoral radiographs essential.
- Determine if teeth are truly missing, and/or if permanent teeth are present, if deciduous teeth are persistent/retained.
- Pre-purchase full mouth radiographs on 8–10-week-old puppies can identify if permanent tooth structures are present (though there is no guarantee they will erupt).

DIAGNOSTIC PROCEDURES

- Complete oral examination
- Appropriate preoperative diagnostics when indicated prior to procedure

TREATMENT

SURGICAL CONSIDERATIONS

- Appropriate antimicrobial and pain management therapy when indicated.
- Appropriate patient monitoring and support during anesthetic procedures.
- None indicated unless an unerupted or involved tooth is found radiographically.

MEDICATIONS

DRUGS

None indicated

FOLLOW-UP

None needed

EXPECTED COURSE AND PROGNOSIS

MISCELLANEOUS

- If multiple teeth are missing or they are missing bilaterally, there could be a familial tendency; consider removing from breeding stock.
- In some breeds (Doberman pinscher, rottweiler) or Schutzhund trained dogs, any missing teeth may be considered a serious fault, and pre-purchase radiographs on puppies may be helpful.

SEE ALSO

- Tooth Formation/Structure, Abnormal
- Dentigerous Cyst

TOOTH RESORPTION—CAT

BASICS

DEFINITION

Dental resorption of unknown etiology

PATHOPHYSIOLOGY

- The cause of feline tooth resorption is unknown; odontoclasts, found in the defects, cause resorption of dental hard tissue.
- Odontoclasts attach to the lacunar surface of intact dental tissue; resorption progresses and reparative bone-like or cementum-like tissue covers the excavated dentin; inflamed granulation tissue often occupies defects in the crown of the tooth.
- Most resorption occurs in the root; both external and internal resorption may take place over time, remodeling replaces dentinal tissue with bone-like or cementum-like tissues, radiographically appearing as ankylosis.

SYSTEMS AFFECTED

Gastrointestinal—oral cavity

INCIDENCE/PREVALENCE

- Nearly 50% of cats older than 5 years old will have at least one tooth affected by resorption.
- Prevalence increases with age.

SIGNALMENT

Species

Cats

Breed Predilections

Possibly Asian shorthaired, Siamese, Persian, and Abyssinian cats

SIGNS

Historical Findings

- Most affected cats do not show clinical signs; some show hypersalivation, or difficulty chewing; some cats pick up and drop food (especially hard food) when eating; others hiss while chewing.
- Some cats have behavior changes—reclusive or aggressive.

Physical Examination Findings

- A cotton-tipped applicator applied to the suspected tooth resorption (Stages 2–4) usually causes pain evidenced by jaw spasms.
- Tooth resorption can occur above or below the gingival margin; most are first noticed at the labial or buccal surface near the cementoenamel junction where the free gingiva meets the tooth surface, though root lesions usually precede these; calculus and hyperplastic gingival may obscure the lesion.
- Tooth resorption can be found on any tooth; the most common teeth affected are the mandibular third premolar and molar, followed by the maxillary third and fourth premolars.
- Under general anesthesia, the lesions are examined with a fine dental explorer which helps identify subgingival lesions at the cementoenamel junction; the furcation area is a frequent site, and the examiner must distinguish tooth resorption from disease limited to alveolar bone loss.

Classification of Tooth Resorption

- Stage 1 (TR 1): Mild dental hard tissue loss (cementum or cementum and enamel).
- Stage 2 (TR 2): Moderate dental hard tissue loss (cementum or cementum and enamel with loss of dentin that does not extend to the pulp cavity).
- Stage 3 (TR 3): Deep dental hard tissue loss (cementum or cementum and enamel with loss of dentin that extends to the pulp cavity); most of the tooth retains its integrity.
- Stage 4 (TR 4): Extensive dental hard tissue loss (cementum or cementum and enamel with loss of dentin that extends to the pulp cavity); most of the tooth has lost its integrity.
- (TR4a) crown and root are equally affected; (TR4b) crown is more severely affected than the root; (TR4c) root is more severely affected than the crown.
- Stage 5 (TR 5): Remnants of dental hard tissue are visible only as irregular radiopacities and gingival covering is complete.
- This classification is based on the assumption that tooth resorption is a progressive condition.
- See “Imaging” for additional classification scheme (Type 1–3).

CAUSES

- The etiology is unknown; likely multifactorial.
- Nutritional, inflammatory, and hereditary causes suspected.
- Hyperreactivity to inflammatory cells, dental plaque, and/or calculus; endotoxins; prostaglandins, cytokines, and proteinases are under investigation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Oropharyngeal inflammation including caudal stomatitis

IMAGING

- Intraoral radiology is essential in making definitive diagnosis and planning treatment.
- Radiographic appearance varies from minute radiolucent defects of the tooth primarily at the cementoenamel junction to ankylosis with alveolar bone and root replacement resorption.
- Tooth resorption is also classified as Type 1–3 based on the radiographic appearance of the tooth and the periodontal ligament space.
- Type 1—a focal or multifocal radiolucency is present in the tooth with otherwise normal radiopacity and normal-appearing periodontal ligament space.
- Type 2—narrowing or disappearance of the periodontal ligament space in at least some areas and decreased radiopacity of part of the tooth.
- Type 3—features of both Type 1 and Type 2 are present in the same tooth. A tooth with this appearance has areas of normal and narrow or lost periodontal ligament space, and there is focal or multifocal radiolucency in the tooth and decreased radiopacity in other areas of the tooth.

TREATMENT

DIET

Add water to diet to soften.

CLIENT EDUCATION

Daily brushing and use of a cotton-tipped applicator applied to the gingival margin may help control plaque.

SURGICAL CONSIDERATIONS

- Stage 1 lesions—a shallow defect is noted; the lesion is minimally sensitive because it has not entered dentin; therapy includes thorough cleaning and polishing; gingivectomy and odontoplasty are adjunctive.
- Stage 2 lesions—penetrate the dentin; often require either extraction via flap exposure or crown reduction and gingival closure (see below).
- Stage 3 lesions—enters the endodontic system; require either extraction via flap exposure or crown reduction (see below).
- Stage 4 lesions—the crown is eroded or fractured with part of it remaining; gingiva grows over the root fragments, yielding a sensitive bleeding lesion upon probing; additional extraction may be needed (below).
- Stage 5 lesions—the crown is gone and scant root fragments remain; debride any inflamed areas. If the periodontal ligament is apparent (Types 1 and 3), the tooth should be surgically extracted via flap exposure.
- If the periodontal ligament is not apparent due to root replacement (Type 2), the crown can be reduced below the gingiva with a high-speed water-cooled drill followed by gingival closure over the root.

MEDICATIONS

None

MISCELLANEOUS

SYNOMYMS

- Cervical line erosion
- Chronic subgingival tooth erosion
- External odontoclastic resorptive lesions
- Feline odontoclastic resorption lesions
- FORL
- Idiopathic buccocervical erosion
- Neck lesions
- Subgingival resorative lesions

ABBREVIATIONS

TR = tooth resorption

Authors Jan Bellows

TOOTH ROOT ABSCESS (APICAL ABSCESS)

BASICS

OVERVIEW

- An abscess is a localized collection of pus in a cavity formed by the disintegration of tissues.
- Acute and chronic phases on the basis of severity of pain and presence or absence of systemic signs and symptoms.
- Accumulation of inflammatory cells at the apex of a non-vital tooth—periapical abscess.
- Phoenix abscess:** acute exacerbation of a chronic periapical abscess.
- An abscess spreads along the pathway of least resistance from the tooth apex, resulting in osteomyelitis and, if perforated through the cortex, a cellulitis that can burst through the skin to create a cutaneous sinus.
- Systemic spread of bacteria (bacteremia and pyemia) can affect other organ systems.
- Periodontal disease can extend to the apical region of the tooth, resulting in endodontic involvement (perio-endo lesion).
- Can involve any teeth; canines and carnassial teeth are most commonly affected.
- Can arise without the presence of bacteria (sterile abscess).

SIGNALMENT

- Dogs and cats.
- Any age can occur in deciduous and permanent dentition.
- Usually occurs in active animals that bite or chew a lot.

SIGNS

- Tooth is visibly broken with or having near pulpal exposure—90% of cases.
- Tooth may appear discolored.
- Tooth is not sensitive to percussion or cold or hot liquids or foods—note: acute tooth fracture with pulp exposure would be sensitive.
- Facial swelling: usually localized but can spread, resulting in a cellulitis.
- Cutaneous sinus exuding pus—suppurative apical periodontitis.
- Facial sensitivity may be slight but could be extensive if there is no draining.
- Animal does not want to chew, especially on the affected side (plaque and calculus may accumulate), or will bite, but release quickly instead of holding on.
- Tooth may be asymptomatic for a long time but will be affected eventually.
- Tooth may be clinically asymptomatic, yet bacteremia may be occurring.
- A deep periodontal pocket may extend to the apex of the affected tooth.
- Putrid odor.
- Tooth may be loose and painful on palpation.
- May have facial lymphadenitis.

T

- Sinusitis—maxillary sinus is most commonly affected.
- Sense of smell may be affected, especially with drug, bomb, or food-sniffing working dogs.

CAUSES & RISK FACTORS

- Any pulpal trauma: direct blow with fracture of crown; defense (fighting—canine teeth), chewing hard objects (carnassial teeth); malocclusive trauma; tug-of-war; bone plating that damaged roots.
- Bacteria—the pulp can be affected by bacteria from dental caries, exposed dentinal tubules, or extension into endodontic system.
- Thermal heat resulting in pulpal necrosis—electrical cord burns, iatrogenic caused by overpolishing during an oral hygiene procedure or use of rotary burs.
- A deep periodontal pocket, especially at the palatal root of a small dog, can involve the apex where bacteria can enter the pulp system.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Tooth resorption—radiographs show no apical lucency or abscessation.
- Squamous cell carcinoma and fibrosarcoma—rapidly growing and invasive; displace and increase mobility of the teeth.
- Cementomas—radiographically show enlarged apical roots with a thin radiolucent zone continuous with the periodontal ligament.
- Ameloblastoma—displaces and increases mobility to the teeth; slowly enlarges.
- Cysts—radiographs usually show a very large lytic area; can mimic apical abscesses, which can become cystic (radicular cysts, apical periodontal granulomas); conventional endodontic treatment is unsuccessful; primordial cyst occurs at the site of a congenitally missing tooth and radiographically has a round oval radiolucency with a thin radiopaque border.
- Dentigerous cyst—occurs from the follicular cyst of an impacted or embedded tooth (usually the first mandibular premolars in dogs); radiographs show a tooth within the cyst.
- Periapical scar—usually occurs on an endodontically treated tooth where there has been no further increase in the radiographic apical lucency after a 6-month post-treatment period.
- Normal anatomy—mental foramen can be mistaken for apical lucencies on radiographic interpretation (the middle mental foramen just apical to second mandibular premolar).

CBC/BIOCHEMISTRY/URINALYSIS

CBC may show a leukocytosis and/or a mild regenerative anemia.

IMAGING

- Key diagnostic aid—demonstrates thickening of the apical periodontal ligament; ill-defined radiolucency; shows bone loss at the apex as the lesion becomes chronic.
- As the lesion progresses, radiographic lesions consistent with osteomyelitis and cellulitis occur.
- If fistulization has occurred, can place a gutta percha cone into the sinus tract and take a radiograph to identify the affected tooth.

DIAGNOSTIC PROCEDURES

- Surgical removal of the abscess site (surgical endodontics) or extraction.
- Endodontic treatment evaluation in 6 months to a year.
- Transillumination with a strong fiber-optic light can help the clinician by distinguishing between a vital and necrotic pulp.

PATHOLOGIC FINDINGS

- Apical area has a central area of liquefaction necrosis containing disintegrating neutrophils and cellular debris, surrounded by macrophages, lymphocytes, and plasma cells; can see bacteria.
- Extension of the lesion into cancellous bone results in inflammation of the periapical bone and resorption.
- Chronic changes may develop tracts that can be lined with epithelium; osteomyelitis or cellulitis lesions may become fibrotic with a capsule (radicular cyst and/or a periapical periodontal granuloma).

TREATMENT

- Drainage and elimination of the focus of infection.
- Extraction of the tooth involved, with curettage of the apical infected area.
- Endodontic treatment of the involved tooth (surgical if lesion large).
- Chronic conditions require surgical removal of the granulation tissue and curettage of the tract.
- After treatment, cold packs on the area will help reduce inflammation.
- Complete rest for a few days.
- Give nothing hard to chew for a few days.

MEDICATIONS

DRUG(S)

- Antibiotics preoperatively to prevent systemic spread of infection.
- Broad-spectrum antibiotic postoperatively for 7–10 days.
- Analgesics preoperatively, intraoperatively, and postoperatively for 3–4 days.

(CONTINUED)

TOOTH ROOT ABSCESS (APICAL ABSCESS)

- If a surgical endodontic treatment or an extraction was performed, a protective collar may be required.

**FOLLOW-UP**

- Recheck 10 days postoperatively.
- General examination of the area; percussion to test for sensitivity, healing of the extraction

or surgical endodontic site, and integrity of the endodontic access fillings.

- Recheck in 6 months to a year; repeat radiographs to see if the lesion has resolved (in endodontic treatment).
- Avoid traumatic injuries (e.g., letting the dog chase cars, hard chew toys, stop fighting).
- Curtail bite work—avoid handler sleeves that have tears or hole in them and avoid torsion movements.

- Check the mouth regularly for any trauma to additional teeth.

TOXOPLASMOSIS

BASICS

DEFINITION

Toxoplasma gondii—an obligate intracellular coccidian protozoan parasite that infects nearly all mammals; Felids are the definitive hosts; all other warm-blooded animals are intermediate hosts.

PATHOPHYSIOLOGY

- Severity and manifestation—depend on location and degree of tissue injury caused by tissue cysts.
- Infection—acquired by ingestion of tissue cysts in intermediate hosts or oocysts shed by felids; organisms spread to extra-intestinal organs via blood or lymph; results in focal necrosis to many organs (heart, eyes, CNS).
- Acute disseminated infection rarely fatal.
- Chronic disease—tissue cysts form; low-grade disease; usually not clinically apparent unless immunosuppression or concomitant illness allows organism to proliferate, causing an acute inflammatory response.
- Clinical disease—often associated with other infections that cause severe immunosuppression (e.g., canine distemper, FIP, and FeLV).

SYSTEMS AFFECTED

- Multisystemic—usually the same in cats and dogs.
- Ophthalmic—approximately 80% of affected cats have evidence of intraocular inflammation, most commonly uveitis.

INCIDENCE/PREVALENCE

- Approximately 30% of cats and up to 50% of people serologically positive for *T. gondii*.
- Most animals asymptomatic.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Cats more commonly symptomatic than dogs

Mean Age and Range

In one study, mean age 4 years; range 2 weeks–16 years

Predominant Sex

Male cats—more common

SIGNS

General Comments

- Determined mainly by site and extent of organ damage.
- Acute—at the time of initial infection.
- Chronic—reactivation of encysted infection; caused by immunosuppression.

Historical Findings

- Non-specific signs of lethargy, depression, and anorexia.
- Weight loss.
- Fever.
- Ocular discharge, photophobia, miotic pupils (cats).
- Respiratory distress.
- Neurologic—ataxia; seizures; tremors; paresis/paralysis; cranial nerve deficits.
- Digestive tract—vomiting; diarrhea; abdominal pain; jaundice.
- Stillborn kittens.

Physical Examination Findings

Cats

- Most severe in transplacentally infected kittens, which may be stillborn or die before weaning.
- Surviving kittens—anorexia; lethargy; high fever unresponsive to antibiotics; reflect necrosis/inflammation of lungs (dyspnea, increased respiratory noises), liver (icterus, abdominal enlargement from ascites), and CNS (encephalopathic).
- Respiratory and gastrointestinal (postnatal)—most common; anorexia; lethargy; high fever unresponsive to antibiotics; dyspnea; weight loss; icterus; vomiting; diarrhea; abdominal effusion.
- Neurologic (postnatal)—seen in < 10% of patients; blindness; stupor; incoordination; circling; torticollis; anisocoria; seizures.
- Ocular signs (postnatal)—common; uveitis (aqueous flare, hyphema, mydriasis); iritis; detached retina; iridocyclitis; keratic precipitates.
- Rapid course—acutely affected patients with CNS and/or respiratory involvement.
- Slow course—patients with reactivation of chronic infection.

Dogs

- Young—usually generalized infection; fever; weight loss; anorexia; tonsillitis; dyspnea; diarrhea; vomiting.
- Old—tend to localized infections; mainly associated with neural and muscular systems.
- Neurologic—quite variable; usually reflect diffuse neurologic inflammation; seizures; tremors; ataxia; paresis; paralysis; muscle weakness; tetraparesis.
- Ocular—rare; similar to those found in cats.
- Cardiac involvement—occurs; usually not clinically apparent.

CAUSE

T. gondii

RISK FACTORS

Immunosuppression—may predispose to infection or reactivation: FeLV, FIV, FIP, hemotropic mycoplasma, canine distemper, and glucocorticoid or antitumor chemotherapy or post-renal transplant.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Cats

- Intraocular disease (anterior uveitis)—FIP; FeLV; FIV; immune-mediated; trauma; lens-induced; corneal ulceration with reflex uveitis.
- Dyspnea (respiratory signs)—asthma; cardiogenic; pneumonia (bacterial, fungal, parasitic); neoplasia; heartworm disease; pleural disease (effusions); diaphragmatic hernia; chest wall injury.
- Neurologic (causes of meningoencephalitis)—viral (FIP, rabies, pseudorabies); fungal (cryptococcosis, blastomycosis, histoplasmosis); parasitic (cuterebriasis, coenurosis, aberrant heartworm

migration); bacterial; idiopathic disease (feline polioencephalomyelitis).

Dogs

- Often associated with other immunosuppressive diseases—e.g., signs of distemper may be seen.
- Differentiate from *Neospora* or *Sarcocystis* which are similar morphologically.
- Consider other conditions causing multifocal signs—infectious or inflammatory toxicity; metabolic disease.

CBC/BIOCHEMISTRY/URINALYSIS

CBC (Cats)

- Most show mild normocytic normochromic anemia.
- Leukopenia—approximately 50% of patients with severe disease; mainly owing to lymphopenia.
- Neutropenia—alone or in addition to lymphopenia and a degenerative left shift.
- Leukocytosis—may occur during recovery.

Biochemistry

- ALT and AST—marked increase in most patients.
- Hypoalbuminemia.
- Cats—icterus seen in approximately 25% of patients; mildly low serum calcium concentrations often seen with pancreatitis; amylase levels unreliable.

Urinalysis (Cats)

- Mild proteinuria—small proportion of patients.
- Bilirubinuria—especially with icterus.

OTHER LABORATORY TESTS

Serology

- IgM, IgG, and antigen serum titers—most definitive information from one sample; determine type of infection (active, recent, chronic) with a follow-up sample taken 3 weeks later.
- IgM—single serologic titer of choice for diagnosis of active infection; elevated 2 weeks post-infection (usually coincides with onset of clinical signs); persists for a maximum of 3 months; then falls; prolonged titer: reactivation or delay in antibody class shift to IgG (result of immunosuppression from FeLV or FIV infection or steroid therapy).
- IgG—titers rise 2–4 weeks post-infection; persist > 1 year; single high titer not diagnostic for active infection; four-fold increase over a 3-week period suggests active infection.

- Antigen—positive 1–4 weeks post-infection; because it remains positive during active or chronically persistent infections, does not add much to antibody titer results.
- A tentative antemortem diagnosis of clinical disease can be based on clinical and serologic parameters: (a) serologic evidence of recent or active infection—high IgM titers, four-fold change in IgG titers, (b) exclusion of other causes of the clinical syndrome, and (c) beneficial response to anti-*Toxoplasma* drugs.
- PCR—used to verify presence of *T. gondii* in biologic specimens; available from several laboratories.

(CONTINUED)

TOXOPLASMOSIS**IMAGING**

Radiographs—may see mixed pattern of patchy alveolar and interstitial pulmonary infiltrates, pleural and abdominal effusions, and hepatomegaly.

DIAGNOSTIC PROCEDURES

- PCR may be the most prudent choice in suspect cases since many protozoa are morphologically similar and are difficult to distinguish in tissues.
- CSF—high leukocyte count (both mononuclear cells and neutrophils) and protein in encephalopathic patients.
- Cytology—organism rarely detected in body fluids during acute infection (CSF, pleural or peritoneal effusions); bronchoalveolar lavage effective in identifying organisms in affected cats with signs of pulmonary involvement.
- Fecal—evaluation with Sheather's sugar solution may be diagnostic; fecal oocyst shedding rarely occurs during clinical disease; oocysts may be detected on routine examination in asymptomatic cats but are morphologically indistinguishable from *Hammondia* spp. and *Besnoitia*; distinguish organisms via mouse inoculation.

PATHOLOGIC FINDINGS

- Necrotic foci—up to 1 cm; most often in liver, pancreas, mesenteric lymph nodes, and lungs; necrosis of brain (1 cm areas of discoloration).
- Ulcers and granulomas—may be seen in stomach and small intestine.
- Potentially no gross lesions.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Usually outpatient.
- Inpatient—severe disease; patient cannot maintain adequate nutrition or hydration.
- Confine—patients with neurologic signs.

NURSING CARE

Dehydration—intravenous fluids

CLIENT EDUCATION

- Cats—prognosis guarded in patients needing therapy; response to therapy inconsistent.
- Neonates and severely immunocompromised animals—prognosis worse.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Clindamycin—25–50 mg/kg PO or IM daily, divided into two doses, for at least 2 weeks after clinical signs clear.
- 1% prednisone drops—every 8 hours for 2 weeks for uveitis; use concurrently.

PRECAUTIONS

Clindamycin—anorexia, vomiting, and diarrhea (dose-dependent).

ALTERNATIVE DRUG(S)

- Sulfadiazine (30 mg/kg PO q12h) in combination with pyrimethamine (0.5 mg/kg PO q12h) for 2 weeks; can cause depression, anemia, leukopenia, and thrombocytopenia, especially in cats.
- Folinic acid (5 mg/day) or brewer's yeast (100 mg/kg/day)—correct bone marrow suppression caused by sulfadiazine/pyrimethamine therapy.

**FOLLOW-UP****PATIENT MONITORING*****Clindamycin***

- Examine 2 days after initiation treatment—clinical signs (fever, hyperesthesia, anorexia, uveitis) should begin to resolve; uveitis should resolve completely within 1 week.
- Examine 2 weeks after initiation of treatment—assess neuromuscular deficits; should partially resolve (some deficits permanent owing to CNS or peripheral neuromuscular damage).
- Examine 2 weeks after owner-reported resolution of signs—assess discontinuing treatment; some neuromuscular deficits permanent.

PREVENTION/AVOIDANCE***Cats***

- Diet—prevent ingestion of raw meat, bones, viscera, or unpasteurized milk (especially goat's milk), or mechanical vectors (flies, cockroaches); feed only well-cooked meat.
- Behavior—prevent free-roaming to hunt prey (birds, rodents) or to enter buildings where food-producing animals are housed.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—guarded; varied response to drug treatment.
- Acute—prompt and aggressive therapy often successful.
- Residual deficits (especially neurologic) cannot be predicted until after a course of therapy.
- Ocular disease—usually responds to appropriate therapy.
- Severe muscular or neurologic disease—usually chronic debility.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Young dogs—distemper.
- Cats—FeLV, FIP, and FIV; FIV infection does not affect clinical outcome or the ability of the animal to mount a protective immune response to subsequent reinfection; renal transplant.

AGE-RELATED FACTORS

Disease worse in neonates

ZOONOTIC POTENTIAL

- Biggest danger is infection of pregnant women or immunocompromised individuals.
- Young cats are most likely to be shedding oocysts.
- Important: oocysts need to be sporulated to be infectious. Unsporulated

oocysts are shed in the feces and need at least 24 hours to sporulate.

- Cats—healthy animals with a positive antibody titer pose little danger to humans; animal with no antibody titer at more risk of becoming infected, shedding oocysts in the feces, and constituting a risk to humans.
- Avoid contact with oocysts or tissue cysts—do not feed raw meat; wash hands and surfaces (cutting boards) after preparing raw meat; boil drinking water if source is unreliable; keep sandboxes covered to prevent cats from defecating in them; wear gloves when gardening; wash hands and vegetables before eating to avoid contact with oocyst soil contamination; empty cat litter boxes daily; disinfect litter boxes with boiling water; control stray cat population to avoid oocyst contamination of environment.
- Pregnant women—avoid all contact with a cat that is excreting oocysts in feces; avoid contact with soil and cat litter; do not handle or eat raw meat (to kill organism, cook to 66°C; 150°F).
- T. gondii* causes abortion in sheep; prevent cats from ingesting placenta or aborted fetuses and keep cats from defecating in sheep feed to break the life cycle and decrease the zoonotic potential.

PREGNANCY/FERTILITY/BREEDING

- Parasitemia during pregnancy—spread of organism to fetus; probably does not happen unless first-time infection of dam occurs during pregnancy (as with humans).
- Placental transmission rare.

ABBREVIATIONS

- ALT = alanine aminotransferase
- AST = aspartate aminotransferase
- CNS = central nervous system
- CSF = cerebrospinal fluid
- FeLV = feline leukemia virus
- FIP = feline infectious peritonitis
- FIV = feline immunodeficiency virus
- PCR = polymerase chain reaction

TRACHEAL AND AIRWAY COLLAPSE

BASICS

DEFINITION

- Static or dynamic reduction in the luminal diameter of the large conducting airway with respiration.
- Can involve the cervical trachea, the intrathoracic trachea, or both segments.
- Airway collapse (bronchomalacia) refers to collapse of lobar bronchi and smaller airways, which can be seen in conjunction with tracheal collapse (tracheobronchomalacia) or alone.
- Compression of the trachea or bronchi due to hilar lymphadenopathy or external mass lesions—not considered part of this condition.

PATOPHYSIOLOGY

- Hypocellular tracheal cartilage in the cervical region identified historically in some small-breed dogs.
- Lack of chondroitin sulfate and/or decreased glycoproteins within the cartilage matrix results in a reduction in bound water and loss of rigidity in the cartilage.
- Causes of bronchomalacia not established—cartilage abnormalities could include a mechanism similar to cervical tracheal collapse, defects in chondrogenesis, nutritional deficiencies, or degenerative changes caused by chronic airway disease.
- Collapse—weak tracheal cartilage allows flattening of the normal ring structure; trachea collapses in a dorsoventral direction when pressure fluctuates within the airway lumen. During inspiration, intrapleural pressure becomes more negative leading to a drop in intra-airway pressure. Atmospheric pressure exceeds airway pressure in the cervical region and lack of cartilage support results in cervical collapse. During forced expiration, intrapleural pressure becomes positive and exceeds intrathoracic intra-airway pressure. When cartilaginous airway walls are weakened by bronchomalacia, intrathoracic airway collapse occurs, on expiration.
- Increased tension on the trachealis dorsalis muscle or neurogenic atrophy of the muscle causes stretching of the dorsal tracheal membrane with protrusion into the airway lumen.
- Coughing—mechanical trauma to the tracheal mucosa from collapse of the dorsal tracheal membrane exacerbates airway edema and inflammation.
- Upper airway obstruction worsens clinical signs, and chronic increases in respiratory effort could lead to secondary abnormalities in laryngeal structure and function.
- Small airway disease augments the trans-airway pressure gradient and potentiates collapse in the intrathoracic region.

T

SYSTEMS AFFECTED

- Respiratory—chronic airway irritation.
- Cardiovascular—pulmonary hypertension.
- Nervous—can be involved when syncope

develops from hypoxia or a vasovagal reflex associated with cough.

GENETICS

Unknown, tracheal collapse common in small toy breed dogs.

INCIDENCE/PREVALENCE

Common clinical entity

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Primarily dog, rarely cat

Breed Predilections

Tracheal collapse—miniature poodles, Yorkshire terriers, Chihuahuas, Pomeranians, other small and toy breeds. Bronchomalacia—all breeds.

Mean Age and Range

- Middle-aged to elderly—onset of signs at 2–14 years of age
- Severely affected animals < 1 year of age.

SIGNS

Historical Findings

- Usually worsened by excitement, heat, humidity, exercise, or obesity.
- Dry honking cough.
- Often have a chronic history of intermittent coughing or difficulty breathing.
- Retching—often seen due to attempts to clear respiratory secretions from the larynx.
- Tachypnea, exercise intolerance, and/or respiratory distress—common.
- Cyanosis or syncope—seen in severely affected individuals.

Physical Examination Findings

- Increased tracheal sensitivity—virtually always seen.
- Respiratory distress—inspiratory with cervical collapse; expiratory with intrathoracic collapse.
- Stridor or musical sounds ausculted over narrowed cervical trachea.
- An end-expiratory snap—heard when a large intrathoracic airway collapses during forceful expiration then reopens.
- Crackles—due to small airway collapse or chronic bronchitis. Wheezes suggest concurrent bronchitis.
- Mitral insufficiency murmurs—often found concurrently in small-breed dogs.
- Normal to low heart rate and/or marked respiratory arrhythmia.
- Loud second heart sound—suggests pulmonary hypertension.
- Hepatomegaly—cause unknown.

CAUSES

- Unknown etiology—congenital, nutritional, or familial defects of chondrogenesis suspected.
- Chronic small airway inflammation suggested to contribute to bronchomalacia but relationship not clearly established.

RISK FACTORS

- Obesity
- Airway infection or inflammation
- Upper airway obstruction
- Endotracheal intubation

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious tracheobronchitis
- Tracheal or laryngeal obstruction or foreign body
- Chronic bronchitis
- Pneumonia—viral, bacterial, fungal, parasitic, eosinophilic
- Bronchiectasis

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—can show an inflammatory leukogram secondary to chronic stress or concurrent infection.
- Increased liver enzymes common.

OTHER LABORATORY TESTS

Elevated bile acids—mechanism unclear.

IMAGING

Thoracic Radiography

- Airway collapse evident on a lateral thoracic radiographic in a large percentage of dogs with airway collapse, however, the location of collapse on static radiographs agreed with the site determined by fluoroscopy in < 50% of cases.
- Inspiratory radiographs—show primarily cervical collapse and collapse at the thoracic inlet.
- Expiratory radiographs—show intrathoracic tracheal collapse; can also note collapse at the carina, ballooning of the cervical trachea, and cranial herniation of the lung lobe through the thoracic inlet.
- Right-sided heart enlargement—can be seen secondary to chronic pulmonary disease and cor pulmonale, or heart can be artificially enlarged due to obesity or breed conformation.

Fluoroscopy

Dynamic collapse of the cervical or intrathoracic trachea and/or dorsal tracheal membrane can be visible during tidal respirations—usually more easily identified after induction of cough. Cranial lung herniation through the thoracic inlet is common.

DIAGNOSTIC PROCEDURES

Caution is warranted in anesthetizing and intubating dogs with tracheal collapse because endotracheal tube irritation can worsen clinical signs. Loss of respiratory drive from anesthetic drugs or excess excitement on recovery can precipitate a crisis.

Tracheal Wash

Use oral intubation (rather than the transtracheal approach) with a small endotracheal tube and a sterile catheter when obtaining samples for cytologic examination and bacterial culture/susceptibility.

Bronchoscopy

- Grade the severity of collapse; Grade I—slight protrusion of the dorsal tracheal membrane into the airway lumen; diameter reduced by < 25%, Grade II—reduction of the tracheal lumen by 50%, Grade III—

(CONTINUED)

reduction of the tracheal lumen by 75%, Grade IV—tracheal rings flattened; < 10% of the tracheal lumen can be seen; in some cases (particularly Yorkies), a double lumen trachea is observed, where tracheal rings have bowed dorsally to contact the trachealis muscle.

- Identify small airway disease—collapse or inflammation. Submit airway samples for cytologic examination and bacterial/susceptibility; specific culture for *Mycoplasma* is recommended.

Cytology

- Unremarkable in uncomplicated tracheal or airway collapse.
- Neutrophilia without intracellular bacteria or marked bacterial growth—indicates airway inflammation.
- Sepsis and suppuration along with marked bacterial growth of a pathogen—suggests pulmonary infection.

PATHOLOGIC FINDINGS

- Dorsal trachealis muscle—elongated.
- Cartilage rings—flattened.
- Tracheal mucosal inflammation in some cases.
- Hypocellularity of the cartilage with low glycoproteins and chondroitin sulfate—can be noted via histopathologic examination or electron microscopy.
- Can also see changes associated with chronic inflammatory airway disease.

**TREATMENT****APPROPRIATE HEALTH CARE**

- Outpatient—stable patients.
- Inpatient—oxygen therapy and sedation for severe respiratory distress. Sedation and cough suppression—butorphanol ($50\text{ }\mu\text{g/kg}$ SC); addition of acepromazine ($25\text{ }\mu\text{g/kg}$ SC) can enhance sedative effects and further reduce the cough reflex.

NURSING CARE

Oxygen therapy and sedation with butorphanol and/or acepromazine for severely distressed patients.

ACTIVITY

- Severely limited until patient is stable.
- During management of disease—gentle exercise recommended to encourage weight loss.

DIET

- Many affected dogs improve after losing weight.
- Institute weight-loss program with restriction of caloric intake; use a gradual weight-loss program (1–2% weight loss per week).

CLIENT EDUCATION

- Warn client that weight gain, overexcitement, and humid conditions can precipitate a crisis.
- Advise client to use a harness instead of a collar.
- Advise owners that tracheal collapse is irreversible and that treatment strategies are designed to lessen

triggers of cough.

- For surgical candidates, advise owner of the likelihood of complications after surgery (e.g., persistent cough, respiratory distress, or laryngeal paralysis); some patients can require a permanent tracheostomy. For stent candidates, advise owners of need for extensive follow-up to avoid stent fracture, migration, or granulation tissue formation.

SURGICAL CONSIDERATIONS

- Treatment of upper airway obstructive disorders (elongated soft palate, everted laryngeal saccules)—can reduce tracheal signs.
- Placement of extraluminal C-shaped rings by a skilled surgeon in selected patients with cervical collapse will enhance quality of life and reduce clinical signs when adequate stabilization of the airway can be achieved and when bronchomalacia does not limit resolution of disease.
- Intraluminal stents are life-saving in selected cases with intrathoracic airway collapse that fail aggressive medical management.

DRUG(S) OF CHOICE

- Narcotic cough suppressants (butorphanol at $0.5\text{--}1\text{ mg/kg PO q4\text{--}8h}$ or hydrocodone at $0.22\text{ mg/kg PO q4\text{--}8h}$) used to break the cycle of cough; reduce dose rate to the least frequent administration that controls signs.
- Reduction of tracheal inflammation—prednisone (0.5 mg/kg PO q12h then 0.25 mg/kg q12h) for a total of 5–7 days may help. Inhaled steroids given via facemask and spacing chamber are preferred to avoid systemic effects of panting and weight gain.
- Sustained-release theophylline (10 mg/kg PO q12h)—thought to reduce the pressure gradient in small airways and decrease cough in dogs with intrathoracic airway collapse—bronchodilators have no effect on tracheal diameter.
- Bacterial infection uncommon but doxycycline ($3\text{--}5\text{ mg/kg PO q12h}$) is sometimes beneficial, perhaps through reduction in bacteria within the airway or reduction of inflammation.

RECAUTIONS

Avoid long-term steroid use because of the propensity for weight gain and diseases associated with immunosuppression.

POSSIBLE INTERACTIONS

Theophylline metabolism—increased by concurrent treatment with ketoconazole or phenobarbital, which results in inadequate plasma concentration; decreased by fluoroquinolones (e.g., enrofloxacin), erythromycin, cimetidine, steroids, β -blockers, mexiletine, and thiabendazole, which results in toxic plasma concentration and gastrointestinal upset, nervousness, or tachycardia; adjust dosages when concurrent use is necessary.

ALTERNATIVE DRUG(S)

Over-the-counter cough suppressants—rarely reduce cough.

TRACHEAL AND AIRWAY COLLAPSE**FOLLOW-UP****PATIENT MONITORING**

- Body weight
- Exercise tolerance
- Pattern of respiration
- Incidence of cough

PREVENTION/AVOIDANCE

- Avoid obesity in breeds commonly afflicted.
- Avoid heat and humidity.
- Use harness rather than leash.

POSSIBLE COMPLICATIONS

Intractable respiratory distress leading to respiratory failure or euthanasia.

EXPECTED COURSE AND PROGNOSIS

- Combinations of medications along with weight control can reduce clinical signs, but patient will likely cough throughout life and can suffer recurrent exacerbations of disease.
- Surgery—benefits many dogs with cervical collapse.
- Stent placement—benefits some dogs, primarily those with intrathoracic collapse. Medications usually required post-procedure.
- Prognosis—based on bronchoscopic evidence of airway obstruction and development of complications.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- Chronic bronchitis.
- Laryngeal paralysis.
- Pulmonary hypertension.
- Breeds of dogs that develop tracheal collapse also commonly have mitral insufficiency.

SEE ALSO

- Bronchitis, Chronic
- Canine Infectious Respiratory Disease

TRACHEAL PERFORATION

BASICS

OVERVIEW

Tracheal perforation is a loss of integrity of the tracheal wall, allowing leakage of air to create subcutaneous (SC) emphysema, pneumomediastinum, pneumopericardium, pneumothorax, and pneumoretroperitoneum. Caused by penetrating, intraluminal, or blunt cervical or thoracic trauma. Severity ranges from small perforation to complete avulsion. With complete avulsion, mediastinal tissues can form a pseudomembrane to maintain airway patency.

SYSTEMS AFFECTED

- Respiratory—compromise of airway, possible pneumomediastinum and pneumothorax.
- Cardiovascular—pneumothorax and tension pneumothorax can decrease venous return and cardiac output.
- Nervous, Musculoskeletal—depends on severity of hypoxia.
- Skin—SC emphysema, initially cervical but can affect entire body.

SIGNALMENT

Dog and cat—no breed, age, or sex predilection

SIGNS

- Onset: immediate or up to 1 week after injury.
- SC emphysema and respiratory distress are most common.
- Other signs: anorexia, lethargy, gagging, ptalism, vomiting, coughing, hemoptysis, inspiratory stridor, and shock.

CAUSES & RISK FACTORS

- Penetrating cervical wounds: bite wounds, gunshots, arrows.
- Iatrogenic perforation during transtracheal wash, jugular venipuncture, cervical surgery, radiation therapy, tracheal stent fracture, or failure to deflate cuff or to stabilize the tube while repositioning patient. Overinflation of endotracheal cuff can cause a linear tear in the trachealis muscle at thoracic inlet or intrathoracic trachea. Occurs most often with dental procedures.
- Blunt trauma can cause intrathoracic tracheal avulsion.

T

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anesthesia—barotrauma resulting in alveolar rupture and pneumothorax.
- Penetrating wounds—perforation of esophagus or cervical bite.
- After blunt trauma—pulmonary contusions, pneumothorax, rib fractures.
- Other differentials include intrathoracic tracheal compression by mediastinal mass, spontaneous pneumothorax, pleural effusion, and bronchoesophageal fistula.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

Arterial blood gas analysis can show hypoxemia, hypercarbia, and respiratory acidosis.

IMAGING

- Lateral cervical and thoracic radiographs are essential. SC emphysema, pneumomediastinum, pneumopericardium, and pneumothorax can be seen.
- In cases of tracheal avulsion, site of disruption may be visible.
- Abdominal radiographs occasionally show pneumoretroperitoneum.
- Computed tomography can be useful to identify location and extent of tracheal damage.

DIAGNOSTIC PROCEDURES

- Tracheoscopy used to confirm tracheal perforation or avulsion and characterize severity; false-negatives can occur.

TREATMENT

- Hospitalization is indicated.
- Oxygen supplementation with 95% O₂ for 4 hours will decrease SC emphysema.
- Minimal handling to reduce stress, most cases of iatrogenic perforation will heal.
- If pneumothorax develops, thoracocentesis +/- thoracostomy tubes can be required.
- If patient decompensates, surgical exploration is indicated.
- Tracheal rupture secondary to blunt trauma or penetrating injury requires surgical repair.
- If tracheal avulsion is present, intubate only the proximal segment using an undersized endotracheal tube. Avoid positive-pressure ventilation to prevent disruption of pseudomembrane.
- Cervical tracheal perforation—approach via ventral midline, can require a partial median sternotomy. Damaged areas of trachea are often on the dorsolateral surface: debride and repair with 3-0 to 5-0 monofilament absorbable suture.
- Tracheal resection and anastomosis is indicated for severe tracheal damage or tracheal avulsion.
- Intrathoracic tracheal avulsion—approach via a right lateral 3rd or 4th intercostal thoracotomy. Open the pseudomembrane and intubate the caudal segment. Preplace sutures, guide an endotracheal tube from the cranial segment into the caudal segment, and complete repair.

MEDICATIONS

DRUG(S)

Broad-spectrum antibiotic therapy if caused by bite wounds.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Sedation—use with caution, can decrease respiratory drive.
- Corticosteroids are not indicated unless there is a large degree of upper airway swelling.

FOLLOW-UP

PATIENT MONITORING

- Monitor respiratory rate and effort, mucous membrane color, capillary refill time, pulse quality, and heart rate, and auscult frequently.
- Pulse oximetry and/or arterial blood gases.
- Thoracic radiographs to monitor pneumomediastinum, pneumothorax and help detect tracheal stenosis. Tracheoscopy required in some cases.

PREVENTION/AVOIDANCE

- Use of 3 mL syringe for cuff inflation for cats and small dogs to prevent overinflation of cuff.
- Disconnect endotracheal tube from anesthetic circuit when repositioning animal during anesthesia.

POSSIBLE COMPLICATIONS

- Tracheal stricture and stenosis at site of perforation or repair.
- Laryngeal paralysis from damage to recurrent laryngeal nerve.
- Dehiscence of tracheal anastomosis site.
- Sepsis (rare).
- Death, particularly at induction of anesthesia with complete tracheal avulsion.

EXPECTED COURSE AND PROGNOSIS

- Most cases respond well to appropriate therapy.
- Complete tracheal avulsion—guarded prognosis. Without surgery—extremely poor prognosis due to stricture formation.

MISCELLANEOUS

ASSOCIATED CONDITIONS

With tracheal perforation caused by blunt trauma, can have pulmonary contusions, pneumothorax, rib fractures, and hemothorax

PREGNANCY/FERTILITY/BREEDING

Hypoxia can result in fetal distress and death.

TRANSITIONAL CELL CARCINOMA

BASICS

DEFINITION

Malignancy arising from the transitional epithelium within the kidney, ureters, urinary bladder, urethra, prostate, or vagina.

PATHOPHYSIOLOGY

The underlying etiology of TCC remains unclear. It is possible that an environmental carcinogen may initiate or promote the malignant transformation of the transitional epithelium.

SYSTEMS AFFECTED

- Renal/Urologic—the most common site affected is the trigone of the urinary bladder. Local invasion of the distal ureter is not uncommon and may lead to post-renal azotemia. The apex of the urinary bladder is more often affected in cats, although because of late detection the entire bladder is often involved by the time of diagnosis.
- Reproductive—the vagina is a possible site of primary TCC. The prostate may be involved through local invasion, or as the primary site of TCC.
- Other systems may be affected through metastases (e.g., most commonly regional lymph nodes and lungs; other sites include bone, brain, eye) or paraneoplastic syndromes (hypertrophic osteopathy has been reported secondary to TCC of the urinary bladder).

GENETICS

N/A

INCIDENCE/PREVALENCE

- < 1% of all reported malignancies in dogs
- Rare in cats

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Middle-aged to old, spayed female, small-breed dogs most commonly reported with the disease.

Species

Dog and cat

Breed Predilections

- Scottish terriers are at 18 times the risk compared to other breeds.
- West Highland white terriers, Shetland sheepdogs, Beagles, American Eskimo dogs, dachshunds.
- May occur in any breed.
- No breed predisposition in cats.

Mean Age and Range

Dogs—8 years, range 1 to 15+ years

Predominant Sex

Female

SIGNS

General Comments

- Signs are similar to those of bacterial urinary tract infection or urolithiasis.

- Consider TCC in animals showing temporary or no response to appropriate antibiotic therapy.

Historical Findings

- Complaints of recurrent stranguria, pollakiuria, hematuria, dysuria, urinary incontinence, or any combination of the above signs should initiate a search for TCC.
- Signs may temporarily respond to antibiotic therapy.

Physical Examination Findings

- Often normal.
- Occasionally, urethral thickening can be appreciated on digital rectal examination or a mass might be palpable in the caudal abdomen/urinary bladder region.
- Urethral/vaginal/prostatic TCC may be palpable on rectal examination.
- Enlarged intrapelvic or sublumbar lymph nodes can be palpable on rectal examination.

CAUSES

- Dogs—reported risk factors include obesity, environmental carcinogens, chronic exposure to organophosphates or carbamates, and (rarely) long-term or a large bolus dose of cyclophosphamide.
- Cats—unknown.

RISK FACTORS

Dogs—Scottish terrier breed, obesity, exposure to organophosphates or carbamates, cyclophosphamide therapy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Non-neoplastic—bacterial urinary tract infection, urolithiasis, urethritis, vaginitis, prostatitis.
- Neoplastic—other primary neoplasia (e.g., squamous cell carcinoma, transmissible venereal tumor), or metastatic neoplasia (e.g., locally infiltrative prostatic carcinoma).

CBC/BIOCHEMISTRY/URINALYSIS

- CBC and biochemistry usually within normal limits.
- Biochemistry profile may show signs of renal and/or post-renal azotemia if urethral or urethral obstruction exists.
- Urinalysis may reveal epithelial cells with criteria of malignancy—caution should be exercised if the sample is inflammatory as epithelial cells may exhibit criteria of malignancy in the presence of inflammation.

OTHER LABORATORY TESTS

- Urine culture and sensitivity are indicated, as concurrent urinary tract infection is common; however, caution is advised when performing cystocentesis on patients suspected to have TCC as tumor seeding along the needle tract may occur.
- Biopsy (surgical, traumatic catheter, or cystoscopic) is gold standard for definitive

diagnosis. Even with a low yield of tissue samples of some traumatic catheterizations, typically enough cells are obtained to get a cytologic diagnosis.

IMAGING

Thoracic Radiography

- Metastatic patterns include multiple, well-defined interstitial nodules, increased interstitial pattern, and alveolar infiltrates.

Abdominal Radiography

- Unlikely to reveal specific urinary bladder disease unless the mass is mineralized (rare).
- May reveal sublumbar lymphadenomegaly or bony metastasis.

Double Contrast Cystography

- Dogs—space-occupying lesion, usually at trigone of the urinary bladder.
- Cats—space-occupying lesion, may be at the apex of the urinary bladder.
- Depending on the primary site, intravenous pyelography, voiding urethrogram, or vaginogram may be indicated.

Ultrasonography

- 2D ultrasonography is a highly sensitive imaging modality, helpful in identifying location and extent of disease; however, not a reliable method for monitoring response to therapy.
- 3D ultrasonography is a more accurate tool for monitoring tumor volume and response to therapy.

Computed Tomography

Computed tomographic imaging of TCC is the most accurate way to measure tumor volume.

OTHER DIAGNOSTIC PROCEDURES

Exploratory Laparotomy

- Used to obtain biopsies of the primary tumor and regional lymph nodes.
- Surgical cure very unlikely due to the infiltrative nature of the tumor.
- Because tumor seeding is recognized with TCC, change surgical gloves and instruments after handling the tumor.

Cystoscopy

A less invasive way to identify and biopsy TCC within the urinary bladder or urethra.

Traumatic Catheterization

Use a polypropylene catheter to traumatically obtain small tissue samples for histologic or cytologic diagnosis.

Ultrasound-Guided Biopsy

Not recommended, as seeding of the biopsy tract with viable tumor cells is a highly possible sequelae.

GROSS AND HISTOPATHOLOGIC FINDINGS

- Irregular to diffuse thickening of the urinary bladder mucosa.
- Metastasis to regional lymph nodes, lungs, and bones (i.e., vertebra, pelvis) possible.

TRANSITIONAL CELL CARCINOMA

(CONTINUED)

TREATMENT

Radiotherapy likely to become a more common option with intensity-modulated or TomoTherapy machine options.

INPATIENT VERSUS OUTPATIENT

- Initial workup and diagnosis takes 1–2 days.
- Stable patients need not be hospitalized.

ACTIVITY

Normal

DIET

Normal, unless concurrently in renal failure

CLIENT EDUCATION

- Long-term prognosis poor.
- Palliation often attainable.
- Disease not usually surgically resectable in dogs.

SURGICAL CONSIDERATIONS

- TCC is highly exfoliative and highly transplantable—multiple reports of surgically induced seeding of TCC exist.
- All surgical instruments and gloves should be replaced after contacting the tumor.
- Up to 50% of the urinary bladder can be resected with minimal loss of function.
- Tube cystostomy placement may greatly prolong survival times by bypassing urethral obstruction.
- Urethral stenting may also prolong survival by temporarily relieving obstruction.

MEDICATIONS

DRUG(S) OF CHOICE

- Piroxicam (0.3 mg/kg PO q24h with food) reported to have activity in approximately 15% of cases with a median survival of 180 days.
- Combination therapy of mitoxantrone (5 mg/m^2 IV q3 weeks) and piroxicam has a reported response rate of 35% with a median survival of 291 days.
- Metronomic (continuous, low-dose) chemotherapy with chlorambucil (4 mg/m^2 PO q24h) may play a role in the management of this disease.

CONTRAINDICATIONS

- Piroxicam—do not use in animals with known gastrointestinal erosions or ulcers, do not use in animals with renal insufficiency.

T

- Piroxicam—do not combine with cisplatin.
- Piroxicam therapy appears to be tolerated in cats, but at a reduced dosing frequency (q48h) in comparison to dogs.

PRECAUTIONS

- Animals with TCC may have renal damage either due to hydroureter, hydronephrosis, or pyelonephritis secondary to chronic urinary tract infection associated with the tumor.
- Dogs being treated with chemotherapy should be monitored for myelosuppression.
- Seek advice before initiating therapy if unfamiliar with cytotoxic drugs.

POSSIBLE INTERACTIONS

Cisplatin should not be used concurrent with other nephrotoxic drugs (e.g., aminoglycoside antibiotics).

ALTERNATIVE DRUG(S)

Antibiotics—antibiotic therapy should be administered as necessary.

FOLLOW-UP

PATIENT MONITORING

- Contrast cystography or ultrasonography every 6–8 weeks to determine disease status.
- Thoracic radiographs and abdominal ultrasound every 2–3 months to monitor for metastatic disease.

PREVENTION/AVOIDANCE

Advise client regarding frequent urination following cyclophosphamide therapy to minimize contact time with the urinary bladder mucosa.

POSSIBLE COMPLICATIONS

- Urethral or ureteral obstruction and renal failure.
- Metastatic disease to regional lymph nodes, lungs, or bone.
- Recurrent urinary tract infection.
- Urinary incontinence.
- Myelosuppression of gastrointestinal toxicity secondary to chemotherapy.
- Gastrointestinal ulceration secondary to piroxicam therapy.

EXPECTED COURSE AND PROGNOSIS

- Long-term prognosis is guarded.
- Progressive disease likely.
- Median survival: no therapy—4–6 months; with therapy—6–12 months.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Recurrent urinary tract infections
- Post-renal azotemia
- Paraneoplastic hypertrophic osteopathy

TRANSMISSIBLE VENEREAL TUMOR

BASICS

OVERVIEW

- Sexually, or other direct contact, transmitted, naturally occurring tumor.
- Appears to be more common in temperate areas and large cities.

SIGNALMENT

Intact dogs of either sex

SIGNS

- Red, friable, lobulated mass on the mucosa of the vagina, penis or other mucous membranes.
- Oral mucosa may be affected.
- Owners may report blood dripping from the affected area or excessive licking of the genital area.
- Tumor protrusion may be noticed.

CAUSES & RISK FACTORS

- Direct transplantation of tumor cells onto abraded mucosa, either by coitus or oral transmission.
- Intact, free-roaming dogs are at greater than average risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other neoplasia (e.g., squamous cell carcinoma, cutaneous lymphoma).
- Vaginal hyperplasia.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually unremarkable.
- Urinalysis (free-catch) reveals hematuria and abnormal cells in some patients if the tumor is within the urogenital tract.

OTHER LABORATORY TESTS

N/A

IMAGING

- Thoracic radiographs, although this tumor type is rarely metastatic.

- Abdominal ultrasonography to evaluate mesenteric lymph nodes.

DIAGNOSTIC PROCEDURES

- Careful palpation of regional lymph nodes, and perform aspirates with cytology when clinically indicated.
- Examination of impression smears or aspirates of the tumor reveals homogenous sheets of round to oval cells with prominent nucleoli, scant cytoplasm, and multiple clear cytoplasmic vacuoles.
- Biopsy offers definitive diagnosis.

TREATMENT

- May spontaneously regress, treatment is recommended as spontaneous remissions are not reliable.
- Surgical excision of tumors is often followed by recurrence.
- Radiotherapy alone may be curative.
- Medical therapy is often curative.

MEDICATIONS

DRUG(S)

- Vincristine sulfate (0.5–0.7 mg/m² IV once weekly for 2 weeks beyond complete resolution of gross disease).
- If only partial or no remission, doxorubicin (30 mg/m² IV every 3 weeks) may be tried.

CONTRAINdicATIONS/POSSIBLE

INTERACTIONS

- Myelosuppression secondary to vincristine or doxorubicin administration.
- Doxorubicin may be cardiotoxic, use with caution once a cumulative dose of 150 mg/m² is reached.
- Tissue sloughing if either vincristine or doxorubicin is administered perivascularly.
- Seek advice before initiating therapy if unfamiliar with cytotoxic drugs.

FOLLOW-UP

PATIENT MONITORING

CBC and platelet count before each chemotherapy treatment.

PREVENTION/AVOIDANCE

- Neuter animals
- Prevent animals from roaming free

POSSIBLE COMPLICATIONS

- Tumor recurrence possible following incomplete surgical excision or re-exposure.
- Metastatic disease uncommon, but reported to occur in regional lymph nodes, eye, and spinal cord.

EXPECTED COURSE AND PROGNOSIS

Most cases of TTVT have an excellent response to therapy (primarily chemotherapy or radiotherapy) and an excellent prognosis.

MISCELLANEOUS

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

- Pregnant animals should not be treated with chemotherapy.
- Animals may be infected with TTVT during coitus.

ABBREVIATION

TTVT = transmissible venereal tumor

TRAUMATIC MYOCARDITIS

BASICS

OVERVIEW

- Traumatic myocarditis is the term applied to the syndrome of arrhythmias that sometimes complicates blunt trauma; it is a misnomer, because myocardial lesions (if present) are more likely to take the form of necrosis than inflammation.
- Direct cardiac injury may not be necessary for development of post-traumatic arrhythmia; extracardiac factors are likely to be etiologically important.
- The prevalence of serious arrhythmias after blunt trauma is relatively low but some patients develop clinically important rhythm disturbances; therefore, the cardiac rhythm of all victims of trauma should be carefully assessed.
- Ventricular tachyarrhythmias occur in most affected patients; supraventricular arrhythmias and bradycardias are uncommon. Ventricular rhythms that complicate blunt trauma are often relatively slow and detected only during pauses in the sinus rhythm; they are most appropriately referred to as AIVRs. The QRS complexes are wide and bizarre; the rate is > 100 bpm but generally < 160 bpm. Usually, these rhythms are electrically and hemodynamically benign.
- Dangerous ventricular tachycardias can also complicate blunt trauma and can also evolve from seemingly benign AIVRs, compromising perfusion and placing the patient at risk for sudden death.

SIGNALMENT

Dog; rarely cat

SIGNS

Historical Findings

- Trauma, most often from road accidents.
- Arrhythmias often noticed within 48 hours of trauma.

Physical Examination Findings

- Arrhythmias may be inapparent if the rate of an AIVR closely matches the sinus rate.
- Rapid, irregular rhythms in some patients.
- Signs of poor peripheral perfusion (e.g., weakness, pale mucous membranes, and weak femoral pulses) in patients with rapid, poorly tolerated ventricular rhythms.

CAUSES & RISK FACTORS

- Blunt trauma • Hypoxia • Autonomic imbalance • Electrolyte derangements
- Acid-base disturbances

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- AIVRs should be differentiated from ventricular tachycardia. • AIVRs—usually

initiated by late diastolic ventricular (escape) complexes or fusion complexes; heart rate is generally 100–160 bpm. • Ventricular tachycardia—usually initiated by a ventricular premature complex; heart rates exceed 160 bpm.

CBC/BIOCHEMISTRY/URINALYSIS

- Creatine kinase, liver enzymes, and lactic dehydrogenase often high because of organ trauma.
- High serum troponin concentrations suggest myocardial necrosis.
- Electrolyte derangements (particularly hypokalemia and hypomagnesemia) predispose to ventricular arrhythmia.

OTHER LABORATORY TESTS

N/A

IMAGING

Thoracic Radiographic Findings

Evidence of trauma, including pneumothorax, rib fractures, and pulmonary contusion in some patients.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

Ventricular arrhythmias, as previously discussed

TREATMENT

- Treat extracardiac conditions, including pain, electrolyte derangements, and hypoxia, which can predispose to ventricular arrhythmia.
- Thoracic radiographs for all patients with blunt trauma; identify and remedy disorders such as pneumothorax.
- The need for antiarrhythmic therapy is predicated on clinical signs and the electrocardiographic character of the arrhythmia; pharmacologic suppression of AIVR is usually unnecessary.
- Fluid therapy for shock.

MEDICATIONS

DRUG(S)

- First treat rapid ventricular rhythms or those associated with hemodynamic compromise with lidocaine (2 mg/kg boluses IV); a total of 6–8 mg/kg can be administered over 10–12 minutes. Start a lidocaine infusion (25–75 µg/kg/minute) if there is conversion to sinus rhythm, or clinically relevant slowing of rate after lidocaine boluses.
- If lidocaine administration fails to effect conversion to sinus rhythm, try procainamide, or, with caution, beta-blockers such as esmolol or propranolol, or even class III agents such as sotalol.
- Consider DC conversion while animal is under anesthesia or heavy sedation, to treat rapid, hemodynamically unstable ventricular rhythms that do not respond to drug therapy.

• Antiarrhythmic agents are not necessarily benign; they can worsen existing arrhythmias and provide a substrate for development of new arrhythmias (proarrhythmia); carefully weigh the relative risk or benefit of every contemplated intervention.

- CONTRAINdications/POSSible INTERACTIONS**
N/A

FOLLOW-UP

- ECG monitoring of animals with arrhythmias is recommended; generally, the arrhythmias that complicate blunt trauma are self-limiting and resolve within 48–72 hours.
- If antiarrhythmic therapy is deemed necessary, it can often be discontinued after 2–5 days.
- Although dangerous arrhythmias occasionally complicate blunt trauma, the prognosis usually depends on the severity of extracardiac injury.

MISCELLANEOUS

SEE ALSO

- Idioventricular Rhythm • Shock, Cardiogenic • Ventricular Tachycardia

ABBREVIATIONS

- AIVR = accelerated idioventricular rhythm
- ECG = electrocardiogram

TREMORS

BASICS

DEFINITION

Rhythmic, oscillatory, involuntary, abnormal, or normal movement of all or part of the body.

PATHOPHYSIOLOGY

Abnormal or normal movement caused by the alternate or synchronous contraction of reciprocally innervated, antagonistic muscles.

SYSTEMS AFFECTED

- Nervous
- Endocrine/Metabolic
- Musculoskeletal—muscle weakness or pain
- Behavioral—fear

GENETICS

The role of genetics in tremor syndromes is largely unknown with the exception of X-linked hypomyelination in male springer spaniels.

INCIDENCE/PREVALENCE

N/A

SIGNALMENT

- Dog and cat
- In general, any dog or cat may develop tremors. However, certain tremor syndromes have specific signalment.
- Corticosteroid-responsive tremor syndrome (generalized tremor syndrome, white shaker syndrome)—small to medium-size breed (< 15 kg), young adult dogs (< 5 years), regardless of coat color. A similar syndrome has recently been observed in 2 cats.
- Idiopathic head tremors (head bobbing)—Doberman pinschers, English bulldogs, French bulldogs, Boxers, and Labrador retrievers are overrepresented.
- Orthostatic tremors—young, adult, giant-breed dogs.
- Benign pelvic limb tremors in older dogs: terriers predisposed.
- Hypomyelination—puppies; chow chows, springer spaniels, Samoyeds, Weimaraners, and Dalmatians.

SIGNS

- Localized or generalized
- Localized—most often involves the head or the pelvic limbs

CAUSES

Tremors Primarily Affecting the Head

- Cerebellar lesions leading to intention tremors—degenerative; congenital; metabolic; infectious; immune-mediated; neoplastic; traumatic; toxic causes; vascular.
- Idiopathic head tremors (head bobbing)—unknown cause.

Tremors Primarily Affecting the Limbs

- Orthostatic tremors—unknown cause. Seen in the thoracic and pelvic limbs of young, adult, giant-breed dogs. Tremors are present

when standing and disappear in ambulating and recumbent animals.

- Compressive lesions of the spinal cord or nerve roots—lumbosacral stenosis; intervertebral disc disease; neoplasia; discospondylitis.
- Neuromuscular disease—peripheral neuropathy; neuromuscular junction abnormality; myopathy.
- Metabolic disorder causing weakness—hypoglycemia, hypoadrenocorticism, hypocalcemia, magnesium imbalance. Metabolic causes of tremors may also present as generalized tremors.
- Benign pelvic limb tremors in older dogs—unknown cause.

Generalized Tremors

- Corticosteroid-responsive tremor syndrome (generalized tremor syndrome, white shaker syndrome)—believed to be immune-mediated.
- Hypomyelination: specific defect in myelin formation unknown.
- Intoxications—metaldehyde (snail bait); mycotoxins (penitrem A and roquefortine); organophosphates; hexachlorophene; bromethalin; ivermectin; moxidectin; pyrethrins/pyrethroids; lead; 5-fluorouracil; macadamia nuts; theobromine; anatoxin-a; marijuana; zolpidem; clozapine, dysautonomia (although toxin is suspected, exact toxin is unknown); castor beans (*Ricinus communis*); carbon monoxide; many others.
- Degenerative neurologic disease—storage disease; Lafora disease; spongiform encephalopathy.
- Behavioral: fear.
- Hypothermia.

RISK FACTORS

- Presence of concurrent metabolic diseases that can cause tremors (hypoglycemia, hypoadrenocorticism, hypocalcemia, magnesium imbalance).
- Exposure to a known tremorgenic toxin.
- Exposure to fear-producing or hypothermia-inducing situations.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differentiate tremor from constant repetitive myoclonus, seizures, and myokymia/neuromyotonia.
- Constant repetitive myoclonus—rhythmic contractions usually involving one or more pelvic limb muscles and/or muscles of mastication. Seen most often with distemper virus infection.
- Seizures—may be associated with autonomic disturbances (e.g., urination, defecation, and salivation) and alterations of consciousness.

- Myokymia/neuromyotonia—characteristic vermicular skin rippling caused by muscle contraction and often brought on by excitement or excessive stimulation.

Tremors Primarily Affecting the Head

- Assess for additional neurologic deficits suggesting cerebellar disease; intention tremors are a clinical sign of cerebellar disease; intention tremors worsen when the patient attempts to move the head in a goal-oriented manner; ataxia and dysmetria help determine the neuroanatomic diagnosis.
- Idiopathic head tremors (head bobbing)—patient usually young at onset; sporadic; up-and-down (yes) or side-to-side (no) direction; anatomic origin unknown; no other neurologic deficits present and mentation is not affected.

Tremors Primarily Affecting the Limbs

- Diseases of the lumbosacral spinal cord, cauda equina, and associated peripheral nerves; musculoskeletal diseases.
- Metabolic diseases (may also cause generalized tremors)—hypoglycemia, hypoadrenocorticism, hypocalcemia, magnesium imbalance.
- Neuromuscular disease—peripheral neuropathy; neuromuscular junction abnormality; myopathy.

Generalized Tremors

- Young dog (6–8 weeks)—congenital myelination abnormality; check breed incidences.
- Young adult dog—assess history for toxin exposure; consider corticosteroid-responsive tremor syndrome (generalized tremor syndrome, white shaker syndrome) in young, small-breed dogs.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal with associated primary brain disease.
- Assess for metabolic disease; may find hypoglycemia, hypocalcemia, magnesium imbalance, pattern consistent with hypoadrenocorticism.
- Some myopathies are characterized by high CK, AST, and ALT.

OTHER LABORATORY TESTS

If tremors are affecting the limbs and weakness is suspected, consider testing for hypoadrenocorticism (ACTH stimulation test) and myasthenia gravis (acetylcholine receptor antibody titer).

IMAGING

- Localized to the pelvic limbs—survey radiography, CT, and/or MRI of the vertebral column and spinal cord from L4 to S3.
- Generalized tremors—in hypomyelination, MRI may reveal lack of myelin; in corticosteroid-responsive tremor syndrome (generalized tremor syndrome, white shaker syndrome) MRI usually normal.
- Intention tremor—MRI of the brain, with special attention to the cerebellum.

TREMORS

(CONTINUED)

DIAGNOSTIC PROCEDURES

- CSF analysis—sensitive but nonspecific; in corticosteroid-responsive tremor syndrome (generalized tremor syndrome, white shaker syndrome) mild mononuclear pleocytosis, but CSF may also be normal; in other encephalitides involving the cerebellum, results vary with cause of disease and duration.
- Electromyography of hind limb muscles—may help diagnosing neuromuscular disease if pelvic limb tremor.

PATHOLOGIC FINDINGS

Dependent on underlying cause of tremor.

TREATMENT

- Treat the underlying primary disease.
- Outpatient, unless surgical treatment is indicated (lumbosacral disease that requires decompression and stabilization).
- Avoid excitement and exercise—may worsen many tremors.
- Degenerative neurologic diseases (e.g., storage disease, spongiform encephalopathy)—no treatment available.
- Hypomyelination—generally not treatable; some breeds improve with maturity (e.g., chow chows).
- Idiopathic head tremors (head bobbing)—no effective treatment available; benign tremor that occurs sporadically; has few health consequences.
- Suspected intoxication—remove patient from further exposure; consult with a poison control center for possible antidote.

MEDICATIONS

DRUG(S) OF CHOICE

- Usually do not respond to antiepileptic drugs (e.g. phenobarbital or diazepam).
- Tremors associated with some toxicities, especially metaldehyde (snail bait), may be treated with methocarbamol (dogs: 50–150 mg/kg IV, maximum dose 330 mg/kg in 24h) and appropriate decontamination.
- Corticosteroids—immunosuppressive dose to treat corticosteroid-responsive tremor

syndrome (generalized tremor syndrome, white shaker syndrome)

- Antibiotics—for discospondylitis; choose on the basis of culture and sensitivity of the lesion, blood, or urine.
- Cerebellar diseases—depends on the underlying etiology.
- Gabapentin—5–20 mg/kg up to q8h may be helpful in treatment of some tremors.

CONTRAINDICATIONS

Sympathomimetic drugs—may worsen condition.

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Monitor the primary disease
- Corticosteroid-responsive tremor syndrome (generalized tremor syndrome, white shaker syndrome)—monitor weekly initially to assess response to treatment.

PREVENTION/AVOIDANCE

Prevent re-exposure in the cases of toxicity.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Idiopathic head tremors (head bobbing)—excellent prognosis, no treatment needed.
- Orthostatic tremors—slowly progressive; disappear when patient ambulates or when patient is recumbent.
- Benign pelvic limb tremors in older dogs—can be slowly progressive; disappear when patient ambulates or when patient is recumbent.
- Hypomyelination—may stabilize and even improve as animal ages.
- Corticosteroid-responsive tremor syndrome (generalized tremor syndrome, white shaker syndrome)—most respond to corticosteroid therapy; some may need low-dose corticosteroid therapy indefinitely.

TRICHINOSIS

BASICS

OVERVIEW

- The life cycle of the nematode *Trichinella* is unusual—the intermediate host and the definitive host are the same animal.
- Adults infect the small intestine of a wide range of carnivores (including dogs and people) and omnivores (pigs, rodents), causing mild GI disease.
- Larvae—burrow into the intestine, gain access to the bloodstream, and encyst in skeletal muscle throughout the body.
- Encysted larvae are infective for the next host.
- Of major zoonotic importance—humans obtain infection by eating poorly cooked meat containing sequestered larvae from a wide range of animals (pigs, bears, seals, horses).
- Causes severe myositis and sometimes death in humans.
- In China—eating dog meat is an important source of trichinosis in humans.
- Worldwide distribution.

SIGNALMENT

- Hunting dogs (including those that fox hunt)—high rate of infection.
- Puppies—more susceptible to infection than older dogs.

SIGNS

- Mild GI upset—vomiting, diarrhea.
- Myalgia, muscle stiffness—mild and rarely observed.
- Cardiac infection can result in syncope due to conduction disturbances.
- Non-healing ulcerative skin lesion in a cat—rare.

CAUSES & RISK FACTORS

- Trichinella spiralis*—dogs and cats become infected by eating L1 larvae sequestered in the muscle of other animals. *Trichinella nativa*—reported to cause a non-healing ulcerative skin lesion in a cat.
- Sources of infection—wild-caught rodents or the carcasses of carnivores; dogs: foxes, opossum, raccoons, and wild pigs.
- L1 larvae—molt to adults in the small intestine.
- Adult worms—produce large numbers of “pre larvae,” which are injected into the intestinal mucosa.
- Pre larvae—migrate via lymphatics initially, then the bloodstream to skeletal muscles

where they coil up and develop to L1 in cyst-like structures.

- L1 larvae—remain infective in the muscle for months to years.
- Ingestion of large numbers of larvae—results in same degree of muscle sequestration as very small infections because most infecting larvae in large infections pass right through the GI tract without developing to adults.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of mild transient gastroenteritis—dietary indiscretion; early inflammatory bowel disease; drugs (antibiotics); parasites (giardiasis, trichomoniasis, whipworms); infectious agents; partial foreign body (hair balls in cats).

CBC/BIOCHEMISTRY/URINALYSIS

CBC—eosinophilia during acute stage of infection; may persist for several weeks in severe infections.

OTHER LABORATORY TESTS

- Identification of the small adults (female 3 mm, male 1.5 mm) in the feces—may require examination of feces collected over time.
- Adults and larvae in feces—distinguished from the larvae of *Crenosoma*, *Angiostrongylus*, and *Filaroides* by the stichosome esophagus (both adults and larvae), copulatory lobes (male), and presence of pre larvae within the uterus (female).
- May identify pre larvae in blood (100 µm as opposed to the ~300 µm of larvae of *Dirofilaria immitis* and *Dipetalonema reconditum*)—by modified Knot's technique.
- The meat industry has utilized squash preparations of tissue to search for encysted larvae.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Muscle biopsy—diagnostic method of choice; L1 larvae with characteristic stichosome esophagus in “cysts.”

TREATMENT

- No specific treatment required for GIT signs or myalgia.

- Albendazole—shown to significantly reduce muscle larval forms.
- Because of the efficacy of albendazole, fenbendazole is likely to be efficacious with no side effects.

MEDICATIONS

DRUG(S)

- Fenbendazole 50 mg/kg PO q24h for 10 days.
- Albendazole 50 mg/kg PO q12h for 7 days.

CONTRAINdications/POSSIBLE INTERACTIONS

Albendazole—has been shown to cause myelosuppression in cats and dogs at these doses.

FOLLOW-UP

If using albendazole—monitor CBC for signs of pancytopenia.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Trichinosis is common throughout the world. Human infection is associated with ingestion of undercooked pork, bear, and horse. Freezing of pork products for 20 days is typically adequate to kill *T. spiralis* in pork; however, this method may not be sufficient for species of *Trichinella* infecting bears and other wildlife.

ABBREVIATIONS

- GI = gastrointestinal
- GIT = gastrointestinal tract

TRICHOMONIASIS

BASICS

OVERVIEW

- Enteric pear-shaped motile flagellated protozoa similar to *Giardia*—inhabits the large intestine of cats. Similar organisms live in the intestinal tract of a variety of mammals.
- One species, *Tritrichomonas blagburni*, causes diarrhea in cats.
- Co-infection with *Giardia*—common.

SIGNALMENT

Young cats—usually under 1 year (range: 3 months–13 years). Catteries have a particularly high prevalence.

SIGNS

Cats

- Intermittent large bowel diarrhea.
- Diarrhea occasionally contains blood and mucus.
- Anus—may become edematous, erythematous, and painful in kittens.
- Rectal prolapse—if anal irritation becomes severe.
- Diarrhea—improves with antibiotic treatment but reoccurs when treatment stops.
- Median length of time of diarrhea is about 9 months, with resolution in most cats by 2 years.
- Persistence of infection after the resolution of diarrhea is common.

CAUSES & RISK FACTORS

- Tritrichomonas blagburni*—causes diarrhea in cats.
- T. blagburni*—high prevalence in catteries and show cats, but very low in feral or indoor cats.
- Pathogenic factors leading to infected cats developing diarrhea—endogenous bacterial flora, adherence of parasite to host epithelium, and cytotoxin and enzyme elaboration.
- Parasites colonize the terminal ileum, cecum, and colon—leads to large bowel diarrhea.
- Pentatrichomonas* spp. (family: Trichomonads)—inhabit the large intestine of cats, dogs, and humans. Non-pathogenic in dogs and cats—except very rarely when it may become an opportunistic pathogen.
- T. foetus*—causes infertility and abortion in cattle.

T

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Cats

Dietary indiscretion; inflammatory bowel disease; neoplasia (especially GI lymphoma); drugs (antibiotics); toxins (lead); parasites (cryptosporidiosis, *Giardia*, hookworms, roundworms); bacterial agents (salmonellosis, GI bacterial overgrowth, clostridia); systemic organ dysfunction (renal, hepatic, pancreatic, cardiac); metabolic (hyperthyroidism).

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal—may reflect diarrhea

OTHER LABORATORY TESTS

- Direct fecal smear—low sensitivity.
- Method—dilute fresh feces 50:50 in saline, cover slip, examine at 40X objective with condenser lowered to increase contrast.
- Distinguish from *Giardia* (concave ventral disc, spiral forward motion)—*T. blagburni* has jerky forward motion, spindle-shaped, undulating membranes.
- T. blagburni* trophozoites—are not seen on fecal flotation.
- T. blagburni* trophozoites—will not survive refrigeration.
- Fecal protozoal culture—use commercial media in a 37°C incubator (In Pouch TF, Biomed Diagnostics, San Jose, CA).
- Method—inoculate with 0.05 g of fresh feces, examine for motile trophozoites daily for 12 days.
- Giardia* and *P. hominis*—do not grow after 24 hours in In Pouch culture system.
- PCR—more sensitive than fecal culture in cats and commercially available.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Essential to rule out coexisting disease (cryptosporidiosis, giardiasis, bacterial), especially if diarrhea persists after specific treatment.

- Treatment may decrease the severity of diarrhea but may also cause prolongation of time to resolution of diarrhea.

MEDICATIONS

DRUG(S)

- P. hominis*—metronidazole (20 mg/kg, PO q12h for 7 days).
- T. blagburni*—All attempted drug treatment protocols to date have failed.

CONTRAINdications/POSSIBLE INTERACTIONS

- Glucocorticoids may exacerbate clinical disease.
- High doses of metronidazole (usually > 30 mg/kg) for extended periods may cause neurologic signs.

FOLLOW-UP

- Most cats spontaneously resolve their diarrhea but may take years (range: 4 months–2 years).
- Relapses of diarrhea are common and often precipitated by dietary changes, stress of travel, and treatments of other conditions.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Possible zoonotic transmission should be discussed with owner.

ABBREVIATIONS

- FIP = feline infectious peritonitis
- GI = gastrointestinal
- PCR = polymerase chain reaction

Suggested Reading

Stockdale HD, Dillon AR, Newton JC, et al. Experimental infection of cats (*Felis catus*) with *Tritrichomonas foetus* isolated from cattle. Vet Parasitol 2008, 154:156–161.

Consulting Editor Stephen C. Barr

TRIGEMINAL NEURITIS, IDIOPATHIC

BASICS

OVERVIEW

Sudden bilateral paralysis of trigeminal mandibular branches resulting in inability to close the mouth. Lesions are characterized by extensive nonsuppurative trigeminal neuritis, demyelination, and rare axonal degeneration affecting all portions of the trigeminal nerve and ganglion without brainstem involvement.

SIGNALMENT

- Primarily adult dogs
- Rare in cats

SIGNS

- Acute onset of a dropped jaw.
- Inability to close the mouth.
- Drooling.
- Difficulty in prehending food, messy eating.
- Swallowing is intact when food and water are placed in the caudal portion of the mouth.
- Approximately one-third of affected dogs will exhibit decreased facial sensation.
- Few dogs have sympathetic involvement of the head (Horner's syndrome).
- Long-term muscle atrophy depending on degree of axonal involvement.

CAUSES & RISK FACTORS

Unknown; auto-immune disorder suspected

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Musculoskeletal disorders of the temporomandibular joints and jaw—differentiated by history of trauma, pain, and physical examination findings.
- Rabies—always initially consider until there is sufficient evidence to rule it out.
- Encephalitis involving the motor nuclei of bilateral trigeminal nerve.

- Neoplasia—involve both mandibular nerves with myelomonocytic leukemia, lymphoma, and neurofibrosarcoma reported; usually does not have an acute onset.
- Masticatory muscle myositis—presentation excludes this condition characterized by trismus and difficulty/inability to open the mouth (“locked jaw”).

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

IMAGING

MRI—diffuse enlargement of affected nerves that appear isointense to hyperintense on T2 weighted images if edema is present; contrast enhancement on post-contrast T1-weighted images.

DIAGNOSTIC PROCEDURES

- No specific test.
- Skull radiography, MRI, CSF, and muscle biopsy—to rule out differentials.

TREATMENT

- Recovery within 2–3 weeks of onset. Supportive treatment necessary during this period.
- Outpatient if owner is able to help the patient eat and drink.
- Patient cannot prehend or move food and water to the throat but can swallow if the bolus is placed in the caudal portion of the mouth and the jaw is manually held closed. Water and slurry food can also be placed, with a syringe, in the corner of mouth with the head slightly elevated.
- Fluids—subcutaneously if oral support insufficient.
- Esophagostomy or gastrostomy tubes—rarely necessary to maintain adequate food intake.

MEDICATIONS

DRUG(S)

Corticosteroids not indicated as there is no evidence that they improve recovery. Furthermore, side effects (polyuria and polydipsia) can make management difficult.

FOLLOW-UP

- Self-limiting disorder.
- Full recovery in 2–3 weeks.
- Bilateral symmetrical masticatory muscle atrophy but without trismus.

MISCELLANEOUS

SYNONYMS

- Dropped jaw
- Trigeminal neuropathy
- Mandibular paralysis

ABBREVIATIONS

- CSF = cerebrospinal fluid
- MRI = magnetic resonance imaging

TULAREMIA

BASICS

OVERVIEW

- *Francisella tularensis*—small Gram-negative coccobacillus; type A, more virulent, found in rabbits and ticks; type B, waterborne, found in rodents and ticks; in North America principally found in wild lagomorphs (cottontail, jack, snowshoe) and rodents (moles, squirrels, muskrats, beavers); facultative intracellular parasite; survives and grows in liver-producing granulomas and/or abscesses.
- Peak occurrence—late spring; June—August; December.
- Northern hemisphere—absent from United Kingdom, Africa, South America, Australia; in United States most cases found in Missouri, Alaska, Oklahoma, South Dakota, Tennessee, Kansas, Colorado, Illinois, Utah, and Maine. Cases occurring in wildlife in Gateway National Recreation Area in New York City and New Jersey.
- Increasing number of tularemia outbreaks in regions of Europe outside the classic endemic areas in recent years has prompted renewed interest in this rare infectious disease.
- Infection—ingestion of tissue or body fluids of an infected mammal or contaminated water; bitten by blood-sucking arthropod (tick), flies, mites, midges, fleas, or mosquitoes; few bacteria needed to infect cats through skin, airways, or conjunctiva; larger number required to infect through the gastrointestinal tract.
- Skin contact—organism multiplies locally (papule) 3–5 days after contact; ulcerates 2–4 days later; spreads via lymphatics to regional LN and bloodstream; results in septicemia (lung, liver, spleen, LN, bone marrow).
- Ingestion—may involve lymphadenopathy of cervical and mesenteric LN followed by septicemic spread; distribution of lesions to face, oral cavity, tonsils, intestines, and LN.
- Acute disease—2–7 days after contact with organism.
- Tularemia has a high aerosol-related infection rate, low infectious dose, and the ability to induce fatal disease.
- *F. tularensis* is considered a potential biologic warfare agent; occurrence of a cluster of pneumonia cases in companion animals may indicate animals as sentinels and the potential risk for human disease.

T

SIGNALMENT

- Cat—occasionally
- Dog—rarely (dogs in oral contact with diseased wildlife or carcasses may act as “living fomites” to contaminate in-contact humans).

SIGNS

- Sudden onset of anorexia, lethargy, fever (40–41°C; 104–106°F).

- Enlarged palpable submandibular and cervical LN.
- Tender abdomen, palpable mesenteric LN, hepatomegaly—depending on stage of disease.
- Multifocal white patches or ulcers along glossopalatine arches and tongue.
- Icterus.

CAUSES & RISK FACTORS

- Organism—all *Francisella* biogroups may infect cats but may differ in virulence; some cats may have mild infection.
- Hunter or outdoor cats in endemic areas.
- Infected wildlife in the area of hunting activity.
- Exposure to infected blood-sucking parasites.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Any acute disease state manifested by acute lymphadenopathy, malaise, oral ulceration, and fatal outcome—consider tularemia.
- Pseudotuberculosis (*Yersinia pseudotuberculosis*)—usually vomiting and diarrhea.
- Babesiosis, Babesia, Theileria, in dogs and cats.
- Calicivirus in cats.
- Feline immunodeficiency virus.
- Toxoplasmosis, in cats

CBC/BIOCHEMISTRY/URINALYSIS

- Initially severe panleukopenia; then leukocytosis with left shift, toxic neutrophils, thrombocytopenia.
- Hyperbilirubinemia.
- Hyponatremia.
- Hypoglycemia.
- Alanine aminotransferase—elevated.
- Bilirubinuria.
- Hematuria.

OTHER LABORATORY TESTS

Serology with tube agglutination or ELISA—possible; difficult to perform except in reference laboratory; all animals do not necessarily respond serologically to infection.

DIAGNOSTIC PROCEDURES

- Direct smear—lesion or biopsy; difficult to see organism on Gram staining.
- Cultural isolation—by reference laboratory only; blood, pleural fluid, LN aspirate onto cysteine- or cystine-containing media; not recoverable on routine laboratory media; bacteria do not need CO₂ for growth.
- **Caution:** use extreme care when working with infected specimens or isolates due to low infectious dose.
- Direct fluorescent antibody testing—clinical materials or tissues; rapid assay of infection status.
- Molecular testing of tissues in laboratories having validated diagnostic protocols.

PATHOLOGIC FINDINGS

- Multifocal white patches or ulcers along glossopalatine arches and tongue.
- Oral, tonsillar ulceration.
- Lymphadenopathy of cervical, retropharyngeal, or submandibular LN with abscessation.
- Diffuse intestinal lesions.
- Mesenteric lymphadenopathy, hepatosplenomegaly, and icterus.

TREATMENT

- Inpatient with good nursing care; infection control protocols VERY important due to low infectious dose/zoonotic nature of disease.
- Early treatment important to prevent high mortality; treatment often unsuccessful.
- Treat for ectoparasites.

MEDICATIONS

DRUG(S)

Treat all cases empirically until laboratory confirmation obtained.

Cats

- Little information available on the efficacy of antimicrobials **because of high mortality if patient not treated early.**
- Early treatment with amoxicillin (20 mg/kg PO q8h for 5–7 days or 20 mg/kg IM or SC q12h for 5 days) in combination with gentamicin (4.4 mg/kg IM or SC q12h once and then q24h thereafter until a clinical response or until 7 days) has been successful.
- Fluoroquinolones are showing promise as a potential new treatment drug (ciprofloxacin).

FOLLOW-UP

PATIENT MONITORING

Monitor for DIC—may occur late in the infection

PREVENTION/AVOIDANCE

- Travel with pet—avoid endemic areas.
- Endemic areas—confine animals to control exposure to and ingestion of wildlife and their ectoparasites (ticks); ectoparasite control by periodic spraying or dusting of animal and pastures.
- Neuter cats—limit hunting behavior and wildlife exposure.
- Take precautions to limit contamination of food and water with carcasses of infected wildlife.

EXPECTED COURSE AND PROGNOSIS

Prognosis poor if not treated early; prognosis poor if mesenteric LN palpable.

(CONTINUED)

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

- Extremely high.
- All personnel in contact with patient or body fluids must use face mask, gloves, and gowns to avoid infection.
- Isolate patients.
- In emerging disease areas, cat ownership is a disease risk for humans.
- Bites and scratches pose a risk for humans.
- Do not mistake for bite abscess in cats or Plague.

SYNONYMS

- Rabbit fever
- Deerfly fever
- Market men's disease

ABBREVIATIONS

- DIC = disseminated intravascular coagulation
- ELISA = enzyme-linked immunosorbent assay
- LN = lymph node(s)

TYZZER DISEASE

BASICS

OVERVIEW

- *Clostridium piliformis* (formerly *Bacillus piliformis*)—Gram-negative bacterium; 0.5 × 10–40 µm in size; an obligate intracellular pathogen.
- Infection—organism thought to initially proliferate in intestinal epithelial cells; spreads to the liver via the hepatic portal vein; hepatic colonization associated with multifocal periportal hepatic necrosis; occasional spread to other organs (focal myocarditis, enteric lymphadenitis).

SIGNALMENT

- Dogs and cats
- Any age; young at higher risk

SIGNS

- Rapid onset of lethargy, depression, anorexia, abdominal discomfort, hepatomegaly, and abdominal distention; followed by hypothermia. Death—within 24–48 hours.
- Fecal matter—diarrhea infrequent; small amounts of pasty feces more common.

CAUSES & RISK FACTORS

- *C. piliformis*.
- Contact with rodents—may be a risk factor.
- Neonates and immunocompromised animals (e.g., distemper, FeLV, feline panleukopenia, familial hyperlipoproteinemia)—seem to be at greatest risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diagnosis usually made at necropsy—rapid and highly fatal disease diagnosis.

- Distinguished from other causes of sudden death and acute hepatitis.
- Other causes of acute enterocolitis in kittens.

CBC/BIOCHEMISTRY/URINALYSIS

ALT—marked elevations in blood samples taken shortly before death.

OTHER LABORATORY TESTS

- Serology—identify latent infections in rodent colonies; could be used to investigate illness in dogs and cats.
- Isolation of organism—requires inoculation of mice, embryonating eggs, or cell culture.
- Immunocytochemistry and PCR of affected tissues.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Gross

- Multifocal whitish-gray to hemorrhagic foci throughout the liver; may also occur in other viscera.
- Focal myocarditis thickening and congestion of the intestine mesenteric lymphadenopathy—reported.
- Widely disseminated lesions, including severe myocarditis, hepatitis, enterocolitis, intestinal leiomyositis, and adrenal cortical adenitis, have been reported in a dog.

Histologic

- Multifocal hepatic necrosis.
- Necrotic ileitis or colitis.
- Intracellular filamentous organisms—usually numerous; difficult to visualize with H&E; require silver stains (e.g., modified Steiner or Warthin-Starry).

TREATMENT

None effective

MEDICATIONS

DRUG(S)

UNRULY BEHAVIORS: JUMPING, PULLING, CHASING, STEALING—DOGS

BASICS

DEFINITION

- Jumping—standing on rear legs with front legs on a person or object or leaping in the air with or without landing against the person.
- Pulling—to exert force on the leash to cause motion towards the source of the force (the dog).
- Chasing—pursuing a moving person, animal, or object.
- Stealing—the taking of an item not intended to be used by the dog.

PATOPHYSIOLOGY

- All are within the range of normal dog behaviors.
- Insufficient outlets for normal activities may contribute.
- Jumping up as part of excessive greeting can be associated with separation anxiety or social anxiety.
- Pulling can be associated with different motivational states including but not limited to fear, anxiety, excitement, and predatory behavior.
- Pathologic hyperactivity disorders may be a contributing factor in rare cases.

SYSTEMS AFFECTED

- Behavioral
- Gastrointestinal

SIGNALMENT

Species

Dogs

Breed Predilection

Herding and hunting breeds may be more likely to chase.

Mean Age and Range

More common in younger dogs but occurs at any age.

SIGNS

Historical Findings

- Jumping up on people occurs more commonly in association with arrivals or departures or greeting at other times; it is also associated with exploring the contents of countertops or tables.
- Pulling may be more likely in the beginning of a walk or when seeing, hearing or perhaps smelling a stimulus (e.g., person, other dog, or object of interest) but can occur at any point.
- Items displaced, chewed or ingested are common complaints in stealing.

Physical Examination Findings

- Usually unremarkable unless underlying medical problems.
- Nails worn down.

CAUSES

- Jumping up is normal greeting and play behavior. Excitement, encouragement of the behavior, or inadvertent rewarding of the behavior perpetuates it. Separation anxiety may result in excessive jumping on owners when returning home or leaving. Social anxiety may cause overly exuberant greeting of visitors, with jumping.
- Pulling can occur when a dog is not taught how to walk on leash

or in the presence of different motivational states. A dog may pull towards or away from something it is afraid of or excited/anxious about.

- Stealing is a normal acquisitive behavior. It can be an attention-seeking behavior or motivated by the appeal of the odor, texture or taste of an item with which to chew, eat or play. Stealing can occasionally be related to separation anxiety, in which the dog may steal an item when anxious as the owner is preparing to leave or when the dog is separated from the owner but the owner is still in the house.
- Chasing is a normal behavior, as part of herding, hunting, play, and defense.

RISK FACTORS

- Inadequate exercise.
- Under-stimulation.
- Stealing food—restricted or weight-reduction diets, phenobarbital, benzodiazepines, glucocorticoids, hyperadrenocorticism, and diabetes mellitus.
- Chasing—common in herding breeds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Stealing

- Separation anxiety—escapes or attempts escape from confined areas in the owner's absence. Often occurs at entrances and in crates. Usually associated with other signs consistent with separation anxiety, including vocalization, urination, defecation, destruction, or salivation, in the owner's absence.
- Other anxiety or phobia (e.g., thunderstorm, fireworks).

CBC/BIOCHEMISTRY/URINALYSIS

- Usually unremarkable.
- May have abnormalities consistent with system affected.

OTHER LABORATORY TESTS

As indicated to rule out source of pain or endocrine or neurologic disease (LDDST, UC:Cr, bile acids, CSF analysis).

IMAGING

Radiographs, ultrasound, MRI, or CT scan if indicated by physical/neurologic exam findings.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient management

ACTIVITY

Increase the dog's daily exercise, opportunities for mental stimulation.

DIET

Review energy requirements in food-stealing cases.

CLIENT EDUCATION

Jumping

- During training, prevention of jumping-up behavior is essential.
- A head collar and leash facilitate training to gently guide the dog away from jumping.
- Train sit for all interactions (doggy please) so that a calm sit becomes the default behavior for anything of value.
- Greeting visitors outside might diminish jumping behavior. The dog's access to the situation can be restricted by confinement (e.g., other room, crate) until the visitor is seated. In some dogs this may also reduce the arousal associated with jumping up.
- Teach "Sit" and "Stay" as an alternative method to greet people, beginning with highly valued rewards (food treats, toys) in areas of the home where the dog is calm and tractable.
- Food rewards should be used consistently initially.
- Add the word "Stay" when the duration of sitting is a few seconds; take a step away, return to the dog, and give the food reward. Build up the time away from the dog to 3–5 minutes.
- Repeat exercises near the door and then with the addition of leaving and returning.
- Next ask the dog to sit for a food reward when returning from gradually longer absences.
- Familiar visitors can enter, ask the dog to sit, and give a food reward.
- Eventually the food rewards can be reduced to intermittent but frequent use.
- Dogs that like to retrieve and are too excited to sit may do better if a ball is tossed as a visitor enters. This may be particularly effective if the dog is taught to sit prior to an item being tossed.
- The owner should walk calmly to the door and speak in a quiet voice to avoid increasing the dog's excitement.
- People should avoid rewarding the jumping with any form of attention including pushing the dog off. Do not acknowledge or interact with the dog; hold arms against the body and turn body away from the dog. Some dogs will stop jumping and ignore the person, at which point they can say sit and reward if successful.
- Stepping on the dog's toes, squeezing the paws, and other punishment are usually ineffective and can lead to fear and aggression, therefore should be avoided.

Pulling

- A dog's natural walking speed may be faster than their owner's.
- A no-pull harness or head collar can be helpful and may be all that is needed.
- A brief play session in a fenced in yard before a walk, may decrease initial energy and decrease pulling (although some dogs get more aroused immediately after exercise).
- Pulling related to fear, anxiety, or excitement requires desensitization (gradual exposure) and counter-conditioning (teaching a different response) to the stimulus as discussed under chasing below.
- With proper application of positive reinforcement pulling can be resolved.
- One method is to use a

UNRULY BEHAVIORS: JUMPING, PULLING, CHASING, STEALING—DOGS

food lure to reward the dog for walking next to a person. Have highly desirable small treats in the hand on the same side as the dog; initially give every few seconds. If the dog pulls ahead, stop, call the dog's name and/or ask it to "Look" (see chasing), reward the behavior and resume walking. Over time decrease the frequency of giving the treat until it is every minute or two. Many dogs learn to come to the owner for a treat when they learn the "Look" command. • A second method is to stop walking as soon as the dog starts to pull. When the dog stops moving call the dog's name and/or ask it to "Look" and reward the behavior and continue walking when the leash is slack. If the dog pulls again repeat the process. • Other methods involve leash corrections which are a form of punishment with the intent of reducing undesirable behaviors rather than training what is desirable. Sharp jerking on the leash or turning suddenly may cause fear, pain, discomfort, and injury to the neck and trachea.

Chasing

• A no-pull harness or head collar can be helpful in controlling the dog and reorienting it toward the owners, in the presence of the chase stimulus. Herding breeds exhibit a phenotypic behavior that may respond better to control and management than to treatment. • Dogs that chase need to be desensitized and counter-conditioned to the stimulus. • The owner should practice the same sit-and-stay exercises as described above, with the addition of a "Look" command using a treat brought up to the owner's eye. This will help get the dog's attention and focus it on the owner when it sees the moving stimulus. • Initially work with the dog inside without distractions, to train, sit, stay, and look. • Next work in a quiet yard with the dog on a leash, have the dog sit, stay, step away, return, look, and give the food reward. When the dog is successful, the process can be repeated in different parts of the yard with gradually more intense distractions. • Training should begin without the chase stimulus present. If the owner is able to keep the dog's attention, the owner should then stage the chase stimulus (such as a bike or person jogging) to pass by at a sufficient distance and slow enough speed while training and rewarding sit, stay and look. Over future sessions, the intensity of the stimulus can be gradually increased. • When the dog is able to ignore the chase stimulus in the yard, the owner can incorporate the same exercises in a park or on a walk while maintaining sufficient distance from the stimuli. When the owner sees the chase stimulus, he or she should ask the dog to sit, stay, and look, and then reward the dog.

Stealing

- The dog's investigative behavior and attempts to initiate play and chase may result in stealing. If the result is enjoyable the behavior is rewarded. • Adequate attention, exercise, and toys before times of inattention (e.g., making dinner, working, watching TV) will help to decrease the motivation for stealing. • If the dog steals, the owners should ignore the dog, walk away, get a treat, and call the dog. As the dog drops the item, the owner can say "Drop," "Good dog," and give the dog the treat or click and treat if the dog is clicker trained. The dog is being rewarded for relinquishing the item. • The owner might also need to use a stay and give a second treat or a chew toy to be able to retrieve the dropped item. Another option is to scatter a number of treats for the dog to pick up while the item is removed. • If the dog retreats under furniture, the owner should not pursue. If the dog feels threatened or cornered, it may defend itself aggressively. If it is imperative that the item be retrieved, the client may need to lure the dog out of hiding with even higher-value treats or offer a walk or favored game. The owner should keep a log of when and what the dog steals, where they were at the time, and what they were doing to determine when and why the dog is stealing and whether it might be due to separation anxiety. In addition, the owners should video record the dog to see its response during their absence. See separation anxiety for more details. • For food stealing, food needs to be kept out of the dog's reach, since acquiring food is highly rewarding. Confinement training or gating the dog out of food preparation and dining areas may be necessary. • Products that deter with mild aversion such as motion-activated alarms or sprays can help correct the stealing behavior. If the dog steals food because it is on a diet, a protein source such as plain cooked chicken or other meat or low-calorie foods such as raw or cooked vegetables can be added to help increase the feeling of fullness.

MEDICATIONS

DRUG(S) OF CHOICE

None

FOLLOW-UP

PATIENT MONITORING

Every 2–3 weeks initially.

PREVENTION/AVOIDANCE

Close supervision, exercise, and exposure to varied stimuli as a young puppy and attending puppy classes and ongoing training can help to prevent and manage unruly behaviors.

POSSIBLE COMPLICATIONS

Injury as a result of escaping a fence, chasing a stimulus, or ingesting an inappropriate item.

EXPECTED COURSE AND PROGNOSIS

Generally good response to treatment for jumping, pulling, and stealing if the owner is consistent. Guidance and support of a force-free reward-based trainer may help to improve success. Chasing behaviors may be more difficult and resistant.

MISCELLANEOUS

AGE-RELATED FACTORS

Younger dogs need more activity than many owners anticipate.

SEE ALSO

BASICS

OVERVIEW

Occurrence of a urolith (calculus) within the lumen of a ureter (ureterolith); most ureteroliths originate in the renal pelvis and so commonly occur in association with nephroliths. If the uroliths pass through the ureters into the lower urinary tract, a dog or cat may be asymptomatic or may have silent hematuria. If both ureters become totally obstructed in an otherwise healthy untreated dog or cat, death will occur in approximately 4 or 5 days.

SIGNALMENT

- Dog and cat.
- Breed, age, and sex predispositions vary with type of nephrolith.

SIGNS

- May be initially asymptomatic.
- Pain (ureteral colic) during passage of ureteroliths or following acute ureteral obstruction.
- Renomegaly if ureteral obstruction leads to hydronephrosis.
- “Big kidney, little kidney syndrome” is being recognized with increasing frequency in cats in which obstruction of one ureter has previously occurred, resulting in a shrunken end-stage kidney; signs of renal failure and hydronephrosis occur due to obstruction of the remaining functional kidney.
- Unilateral ureteral obstruction results in azotemia and uremic clinical signs only when the function of the contralateral kidney is compromised.
- Signs referable to a lower urinary tract infection or septicemia may be present concurrently with ureterolithiasis.
- Ureteral rupture may occur, resulting in urine accumulation in the retroperitoneal space.
- Cats with distal ureteral obstruction may have signs of dysuria and pollakiuria.

CAUSES & RISK FACTORS

- For a list of causes, see chapters on each urolith type.
- Most ureteroliths in dogs and cats are composed of calcium oxalate. Dogs may form struvite nephroliths and subsequent ureteroliths from infection with urease-producing bacteria. Cats may have ureteroliths composed of dried solidified blood clots.
- Circumcaval ureters (more commonly in right ureter) appear to predispose cats to obstruction of the ureter by ureteroliths and secondary ureteral stricture formation.
- Prior treatment of nephroliths by extracorporeal shock wave lithotripsy, medical dissolution, or surgery to remove nephroliths may be additional risk factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Consider in all cases of renal failure unilateral or bilateral renomegaly, abdominal pain, or fluid accumulation in the retroperitoneal space. Obstruction to urine outflow to both kidneys will not produce the same magnitude of renomegaly as unilateral obstruction because the patient will perish as a result of bilateral disease before the changes in the kidneys occur.
- Radiopacities detected by survey abdominal radiography that may be confused with ureteroliths include particulate fecal material in the colon, mammary gland nipples, peritoneoliths, calcified lymph nodes, and mineralization of the renal pelvis.
- Radiolucent ureteroliths may be difficult to differentiate from ureteral blood clots. Other causes of ureteral obstruction include intraluminal tumors, ureteroceles, ureteral strictures (secondary to ureteroliths, circumcaval ureter, prior surgery or trauma), and extraluminal compression. Hydroureter and hydronephrosis may occur because of ureteral ectopia, pyelonephritis, and obstruction of the ureteral opening at the trigone (most commonly due to transitional cell carcinoma of the bladder).

CBC/BIOCHEMISTRY/URINALYSIS

These tests evaluate renal function and screen for concurrent disease before the ionized treatment of ureterolithiasis. Urinalysis, serum calcium concentration, and fractional excretion of electrolytes may permit estimation of urolith composition pending results of definitive analysis.

OTHER LABORATORY TESTS

- Submit all retrieved ureteroliths for quantitative analysis to determine appropriate preventive strategies.
- Patients (other than Dalmatians and bulldogs) with urate stones should be evaluated for portosystemic shunts.
- Blood pressure should be monitored since hypertension is common with CKD secondary to ureteral obstruction.

IMAGING

- Radiography—radiopaque ureteroliths may be visualized. If obstruction and hydronephrosis have occurred, renomegaly may be apparent. If ureteral rupture occurs, contrast in the retroperitoneal space may be lost. Small uroliths may not be visualized on radiographs even if they are radiopaque.
- Contrast radiography—when ureteroliths are suspected, but cannot be documented, an intravenous urogram may help to identify the site of obstruction and will also distinguish ureteral rupture from retroperitoneal hemorrhage. In many instances the damaged tubules do not concentrate contrast media

URETEROLITHIASIS

adequately, resulting in poor delineation of the ureter. Intraoperative nephropelvocentesis is performed during surgical placement of SUB or ureteral stents in cats, allowing for confirmation as part of the surgical correction.

- Ultrasonography—valuable for detecting hydronephrosis or hydroureter. Changes suggesting pyelonephritis may also be detected by ultrasound. The dilated proximal ureter may be traced to the ureterolith and thus allow ultrasonographic confirmation. Ureteroliths are not observed ultrasonographically in approximately 25% of cats with ureteroliths.

- Computed tomography before and after IV contrast can be used to confirm obstructive ureteroliths if they are suspected but not confirmed by other imaging modalities.

DIAGNOSTIC PROCEDURES

- Nuclear scintigraphy alone should not be used to determine whether or not to preserve or surgically remove a kidney.
- Voiding urohydropropulsion may be performed to retrieve ureteroliths that have spontaneously passed into the bladder.

PATHOLOGIC FINDINGS

Gross changes in the kidney—progressive dilation of the pelvis and calyces; in advanced cases, the kidney may be transformed into a thin-walled sac with only a thin shell of atrophic cortical parenchyma; ureteral dilation proximal to the site of obstruction is typical.

TREATMENT

- Remove or bypass ureteroliths that are causing obstruction (i.e., causing hydronephrosis or hydroureter) or that have not moved on sequential radiographs.
- Ureteroliths in dogs have been successfully treated with ESWL. Calcium oxalate uroliths from cats are intrinsically resistant to fragmentation via shockwave lithotripsy and this mode of therapy has been less successful in this species.
- Surgical techniques recommended for removal of ureteroliths vary, depending on the site of obstruction, the presence or absence of infection, and the degree of function of the associated kidney. SUB is effective for relief of ureteral obstruction in cats and is often the preferred surgical procedure for cats.
- Ureteroneocystotomy may be performed for ureteroliths in the middle and distal ureter: the ureter proximal to the obstruction is excised and reimplanted into the bladder. Ureteroliths in the proximal ureter may be removed by ureterotomy. Performance of a ureterotomy or ureteroneocystotomy in cats requires experience in microsurgical techniques. When the contralateral kidney functions normally and severe end-stage hydronephrosis is present in the affected

URETEROLITHIASIS

(CONTINUED)

kidney, ureteronephrectomy may be appropriate.

- Ureteral stent placement to bypass obstructive ureteroliths relieves the obstruction and causes passive ureteral dilation. Ureteral stents may be placed surgically in dogs and cats or through cystoscopy in female dogs.

MEDICATIONS

DRUG(S)

- Medical dissolution is largely ineffective for ureteroliths.
- Therapy aimed at prevention of recurrent disease is imperative following relief of obstruction.
- For ureteroliths that are not causing severe obstruction or severe renal functional problems, allowing time for the ureterolith to spontaneously pass down the ureter to the bladder may eliminate the need for ureteral surgery.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Attempts to prevent one type of urolith may promote formation of a second type.

FOLLOW-UP

PATIENT MONITORING

- Following SUB placement, sampling the SUB for urinalysis and culture along with flushing the SUB under ultrasonographic monitoring is recommended every 3 months.
- Following successful removal of ureteroliths, recheck every 3–6 months for recurrence of uroliths and to ensure owner compliance with preventive measures; urinalysis, radiographs (or ultrasound), and a urine culture are usually appropriate.

PREVENTION/AVOIDANCE

- Elimination of factors predisposing to the development of urolithiasis.
- Specific therapy depends on the mineral composition of the urolith.

POSSIBLE COMPLICATIONS

Hydronephrosis, CKD, recurrent urinary tract infection, pyelonephritis, sepsis, ureteral rupture, ureteral stricture, hypertension.

EXPECTED COURSE AND PROGNOSIS

Highly variable; if unilateral disease is present, the opposite kidney retains adequate

function, and recurrence is prevented, the prognosis is good. Prognosis is good for cats with SUB or ureteral stent placement that recover renal function to stage 1–2 CKD.

MISCELLANEOUS

ABBREVIATIONS

- CKD = chronic kidney disease
- ESWL = extracorporeal shock wave lithotripsy
- SUB = subcutaneous ureteral bypass

Acknowledgment The author and editors acknowledge the prior contribution of Harriet M. Syme.

BASICS

OVERVIEW

- Occurs when the mucosal lining of the distal portion of the urethra prolapses through the external urethral orifice.
- Systems affected include urinary, reproductive (bleeding may only occur during penile erection), and hemic/lymph/immune (blood loss can be severe enough to cause anemia, especially in smaller breeds of dogs).
- Prolapsed urethras often appear as a congested, pea-shaped mass protruding from the distal end of the penis. They often are associated with varying degrees of hemorrhage. Excessive licking may result in further traumatic damage to the exposed urethral mucosa.

SIGNALMENT

- Dog, cat (rare).
- Most common in English bulldog, Boston terrier, and Yorkshire terrier.
- Mean age, 18 months; range, 4 months–5 years.
- Reported in male dogs and extremely rare in male cats.

SIGNS

- Intermittent or persistent bleeding from the urethra independent of urination.
- Intermittent or persistent licking of the penis.
- Dysuria and pollakiuria caused by concomitant disorders may also be present.

Physical Examination Findings

- Red to purple, pea-sized, doughnut-shaped mass protruding from the distal end of the penis.
- Pale mucous membranes if bleeding is severe.
- Necrosis of the prolapsed urethra may occur secondary to drying or self-induced trauma from licking.
- Uroliths may be palpable in the urinary bladder or urethra.

CAUSES & RISK FACTORS

- May result from sexual excitement and/or unrelated disorders (e.g., infections, uroliths, neoplasia) of the lower urinary tract.
- Increased intra-abdominal pressure secondary to dysuria associated with urocystoliths may be a predisposing factor.
- Other proposed causes include abnormal development of the urethra with superimposed increased intra-abdominal pressure as a consequence of brachycephalic airway syndrome, dysuria, or sexual activity. This increased intra-abdominal pressure could impair venous return of blood through the pudendal veins, predisposing susceptible dogs to engorgement of the corpus spongiosum surrounding the distal urethra.
- Breed predisposition (bulldogs and Boston terriers).

• Abnormal urethral anatomy associated with increased intra-abdominal pressure secondary to upper airway obstructive syndrome, any cause of persistent dysuria, and/or sexual excitement may be risk factors. Increased intra-abdominal pressure could impair venous return of blood through the pudendal veins, predisposing susceptible dogs to engorgement of the corpus spongiosum surrounding the distal urethra.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Prostatic disease
- Persistent penile frenulum
- Fractures of the os penis
- Balanoposthitis
- Urethritis
- Testicular disease
- Urethroliths
- Coagulopathy
- Urethral neoplasia

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—may reveal regenerative anemia.
- Serum biochemistries—usually normal.
- May not detect significant hematuria in urine collected by cystocentesis, but a voided urine sample may reveal hematuria.
- Urine culture and sensitivity.

OTHER LABORATORY TESTS

Coagulation profile may rule out coagulopathy.

IMAGING

- Survey abdominal radiographs—useful to rule out radiodense uroliths and to evaluate the prostate gland.
- Double-contrast cystography and positive-contrast urethrography—useful to rule out radiolucent uroliths, other urethral disorders, and prostatic disease.
- Abdominal ultrasonography—useful to further evaluate the prostate and urinary bladder.

DIAGNOSTIC PROCEDURES

- Ejaculation—useful to evaluate urethra during penile erection; some urethral prolapses are present only during penile erection.
- Evaluation of ejaculates may also facilitate evaluation of prostatic fluid for evidence of prostatic disease.

TREATMENT

- May not be required if prolapsed urethra is asymptomatic or only associated with episodic bleeding.
- If prolapsed urethra is present only during penile erection, consider castration prior to attempting surgical removal of prolapsed

URETHRAL PROLAPSE

tissue; diethylstilbestrol given for 3–6 weeks after surgery may reduce frequency of erections. If cause is unknown, a recent retrospective study found castration status did not affect prolapse development or outcome.

- Consider surgery for patients with excessive bleeding, pain, or extensive ulceration and/or necrosis of the prolapsed tissue. Also consider surgery if troublesome relapses are associated with medical management.

• Satisfactory results have been obtained by manual reduction of the prolapse followed by urethropexy using a grooved director instrument that reduces the prolapsed urethra at the same time as guiding suture placements. Grooved director instruments are often included in standard spay instrument packs or can be purchased from most medical supply companies.

- If surgery is necessary, Elizabethan collars or similar restraint devices may be needed to prevent licking-induced trauma to the surgical site.

• CO₂ laser surgical technique may improve hemostasis, visualization and accuracy of the surgeon. In addition, it may decrease postoperative swelling. Prior to performing procedure, insert an appropriate catheter into the urethral lumen to avoid accidental transection of the urethra with the laser. When performing the procedure, do not use superpulse settings because they may interfere with hemostasis. Choosing a larger tip size (0.8 mm) for the laser may improve hemostasis.

- A recent study revealed that postoperative hemorrhage and prolapse recurrence may be reduced with use of a simple continuous suture pattern for urethral anastomosis and by administration of postoperative sedation.

• Regardless of treatment chosen, advise the client that recurrence is possible (57% in a recent study), particularly if an underlying cause for the urethral prolapse cannot be found and corrected.

- Because brachycephalic breeds are at risk for this problem, use caution in choosing an anesthetic regimen; monitor brachycephalic breeds carefully during anesthesia to ensure maintenance of adequate oxygenation.

MEDICATIONS

DRUG(S)

- Bacterial urethritis warrants use of appropriate antibiotics.
- May need to consider using diethylstilbestrol for 3–6 weeks after surgery to reduce frequency of erections.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Because of the possibility of bone marrow suppression, consider risk:benefit ratios before

URETHRAL PROLAPSE

(CONTINUED)

giving estrogens, especially if patients are already anemic.

FOLLOW-UP

PATIENT MONITORING

Re-evaluate the patient at least 7–10 days following surgery, for evidence of severe hemorrhage or recurrence of urethral prolapse.

PREVENTION/AVOIDANCE

If urethral prolapse is associated with penile erection, advise owners to prevent contact with female dogs or situations likely to cause penile erection.

POSSIBLE COMPLICATIONS

- Most common postoperative complication was hemorrhage (39%) which was less common when a simple continuous pattern was used for resection and anastomosis.

- Prolapse recurred 57% of time but was less common in dogs that were given postoperative butorphanol or acepromazine.
- Advise owners that recurrence of the prolapse may occur, especially if an underlying cause has been detected and eliminated or controlled.

EXPECTED COURSE AND PROGNOSIS

- Urethral prolapse may persist without significant sequelae. Therefore, some dogs may not require therapy.
- Other dogs may not have problems after castration and/or surgical correction of a prolapsed urethra.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Concurrent urethritis is common
- Concurrent urolithiasis may be a predisposing cause

URINARY RETENTION, FUNCTIONAL

BASICS

DEFINITION

Incomplete voiding unassociated with urinary obstruction

PATHOPHYSIOLOGY

Micturition voiding phase disorder.

Incomplete voiding due to neurogenic or myogenic failure, or both; associated with hypocontractility of the urinary bladder, or excessive outlet resistance, or both.

SYSTEMS AFFECTED

- Renal/Urologic • Endocrine/Metabolic
- Neuromuscular

GEOGRAPHIC DISTRIBUTION

• Worldwide. • Dysautonomia: Europe (Great Britain, Scandinavia), USA (Midwest), sporadic cases in Dubai, New Zealand, and Venezuela.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Chondrodystrophic breeds with IVDD.
- Manx cats with congenital sacral spinal lesions.
- Large-breed dogs (German shepherd dogs) with acquired cauda equina syndrome.
- Labrador retrievers, German shorthaired pointers, German shepherd dogs with dysautonomia.

Mean Age and Range

Young adult dogs with functional urinary obstruction

Predominant Sex

More common in males than females

SIGNS

General Comments

Signs include primary and secondary abnormalities of voiding dysfunction.

Historical Findings

- Frequent attempts to urinate, straining to urinate, or not voiding.
- Attenuated, interrupted, or prolonged urine stream.
- Urinary leakage occurs when pressure in bladder exceeds urethral outlet closure pressure (overflow or paradoxical incontinence).
- Vomiting, lethargy, painful abdomen with rupture or inflammation of the urinary tract.

Physical Examination Findings

- Palpably distended urinary bladder and/or inappropriate residual urine (normal 0.2–0.4 mL/kg) after attempts of voiding.
- Possibly, abnormal neurologic examination (see "Differential Diagnosis").
- Rarely, abdominal distension, abdominal pain, or signs of post-renal azotemia.
- Overflow urinary incontinence.

CAUSES

Hypocontractility of the Urinary Bladder (Detrusor Muscle), (Detrusor Atony)

- Usually caused by bladder overdistension.
- Can have neurologic dysfunction or previous urinary obstruction.
- Neurogenic causes include lesions of the pelvic nerves, sacral spinal cord, and suprasacral spinal cord.
- Sacral spinal cord lesions (e.g., congenital malformations, cauda equina compression, lumbosacral disc disease, and vertebral fractures/dislocations) can result in a flaccid, overdistended bladder with weak outlet resistance (lower motor neuron bladder).
- Suprasacral spinal cord lesions (e.g., intervertebral disc protrusion, spinal fractures, and compressive neoplasms) can result in a distended, firm bladder that is difficult to express (upper motor neuron bladder).
- Dysautonomia could lead to detrusor atony with urine retention.
- Electrolyte disturbances or metabolic disorders associated with generalized muscle weakness can affect detrusor muscle contractility.
- Canine hyperadrenocorticism can cause polyuria, bladder distention, and mild urine retention.
- Drugs causing varying degrees of myogenic failure include tricyclic antidepressants, calcium channel blockers, anticholinergic agents, and opioids.

Functional Urinary Obstruction

- Excessive or inappropriate outlet resistance prevents complete voiding during bladder contraction.
- In patients with suprasacral spinal lesions (typically T3–L3) or midbrain disorders, urethral outlet resistance becomes uninhibited and remains excessive or is not coordinated with voiding contractions (detrusor-urethral dyssynergia).
- Associated with sacral lesions and local neuropathy.
- Idiopathic.
- Excessive urethral resistance (often called urethrospasm) may be seen after urethral obstruction or in association with urethral or pelvic surgery, urethral inflammation, or prostate disease.

RISK FACTORS

- Urethral obstruction
- Pelvic or urethral surgery
- Anticholinergic medications
- Epidural analgesia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- When no voiding is observed, differentiate from oliguria, anuria, and urinary tract rupture.
- Differentiate from physical and mechanical obstruction. Clinical signs associated with urinary obstruction include pollakiuria, stranguria, and hematuria; patients with mechanical obstruction may void a few drops of urine after long periods of straining.
- Neurologic findings in dogs with supraspinal lesions affecting micturition include paralysis or paresis of pelvic and

sometimes thoracic limbs, hyperreflexia of affected limbs, and cervical, thoracolumbar, and lumbar pain. The bladder is usually distended, firm, and difficult to express. In patients with chronic or partial lesions, reflexive voiding may return, characterized by incomplete, involuntary detrusor contractions with outlet spasticity.

• Neurologic findings in dogs with sacral lesions affecting micturition include pelvic limb paresis with hyporeflexia, depressed anal and tail tone, perineal sensory loss, and depressed bulbospongiosus reflexes. Lumbosacral pain can be the only sign. The bladder is typically distended, flaccid, and easy to express.

• A urine stream that can be initiated but is abruptly halted is typical of idiopathic detrusor-urethral dyssynergia. Manual palpation may confirm detrusor contractions, which persist after flow terminates, and may suggest a high residual urine volume.

• In patients recovering from urinary obstruction, inability to void may result from re-obstruction, excessive (functional) urethral resistance, or detrusor atony caused by overdistension. If the urinary bladder can be expressed via gentle palpation applied through the abdomen, detrusor atony is likely. If resistance to manual expression is encountered and urethral obstruction can be ruled-out by examination or transurethral catheterization, functional obstruction is likely.

• Clinical signs accompanying urine retention in patients with dysautonomia may include mydriasis, prolapsed third eyelids, xerostomia, regurgitation or vomiting, megaesophagus, reduced or absent anal tone, diarrhea or constipation, and bradycardia.

CBC/BIOCHEMISTRY/URINALYSIS

- Test results rule-out metabolic causes of neuromuscular disease; also used to evaluate post-renal azotemia.
- Urinalysis may reveal UTI, trauma, or inflammation.

IMAGING

- Use survey radiographs and ultrasound to rule-out obstructing uroliths, pelvic trauma, lumbosacral disease, caudal abdominal masses.
- Use contrast cystourethrography or vaginourethrography, or occasionally, cystourethroscopy, to rule-out obstructive lesions.
- Use myelography, epidurography, CT, MRI to localize neurologic lesions.

DIAGNOSTIC PROCEDURES

- Neurologic exam—assessment of caudal spinal and peripheral nerve function through examination of anal tone, tail tone, perineal sensation, and bulbospongiosus reflexes.
- Transurethral catheterization may be required to rule-out urethral obstruction; catheters should pass easily in animals with no mechanical obstruction and in those with extramural urethral compression (e.g., caused by a smooth bladder neck mass, a large prostate gland, or a caudal abdominal mass).
- Diagnosis of dysautonomia is based on systematic pharmacologic testing of

URINARY RETENTION, FUNCTIONAL

(CONTINUED)

autonomic responses. • Use urodynamic procedures to confirm detrusor atony or functional urethral obstruction, or to document detrusor-urethral dyssynergia; detrusor areflexia may be documented by cystometrographic studies; inappropriate urethral resistance or urethral spasm occasionally is documented by resting urethral pressure profilometry; combined cystometry and urethral pressure measurements or uroflow studies are necessary to document dyssynergia.

PATHOLOGIC FINDINGS

Detrusor Atony

- Previously overdistended bladder may not be discernable on gross pathology.
- Caudal vertebral hypoplasia or aplasia and various sacral spinal cord lesions (abnormal cover, meningomyeloceles, intradural lipomas) in some Manx cats.
- Light microscopy in chronic cases may show widespread degeneration of smooth muscle cells, cholinergic axons, and intrinsic nerves.

Functional Urethral Obstruction

- Various suprasacral neurologic diseases (e.g., IVDD, FCE)
- Urethritis
- Prostatitis

TREATMENT

APPROPRIATE HEALTH CARE

Usually managed as inpatients until adequate voiding function returns.

NURSING CARE

- Manage azotemia, electrolyte imbalances, and acid-base disturbances associated with acute urine retention (rare).
- Identify UTI and treat appropriately.
- Keep the urinary bladder small by intermittent or indwelling transurethral catheterization or frequent manual compression.

CLIENT EDUCATION

Advise clients that complete voiding function may not return. Monitor for signs of complete obstruction, uremia, and UTI.

SURGICAL CONSIDERATIONS

Consider surgical options for salvaging urethral patency in some patients; perineal urethrostomy indicated in male cats with unmanageable distal urethral resistance.

U

MEDICATIONS

DRUG(S) OF CHOICE

Detrusor Atony

- Bethanechol (5–25 mg/dog PO q8–12h; 1.25–7.5 mg/cat q8–12h)—a cholinergic agent; may increase detrusor contractile input in partially denervated or acutely overdistended bladders.
- Metoclopramide (dog and cat, 0.2–0.5 mg/kg PO q8h)—a

dopamine antagonist; may stimulate detrusor contraction.

- Cisapride (dog, 0.5 mg/kg PO q8h; 1.25–5 mg/cat q8–12h)—a smooth muscle prokinetic agent; may promote bladder emptying.

Functional Urethral Obstruction

- Prazosin (dog, 1 mg/15 kg PO q8–24h; cat, 0.25–0.5 mg/cat PO q12–24h or 0.03 mg/kg IV) or phenoxybenzamine (dog, 0.25–0.5 mg/kg PO q12–24h; cat, 1.25–7.5 mg/cat PO q12–24h)— α -adrenergic antagonists reduce smooth muscle contraction in the urethra.
- Diazepam (dog, 2–10 mg/dog PO q8h; cat, 1–2.5 mg/cat PO q8h or 0.5 mg/kg IV)—relaxes striated muscle of the external urethral sphincter.
- Acepromazine (dog, 0.5–2 mg/kg PO q6–8h; cat, 1–2 mg/kg PO q6–8h)—a phenothiazine tranquilizer and general muscle relaxant with α -adrenergic blocking effects on urethral tone; may be effective in cats with excessive urethral resistance.
- Dantrolene (dog, 1–5 mg/kg PO q8–12h; cat, 0.5–2 mg/kg PO q8h or 1 mg/kg IV) striated muscle relaxant; appears to be effective in reducing distal urethral resistance in cats.
- Baclofen (dog, 1–2 mg/kg PO q8h)—a spinal reflex inhibitor; acts as a skeletal muscle relaxant; limited clinical evaluation in dogs and cats.

CONTRAINDICATIONS

- Baclofen in cats.
- Acepromazine, phenoxybenzamine, and prazosin have vasodilatory effects—use with caution in volume-depleted or azotemic patients and those with cardiac disease.
- Acepromazine and diazepam—can cause sedation; use with caution in lethargic patients.

PRECAUTIONS

- Confirm adequate outlet for urine flow before administering bethanechol since it can increase muscular contraction of the urinary bladder neck and proximal urethra. Pretreat with α -agonists (e.g., phenoxybenzamine, prazosin).
- Prazosin may cause potent “first-dose” hypotension; to minimize risk, initial dosage should be one-half of total dosage.
- Acute hepatopathy is an uncommon complication of oral diazepam in cats.

POSSIBLE INTERACTIONS

Cisapride can enhance the sedative effect of diazepam.

FOLLOW-UP

PATIENT MONITORING

- Reassess residual urine volume by urinary bladder palpation or by periodic transurethral catheterization.
- Slowly withdraw medications after primary causes are corrected and adequate voiding function has occurred for several days.
- Perform serial urinalysis and

urine culture to detect UTI in patients with chronic urine retention.

POSSIBLE COMPLICATIONS

- UTI
- Permanent detrusor muscle injury and atony; bladder or urethral rupture
- Post-renal azotemia

EXPECTED COURSE AND PROGNOSIS

- Good for acute detrusor atony caused by overdistension, acute reversible neurologic lesions, acute functional obstruction associated with irritative urethral disorders or resolving obstruction—recovery often occurs within 1 week.
- Fair to poor for chronic detrusor atony or chronic functional obstruction—urinary function usually recovers as motor function of the limbs recovers. If functional obstruction responds to α -agonists, prolonged administration may be required.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- UTI
- Azotemia

PREGNANCY/FERTILITY/BREEDING

Bethanechol is contraindicated

URINARY TRACT OBSTRUCTION

BASICS

DEFINITION

Restricted flow of urine from the kidneys through any point of the urinary tract to the external urethral orifice.

PATHOPHYSIOLOGY

- Physical or functional obstruction of the urinary tract resulting in partial or complete cessation in renal excretory function. As luminal pressure builds it is transmitted to the level of the kidney and its functional units (nephrons). As tubular pressure exceeds filtration pressure, GFR ceases. Ensuing pathophysiologic consequences depend on site, degree, and duration of obstruction. Complete obstruction produces a pathophysiologic state characterized by uremia, acidemia and hyperkalemia.
- Perforation of the excretory pathway with extravasation of urine (urethral tear or bladder rupture) is a functional equivalent.

SYSTEMS AFFECTED

- Renal/Urologic.
- Cardiovascular, gastrointestinal, nervous, and respiratory systems also affected relative to duration of obstruction and severity of metabolic derangement.

SIGNALMENT

- Dog and cat
- More common in males than females

SIGNS

Historical Findings

- Pollakiuria (common)
- Stranguria
- Diminished to absent urine stream
- Vocalizing, frequent trips to the litter box (cats)
- Gross hematuria
- Signs of uremia that develop when urinary tract obstruction is complete (or nearly complete): lethargy, reduced appetite, and vomiting

Physical Examination Findings

- Excessive (i.e., overly large or turgid) or inappropriate (i.e., remains after voiding efforts), palpable distension of the urinary bladder, especially in conjunction with lower urinary tract signs.
- Abdominal distention/discomfort.
- Uroliths are often palpable in the urethras of obstructed male dogs.
- Signs of severe uremia: dehydration, weakness, hypothermia, and/or bradycardia with moderate hyperkalemia, altered mentation, or sinus tachycardia from pain/stress.

CAUSES

Intraluminal Causes

- Urolithiasis—most common in male dogs.
- Urethral plugs—most common in male cats.
- Idiopathic—no overt intraluminal physical obstruction; may involve functional obstruction (see below).
- Additional causes include blood clots, sloughed tissue.

Intramural Causes

- Neoplasia of the bladder neck or urethra—more common in dogs.
- Prostatic disorders (neoplasia, prostatitis, etc.) in male dogs.
- Edema, hemorrhage, or spasm of muscular components at sites of intraluminal obstruction and/or associated with lower urinary tract inflammation. Can contribute to persistent or recurrent obstruction to urinary flow after removal of the intraluminal material and/or following catheterization attempts.
- Stricture at a site of prior injury or inflammation, may impede urine flow or may predispose to intraluminal obstruction.
- Ruptures, lacerations, and punctures—usually caused by traumatic incidents.

Miscellaneous Causes

- Displacement of the urinary bladder into a perineal hernia
- Neurogenic (see Urinary Retention, Functional)

RISK FACTORS

- Urolithiasis, particularly in males
- Feline lower urinary tract disease, particularly in males
- Prostatic disease in male dogs

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Owners may have difficulty distinguishing urinary obstruction from constipation.
- Signs of feline idiopathic cystitis can also be difficult to distinguish from obstruction, especially if there are no signs of systemic illness. Determination of bladder size (large/firm with obstruction, small with cystitis) can help distinguish.
- Animals whose urinations are not routinely observed by owners can present for signs referable to systemic illness (uremia) rather than concern for obstruction.
- Evaluation of any azotemic patient, in conjunction with history and physical exam, should include consideration of possible post-renal causes (e.g., urinary obstruction).
- Once recognized, diagnostic efforts focus on assessing the degree of systemic impact and metabolic derangement, as well as identifying the location and cause of obstruction.

CBC/BIOCHEMISTRY/URINALYSIS

- Results of a hemogram are usually normal, but a stress leukogram may be seen.
- Biochemical analysis reveals azotemia, hyperphosphatemia, metabolic acidosis, hyperkalemia, and decreased ionized calcium proportional to the duration of complete obstruction. Cats may also have stress hyperglycemia.
- Hematuria and proteinuria are common. Crystalluria may be associated with urolithiasis, though can be present in the absence of stones. Atypical epithelial cells may be seen in patients with neoplasia.

OTHER LABORATORY TESTS

- Given the potential for concurrent urinary tract infection in obstructed dogs (especially secondary to uroliths), urine culture may be beneficial. However, cats with obstruction are unlikely to have bacterial cystitis, and presenting urine culture is not recommended.
- Uroliths passed or retrieved should be sent for crystallographic analysis to determine their mineral composition.

IMAGING

Abdominal Radiography

- Uroliths—often demonstrated by survey radiography; some are difficult or impossible to see because of their size, composition, or location.
- Positive-contrast urethrography is beneficial for detecting intraluminal and intramural lesions of the urethra; double-contrast cystography is the most sensitive method of detecting lesions of the bladder lumen and wall.

Abdominal Ultrasonography

Ultrasonography is highly sensitive in detecting lesions of the bladder and proximal urethra (including the prostate gland in male dogs) and upper urinary tract (i.e., ureter or renal pelvis) obstruction.

ADDITIONAL DIAGNOSTIC PROCEDURES

- Electrocardiography may detect abnormalities secondary to hyperkalemia, including tall T waves, prolonged PR interval, widened QRS complexes, loss of P waves, bradycardia, and atrial standstill.
- Transurethral catheterization has diagnostic and therapeutic value. With attempted passage of the urinary catheter, the location and nature of obstructing material may be determined. Some or all of the obstructing material (e.g., small uroliths and feline urethral plugs) may dislodge and pass antegrade out of the urethra or retrograde into the bladder. Animals that cannot urinate despite being readily catheterized likely either have intramural lesions or functional urinary retention.
- Cytologic evaluation of specimens obtained with the assistance of catheters may be diagnostic, particularly carcinomas of the urethra or bladder and some prosthetic diseases.
- Cystoscopy can be helpful, particularly in female dogs with intramural lesions of the bladder neck or urethra.

TREATMENT

EMERGENCY MANAGEMENT

- Complete obstruction is a medical emergency that can be life-threatening; treatment should be started immediately.
- Initial goals are combating metabolic derangements of post-renal uremia, especially significant hyperkalemia, and establishing urinary patency.
- Intravenous fluids

URINARY TRACT OBSTRUCTION

(CONTINUED)

administration of isotonic crystalloid based on degree of cardiovascular compromise, dehydration, and potential for post-obstructive diuresis. • For severe hyperkalemia ($K^+ > 8 \text{ mmol/L}$, significant bradycardia/ECG changes); administer calcium gluconate (1 mL/kg over 3–5 minutes, titrated based on resolution of ECG changes), regular insulin (0.1–0.2 U/kg IV once) and dextrose bolus (1 mL/kg IV, diluted, over 5 minutes). May need 50% dextrose to continue on dextrose infusion (2.5–5%) for 4–6 hours to avoid hypoglycemia. For more severe hyperkalemia or acidemia ($K^+ > 10 \text{ mmol/L}$, pH < 7.1) consider sodium bicarbonate (1 mL/kg IV over 5–10 minutes). • Decompressive cystocentesis may allow more immediate relief of intravesicular pressure, resumption of GFR, and decreased back-pressure for catheterization efforts. • Urethral catheterization under heavy sedation or general anesthesia (see below) to relieve physical obstruction and establish urethral patency. • Flushing urinary bladder until clear effluent, attach to sterile collection system.

NURSING CARE

- Post-obstructive management geared toward maintaining fluid balance, continued correction of metabolic derangements, and sedation/analgesia (see below). • Rate of fluid administration should be determined based on maintenance, dehydration and ongoing losses. Some patients can experience a post-obstructive diuresis, with significant urinary losses. It is important to keep up with these losses to avoid dehydration.
- Hyperkalemia should resolve within hours after de-obstruction and may eventually need to be supplemented. Azotemia should also significantly decrease within 12–24 hours.
- Patients with urolithiasis will often require cystotomy for stone removal with associated postoperative care.

MEDICATIONS

DRUG(S)

- Sedation/analgesia/anesthesia for urethral catheter placement should be selected based on patient stability, and potential concern for decreased renal clearance. Acepromazine plus an opioid (e.g., methadone, buprenorphine) if stable, opioid plus benzodiazepine if unstable. Ketamine and a benzodiazepine is a commonly used injectable combination. General anesthesia, after premedication and induction, may be indicated as it provides the most urethral relaxation, especially for obstructed dogs.
- In the post-obstructive period, continued sedation and analgesia is beneficial.

- Urethral relaxants, such as acepromazine and/or prazosin, may be beneficial for post-obstructive cats or patients with neurogenic urine retention.
- Antibiotics may be indicated with infection (e.g., UTI or prostatitis), ideally only when strongly suspected or with documented evidence (such as cytology or positive culture). Antibiotics should not be administered to prevent UTI while a urinary catheter is in place as this is not effective and can promote bacterial resistance.

CONTRAINdications

- Corticosteroids are contraindicated while a urinary catheter is in place. This can predispose to the development of urinary tract infection. • Given their potential impact on renal blood flow, nonsteroidal anti-inflammatory medications should be initially avoided in more metabolically compromised patients.

PRECAUTIONS

- Avoid drugs that reduce blood pressure (e.g., acepromazine) or induce cardiac dysrhythmia (e.g., ketamine) until dehydration and hyperkalemia are resolved.

FOLLOW-UP

PATIENT MONITORING

- If the initial electrocardiogram indicates life-threatening changes, continuous monitoring to guide treatment and evaluate response is warranted. • Assess urine production and hydration status frequently, and adjust fluid administration rate accordingly (as described above). • Monitor renal values and electrolytes. Sicker patients may require more frequent monitoring (q6–12), whereas once daily may be sufficient for more stable patients. • The urinary catheter can be removed once metabolic derangements and post-obstructive diuresis has resolved, and/or the urine appears to be clear of gross debris, clots, etc. • After urinary catheter removal, close monitoring to verify the ability to urinate adequately for at least 12–24 hours. • Cats may benefit from continued pain medication and urethral relaxation for 5–7 days at home, as well as recommendations for increased water intake and environmental enrichment to help decrease risk of re-obstruction.

POSSIBLE COMPLICATIONS

- Death. • Injury to the excretory pathway (e.g., urethral tear) while trying to relieve obstruction. • Urine leakage or bladder rupture if decompressive cystocentesis performed. • Hypokalemia during

post-obstructive diuresis. • Recurrence of obstruction.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Bradycardia secondary to hyperkalemia
- Azotemia, hyperphosphatemia, and metabolic acidosis

AGE-RELATED FACTORS

In older dogs, the underlying cause of obstruction (e.g., neoplasia and prostate disease) often is difficult to treat.

SYNOMYS

Urethral obstruction

UROLITHIASIS, CALCIUM OXALATE

BASICS

DEFINITION

Formation of calcium oxalate (CaOx) uroliths within the urinary tract and associated clinical conditions (e.g., urinary obstruction, idiopathic hypercalcemia, chronic kidney disease).

PATOPHYSIOLOGY

Presence of hypercalciuria, hyperoxaluria, hypocitraturia, and defective crystal growth inhibitors.

Hypercalciuria

In dogs, normocalcemic hypercalciuria is thought to result from either intestinal hyperabsorption of calcium (so-called absorptive hypercalciuria: type 1—dietary independent, type 2—dietary dependent, and type 3—phosphaturic induced hypervitaminosis D) or reduced renal tubular reabsorption of calcium (so-called renal-leak hypercalciuria). Hypercalcemic hypercalciuria results from excessive glomerular filtration of mobilized calcium, which overwhelms normal renal tubular reabsorptive mechanisms (called resorptive hypercalciuria, since bone resorption is associated with high serum calcium concentrations).

Hyperoxaluria

In humans, hyperoxaluria is associated with inherited abnormalities of excessive oxalate synthesis (i.e., primary hyperoxaluria types I, II, and III), excess consumption of foods containing high quantities of oxalate or oxalate precursors, pyridoxine deficiency, and disorders associated with fat malabsorption (i.e., fat complexes with intestinal calcium augmenting intestinal absorption of oxalate). Lack of oxalate degrading bacteria in the intestine can increase the quantity of oxalate absorbed from the diet and the quantity excreted in urine.

Hypocitraturia

Urine citrate inhibits calcium oxalate urolith formation. By complexing with calcium ions to form the relatively soluble salt calcium citrate, citrate reduces the quantity of calcium available to bind with oxalate. In normal dogs, acidosis is associated with low urinary citrate excretion, whereas alkalosis promotes urinary citrate excretion.

Defective Crystal Growth Inhibitors

In addition to urinary concentrations of calculogenic minerals, large molecular weight proteins in urine, such as Tamm-Horsfall mucoprotein, nephrocalcin and osteopontin, have a profound ability to enhance solubility of calcium oxalate. Preliminary studies of urine obtained from dogs with calcium oxalate uroliths revealed that nephrocalcin had fewer carboxyglutamic acid residues than nephrocalcin isolated from normal dog urine.

Feeding Diets Promoting Urine Acidification

Epidemiologic studies have revealed that feeding diets designed to promote aciduria is a common risk factor in cats and dogs. In several species, acidic urine is associated with hypercalciuria (bone mobilization of calcium, increased glomerular filtration of calcium, and decreased renal tubular reabsorption of calcium) and hypocitraturia (increased renal tubular reabsorption).

SYSTEMS AFFECTED

Renal/Urologic

INCIDENCE/PREVALENCE

In dogs, calcium oxalate accounts for approximately 42% of the uroliths removed from the lower urinary tract and 45% of those removed from the upper urinary tract. In cats, calcium oxalate accounts for approximately 42% of the uroliths removed from the lower urinary tract and 90% of those retrieved from the upper urinary tract.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Dogs—reported in many breeds. Six breeds represent 60% of cases: miniature schnauzer, Lhasa apso, Yorkshire terrier, bichon frise, shih tzu, and miniature poodle.
- Cats—Himalayan, Scottish fold, Persian, ragdoll, and Burmese are at greater risk.

Mean Age and Range

- Dogs— 8.5 ± 3 years; 60%, 6–11 years
- Cats—97% > 2 years; 53%, 7–15 years

Predominant Sex

Mostly male dogs (73%) and male cats (55%)

SIGNS

General Comments

- Asymptomatic in some animals.
- Depend on location, size, and number of uroliths.
- Animals with nephroliths are typically asymptomatic but may have persistent hematuria.
- Ureteral obstruction associated with contralateral microrenale, ipsilateral hydronephrosis, and acute onset of uremia occurs frequently in cats with chronic kidney disease.

Historical Findings

- Typical signs of urocystoliths or urethroliths include pollakiuria, dysuria, and hematuria. Some may present for urethral obstruction.
- Nephroureteroliths common in cats with chronic kidney disease.

Physical Examination Findings

- Detection of urocystoliths are by abdominal or urethral palpation; failure to palpate uroliths does not exclude them from consideration.

- Large urinary bladder if patient has complete urethral obstruction (more common in cats).

- Urocystoliths with irregular contours rarely cause complete urethral obstruction.

CAUSES

See “Pathophysiology”

RISK FACTORS

- Oral calcium supplements given independent of meals.
- Feeding acidifying foods that promote formation of acidic urine (less than a pH of 6.6 in dogs and 6.25 in cats) was associated with CaOx urolithiasis. In normal cats alkaline urine was associated with the lowest saturation for CaOx.
- Excessive dietary protein, sodium (greater than 1.2% DMB or 350 mg/100 kcal) and vitamin D promote hypercalciuria.
- Additional dietary oxalate (e.g., chocolate and peanuts) and ascorbic acid promote hyperoxaluria.
- Exogenous or endogenous exposure to a high concentration of glucocorticoids and furosemide promote hypercalciuria
- Pyridoxine (vitamin B₆)-deficient diets (e.g., homemade) promote hyperoxaluria.
- Consumption of dry diets is associated with a higher risk for calcium oxalate urolith formation than consumption of high-moisture canned diets.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other common causes of hematuria, dysuria, and pollakiuria, with or without urethral obstruction, include urinary tract infection, urinary tract neoplasia, and idiopathic feline lower urinary tract disease.
- Other common radiodense uroliths include those composed of magnesium ammonium phosphate, calcium phosphate, cystine, and silica.

CBC/BIOCHEMISTRY/URINALYSIS

- Urinary tract mineralization may resemble uroliths.
- Results usually unremarkable.
- Urinary sediment evaluation may reveal calcium oxalate crystals, but absence of crystalluria does not exclude uroliths as a possibility.
- Hypercalcemia (rare in dogs, more common in cats) should be further evaluated to determine its cause and contribution to urolith formation.

OTHER LABORATORY TESTS

Quantitative mineral analysis of uroliths

IMAGING

- Calcium oxalate uroliths ≥ 2 mm in diameter are radio-opaque and easily detected by survey radiography.

UROLITHIASIS, CALCIUM OXALATE

(CONTINUED)

- Intravenous urography, contrast pyelography, or ultrasonography is required to verify ureteral obstruction.

TREATMENT

APPROPRIATE HEALTH CARE

- CaOx uroliths are not amenable to medical dissolution.
- Small stones that can pass through the urethra (< 3 mm in most dogs > 5 kg) should be removed by voiding urohydropropulsion or basket retrieval. Percutaneous cystolithotomy or routine cystotomy can be used to remove stones in smaller dogs and male cats.
- Consider laser lithotripsy, percutaneous cystolithotomy, or routine cystotomy to remove larger stones from the urinary bladder.
- Urethral surgery is discouraged. Retrograde urohydropropulsion is an effective procedure to flush urethral stones back into the urinary bladder prior to their removal.
- Persistently obstructed ureters require urgent intervention to minimize progressive kidney damage. If fluid therapy, α -adrenergic blocking agents, and diuretics do not relieve the obstruction in 1-3 days, consider ureteral stents in dogs and subcutaneous ureteral access devices in cats to preserve kidney function. When performed by trained surgeons, ureterotomy may be considered for dilated ureters containing very few stones.
- Removal of unobstructing nephroliths is usually not necessary.

ACTIVITY

Reduce during the period of tissue repair after surgery.

DIET

- No reports of dissolution of CaOx uroliths with therapeutic foods. Epidemiologic studies support feeding high moisture foods that promote formation of less acidic urine ($pH > 6.3-6.6$) to minimize formation of calcium oxalate.
- Hypercalcemia in cats without evidence of hyperparathyroidism or malignancy is sometimes minimized by feeding Hill's Prescription Diet Feline w/d. Management of idiopathic hypercalcemia with bisphosphonates and other drugs that inhibit osteoclast function are controversial; their use should be determined on a case-by-case basis weighing their risks and advantages.

CLIENT EDUCATION

- Urolith removal does not alter the factors responsible for urolith formation; eliminating or minimizing risk factors is necessary to minimize recurrence.
- Approximately 50% of dogs reform uroliths within 2 years; a third of cats reform uroliths in 2 years.
- Patients with hypercalcemia typically reform uroliths at a faster rate.

SURGICAL CONSIDERATIONS

- Consider surgical removal of lower tract uroliths that cannot be removed by minimally invasive procedures (e.g., voiding urohydropropulsion, basket retrieval, intracorporeal laser lithotripsy, percutaneous cystolithotomy).
- Avoid performing disfiguring urethrostomies and urethrotomies by using retrograde urohydropropulsion to flush urethroliths into the bladder or using lithotripsy to fragment urethroliths.
- Shock wave lithotripsy is an alternative to surgery for removal of nephroliths and ureteroliths in dogs.
- To minimize urolith reformation over suture nidus, minimize surgical procedures to remove uroliths and use absorbable suture and suture patterns that minimize suture exposure in the lumen of the urinary bladder.
- Only surgeons trained in ureteral surgery should attempt ureterolith removal. However, in lieu of surgery consider ureteral stents in dogs and subcutaneous ureteral access devices in cats.
- Consider parathyroidectomy for patients with primary hyperparathyroidism and hypercalcemia.

MEDICATIONS

DRUG(S) OF CHOICE

No available drugs effectively dissolve calcium oxalate uroliths.

PRECAUTIONS

Steroids and furosemide promote calciuria.

FOLLOW-UP

PATIENT MONITORING

- Post-surgical radiographs are essential to verify complete urolith removal.
- To prevent the need for repeated surgery, evaluate abdominal radiography every 3-5 months to detect urolith recurrence early. Small uroliths are easily removed by voiding urohydropropulsion or stone basket retrieval.

PREVENTION/AVOIDANCE

- Even with appropriate contemporary therapy, CaOx urolith recurrence is common (up to 50% in dogs and 33% in cats in 2 years). Therefore, regular monitoring and compliance check-ins are essential to adjust therapy to extend the interval between recurrences.
- Only recommend high moisture foods (e.g., can, loaf, gravies). Feeding dry foods, combining dry and wet foods, or adding water to dry food is usually ineffective in maintaining consistent low urinary concentrations (specific gravity < 1.020 in

dogs and < 1.030 in cats) of calculogenic minerals.

- Feeding high-sodium foods ($\geq 350 \text{ mg}/100 \text{ kcal}$) should not be recommended as a substitute for feeding high-moisture foods. Their efficacy to promote low urine specific gravity appears to be short-lived (3-6 months) and their use is contraindicated in dogs and cats with kidney disease.
- Avoid feeding diets that promote urine acidification. Diets that promote formation of acidic urine in dogs ($\text{pH} < 6.6$) and cats ($\text{pH} < 6.25$) were associated with CaOx uroliths. A linear increase in urine pH was associated with a linear decrease in urine CaOx saturation in normal cats.
- Commercially manufactured diets have been designed to prevent CaOx recurrence, but they may not be an ideal for all patients.
- Hills Prescription diet u/d for dogs has been shown to decrease calcium and oxalate excretion in dogs with calcium oxalate urolithiasis. This food has lower levels of sodium and protein, and promotes a neutral to alkaline urine. Although it has passed AFCO feeding trials, some consider that the protein quantity is too low. If this is the case consider feeding $\frac{1}{2}$ u/d and $\frac{1}{2}$ of a canned moderate protein senior food that does not acidify the urine (e.g., Prescription diet g/d). Because u/d is higher in fat, dogs with hereditary hyperlipidemia (e.g., some miniature schnauzers) may benefit from a similar feeding mixture.
- Hills Prescription diet w/d has been recommended for dogs with CaOx urolithiasis and fat/lipid intolerance or fat/lipid responsive diseases (e.g., dogs with a history of pancreatitis). Because this diet promotes formation of acidic urine, administer potassium citrate to promote a more favorable urine pH (> 6.5).
- Royal Canin SO has been shown to decrease CaOx relative supersaturation in dogs with calcium oxalate uroliths, but the urine samples were collected by owners in this study, raising the suspicion of incomplete sample collection. Because this diet promotes acidic urine, concomitant administration of potassium citrate is necessary to achieve a more favorable urine pH (> 6.5). We do not recommend dry foods to prevent CaOx uroliths.
- Avoid supplements with vitamins C and D.
- Reevaluate patients in 2-4 weeks after initiation of diet therapy to verify appropriate reduction in specific gravity (< 1.020 for dogs and < 1.030 for cats), appropriate urine pH (≥ 6.5), and amelioration of crystalluria. Do not use inappropriately collected or stored urine samples (e.g., urine collected by owners, refrigerated, or contaminated with debris) to monitor therapeutic efficacy. To promote less-concentrated urine strongly recommend canned or gravy formulations of food or add additional water to all types of food. If urine

(CONTINUED)

is acidic, consider administration of potassium citrate (75 mg/kg PO q12h); adjust dosage to achieve a pH between 6.5 and 7.5. Potassium citrate medications formulated with cranberry are not recommended because cranberry is a source of vitamin C; vitamin C supplementation should be discouraged because of its ability to increase urine oxalate.

- Vitamin B₆ (2–4 mg/kg PO q24–48h) may help minimize oxalate excretion, especially for animals fed homemade or pyridoxine-deficient diets.

- If dietary changes are inadequate at slowing the rate of recurrence, consider hydrochlorothiazide diuretics (dog, 2 mg/kg and cat, 1 mg/kg, q12–24h).
- If the patient is hypercalcemic, correct underlying cause if possible. Consider either Prescription Diet w/d or c/d multicare for cats with idiopathic hypercalciuria; bisphosphonates should be used cautiously.
- *Oxalobacter formigenes* is an intestinal bacterium that ingests oxalate as its sole nutrient. By metabolizing dietary oxalate in the intestine, less oxalic acid is available for absorption and less is excreted in urine. To preserve healthy populations of intestinal *Oxalobacter*, avoid indiscriminate or prolonged use of antimicrobics.

POSSIBLE COMPLICATIONS

- Urocystoliths can pass into and obstruct the urethra in male dogs and cats, especially if the patient is dysuric.
- Dogs that do not consume their daily requirement of some urolith prevention foods may develop various degrees of protein calorie malnutrition.

- Diet-associated hyperlipidemia develops in some patients consuming foods with higher fat content. Miniature schnauzers with hereditary hyperlipidemia are predisposed to pancreatitis when consuming some prevention foods; Hill's Prescription Diet Canine w/d can be used as an alternative. This diet should be supplemented with potassium citrate as needed to maintain a urine pH between 6.5 and 7.5.

EXPECTED COURSE AND PROGNOSIS

- Approximately 50% of dogs and 33% of cats reform uroliths in 2 years. Treatment to minimize recurrence is helpful.
- Patients with persistent hypercalcemia typically reform uroliths at a faster rate.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Conditions predisposing to hypercalciuria (e.g., hyperadrenocorticism, acidemia, hypervitaminosis D, and hyperparathyroidism) or hyperoxaluria (e.g., vitamin B₆ deficiency, hereditary hyperoxaluria, and ingestion of chocolate and peanuts).

AGE-RELATED FACTORS

Rare in young (< 1 year old) animals

PREGNANCY/FERTILITY/BREEDING

Diets used to prevent calcium oxalate uroliths are not appropriate.

SYNONYMS

Oxalate urolithiasis

SEE ALSO

Crystalluria

UROLITHIASIS, CALCIUM PHOSPHATE

BASICS

OVERVIEW

- Calcium phosphate (CP) uroliths within the urinary tract and associated clinical conditions.
- Forms of CP identified in dogs and cats include: calcium phosphate apatite (CAP), calcium phosphate carbonate (CPC), calcium hydrogen phosphate dihydrate (Brushite), and uncommon minerals—tricalcium phosphate (whitlockite) and octacalcium phosphate.
- CP uroliths represent a small fraction (dogs < 1.0%, cats < 0.5%) of all uroliths submitted to the MUC from 1981 to 2013 (Table 1).
- A greater percentage of CP uroliths are found in the upper tract (kidney and ureter) (2.5% cats, 3.5% dogs), than in the lower tract (bladder and urethra). • CP uroliths (excluding brushite) do not have a characteristic shape. Brushite uroliths are typically round and smooth. • Color of CP uroliths are usually cream or tan. Blood clots mineralized with CP are typically black.

SIGNALMENT

- Dog and cat. • Rarely detected in animals < 1 years old. • CPC uroliths occur primarily in female dogs (72%).

SIGNS

- Depend on location, size, and number of uroliths. • Pollakiuria, dysuria, hematuria, and urethral obstruction.
- Nephroureteroliths—typically asymptomatic but may have persistent hematuria or signs referable to concomitant renal failure (primarily cats).

CAUSES & RISK FACTORS

- CPC—commonly a minor component of struvite and calcium oxalate uroliths. • Pure CP uroliths—usually associated with metabolic disorders, e.g., primary hyperparathyroidism, renal tubular acidosis, and excessive dietary calcium and phosphorus.
- Urinary tract infections—Increased calcium excretion in combination with urinary tract infection with urease producing bacteria may be risk factors favoring CPC. • Nephroliths, urocystoliths, and urethroliths composed of blood clots mineralized with CP suggest dystrophic mineralization of tissue, in contrast to metastatic mineralization reflecting abnormal calcium and phosphorus metabolism. • Other risk factors—see Urolithiasis Calcium Oxalate.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other common causes of hematuria, dysuria, and pollakiuria, with or without urethral obstruction, include urinary tract infection and urinary tract neoplasia.
- Other radiodense uroliths—magnesium ammonium phosphate, calcium oxalate, and silica.
- Metastatic or dystrophic mineralization of urinary tract parenchyma may resemble uroliths.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually unremarkable.
- Hypercalcemia or azotemia rarely detected; post-renal azotemia in some animals with complete urinary outflow obstruction.
- Urinary sediment analysis—amorphous crystals in some patients; brushite (calcium hydrogen phosphate dihydrate) forms are elongated, rectangular, lath-shaped crystals.

OTHER LABORATORY TESTS

- Quantitative analysis of retrieved uroliths is necessary to confirm their mineral composition.
- Serum concentrations of parathyroid hormone, parathyroid hormone-related peptide, and hydroxycholecalciferol may help establish underlying causes.

IMAGING

- CP uroliths are radiodense (as dense as bone) and are often detected by survey radiography.
- CP uroliths may be detected by ultrasonography.

OTHER DIAGNOSTIC PROCEDURES

CP uroliths in the urethra and bladder may be detected by cystoscopy.

TREATMENT

- Medical dissolution of CP uroliths remains a goal for the future.
- Consider surgical removal of lower tract uroliths that cannot be removed by minimally invasive procedures (e.g., voiding urohydropropulsion, basket retrieval, intracorporeal lithotripsy, laparoscopic cystotomy).
- Avoid performing disfiguring urethrostomies by using basket retrieval to remove urethroliths, retrograde urohydropropulsion to flush urethroliths into the bladder or using lithotripsy to fragment urethroliths.
- Shock wave lithotripsy is an alternative to surgery for removal of

nephroliths, ureteroliths, and urocystoliths in dogs. • Correction of hyperparathyroidism or other causes of hypercalcemia should minimize further urolith formation.

MEDICATION

DRUG(S)

No effective medications available for dissolving CP uroliths.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Vitamin D supplements, other mineral supplements, glucocorticoids

FOLLOW-UP

PATIENT MONITORING

- Radiography after surgery to verify complete urolith removal is a standard of practice.
- Abdominal radiography or ultrasonography every 3–5 months to enhance early detection of urolith recurrence and prevention of the need for repeated surgery.
- Small uroliths are easily removed by voiding urohydropropulsion or catheter retrieval.

PREVENTION/AVOIDANCE

- A high-moisture (canned) diet formulated to prevent formation of calcium oxalate uroliths may help prevent recurrence.
- Foods for older dogs that are lower in protein, phosphorus, and calcium, and which do not promote acidic urine are usually associated with decreased calcium and phosphorus excretion. Hill's Prescription canned g/d is one example.
- Because of the high moisture content of canned foods and their tendency to promote dilute urine, canned diets are more effective than dry diets in preventing recurrence.
- Avoid excessive acidification or alkalinization of urine.

MISCELLANEOUS

SYNONYMS

Apatite uroliths

Authors Hasan Albasan, Jody P. Lulich, and Carl A. Osborne

Consulting Editor Carl A. Osborne

Table 1

Calcium Phosphate Uroliths submitted to the Minnesota Urolith Center (MUC) in 2013.

	Dog (n = 66,310)	Cat (n = 15,602)
Calcium phosphate carbonate form (CPC)	0.49%	0.08%
Calcium phosphate apatite form (CAP)	0.10%	0.15%
Calcium hydrogen phosphate 2H ₂ O (Brushite)	0.23%	0.04%

UROLITHIASIS, CYSTINE

BASICS

OVERVIEW

- Formation of uroliths, composed of cystine in the urinary tract.
- Occurs with cystinuria, an inborn error of metabolism caused by defective tubular reabsorption of cystine, ornithine, lysine, and arginine (COLA) leading to cystine urolith formation.
- Cystine is freely filtered by glomeruli; most is actively reabsorbed in the proximal tubules.
- Impaired intestinal absorption of these amino acids has not been associated with any nutritional deficiency states in dogs, presumably because they are non-essential amino acids.
- Unless protein intake is severely restricted, cystinuric dogs have no detectable abnormalities associated with amino acid loss. Excessive loss of arginine in urine predisposes cats to hyperammonemic encephalopathy. Some cystinuric dogs may have carnitinuria.
- Cystinuric dogs have been classified into three different types: Type 1 autosomal recessive SLC3A1 mutations found in Newfoundlands, Landseer, and Labrador retrievers; Type 2 autosomal dominant SLC7A9 identified in Australian cattle dogs and European Miniature Pinschers, and Type 3, which has sex limited inheritance and has been identified in Mastiff and related breeds, Scottish Deerhound, and Irish Terriers.
- Because not all cystinuric dogs and cats form uroliths, cystinuria is a predisposing rather than a primary cause of cystine urolithiasis. Cystine is relatively insoluble in acid urine; becomes more soluble in alkaline urine.
- A genetic missense mutation of the SLC3A1 Gene has recently been identified in one cat with cystine uroliths.

SIGNALMENT

- Dogs—primarily adult (mean age 5 years; range 3 months–14 years) males but may also affect females. It occurs in excess of 80 breeds, including dachshunds, English bulldogs, Newfoundlands, Labrador retrievers, Chihuahuas, pit bulls, and French bulldogs. May be detected in male and female Newfoundland and Labradors < 1 year of age.
- Cats—primarily adult (mean age at diagnosis, 3.5 years; range, 4 months–12 years) males and females; most common the domestic shorthair and Siamese breeds.

SIGNS

- Depend on location, size, and number of uroliths; affected animals may be asymptomatic.
- Urocystoliths—include pollakiuria, dysuria, and hematuria.

• Urethroliths—include pollakiuria, dysuria, and sometimes voiding of small smooth uroliths. Complete outflow obstruction may result in post-renal azotemia that may progress to uremia.

• Nephroliths—typically asymptomatic; may be associated with manifestations of hydronephrosis and renal insufficiency.

CAUSES & RISK FACTORS

- Cystinuria is a risk factor.
- Breed predisposition.
- In young and middle-aged dogs with previous history of cystine urolithiasis—recurrence within 6–12 months following surgery unless prophylactic therapy is given.
- Urolith formation—enhanced by acidic, concentrated urine, incomplete and infrequent micturition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Uroliths mimic other causes of pollakiuria, dysuria, hematuria, and/or outflow obstruction.
- Differentiate from other types of uroliths by urinalysis, radiography, and quantitative analysis of voided or retrieved uroliths.

CBC/BIOCHEMISTRY/URINALYSIS

- Cystine crystals are six-sided; insoluble in acetic acid.
- Positive urine cyanide-nitroprusside test.

OTHER LABORATORY TESTS

- Urinary amino acid profiles—reveal abnormal quantities of cystine and, in some dogs and cats, ornithine, lysine, arginine, and other amino acids.
- Quantitative mineral analysis of uroliths.
- DNA test.

IMAGING

- Radiography—the radiodensity of cystine uroliths is similar to that of struvite and silica, less than that of calcium oxalate and calcium phosphate, and greater than that of ammonium urate; when large enough, cystine uroliths can be detected by survey radiography.
- Ultrasonography—can detect cystine uroliths; does not provide reliable information about the radiodensity or shape.

DIAGNOSTIC PROCEDURES

Urethrocytostoscopy—used to detect cystine urethroliths and urocystoliths.

TREATMENT

- In dogs: Medical dissolution of uroliths by combination of *N*-(2-mercaptopropionyl)-glycine (2-MPG) and dietary therapy; Hill's

Prescription Diet Canine u/d reduces urinary excretion of cystine, promotes formation of alkaline urine, and reduces urine concentration; it is used in conjunction with 2-MPG for urolith dissolution and is often effective alone in preventing recurrence of cystine uroliths.

• In one study, castration reduced recurrence of cystine uroliths in dogs identified with Type 3, sex limited inheritance.

• In cats: Diets designed for renal insufficiency and geriatric cats may be suitable to minimize formation. Give enough potassium citrate (40–75 mg/kg PO q12h) to maintain a urine pH of 7.5. Choose a moist formulation diet to help reduce urine concentration. Dissolution with 2-MPG has been studied in a small number of cats at an oral dose of 12–20 mg/kg q12h. Frequency of recurrence was minimized in these cats without adverse side effects.

• In dogs, and cats, remove urocystoliths unable to be dissolved by voiding urohydropropulsion, basket retrieval, lithotripsy, or surgery.

MEDICATIONS

DRUG(S)

Urine Alkalinizers

• For patients that have acidic urine despite dietary therapy and control of urease-positive urinary tract infections.

• Data from cystinuric humans suggest that dietary sodium may enhance cystinuria; thus potassium citrate may be preferable to sodium bicarbonate as a urine alkalinizer. Give enough potassium citrate (40–75 mg/kg PO q12h) to maintain a urine pH of 7.5.

Thiol-Containing Drugs

• 2-MPG decreases urine concentration of cystine by combining with cysteine to form cysteine-2-MPG, which is more soluble than cystine.

• With status as an orphan drug, Thiola™ is only available from the distributor Retrophin. Generic 2-MPG (Tiopronin) may be obtained from compounding pharmacies. In dogs: 2-MPG may be given at a dosage of 15–20 mg/kg PO q12h to dissolve canine cystine uroliths in conjunction with dietary therapy. In our hospital, mean dissolution time was 78 days (range, 11–211 days).

• 2-MPG may be given at a lower dosage (5–10 mg/kg PO q12h) to prevent recurrent canine cystine uroliths.

• In cats: 2-MPG has been studied in a small number of cats at an oral dose of 12–20 mg/kg q12h. Frequency of recurrence was minimized in these cats without adverse side effects.

UROLITHIASIS, CYSTINE

(CONTINUED)

- Drug-induced adverse events associated with 2-MGP are uncommon in dogs; they include reversible Coombs'-positive spherocytic anemia, thrombocytopenia, glomerular proteinuria, myopathy, aggressiveness, and increased hepatic enzyme activity.
- 2-MPG should be used with caution in cats, as the efficacy and safety of 2-MPG has not been thoroughly evaluated in normal or cystinuric cats.

**FOLLOW-UP**

- Minimize recurrence with dietary management or 2-MPG.

- Monitor urolith dissolution at 30-day intervals by urinalysis, survey or contrast radiography, or ultrasonography.
- Although cystine uroliths tend to recur, recurrence does not affect all cystinuric dogs and cats.
- In some older dogs, the rate of recurrence declines as a consequence of a reduction in the magnitude of cystinuria.

**MISCELLANEOUS****ABBREVIATION**

- 2-MPG = *N*-(2-mercaptopropionyl)-glycine

UROLITHIASIS, STRUVITE—CATS

BASICS

DEFINITION

Struvite uroliths and struvite urethral plugs have physical and etiopathogenic differences; thus, these terms should not be used as synonyms. Struvite uroliths are polycrystalline concretions composed primarily of magnesium ammonium phosphate and small quantities of matrix. Struvite feline urethral plugs commonly are composed of large quantities of matrix mixed with crystals (especially magnesium ammonium phosphate). Some urethral plugs are composed primarily of organic matrix, sloughed tissue, blood, and/or inflammatory reactants.

PATOPHYSIOLOGY

- See Urolithiasis, Struvite—Dogs.
- The most commonly encountered form of naturally occurring feline urethral plugs contains relatively large quantities of matrix in addition to minerals, especially struvite. Risk factors associated with formation of MAP crystals contained in urethral plugs are similar to those associated with formation of struvite uroliths. Prevention or control of these risk factors should minimize the recurrence of the struvite component of urethral plugs. Specific causes and composition of urethral plug matrix have not yet been classified. One hypothesis is that plug matrix follows the onset of urinary tract infections or other inflammatory disorders such as idiopathic cystitis.

SYSTEMS AFFECTED

Renal/Urologic—upper and lower urinary tract

INCIDENCE/PREVALENCE

- The prevalence of feline struvite uroliths submitted to the Minnesota Urolith Center declined from 78% in 1981 to 33% in 2002, but then increased to 48% in 2005. Struvite uroliths comprised 46% of feline uroliths in 2013. In comparison, uroliths comprised primarily of calcium oxalate increased from approximately 2% in 1981 to 55% in 2002, but then decreased to 40% in 2005. Calcium oxalate comprised 41% of feline uroliths in 2013. These dramatic changes in the frequency of occurrence of the mineral composition of feline uroliths parallel changes in the composition of manufactured diets.
- Currently, struvite makes up approximately 50% of all types of uroliths in the feline lower urinary tract. Of these, 95% are sterile.
- Struvite has been detected in approximately 8% of feline nephroliths.
- Since 1981, struvite has remained the most common (~90%) mineral in matrix-crystalline urethral plugs.

SIGNALMENT

Species

Cat (see Urolithiasis, Struvite—Dogs)

Mean Age and Range

- Mean age at time of diagnosis is approximately 7 years (range, < 1–22 years).
- Sterile struvite uroliths do not affect immature cats; infection-induced struvite may occur in immature cats:

Predominant Sex

- Struvite uroliths are more common in female cats (55%) than in males (45%).
- Struvite urethral plugs primarily affect males.

SIGNS

General Comments

- Affected cats may be asymptomatic.
- Depend on location, size, number, and cause of uroliths.

Historical Findings

- Typical signs of urocystoliths include pollakiuria, dysuria, perirenia, and hematuria.
- Typical signs of urethroliths include pollakiuria, perirenia, dysuria, and sometimes voiding of small, smooth uroliths.
- Signs of post-renal azotemia (e.g., anorexia and vomiting) are found in some cats with outflow obstruction.
- Manifestations of renal insufficiency (polyuria and polydipsia) are found in some cats with nephroliths.
- Signs typical of outflow obstruction (e.g., dysuria, large painful urinary bladder, and signs of post-renal azotemia) are found in cats with struvite urethral plugs.

Physical Examination Findings

- A thickened, firm, contracted bladder wall is found in some cats with urocystoliths.
- Detection of urocystoliths by palpation is unreliable because it is insensitive.
- Urethral plugs or urethroliths may be detected by examination of the distal penis and penile urethra.
- Outflow obstruction results in an enlarged urinary bladder and signs of post-renal azotemia.

CAUSES

See "Pathophysiology"

RISK FACTORS

- For formation of sterile struvite uroliths, risk factors include mineral composition, energy content, and moisture content of diets; urine-alkalinizing metabolites in diets; quantity of diet consumed; ad libitum versus meal-feeding schedules; formation of concentrated urine; and retention of urine.
- Probable risk factors for infection-induced struvite urolithiasis—include urinary tract infection with urease-producing microbial pathogens, abnormalities in local host defenses that allow bacterial urinary tract infections (including perineal urethrostomies), and the quantity of urea (the substrate of urease) excreted in urine.
- The normal small diameter of the distal urethra of male cats

predisposes them to obstruction with plugs and urethroliths.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Uroliths mimic other causes of pollakiuria, dysuria, perirenia, hematuria, and/or outflow obstruction.
- Differentiate struvite uroliths and urethral plugs from other types of uroliths by signalment, urinalysis, urine culture, radiography, ultrasonography, cystoscopy, and quantitative analysis of voided or retrieved uroliths or plugs.

CBC/BIOCHEMISTRY/URINALYSIS

- Complete outflow obstruction may cause post-renal azotemia (e.g., high serum urea nitrogen, creatinine, and phosphorus).
- Magnesium ammonium phosphate crystals typically appear as colorless, orthorhombic (having three unequal axes intersecting at right angles), coffin-like prisms. They often have three to eight sides.

OTHER LABORATORY TESTS

- Pretreatment quantitative bacterial urine cultures (preferably with specimen obtained by cystocentesis) yield bacterial urinary tract infections in only ~1–3% of affected 2- to 7-year-old patients.
- Quantitative mineral analysis is the accepted standard of practice for uroliths and urethral plugs retrieved during voiding, by voiding urohydropropulsion, by aspiration into a urinary catheter, or by cystoscopy.
- Bacterial culture of inner portions of uroliths retrieved from patients with urease-positive microbes cultured from urine may be of value.

IMAGING

Radiography

- Struvite uroliths—radiodense; may be detected by survey radiography; some struvite urethral plugs may be detected by survey radiography.
- The size and number of uroliths are not a reliable index of probable efficacy of dissolution therapy.
- Contrast urethrocystography helps identify the site(s) of urethral obstruction and urethral strictures.

Ultrasonography

- Detects location and approximate size and number of uroliths. However, tends to overestimate stone size and underestimate stone number.
- Does not indicate degree of radiodensity or shape of uroliths.

DIAGNOSTIC PROCEDURES

Cystoscopy reveals location, number, size, and shape of urethroliths and urocystoliths.

PATHOLOGIC FINDINGS

Urethral plugs may contain red blood cells, white cells, transitional epithelial cells, bacteria, and/or viruses in addition to matrix and minerals.

UROLITHIASIS, STRUVITE—CATS

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

- Retrograde urohydropropulsion to eliminate urethral stones, lavage to remove urethral plugs.
- Voiding urohydropropulsion to eliminate bladder and urethral stones, and/or surgery require short periods of hospitalization.
- Medical dissolution of struvite uroliths is an outpatient strategy.

DIET

- Treatment of sterile struvite uroliths with an appropriate diet (prototype diet is Hill's Prescription Diet Feline s/d) typically results in dissolution within 2–4 weeks of therapy. It has become the treatment standard of practice.
- Infection-induced struvite urocystoliths may be dissolved by feeding a calculolytic diet and an appropriate antimicrobial.
- Continue diet therapy for 1 month after survey radiographic evidence of urolith dissolution.
- Struvite crystalluria may be minimized by feeding magnesium-restricted urine-acidifying diets.
- Canned (moist) foods help to reduce urine concentration of calculogenic metabolites and promote increased frequency of normal voiding.

CLIENT EDUCATION

- If dietary management is used, limit access to other foods and treats.
- Short-term (weeks to months) treatment with a calculolytic diet (Hill's Feline s/d) and antibiotics as needed is effective in dissolving infection-induced struvite uroliths.
- Owners of cats with infection-induced struvite urocystoliths must comply with dosage schedule for antibiotic therapy.
- Avoid feeding calculolytic diets to immature cats.

SURGICAL CONSIDERATIONS

- Ureteroliths cannot be dissolved. Consider surgery for persistent ureteroliths associated with morbidity.
- Urethroliths cannot be medically dissolved. Consider voiding urohydropropulsion to remove urethroliths or urethral plugs. Alternatively, move urethroliths into the bladder by retrograde urohydropropulsion.
- Immovable urethroliths, recurrent urethral plugs, or strictures of the distal urethra may require perineal urethrostomy.
- Consider laser lithotripsy for urocystoliths and/or urethroliths.
- Consider surgical correction if uroliths are obstructing urine outflow and/or if correctable abnormalities predisposing to recurrent urinary tract infection are identified by radiography or other means.
- Uroliths and urethral plugs should be localized before considering surgical correction.
- Radiographs should be obtained immediately following surgery to verify that all uroliths were removed.

MEDICATIONS

DRUG(S)

- Dietary dissolution of infection-induced urocystoliths or requires oral administration of appropriate antibiotics, chosen on the basis of bacterial culture and antimicrobial susceptibility tests. Give antibiotics at therapeutic dosages until the urinary tract infection is eradicated and there is no radiographic evidence of uroliths.
- Buprenorphine may be considered to alleviate clinical signs of discomfort; suggested empirical dose is 15 µg/kg via buccal transmucosal administration q8–12h as needed. Tolteridine may be considered as an anticholinergic and antispasmodic to minimize hyperactivity of the bladder detrusor muscle and urge incontinence; the suggested empirical dose is 0.05 mg /kg PO q12h.

CONTRAINDICATIONS

Do not give urine acidifiers to azotemic patients or immature cats.

PRECAUTIONS

Azotemic patients are at increased risk for adverse drug events.

FOLLOW-UP

PATIENT MONITORING

Check rate of urolith dissolution at monthly intervals by urinalysis, urine culture, survey or contrast radiography, or ultrasonography.

PREVENTION/AVOIDANCE

- Recurrent sterile struvite uroliths in cats may be prevented by using acidifying, magnesium-restricted diets or urine acidifiers. Do not administer urine acidifiers with acidifying diets.
- Consider use of a modified high-moisture, magnesium-restricted, acidifying diet that has not been supplemented with sodium (Prescription Diet c/d Multicare Feline) to minimize recurrence of struvite and/or calcium oxalate crystalluria and uroliths.
- For patients whose urine has been acidified, carefully monitor them for calcium oxalate crystalluria. Change management protocol if persistent calcium oxalate crystalluria develops.
- In patients at risk for both struvite and calcium oxalate crystalluria, focus on preventing calcium oxalate uroliths. Struvite uroliths can be medically dissolved; recurrent calcium oxalate uroliths cannot be dissolved.
- Infection-induced struvite urolithiasis can be prevented by eradicating and controlling urinary tract infections. Use of magnesium-restricted, acidifying diets is not required if the urease-positive microbes can be eradicated.

POSSIBLE COMPLICATIONS

- Urocystoliths may pass into and obstruct the urethra of male cats, especially if the patient is persistently dysuric. Urethral obstruction may be managed by retrograde urohydropropulsion.
- An indwelling transurethral catheter increases the risk for iatrogenic bacterial urinary tract infection and/or urethral stricture.

EXPECTED COURSE AND PROGNOSIS

In our hospital, the mean time for dissolution of feline sterile urocystoliths was 1 month (range, 2 weeks–5 months). The mean time for dissolution of infection-induced struvite urocystoliths was 10 weeks (range, 9–12 weeks).

MISCELLANEOUS

ASSOCIATED CONDITIONS

Any disease that predisposes to bacterial urinary tract infection.

AGE-RELATED FACTORS

Infection-induced struvite is the most common urolith in immature cats. Sterile struvite is rare in immature cats.

SYNOMYMS

- Feline lower urinary tract disease
- Feline urologic disease
- FUS

SEE ALSO

UROLITHIASIS, STRUVITE—DOGS

BASICS

DEFINITION

Formation of polycrystalline concretions (i.e., uroliths, calculi, or stones) composed of MAP (a.k.a. as struvite) in the urinary tract.

PATHOPHYSIOLOGY

Infection-Induced Struvite

- Urine must be supersaturated with MAP for struvite uroliths to form. MAP supersaturation of urine may be associated with several factors, including urinary tract infections with urease-producing microbes, alkaline urine, genetic predisposition, and diet. • If animals are affected by urinary tract infections caused by urease-producing microbes (especially species of *Staphylococcus*, *Proteus*, and *Ureaplasma*) and their urine contains sufficient urea, the result is a unique combination of concomitant elevations in the concentrations of ammonium (NH_4^+), phosphate (PO_4^{3-}), and carbonate (CO_3^{2-}) in an alkaline environment. These conditions favor formation of uroliths containing struvite ($\text{MgNH}_4\text{PO}_4 \cdot 6\text{H}_2\text{O}$), calcium apatite [$\text{Ca}_{10}(\text{PO}_4)_6(\text{OH}_2)$], and carbonate apatite [$\text{Ca}_{10}(\text{PO}_4)_6\text{CO}_3$]. • Consumption of dietary protein in excess of the daily requirement for anabolism results in formation of urea from catabolism of amino acids. • The magnitude of hyperammonuria, hypercarbonaturia, and alkaluria mediated by microbial urease depends on the quantity of urea (the substrate of urease) in urine. • Abnormal urinary excretion of minerals as a result of enhanced glomerular filtration rate, reduced tubular reabsorption, or enhanced tubular secretion is not required for initiation and growth of infection-induced struvite uroliths; however, metabolic and anatomic abnormalities may indirectly induce struvite uroliths by predisposing to urinary tract infections.

Sterile Struvite

- Dietary or metabolic factors may be involved in the genesis of sterile struvite uroliths in dogs.
- Microbial urease is not involved in formation of sterile struvite uroliths.

SYSTEMS AFFECTED

Renal/Urologic

GENETICS

- The high incidence of struvite uroliths in some breeds of dogs such as miniature schnauzers suggests a familial tendency. We hypothesize that susceptible miniature schnauzers inherit some abnormality of local host defenses of the urinary tract that increases their susceptibility to urinary tract infection. • Sterile struvite uroliths were found in a family of English cocker spaniels.

INCIDENCE/PREVALENCE

Struvite uroliths account for approximately 40% of stones affecting the canine lower

urinary tract and 33% of stones affecting the upper urinary tract.

GEOGRAPHIC DISTRIBUTION

Ubiquitous

SIGNALMENT

Species

Dog (see Urolithiasis, Struvite—Cats)

Breed Predilections

- Miniature schnauzer, Shih Tzu, Bichon Frise, miniature poodle, cocker spaniel, and Lhasa apso. • Any breed may be affected.

Mean Age and Range

- Mean age, 6 years (range < 1 to > 19 years).
- Most uroliths in immature (< 12 months old) dogs are infection-induced struvite.

Predominant Sex

More common in females (~85%) than males (~15%), which may be related to the greater propensity of females to develop bacterial UTI.

SIGNS

General Comments

- Some dogs are asymptomatic. • Signs depend on location, size, and number of uroliths.

Historical Findings

- Typical signs of urocystoliths include pollakiuria, dysuria, and hematuria; sometimes small, smooth uroliths are voided.
- Typical signs of urethroliths include pollakiuria and dysuria; sometimes small, smooth uroliths are voided. • Nephroliths may be associated with manifestations of renal insufficiency. Obstruction to urine outflow with bacterial urinary tract infection may result in generalized pyelonephritis and septicemia.

Physical Examination Findings

- Uroliths may be palpated in the urinary bladder and urethra (by rectal exam).
- Obstruction of the urethra may cause enlargement of the urinary bladder.
- Obstruction of a ureter may cause enlargement of the associated kidney.
- Complete urine outflow obstruction combined with bacterial infection may cause ascending urinary tract infection, signs of renal failure, and signs of septicemia.

CAUSES

- Urinary tract disorders that predispose to infections with urease-producing bacteria, fungal pathogens, or ureaplasma in patients whose urine contains a large quantity of urea.
- Specific causes of sterile struvite uroliths are unknown.

RISK FACTORS

- Exogenous or endogenous exposure to high concentrations of glucocorticoids predispose to bacterial urinary tract infection.
- Abnormal retention of urine. • Alkaline urine decreases the solubility of struvite.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Uroliths mimic other causes of pollakiuria, dysuria, hematuria, and/or outflow obstruction. • Differentiate from other types of uroliths by signalment, rectal exam, urinalysis, urine culture, radiography, and quantitative analysis of voided or retrieved uroliths.

CBC/BIOCHEMISTRY/URINALYSIS

- Complete outflow obstruction can cause post-renal azotemia (e.g., high BUN, creatinine, and phosphorus). • Magnesium ammonium phosphate crystals typically appear as colorless, orthorhombic (having three unequal axes intersecting at right angles), coffin-like prisms. They may have three to six or more sides and often have oblique ends.

OTHER LABORATORY TESTS

- Quantitative bacterial culture of urine, preferably collected by cystocentesis.
- Bacterial culture of inner portions of infection-induced struvite uroliths.
- Quantitative mineral analysis of uroliths retrieved during voiding, by voiding urohydropropulsion, by aspiration into a urinary catheter, or by cystoscopy.

IMAGING

- Struvite uroliths are radiodense and may be detected by survey radiography.
- Ultrasonography—can detect uroliths, but provides no information about their density or shape. • Determine precise location, size, and number of uroliths; the size and number are not a reliable index of probable efficacy of dissolution therapy.

TREATMENT

APPROPRIATE HEALTH CARE

- Retrograde urohydropropulsion to move urethral stones and reestablish urethral patency, voiding urohydropropulsion to eliminate bladder stones. • Shock-wave lithotripsy and/or surgery require short periods of hospitalization. • Medical dissolution of struvite uroliths is an outpatient strategy.

DIET

- Infection-induced and sterile struvite urocystoliths and nephroliths may be dissolved by feeding a calculolytic food (Hill's Prescription Diet Canine s/d). • Continue calculolytic diet therapy for 1 month beyond survey radiographic evidence of urolith dissolution. • Avoid use of the protein-restricted diet in patients with protein-calorie malnutrition. The calculolytic diet is designed

UROLITHIASIS, STRUVITE—DOGS

(CONTINUED)

for short-term (weeks to months) dissolution therapy, rather than long-term (months to years) prophylactic therapy. If used, monitor the patient for evidence of protein malnutrition. Avoid prolonged feeding of the calculolytic diet to immature dogs.

CLIENT EDUCATION

- If dietary management is used, limit access to other foods and treats.
- Short-term treatment with a calculolytic food and administration of antibiotics has been effective in dissolving struvite uroliths.
- Comply with dosage schedule for antibiotic and diet therapy.

SURGICAL CONSIDERATIONS

- Ureteroliths cannot be dissolved; consider surgery or shock-wave (ESWL) lithotripsy for persistent ureteroliths associated with morbidity.
- Urethroliths cannot be medically dissolved; consider voiding urohydropropulsion if the urethroliths are likely to pass through the entire length of the urethra. Alternatively, consider lithotripsy or move urethroliths into the bladder by retrograde urohydropropulsion.
- Immovable urethroliths may require urethrotomy or urethrostomy.
- Nephroliths causing outflow obstruction or associated with non-functioning kidneys cannot be dissolved medically.
- Consider surgical correction if uroliths are obstructing urine outflow and/or if correctable abnormalities predisposing to recurrent urinary tract infection are identified by radiography or other means.

MEDICATIONS

DRUG(S)

- Dietary dissolution of infection-induced urocystoliths or nephroliths requires oral administration of appropriate antibiotics, chosen on the basis of quantitative bacterial culture and antimicrobial susceptibility tests. Give antibiotics at therapeutic dosages until there is no radiographic evidence of uroliths and there is laboratory confirmation of eradication of urinary tract infection.
- Patients with infection-induced struvite urocystoliths associated with persistent bacterial infection with urease-producing bacteria and refractory to dietary and antibiotic dissolution may be given AHA (Lithostat, Mission Pharmacal, 12.5 mg/kg PO q12h). AHA is a urease inhibitor that blocks hydrolysis of urea to ammonia.

CONTRAINDICATIONS

AHA is teratogenic and should not be given to pregnant dogs.

PRECAUTIONS

- Diet-induced polyuria will reduce the concentration of antimicrobial drugs in urine; consider this fact when calculating antimicrobial dosages.
- Prolonged administration of AHA at higher doses

induces abnormalities in bilirubin metabolism in some dogs.

- Higher doses of AHA may induce a reversible hemolytic anemia.

FOLLOW-UP

PATIENT MONITORING

Monitor rate of urolith dissolution at monthly intervals by urinalysis, urine culture, ultrasonography, and/or survey or contrast radiography.

PREVENTION/AVOIDANCE

- Infection-induced struvite urolithiasis may be prevented by eradicating and controlling infections by urease-producing bacteria.
- Recurrent sterile struvite uroliths may be prevented by use of acidifying, magnesium-restricted diets (Hill's Prescription Diet Canine c/d) or urine acidifiers.
- Monitor patients whose urine has been acidified for calcium oxalate crystalluria. Change management protocol if persistent calcium oxalate crystalluria develops.
- In patients at risk for both struvite and calcium oxalate crystalluria, focus on prevention of calcium oxalate uroliths—struvite uroliths can be medically dissolved if they recur; recurrent calcium oxalate uroliths cannot be dissolved.

POSSIBLE COMPLICATIONS

- Benefits and risks are associated with feeding struvitolytic diets. Not all patients qualify for dietary medical management, including those with (1) abnormal fluid accumulation, (2) azotemic primary renal failure, and (3) predispositions to pancreatitis (especially miniature schnauzers with hyperlipidemia).
- Urocystoliths may pass into and obstruct the urethra of male dogs, especially if the patient is persistently dysuric. Urethral obstruction may be managed by retrograde urohydropropulsion or lithotripsy.
- Dysuria may be minimized by antimicrobial treatment of bacterial urinary tract infections and oral administration of anticholinergic drugs.
- Dogs that do not consume their daily requirement of the calculolytic diet may develop varying degrees of protein calorie malnutrition. This can be prevented by proper calculation of the daily dietary requirement and adjustment in the quantity of food fed on the basis of serial physical examination.
- Diet-associated polyuria will result in voiding increased urine volume. This may be associated with varying degrees of urinary incontinence in neutered female dogs with a predisposition to estrogen-responsive incontinence.

EXPECTED COURSE AND PROGNOSIS

- In our hospital, the mean time for dissolution of infection-induced urocystoliths in dogs was approximately 3 months (range 2 weeks–7 months). The mean time for dissolution of infection-induced struvite

nephroliths in dogs was 6 months (range 2–10 months). The mean time for dissolution of sterile struvite urocystoliths in dogs was 6 weeks (range 4–12 weeks).

- Compliance with dietary recommendations is suggested by a reduced concentration of urea in serum (approximately 10 mg/dL), and a low urine specific gravity (1.004–1.014).
- If uroliths increase in size during dietary management or do not begin to decrease in size after approximately 4–8 weeks of appropriate medical management, alternative methods should be considered. Difficulty in inducing complete dissolution of uroliths by creating urine under-saturated with struvite should prompt consideration that (1) the wrong mineral component was identified, (2) the nucleus of the uroliths has a different mineral composition than other portions of the urolith, and (3) the owner is not complying with therapeutic recommendations.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Any disease that predisposes to bacterial urinary tract infection.

AGE-RELATED FACTORS

Infection-induced struvite is the most common form of urolith in immature dogs. The uroliths develop as a result of microbial UTI.

PREGNANCY/FERTILITY/BREEDING

- AHA is teratogenic.
- The calculolytic food is not designed to sustain pregnancy.

SYNOMYS

- Phosphate calculi
- Infection stones
- Urease stones
- Triple-phosphate stones

ABBREVIATIONS

- AHA = acetohydroxamic acid
- ESWL = extracorporeal shock wave lithotripsy
- MAP = magnesium ammonium phosphate
- UTI = urinary tract infection

UROLITHIASIS, URATE

BASICS

DEFINITION

Uroliths composed of uric acid, sodium urate, or ammonium urate

PATHOPHYSIOLOGY

- Impaired conversion of uric acid to allantoin causes high concentration of uric acid in serum and urine.
- Patients with portosystemic shunts may develop ammonium urate uroliths because of impaired hepatic metabolism of uric acid and ammonia.

GENETICS

Dalmatians have a breed predisposition to forming urate urolithiasis.

INCIDENCE/PREVALENCE

Approximately 5–8% of uroliths retrieved from dogs and cats

SIGNALMENT

Species

Dog and cat

Breed Predilections

Dalmatians, English bulldogs, and breeds at risk for portosystemic shunts (e.g., Yorkshire terriers).

Mean Age and Range

- Mean age in patients without portosystemic shunts is 3.5 years (range, 0.5 to > 10 years).
- Mean age in patients with portosystemic shunts is < 1 year (range, 0.1 to > 10 years).

Predominant Sex

- More common in male dogs without portosystemic shunts.
- No sex predilection in dogs with portosystemic shunts or cats.

SIGNS

Historical Findings

Hematuria, dysuria, pollakiuria. Possible hepatic encephalopathy in patients with portosystemic shunts.

Physical Examination Findings

- Urethral obstruction
- No signs in some patients
- Stunted growth and copper-colored irises (cats) in patients with portosystemic shunts

CAUSES

Rule out portosystemic shunt

RISK FACTORS

- High purine intake (glandular meat)
- Persistent aciduria in a predisposed animal

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of lower or upper urinary tract disease

CBC/BIOCHEMISTRY/URINALYSIS

- Aciduria, urate crystalluria, azotemia in patients with urinary outflow obstruction.
- Low BUN and microcytosis in patients with portosystemic shunts; reduced production of urea by the liver may mask hypoglycemia, hypoalbuminemia, and increased hepatic enzyme activities in patients with more severe hepatic dysfunction.

OTHER LABORATORY TESTS

Liver function tests such as bile acids have abnormal results in patients with portosystemic shunts.

IMAGING

- Urate uroliths may be radiolucent; may need intravenous pyelogram to detect nephroliths or double contrast cystography to detect urocystoliths. Microhepatitis in patients with portosystemic shunts.
- Ultrasonography may reveal small uroliths and a portosystemic shunt.

DIAGNOSTIC PROCEDURES

Liver biopsy; bile acids, blood ammonia

PATHOLOGIC FINDINGS

In patients with portosystemic shunts, liver biopsy may reveal hepatic atrophy and/or dysplasia.

TREATMENT

APPROPRIATE HEALTH CARE

Urethral or ureteral obstruction may require inpatient treatment. Urate uroliths can be dissolved on outpatient basis.

NURSING CARE

Fluid therapy to correct dehydration

ACTIVITY

Usually not restricted, except after surgery

DIET

For dissolution and prevention, a high moisture, low-purine, urine-alkalinizing diet.

CLIENT EDUCATION

Recurrence of uroliths is possible. Therefore a plan to minimize recurrence should be developed.

SURGICAL CONSIDERATIONS

- Cystotomy, urethrotomy, nephrotomy, percutaneous cystolithotomy, or cystoscopy and retrieval or laser lithotripsy to remove uroliths.
- Portosystemic shunt ligation.

MEDICATIONS

DRUG(S)

Allopurinol (15 mg/kg PO q12h), a xanthine oxidase inhibitor, for dissolution (see Figure 2).

CONTRAINdications

Glucocorticoids and other immunosuppressive drugs may promote hyperuricosuria.

Endogenous Purines
Dietary Purines
↓
Purine Pool

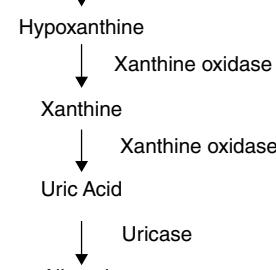

Figure 1.

PRECAUTIONS

Allopurinol is contraindicated in animals with renal failure and is not effective in animals with portosystemic shunts.

POSSIBLE INTERACTIONS

Skin eruption with use of allopurinol and ampicillin.

FOLLOW-UP

PATIENT MONITORING

See Figure 3.

PREVENTION/AVOIDANCE

High-moisture, low-purine, urine-alkalinizing diet

POSSIBLE COMPLICATIONS

- Urethral obstruction
- Uroliths likely to recur if no preventive measures

EXPECTED COURSE AND PROGNOSIS

- Medical dissolution takes an average of 4 weeks, if there is good compliance.
- Medical dissolution usually not successful with portosystemic shunt.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Portosystemic shunt

PREGNANCY/FERTILITY/BREEDING

Low-protein/purine diet is not recommended for pregnant or lactating animals.

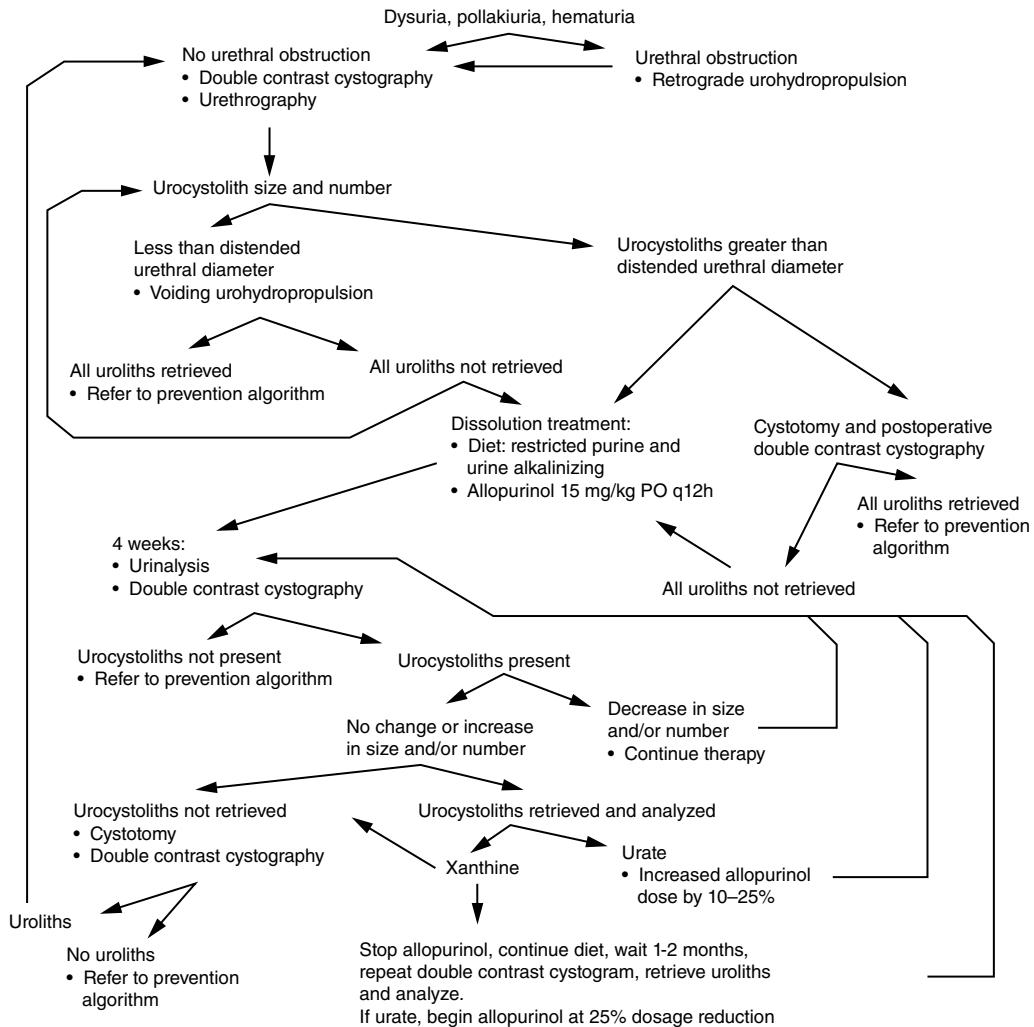

Figure 2.

Algorithm for treatment of urate urocystolithiasis.

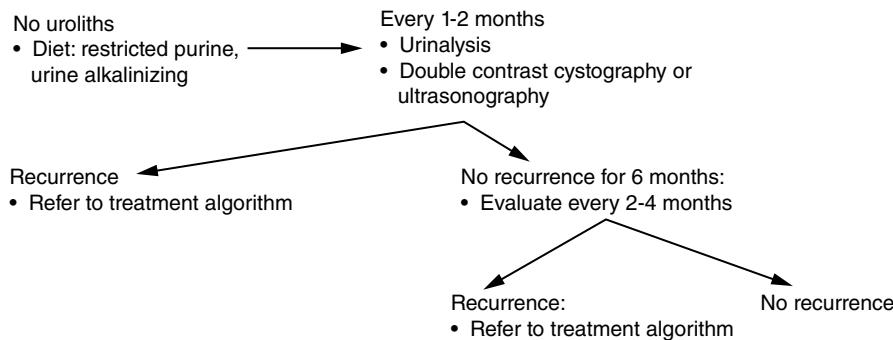

Figure 3.

Algorithm for prevention of urate urocystolithiasis.

UROLITHIASIS, XANTHINE

BASICS

OVERVIEW

- Xanthine, a degradation product of purine metabolism, is converted to uric acid by the enzyme xanthine oxidase. Naturally occurring (enzyme deficiency) or drug-induced (allopurinol) impairment of xanthine oxidase ultimately results in hyperxanthinemia and xanthinuria. • In naturally occurring xanthinuria, a familial or congenital defect in xanthine oxidase activity is likely. A breed predisposition has not been identified in cats (number = 392 submitted to the Minnesota Urolith Center (MUC) 1981–2014). In Cavalier King Charles spaniels, an autosomal recessive mode of inheritance has been postulated to occur. Xanthine nephrolithiasis in a dachshund associated with renal failure has been reported. • Acquired xanthinuria is a common complication of treatment of urate urolithiasis or leishmaniasis with allopurinol. High purine diets increase the risk of xanthinuria in patients treated with allopurinol. • Xanthine is the least soluble of the purines excreted in urine.

SIGNALMENT

- Dog and cat. Naturally occurring xanthinuria is more common in cats than in dogs. • In dogs, allopurinol-induced xanthinuria may affect any breed, age, or gender. Naturally occurring xanthinuria and xanthine uroliths have been observed in young Cavalier King Charles spaniels. • In cats, xanthine uroliths affect adult males (66%) and females (33%) (mean age at diagnosis 3.3 years; range 2 months–13 years). Most common in the domestic shorthair and domestic longhair breeds.

SIGNS

- Dependent on location, size, and number of uroliths. • Pollakiuria, dysuria, hematuria and voiding of small, smooth, yellow uroliths. Complete outflow obstruction may result in azotemia. • May be asymptomatic. Nephroliths may be associated with hydronephrosis and renal insufficiency.

CAUSES & RISK FACTORS

- Xanthinuria • Canine breed predisposition include Cavalier King Charles spaniels and dachshunds. • Cats: uroliths often recur unless prophylactic therapy is initiated.
- Retrospective data from the MUC shows that approximately 11% of cats had > 1 occurrence of xanthine uroliths. Urolith formation enhanced by acid urine pH, highly concentrated urine, and incomplete and infrequent micturition. • In animals given excessive allopurinol, xanthinuria is enhanced by failure to appropriately restrict dietary purine precursors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Uroliths mimic other causes of pollakiuria, dysuria, hematuria, and/or outflow obstruction. • Differentiate from other types of uroliths, especially ammonium urate, by urinalysis, radiography, and quantitative analysis of retrieved uroliths.

CBC/BIOCHEMISTRY/URINALYSIS

Xanthine crystals cannot be distinguished from ammonium urate or amorphous urates by light microscopy. All these crystals are usually brown or yellow-brown and may form spherules of varying size.

OTHER LABORATORY TESTS

- Infrared spectroscopy, X-ray diffraction, or other quantitative techniques are required to differentiate xanthine from ammonium urate, sodium urate, and uric acid. • High-pressure liquid chromatography of urine to detect xanthine, hypoxanthine, and other purine metabolites.

IMAGING

- Radiography—Similar to that of soft tissue. Cannot be reliably detected by survey radiography. • Ultrasonography, double contrast cystography, and intravenous urography aid in detecting uroliths and their location.

OTHER DIAGNOSTIC PROCEDURES

- May be detected by urethrocytostoscopy.
- Uroliths for analysis may be retrieved by aspiration via a transurethral catheter or voiding urohydropropulsion.

TREATMENT

- Medical protocols that consistently promote dissolution of xanthine uroliths have not been developed. • Remove small urocystoliths by voiding urohydropropulsion. • Surgery remains the most reliable method to remove larger active uroliths from the lower urinary tract. • Minimize further growth of existing uroliths by reducing dietary risk factors. Discontinue or reduce allopurinol medication dosages. • Pending further studies in cats with naturally occurring xanthine uroliths, consider canned renal-failure diets to increase urine volume, minimize purine precursors, and minimize formation of acid urine.
- Consider perineal urethrostomies for recurrent urethral obstruction in male cats.

MEDICATIONS

DRUG(S)

Urine Alkalinizers

- Consider in patients that have acid urine despite dietary therapy. • A sufficient quantity

of potassium citrate or sodium bicarbonate should be given to sustain a urine pH of 7.0–7.5.

Allopurinol

- When treating urate urolithiasis in dogs, adjust dosage of allopurinol in context of magnitude of concentration of urine, uric acid, and quantity of dietary purines (see Urolithiasis, Urate). • In dogs, allopurinol-induced uroliths may dissolve by discontinuing allopurinol therapy but continuing a low purine diet.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Do not give allopurinol to cats or dogs with naturally occurring xanthine uroliths.

FOLLOW-UP

- Monitor dissolution at 30-day intervals by urinalysis, contrast radiography or ultrasonography. • Recurrence does not occur in all xanthinuric cats and dogs.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Urate urolithiasis • Nephrolithiasis

SEE ALSO

- Crystalluria • Urolithiasis, Urate

U

UTERINE INERTIA

BASICS

OVERVIEW

Failure to expel fetuses of normal size and with normal presentation and posture through a normal birth canal at the normal end of gestation.

Primary Uterine Inertia

- Multifactorial—failure to establish a normal, progressive myometrial contraction pattern.
- Seen in large-breed dogs with one to two puppies in the litter—failure to initiate parturition at term.
- Occurs with large litter sizes—overstretching of the uterus.

Secondary Uterine Inertia

- Occurs following initiation of parturition where some or all of the litter is not expelled.
- Can be secondary to dystocia or large litter.

SIGNALMENT

Female cat and dog of any age

SIGNS

- Primary—failure to initiate parturition at the end of gestation; dam is typically asymptomatic except for possible vaginal discharge following placental separation; fetal heart rates decline with delay in intervention.
- Secondary—contractions cease despite normal contractions initially; may deliver part of litter and then stop; fetal heart rates decline with delay in intervention.

CAUSES & RISK FACTORS

- Primary—inadequate stimulation from fetuses to initiate cascade of events leading to parturition (small litters); abnormal or inadequate hormones or receptors; systemic disease; obesity; tocolytic administration; hypocalcemia; uterine infection; inadequate or unbalanced nutrition.
- Secondary—follows exhaustion of uterine muscle during normal parturition of large litters; occurs during dystocia after prolonged periods of uterine contraction and eventual uterine fatigue; can occur with uterine torsion and trauma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary—inaccurate predicted parturition date; false pregnancy; non-viable pregnancy.
- Secondary—normal parturition; parturition already complete.

CBC/BIOCHEMISTRY/URINALYSIS

- Normocytic, normochromic anemia (normal in pregnancy).
- Hypercholesterolemia (normal in pregnancy).
- May have low total calcium or low iCa.
- Hypoglycemia may be seen in some bitches but is not thought to play a significant role in uterine inertia.

OTHER LABORATORY TESTS

Serum progesterone < 2 ng/mL for 48 hours prior to parturition in most cases.

IMAGING

- Ultrasonography findings—fetal heart rates sustained < 160–170 indicate stress and need for intervention; separation of the placenta from the uterus—need for immediate intervention to optimize survival of litter.
- Radiographic findings—evaluate for presence; size; and any abnormalities of presentation, position, and posture of fetus(es).

DIAGNOSTIC PROCEDURES

Digital vaginal examination to evaluate for presence of fetus within caudal birth canal and abnormal anatomy causing narrowed birth canal.

TREATMENT

- Inpatient—if live fetus(es) are present and fetal stress is documented, the best option for survival is immediate c-section; surgery is the only option for primary uterine inertia when fetal survival is desired.
- Fluid therapy as needed for hydration.
- Medical—for secondary uterine inertia with non-obstructive dystocia and no evidence of fetal distress.

MEDICATIONS

DRUG(S)

- 10% calcium gluconate (1 mL/5 kg SC q4-6h or 0.2 mL/kg IV)—if hypocalcemia documented.
- 2.5–5% dextrose-containing fluids if hypoglycemic.
- Oxytocin not typically effective as the sole treatment for true uterine inertia cases; use 15–30 minutes after calcium treatment; 0.5–4 IU/dog SC or IM; 0.5–1 IU/cat SC or IM; do not administer to cases of obstructive dystocia.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Cardiac arrhythmia with calcium treatment, monitor electrocardiogram and discontinue treatment if arrhythmia noted. Continuous ECG recommended with IV calcium administration.
- Contractions may resume with calcium treatment and rehydration alone.
- Delaying surgery while pursuing medical management may decrease fetal survival rate.
- Uterine rupture (rare).

FOLLOW-UP

PATIENT MONITORING

- Follow iCa levels in hypocalcemic cases; calcium supplementation indicated while

lactating for cases with eclampsia.

- Monitor dam's temperature and character of vaginal discharge daily for 5–7 days following dystocia or C-section—concern for metritis.

- Tocodynamometry to monitor contractions and fetal wellbeing during parturition (WhelpWise, Veterinary Perinatal Specialties, Wheatridge, CO, 303-423-3429).

PREVENTION/AVOIDANCE

- Optimize breeding management to help increase litter size in cases of primary inertia due to small litter.
- Advise only breeding bitches in good body condition and monitor nutrition during pregnancy.
- Utilize tocodynamometry to identify secondary uterine inertia early; allows prompt augmentation of contractions.
- Remove animals with repeated primary uterine inertia from breeding stock.

POSSIBLE COMPLICATIONS

- Death of viable fetuses if too much time elapses before intervention.
- Primary inertia thought to be heritable in some breeds of dogs and cats.

EXPECTED COURSE AND PROGNOSIS

- Primary uterine inertia—may recur on subsequent pregnancies; elective C-section can optimize fetal survival rate.
- Secondary uterine inertia—will not necessarily recur if due to fetal factors such as large litter size or dystocia due to malpresentation.

MISCELLANEOUS

ASSOCIATED CONDITIONS

SEE ALSO

- Dystocia • Eclampsia

ABBREVIATION

iCa = ionized calcium

UTERINE TUMORS

BASICS

OVERVIEW

- Rare tumors arising from the uterine smooth muscle and epithelial tissues.
- Comprise 0.3–0.4% of tumors in dogs and 0.2–1.5% in cats.
- Dogs—usually benign; leiomyomas, 85%–90%; leiomyosarcoma, 10%; other types (e.g., carcinoma, fibroma, fibrosarcoma, lipoma, plasmacytoma, hemangiosarcoma) rare.
- Cats—usually malignant (adenocarcinoma); include leiomyoma, leiomyosarcoma, fibrosarcoma, fibroma, lipoma, and Müllerian tumor (adenosarcoma).
- Metastasis—may occur with malignant forms.

SIGNALMENT

- Dog and cat.
- No breed predilection reported.
- Middle-aged to older animals usually affected.
- Birt-Hogg-Dube syndrome in German shepherd dogs has been associated with uterine leiomyomas, renal cystadenocarcinomas, and nodular dermatofibrosis.

SIGNS

- Dogs—often clinically silent and discovered incidentally; vaginal discharge; pyometra, infertility; abdominal organ compression or secondary metastatic signs.
- Cats—vaginal discharge (may be hemorrhagic); abnormal estrous cycles; polyuria; polydipsia; vomiting; abdominal distention, infertility, uterine prolapse; signs related to metastatic disease.

CAUSES & RISK FACTORS

- Intact sexual status (hormonal influence)
- Mutated BHD gene in German shepherds

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pyometra
- Other mid-caudal abdominal masses

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities

OTHER LABORATORY TESTS

N/A

IMAGING

- Abdominal radiography—may detect a mid-caudal abdominal mass.
- Thoracic radiography—recommended; assess for distant pulmonary metastasis.
- Ultrasonography—may reveal uterine mass.
- Abdominal CT/MRI—further delineation of mass, assess for metastatic disease.

DIAGNOSTIC PROCEDURES

- Cytologic evaluation—however, tumors might be poorly exfoliative.
- Histopathologic examination—necessary for definitive diagnosis.

TREATMENT

Ovariohysterectomy—treatment of choice

MEDICATIONS

DRUG(S)

Doxorubicin, cisplatin, carboplatin, epirubicin—rational choices for palliation of malignant or metastatic disease.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Doxorubicin—carefully monitor patients with underlying cardiac disease; consider pretreatment and serial echocardiograms and ECG.
- Cisplatin—do not use in dogs with preexisting renal disease; do not use without appropriate and concurrent diuresis; do not use in cats (fatal).
- Chemotherapy may be toxic; seek advice if unfamiliar with these agents.

FOLLOW-UP

PATIENT MONITORING

- Malignant—consider thoracic and abdominal radiographs every 3 months.

- CBC, biochemical profile, and urinalysis (if using cisplatin)—perform before each chemotherapy treatment.

EXPECTED COURSE AND PROGNOSIS

Prognosis—excellent (cure) if benign; guarded if malignant; poor if metastases present; after chemotherapy, unknown.

MISCELLANEOUS

ASSOCIATED CONDITIONS

BHD syndrome in German shepherd dogs has been associated with uterine leiomyomas.

ABBREVIATIONS

- BHD = Birt-Hogg-Dube
- CT = computed tomography
- ECG = electrocardiogram
- MRI = magnetic resonance imaging

UVEAL MELANOMA—CATS

BASICS

OVERVIEW

- Also called feline diffuse iris melanoma.
- The most common intraocular tumor in cats. • Usually arise from the anterior iridal surface with extension to the ciliary body and choroid. • Tend to be flat and diffuse, not nodular (unlike intraocular melanomas in dogs). • Initially has a benign clinical and histologic appearance. • Unique feature—may develop metastatic disease up to several years later. • Metastatic rate may be up to 63%, though another study found metastatic lesions in 3 of 37 feline ocular melanoma cases (8.1%). • Secondary glaucoma may increase the risk for metastasis.

SIGNALMENT

- No sex or breed predisposition. • Average age is 9.5 years, although can affect any adult cat.

SIGNS

Historical Findings

- Iris color change. • Secondary glaucoma leading to mydriasis or buphthalmia, resulting in blindness.

Physical Examination Findings

- Iris surface—thickened, irregular, usually pigmented, though can be non-pigmented.
- Lesions—focal to diffuse; usually flat; slowly progressive; may involve one or both eyes.
- Advanced disease—often see pigmented tumor cells in the aqueous; homogeneously thickened iris. • May note drainage angle infiltration, which may result in secondary glaucoma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Freckles on the surface of the iris that do not appear to change over time—may be benign pigmented lesions; more likely melanocytoma, a benign lesion.
- Heterochromia irides—congenital, non-progressive alteration in iridal pigmentation. • Diffuse iridal color change that results from chronic anterior uveitis. Differs from uveal melanoma by the history of chronic anterior uveitis. • Iris atrophy—the anterior iris stroma is lost, increasing visualization of the heavily pigmented posterior iris tissue. Iris thinning is seen as full-thickness holes in the iris or as retroillumination defects in the iris when light is bounced off the tapetum back through the iris. • Limbal melanomas—benign behavior; usually focal, superiorly located, flat to slightly raised limbal masses that do not invade the uveal tract unless they are very large.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

IMAGING

- Thoracic radiographs and abdominal ultrasonography for extensive lesions—help determine presence and extent of metastatic disease. • Recommended presurgically and every 6 months after the diagnosis if histopathologic diagnosis indicates extensive disease.

DIAGNOSTIC PROCEDURES

- Complete ophthalmic examination, including tonometry and gonioscopy.
- Fine-needle aspiration of the iridal surface (“vacuuming”)—diagnostic value questionable; not beneficial for staging.
- Iridal biopsy—may be performed, not beneficial for staging the disease.
- Melanocytes in the iridocorneal angle and ciliary vessels suggest metastasis may have occurred, but these may not be evident for years later.

TREATMENT

- Varies with age of cat, extent and speed of progression, ophthalmologist's preference, and client's level of concern about the potential for malignancy. • Old cat with slow progression—consider only periodic examinations and serial photography to monitor the progress of the lesion(s). • Younger cat with rapidly progressive disease—consider enucleation.
- Small, isolated, freckle-like lesions have been apparently successfully treated with laser (diode) photoablation, although controlled or long-term follow-up studies are lacking.
- Mild to moderate diffuse iridal involvement—most ophthalmologists prefer a conservative approach of periodic examinations and serial photography to monitor the growth progress of the lesion(s). Enucleation is an alternative if progression can be documented or the owner is highly concerned about the potential for malignancy.
- Extensive iridal involvement resulting in changes in pupil shape or mobility, extra-iridal extension, invasion into the drainage angle, or secondary glaucoma—enucleation is suggested. • Cats with iridal thickening and iridocorneal angle involvement, with and without glaucoma, however, had similar survival times when compared with unaffected age-matched control cats.
- Advanced lesions consisting of infiltrative iris involvement including the posterior epithelium and ciliary body had decreased survival times, presumably as a result of metastatic disease. • When enucleating, use a gentle technique; in humans enucleation has been associated with metastasis.

MEDICATIONS

DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- IOP—quarterly monitoring if surgical options are declined; mild IOP elevation may be treated with oral or topical carbonic anhydrase inhibitors (e.g., dorzolamide or brinzolamide at 1 drop to affected eye q8h, or methazolamide at approximately 6.25 mg per cat PO q12–24h); secondary glaucoma due to melanoma is best controlled by enucleation.
- Common metastasis sites—liver, lungs, regional lymph nodes; monitor periodically.

EXPECTED COURSE AND PROGNOSIS

- One long-term study shows that patients with early iris melanoma have no increased risk of life-threatening metastasis compared to controls, but patients with advanced lesions have dramatically shortened survival times.
- Lesions—focal, multifocal to diffuse; usually flat; pigmentation over months to years (i.e., variable); may involve one or both eyes.
- Advanced disease—often see pigmented tumor cells in the aqueous; homogeneously thickened iris causing abnormal pupil shape and change in pupil mobility. • Prognosis—guarded, even with enucleation; metastasis may not become apparent for several years or may be diagnosed on necropsy.

MISCELLANEOUS

SYNOMYMS

- Diffuse iris melanoma • Iris melanoma

ABBREVIATION

- IOP = intraocular pressure

UVEAL MELANOMA—DOGS

BASICS

OVERVIEW

- Melanomas of the anterior uvea (e.g., iris and ciliary body) and posterior uvea (choroid). • Most common primary intraocular neoplasm in dogs. • Usually benign and unilateral; often destructive to the eye but also can be very slow-growing. • Most often affects the anterior uvea. In a retrospective study of 1842 enucleated eyes with uveal melanoma, 79.2% were benign and 20.8% malignant. • Anterior uveal—4% rate of vascular metastasis to lungs and viscera, but rare for malignant uveal melanoma to metastasize. • Choroidal—rarely metastasize.

SIGNALMENT

- No breed or sex predilection • Anterior uveal—average age 8–10 years • Choroidal melanoma—average age 6.5 years
- Range—2 months to 17 years

SIGNS

Anterior Uveal

- Pigmented scleral or corneal mass.
- Pigmented mass visible in the anterior chamber or posterior to the pupillary margin.
- Irregular pupil. • Uveitis. • Glaucoma.
- Hyphema. • No vision loss—unless mass obstructs the pupil or glaucoma has developed.

Choroidal

- Often missed because of tumor location; usually an incidental finding. • Posterior segment mass on funduscopy. • Very slow growing; rarely require enucleation. • Rare tumor.

CAUSES & RISK FACTORS

- Idiopathic. • Potential transformation of flat, pigmented iris freckles into melanomas.
- Young Labrador retrievers—presumed autosomal recessive inheritance.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Non-neoplastic uveal proliferations—iris freckles are not raised. • Diffuse iris hyperpigmentation secondary to chronic uveitis, particularly in golden retrievers (golden retriever pigmentary uveitis/golden retriever uveitis) and in boxers. • Ocular melanosis in cairn terriers. • Uveal cysts—transilluminate and may move freely within the eye, unlike melanomas. • Granulomatous masses. • Iris bombe. • Ocular perforation with uveal prolapse. • Other ocular neoplastic conditions, especially conjunctival melanoma, which could be misinterpreted as extra-scleral extension of uveal melanoma. Conjunctival

melanoma is usually malignant and behaves aggressively in dogs, making it essential to differentiate it from uveal melanoma.

- Outward scrolling of pupillary margin owing to uveitis (ectropion uvea).

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY TESTS

N/A

IMAGING

Ocular ultrasonography—may help determine the extent of the mass.

DIAGNOSTIC PROCEDURES

- Slit-lamp biomicroscopy—determine size and location of mass. • Transillumination of mass. • Tonometry. • Indirect ophthalmoscopy—with or without concomitant scleral indentation.
- Gonioscopy—evaluate drainage angle for tumor extension. • Ocular ultrasonography—if cornea opaque and cannot visualize deeper ocular structures, or suspect ciliary body mass hidden by iris.

PATHOLOGIC FINDINGS

- Usually restricted to the enucleated globe; biopsy not practical in most patients. • Two cell types usually seen—plump cells filled with melanin, spindle cells. • Benign appearance and low mitotic index (< 2 mitotic figures per 10 high power fields) common. • Mitotic index—most reliable criterion for malignancy; usually 4 mitotic figures per 10 high power fields in clinically malignant tumors. • When submitting eyes for histologic evaluation, request bleached tissue sections and mitotic index. • Best if veterinary ocular pathologist evaluates globe histologically.

TREATMENT

- Usually benign, may opt to monitor every 3–6 months. • Young Labrador retrievers—aggressive growth, need surgery. • Counsel the client about enucleation; this surgery often causes the client emotional distress.
- Emphasize that the condition is unilateral, sparing the fellow eye, and that one-eyed animals function very well. • Indications for enucleation—size of the mass increases rapidly; eye cannot be salvaged; mass spreads diffusely within the eye; visual function significantly impaired; extra-ocular invasion; secondary complications (e.g., glaucoma, signs of pain, and hemorrhage). Note: glaucoma is painful (headache), but owner often does not realize this. • Enucleation technique—use gentle surgical technique to prevent showering of tumor cells into the vascular circulation; avoid tension on optic chiasm, as could blind fellow eye; exenterate the entire orbital contents, if extra-scleral

extension is noted. • Other surgical treatments—infrequently used; sector iridectomy and iridocyclectomy of discrete small masses. • Laser treatment of small iris tumor. • Melanoma vaccine efficacy unknown; vaccine likely ineffective for patients without enucleation. Consider vaccine if malignant melanoma is present, to try to prevent metastasis. Cost is a potential deterrent.

MEDICATIONS

DRUG(S) OR COMPLEMENTARY

ALTERNATIVE MEDICATION

Reseveratrol, a potent antioxidant, inhibits uveal tumor growth in two animal models (mouse and human cell line) of uveal melanoma, but when sourced from the grapeskin, it should be avoided in dogs due to potential toxicity. Grapeseed extract is a safe alternative that may be beneficial to support ocular health of affected dogs.

CONTRAINdicATIONS/POSSIBLE
INTERACTIONS

N/A

FOLLOW-UP

- Postoperative thoracic and abdominal radiography or ultrasonography—at 6 and 12 months if the mitotic index is high or the patient has extra-scleral, vascular, or optic nerve extension. • Evaluate the enucleation site for tumor recurrence.

U

UVEODERMATOLOGIC SYNDROME (VKH)

BASICS

OVERVIEW

- Rare syndrome similar to Vogt-Koyanagi-Harada syndrome in humans.
- Chronic granulomatous inflammatory condition of unknown etiology.
- Affects the eyes, skin, and meninges.
- Clinical signs reflect melanin as the target of inflammation.

PATOPHYSIOLOGY

- Likely an autoimmune process against antigenic components of melanocytes, suspected tyrosinase and related proteins; involves T-cells and macrophages (especially ocular lesions), B-cells, and macrophages.
- Cell-mediated hypersensitivity and antimelanin antibodies demonstrated in humans; similar mechanisms postulated for dogs.

SYSTEMS AFFECTED

- Ophthalmic
- Skin/Exocrine
- Nervous (rarely)

SIGNALMENT

- Dog
- Akita, Samoyed, Siberian husky, Alaskan malamute, and chow chow predisposed
- Other breeds and mixed breeds reported
- Suspected heritability
- No sex predilection
- Mean age of onset 6 months–6 years

SIGNS

- Ophthalmic signs almost always precede dermatologic signs.
- Sudden onset uveitis (photophobia, conjunctival inflammation, pain).
- Secondary changes include glaucoma, cataracts, bullous retinal detachment, and progression to blindness.
- Concurrent or subsequent leukoderma of the nose, lips, and eyelids.
- Depigmented nasal planum may develop crusting and ulceration.
- Concurrent or subsequent striking leukotrichia of the muzzle and periorbital regions.
- Footpads, scrotum, vulva, anus, and oral cavity (hard palate) may also depigment.
- Neurologic symptoms (meningoencephalitis) possible, but very rare.

CAUSES & RISK FACTORS

- Exact cause is unknown.
- Most likely an autoimmune disorder.
- Skin trauma or infectious agent (e.g., virus) are possible triggers.
- Exposure to sunlight can exacerbate the symptoms.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pemphigus foliaceus
- Pemphigus erythematosus
- Discoid lupus erythematosus
- Systemic lupus erythematosus
- Mucocutaneous pyoderma (severe)
- Vitiligo
- Neoplasia—epitheliotropis

lymphoma

- Numerous inflammatory and infectious dermatoses can cause depigmentation.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

ANA—negative

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Skin biopsy necessary for diagnosis, especially when correlated with ocular disease.
- Interpretation of tissue by a dermatopathologist strongly recommended.
- Ophthalmologic consultation strongly recommended.

PATHOLOGIC FINDINGS

Lichenoid dermatosis consisting of mostly histiocytic inflammation; macrophages containing granular melanin pigment; pigmentary incontinence.

TREATMENT

- Aggressive and rapid initiation of immunosuppressive therapy is recommended to prevent formation of posterior synechiae and secondary glaucoma, cataracts, or blindness.
- Retinal exams are the most important means of monitoring progress; improvement in dermatologic lesions may not reflect continued retinal pathology.
- Bilateral enucleation can improve patient comfort and attitude when eye condition worsens and medical treatment is unsuccessful.
- Management by a veterinary ophthalmologist is strongly recommended.

MEDICATIONS

DRUG(S)

- Initial high doses of prednisone (1.1–2.2 mg/kg PO q12–24h) and azathioprine (1.5–2.5 mg/kg PO q24h); the dosages and frequencies should be tapered to q48h for chronic use.
- Azathioprine may be discontinued after a few months of therapy, but prednisone may be necessary indefinitely.
- Cases may improve with initial use of prednisone alone, but delaying aggressive therapy with azathioprine risks irreversible progression of disease.
- Topical or subconjunctival steroids and cycloplegics may be indicated if anterior uveitis is present.
- Refractory cases may require use of systemic cyclosporine.

CONTRAINDICATIONS/POSSIBLE

INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Potential side effects of prednisone and azathioprine—anemia, leukopenia, thrombocytopenia, elevated serum alkaline phosphatase levels, vomiting, and pancreatitis.
- Biweekly serum chemistries and complete blood counts including platelet counts at first; less often as drug dose and frequency are tapered.
- Weekly or biweekly examinations including retinal evaluations initially. Retinal exams are an important means of monitoring the disease; improvement in dermatologic lesions may not mirror improvement in retinal lesions.
- Tapering of drugs should be based on improvement of ocular lesions.
- Severe opportunistic infections with organisms not typically considered pathogenic may occur with combination of cyclosporine and other immunosuppressive agents.

EXPECTED COURSE AND PROGNOSIS

- Generally good for dermatologic symptoms.
- Guarded to poor for vision unless treatment is quickly instituted and is effective.
- Some breeds (e.g., Akita or Siberian husky) may respond less well.

MISCELLANEOUS

SEE ALSO

- Dermatoses, Depigmenting Disorders
- Lupus Erythematosus, Cutaneous
- Lupus Erythematosus, Systemic
- Lymphoma, Cutaneous Epitheliotropic
- Pemphigus

ABBREVIATION

VAGINAL DISCHARGE

BASICS

DEFINITION

Any substance emanating through the vulvar labia

PATHOPHYSIOLOGY

- Dependent on underlying cause of vaginal discharge.
- Discharge may originate from uterus, vagina, vestibule, clitoris, clitoral sinus, perivulvar dermis, or urinary tract.

SYSTEMS AFFECTED

- Reproductive
- Renal
- Skin
- Urinary

INCIDENCE/PREVALENCE

- Unknown as there are many causes.
- Considered a common reason for seeking veterinary care.

SIGNALMENT

- Healthy bitch < 6–12 months of age (prepubertal)—juvenile (puppy) vaginitis and congenital anomalies more common.
- Non-pregnant bitch that has undergone at least one estrous cycle—normal estrus, persistent estrus (cystic ovarian disease or granulosa cell tumor); pyometra; neoplasia.
- Bitch bred in the last 30–70 days—normal parturition (50–70 days) or abortion (< 50 days).
- Bitch that has recently whelped—normal lochia or postpartum metritis more common; subinvolution of placental sites.
- Ovariectomized bitch—vaginal stricture or estrogen-responsive urinary incontinence more common; neoplasia.

SIGNS

Historical Findings

- Discharge from the vulva.
- Licking, scooting, and spotting.
- Attracting male dogs.
- Parturition—with postpartum discharge.
- Recent estrus—with pyometra.
- Hemorrhagic discharge > 8 weeks postpartum—subinvolution of placental sites.
- Vomiting, anorexia—may be seen with metritis and pyometra.

Physical Examination Findings

- Vaginal discharge that may be serosanguinous, purulent, lochial, hemorrhagic, mucoid, or urinous.

CAUSES

Normal Physiologic Conditions

- Proestrus
- Estrus
- Diestrus
- Late pregnancy
- Parturition
- Normal lochia

Pathologic Conditions

- Cystic ovarian disease (persistent estrus).
- Brucella canis*.
- Metritis.
- Pyometra.
- Retained placenta or fetuses.
- Subinvolution of placental sites (hemorrhagic discharge postpartum ≥ 8 weeks).
- Neoplasia—uterus, vagina, urinary tract (including transmissible venereal tumor), ovary (granulosa cell tumor/persistent estrus).
- Vaginitis.
- Estrogen-responsive urinary incontinence.
- Coagulopathy.

- Congenital defects of the distal genital tract—intersex conditions, imperfect embryologic fusion of the Müllerian ducts (vagina), joining of the genital folds (vestibule) and genital swellings (vulvar lips), ectopic ureters.

RISK FACTORS

- Prophylactic antibiotics—may alter normal vaginal flora and predispose to secondary infection.
- Exogenous estrogen—predispose to pyometra in the intact bitch.
- Exogenous androgens—may cause clitoral hypertrophy.
- Exogenous or endogenous progesterone—predispose to pyometra or stump pyometra.
- Obesity—excess skin folds around vulva.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Healthy intact bitch < 6–12 months of age—juvenile vaginitis (prepubertal), normal estrous cycle, urogenital trauma or neoplasia, foreign body, coagulopathy, ectopic ureter(s), congenital abnormalities of the perineum or distal genital tract, intersex conditions, urinary tract disease.
- Non-pregnant bitch that has undergone at least one estrous cycle—normal estrus, persistent estrus (cystic ovarian disease or granulosa cell tumor); pyometra; neoplasia.
- Bitch bred in the last 30–70 days—abortion, pyometra, normal parturition (> 57 days from breeding), fetal/embryonic death, split heat, *Brucella canis* infection.
- Bitch that has recently whelped—lochia (normal up to 6–8 weeks postpartum), subinvolution of placental sites (hemorrhagic discharge ≥ 8 weeks postpartum), postpartum metritis, vaginal trauma, retained placenta or fetus.
- Ovariectomized bitch—vaginal stricture, foreign body, neoplasia, polyps, stump pyometra due to exogenous or endogenous progesterone, exogenous estrogens (exposure to owner's hormone replacement therapy), perivulvar dermatitis, ovarian remnant syndrome, estrogen-responsive urinary incontinence.

CBC/BIOCHEMISTRY/URINALYSIS

- Regenerative anemia—may be normal in pregnancy or during estrus.
- Leukocytosis with a left shift—pyometra or postpartum metritis.
- Elevated BUN and creatinine—pyometra.
- Isosthenuria—with polyuria and polydipsia associated with pyometra.
- Urinalysis—may indicate urinary tract infection.

OTHER LABORATORY TESTS

- Progesterone—determine if bitch is in luteal phase, which increases likelihood of pyometra. Progesterone, 17-hydroxyprogesterone may be secreted in animals with adrenal cortex disease (ACTH stim test; Clinical Endocrinology Service, University of Tennessee; (865)

974-5638). • *Brucella canis* serology—screen with rapid slide agglutination test (D-Tec® CB, Zoetis; (888)963-8471); agar gel immunodiffusion test confirmatory (Cornell University Diagnostic Laboratory, (607)253-3900); bacterial culture of whole blood or lymph node aspirate.

IMAGING

Radiography

- Detect enlarged uterus or ovary, pregnancy.
- Evidence of fetal death—presence of gas around fetus or misalignment and/or collapse of fetal skeleton.

Ultrasonography

- Determine contents of uterus, free fluid in the uterus is characteristic of pyometra, hydrometra, and mucometra.
- Pregnancy diagnosis and embryonic/fetal wellbeing: heartbeat may be seen as early as the 20th day of diestrus, heart rate < 180 bpm indicates fetal stress.
- Masses—neoplasia, granulomas, cystic ovarian disease or granulosa cell tumor, or foreign body; saline distention of the vagina may help visualization.

Contrast Radiography—Vaginogram/Urethrogram/Cystogram/IVP

- Identify abnormal conformation or structure (i.e., neoplasia or foreign body) within the vagina.
- Rule-out vestibulovaginal strictures, rectovaginal and urethrovaginal fistulas.
- Rule-out differentials and help localize the problem.
- Pronounced folds (rugae) of vagina during estrus will cause filling defects (normal).

DIAGNOSTIC PROCEDURES

Vaginal Cytology

- Determine nature of discharge—*inflammatory, hemorrhagic*.
- Evaluate epithelial cells for cornification—cornification present under the influence of estrogen.
- Always performed in order to interpret vaginal cultures.

Vaginal Culture and Sensitivity

- Performed prior to other diagnostic procedures.
- Use guarded swab to sample cranial vagina.
- Most common organisms in the microbiome (commensals and potential pathogens) are *E. coli*, *Streptococcus* spp., *Pasteurella* spp., and *Staphylococcus* spp.

- Other organisms which can be commensals include *Mycoplasma* spp., *Enterobacter* spp., *Pseudomonas* spp., *Klebsiella* spp.
- Reminder: the vagina is not a sterile environment and culture of normal bitches results in growth of normal vaginal flora; use of vaginal cytology and other diagnostic tools is essential for interpretation of culture results.
- Normal microbiome consists of numerous opportunistic pathogens, e.g., *E. coli* and *Mycoplasma* spp.

Vaginoscopy

- Rigid cystourethroscope or ureteroscope; pediatric gastroscope or proctoscope; or flexible endoscope used to visualize vagina.

VAGINAL DISCHARGE

(CONTINUED)

- Identify source of vaginal discharge—uterine, vaginal, vestibular, or urethral.
- Visualize anomalies, persistent hymen, neoplasia, foreign body, trauma, abscess, and evaluate the vaginal and vestibular mucosa.
- Use of specialized scope to flush uterus if indicated.
- Removal of foreign body or biopsy of vaginal mass.

Other

- Digital examination of vestibule, vaginovestibular junction, and distal vagina.
- Biopsy and histopathology of mass lesions.
- Cystocentesis—urine culture and sensitivity.
- Clotting profile.

TREATMENT

- Based on diagnosis
- No treatment for normal causes of vaginal discharge
- Usually treated on outpatient basis except pyometra.
- Also refer to individual disease chapters.

SURGICAL CONSIDERATIONS

- Pyometra may be medically or surgically (OHE) managed.
- Ovariectomy or OHE is treatment of choice for neoplastic conditions.
- Cystic ovarian disease can be medically managed or ovariectomy/OHE performed.
- Removal of foreign body or surgical excision of mass(es).
- Surgical excision or radiation therapy are options for TVT.

MEDICATIONS

DRUG(S) OF CHOICE

- Prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) for uterine evacuation (myometrial contractions) and luteolysis—dinoprost (Lutalyse®)
- 50–100 $\mu\text{g}/\text{kg}$ SC q8–24h daily till progesterone level < 2.0 ng/mL and uterus is cleared of fluid; cloprostolen (Estrumate®)
- 1–5 $\mu\text{g}/\text{kg}$ SC q24h.
- Antibiotic—choice based on guarded cranial vaginal culture and sensitivity.
- Dopamine agonist—may be used in addition to $PGF_{2\alpha}$ for luteolysis via suppression of the luteotropic hormone prolactin—bromocriptine (10 $\mu\text{g}/\text{kg}$ PO) or cabergoline (5 $\mu\text{g}/\text{kg}$ PO) q8–24h until serum progesterone level < 2.0 ng/mL .
- Supportive care including intravenous fluids as indicated.

CONTRAINDICATIONS

Certain antibiotics may be contraindicated during pregnancy and nursing.

PRECAUTIONS

- Prostaglandin $F_{2\alpha}$ —side effects include panting, vomiting, defecation/diarrhea, and possibly hypotension. Side effects last

30–40 minutes and decrease gradually with subsequent doses, quickly metabolized in lungs.

- Dopamine agonists—side effects include vomiting and nausea; can be controlled with antiemetics.
- Strict monitoring of patients being managed medically for pyometra as patient may become endotoxemic or septicemic and require emergency OHE.
- Stabilize patient prior to anesthetic induction for surgical management of pyometra.

ALTERNATIVE DRUG(S)

Aglepristone (Alizin®; 10 mg/kg SC, 2 doses given 24 hours apart)—progesterone receptor antagonist that may be used alone or concurrently with prostaglandin therapy for treatment of pyometra (currently not available in the United States).

FOLLOW-UP

PATIENT MONITORING

Pyometra

- Recheck serum progesterone until < 2.0 ng/mL .
- Recheck ultrasound after progesterone < 2.0 ng/mL to monitor clearance of uterine fluid.
- Recheck CBC and chemistry to monitor systemic health.

SIPS

- Monitor PCV—depending on amount of blood loss.

PREVENTION/AVOIDANCE

- Puppy vaginitis—delay elective OHE until after first estrous cycle in cases of juvenile vaginitis; may avoid chronic vaginitis.
- Avoid exogenous steroids (estrogens, progestins, androgens).

POSSIBLE COMPLICATIONS

Endotoxemia and septicemia may occur with pyometra or metritis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Pyometra and cystic endometrial hyperplasia

AGE-RELATED FACTORS

- Increased risk for pyometra after each estrous cycle.
- Neoplasia more common in older bitches.

ZOONOTIC POTENTIAL

- *Brucella canis*—fluids and fetal tissue during abortion are highly contaminated with organisms.
- Immunocompromised people are at highest risk. Animal caretakers and pathologists are at risk due to high exposure.

PREGNANCY/FERTILITY/BREEDING

- Pyometra—grave prognosis for future fertility in bitches diagnosed with pyometra in conjunction with CEH, better prognosis (successful pregnancies have been reported) if overt signs of CEH not present and bitch is bred and becomes pregnant on next estrous cycle.
- Neoplasia—poor prognosis for future fertility.
- TVT—sexually transmitted disease; breeding should be avoided.
- *Brucella canis*—sexually transmitted disease and grave prognosis for resolution of disease and normal fertility; should not be used for breeding.

VAGINAL HYPERPLASIA AND PROLAPSE

BASICS

OVERVIEW

- Protrusion of spherical or donut-shaped mass from vulva during proestrus or estrus, rarely during gestation, parturition, or after administration of estrogenic drugs. • Type I—slight eversion of vaginal floor cranial to the urethral orifice but no protrusion through vulva. • Type II—vaginal tissue prolapses through vulvar opening (tongue-shaped mass). • Type III—donut-shaped eversion of the entire circumference of vaginal wall, including the urethral orifice, seen ventrally on the prolapsed tissue. • Exaggerated response of vaginal mucosa to estrogen, some affected animals have follicular cysts.
- Despite the name, the change seen histopathologically is edema rather than hyperplasia or hypertrophy if occurring during proestrus or estrus. • Severe prolapse—may occlude urethra and prevent normal urination. • True vaginal prolapse without hyperplasia or edema occurs rarely postpartum and may include uterine body and horns.

SIGNALMENT

- Young (most 18–22 months, range 6 months to 4.6 years), large-breed bitches.
- Predisposed breeds—large and brachycephalic breeds (boxer, mastiff, English bulldog, Saint Bernard); Labrador and Chesapeake Bay retrievers; German shepherd; springer spaniel; walker hound; Airedale terrier; American pit bull terrier. • Hereditary component probable—increased incidence in some family lines.

SIGNS

Historical Findings

- Onset of proestrus or estrus. • Although rare, can be seen during diestrus or at parturition (8–12% of cases occur at parturition); or after administration of estrogenic drugs. • Licking of vulvar area.
- Failure to allow copulation. • Dysuria.
- Previous occurrence.

Physical Examination Findings

- Protrusion of round, tongue-shaped, or donut-shaped tissue mass from the vulva.
- Vaginal examination—locate lumen and urethral orifice; types I and II: vaginal lumen is dorsal to the prolapse; type III: lumen is central to the prolapse; urethral orifice is ventral to the prolapse with all three types.
- Tissue may be dry or necrotic.

CAUSES & RISK FACTORS

- Estrogen stimulation • Genetic predisposition • Dystocia • Increased abdominal pressure

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vaginal polyp—differentiated by vaginal examination. • Vaginal neoplasia—transmissible venereal tumor and leiomyoma; differentiated by signalment, stage of cycle, and vaginal examination. • Clitoral hypertrophy; differentiated by physical examination.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Biopsy (old bitch)—differentiate from neoplasia

TREATMENT

- Outpatient; unless urethral obstruction.
- Breeding—possible by artificial insemination (discuss potential heritability).
- Prolapsed tissue—keep clean and lubricated with sterile water-soluble lubricant.
- Elizabethan collar and clean indoor environment—minimize tissue trauma.
- Instruct client to monitor patient's ability to urinate. • If urethral obstruction present, place indwelling urinary catheter.
- Regression—usually begins in late estrus; should be resolved during early diestrus.
- Recurrence rate—66–100% at next estrous cycle.

SURGICAL CONSIDERATIONS

- Ovariohysterectomy—prevents recurrence; may hasten resolution. • Severe condition—requires surgical reduction or resection; identify and catheterize urethra, 25% recurrence at next cycle after surgery. • With dystocia, cesarean section required, ovariohysterectomy may be necessary.
- Surgical amputation of the prolapsed tissue in an awake, standing bitch has been described. • When occurring during pregnancy, both resection of prolapse and surgical reduction with accompanying hysterectomy have been successfully reported. Vaginal delivery with concurrent vaginal prolapse has been reported; close monitoring for obstructive dystocia is recommended.

MEDICATIONS

DRUG(S)

GnRH (2.2 µg/kg IM) or hCG (1,000 IU IM)—if breeding not planned that cycle; may

hasten ovulation and resolution by a couple of days; not effective if given after ovulation (progesterone > 8–10 ng/mL).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid progestational drugs, they can induce pyometra.

FOLLOW-UP

PATIENT MONITORING

Monitor health of prolapsed tissue and the ability to urinate.

PREVENTION/AVOIDANCE

Ovariohysterectomy—recommended owing to genetic component and likelihood of recurrence.

POSSIBLE COMPLICATIONS

Type III—may affect urethra and prevent normal urination.

EXPECTED COURSE AND PROGNOSIS

- Medical treatment—prognosis for recovery good, except with urethral involvement.
- Surgical intervention for type III—prognosis good.

MISCELLANEOUS

ABBREVIATIONS

- GnRH = gonadotropin-releasing hormone
- hCG = human chorionic gonadotropin

VAGINAL MALFORMATIONS AND ACQUIRED LESIONS

BASICS

DEFINITION

Altered anatomic architecture due to congenital anomalies (imperforate hymen, dorsoventral septum, hymenal constriction, rectovaginal fistula, segmental aplasia, cysts, conformational defects of the vulva) and acquired conditions (vaginal hyperplasia, foreign bodies, strictures, adhesions, fistulas, and neoplasia).

PATOPHYSIOLOGY

Congenital

- Normal embryologic development—the paired paramesonephric (Müllerian) ducts fuse to form the uterine body, cervix, and vagina; urogenital sinus forms the vestibule, urethra, and urinary bladder; hymen (composed of the epithelial linings of the paramesonephric ducts and urogenital sinus and an interposed layer of mesoderm) normally disappears by birth.
- Errors during embryonic development—imperforate hymens; dorsoventral septae; hymenal constrictions (including vestibulovaginal stenoses); vaginal diverticulum (double vagina, vaginal pouch); cysts.

Acquired

- Vaginal scarring—response to trauma (mating, dystocia, sexual abuse) or inflammation; with mature scarring, may note adhesions or strictures, which narrow the diameter of the vagina.
- Vaginal hyperplasia (dogs)—result of an exaggerated response of the vaginal mucosa to estrogen; effect produced is edema rather than hyperplasia or hypertrophy.
- Neoplastic processes—extraluminal leiomyoma most common; usually old patients; no effect of ovarian status on occurrence.

SYSTEMS AFFECTED

- Reproductive—principal effect: interference with natural mating and whelping; frequent concurrent problem: vaginitis.
- Renal/Urologic—ascending urinary tract infections not uncommon; may note urinary incontinence in conjunction with congenital malformations of the hymenal area; interrelationship not understood and is not universally accepted.
- Skin/Exocrine—usually see perivulvar dermatitis secondary to vaginitis, recessed vulva (redundant perivulvar folds or hypoplastic vulva), or urinary incontinence.

GENETICS

Congenital—heritable component may be suspected; no direct evidence.

INCIDENCE/PREVALENCE

- Incidence (congenital)—unknown; conditions may be asymptomatic, especially if the female is never used for breeding.

- Prevalence (vaginal septa)—in one study, reported as 0.03% of all cases seen.

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Congenital—none identified.
- Vaginal hyperplasia—breeds more prone: large and brachycephalic breeds (boxer, mastiff, English bulldog, Saint Bernard); Labrador and Chesapeake Bay retrievers; German shepherd; springer spaniel; walker hound; Airedale terrier; American pit bull terrier.

Mean Age and Range

- Congenital lesion (e.g., imperforate hymen, stenosis, septa)—young (< 2 years of age) intact or spayed females.
- Vaginal hyperplasia—young (< 2 years of age) intact females.
- Acquired lesion (adhesions and strictures)—post-pubertal females of any age.
- Neoplasia—mean age, 10 years; ovarian status has no effect.

SIGNS

Historical Findings

- Vulvar discharge
- Excessive licking of vulva
- Frequent or inappropriate urination
- Stranguria or dyschezia
- Urinary incontinence
- Attractive to males
- Refuses mating
- Mass at vulvar labia

Physical Examination Findings

- Usually normal.
- Evidence of vaginal discharge or perivulvar dermatitis common.
- Recessed or hypoplastic vulva occasionally seen.

CAUSES

- Congenital
- Inflammatory
- Hormonal
- Traumatic
- Neoplastic

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vaginitis—concurrent with many malformations; differentiated by vaginoscopy and positive contrast vaginography.
- Urinary tract infection—differentiated by vaginal cytology and concurrent urinalysis on a sample collected by cystocentesis.
- Pyometra—differentiated by CBC, biochemistry profiles, and abdominal ultrasonography.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC and biochemistry—usually normal.
- Urinalysis—may show evidence of a secondary ascending urinary tract infection.

IMAGING

Positive-Contrast Vaginography

- Defines vaginal vault to the cervix, urethra, cranial vestibule, and urinary bladder.
- Defines the cervical canal and uterine lumen in intact patient during estrus.
- Identifies strictures, septae, persistent hymens, masses,

rectovaginal fistulas, urethrovaginal fistulas, vaginal rupture, and diverticulae.

- Patients should be fasted for 24 hours; give enema 2 hours before the procedure.
- Place patient under sedation or general anesthesia.
- Pass a balloon-tipped Foley catheter in the vestibule; inflate balloon; infuse aqueous iodinated contrast media (1 mL/kg); avoid overdistension and underdistension.
- Vestibulovaginal stenoses: ratio of the maximal height of the vagina to the smallest height of the vestibulovaginal junction—normal > 0.35, mild 0.26–0.35, moderate 0.20–0.25, severe < 0.20.
- Urinary incontinence—may require excretory urography to rule-out ectopic ureters or an intrapelvically positioned bladder neck; urethrocystoscopy.

Abdominal Ultrasonography

- Much of the vagina is not accessible owing to the bony pelvis.
- Cranial vaginal masses may occasionally be imaged.
- Aid visualization by infusing saline into the vagina before examination; helps differentiate luminal from transmural or extraluminal lesions.

DIAGNOSTIC PROCEDURES

- Order in which procedures are performed is important; they are listed here in the recommended order.
- Vaginal culture—identify secondary infections; guarded culturette recommended to avoid contamination from the vestibule and caudal vagina (see Vaginal Discharge; Vaginitis).
- Vaginal cytology—identifies stage of the estrous cycle; reveal inflammatory or neoplastic cells (see Breeding, Timing).
- Digital examination of the vestibule and caudal vagina—measure the diameter; identify caudal strictures or masses; note the size and conformation of the vulva; patient standing with abdomen supported (sedation) or in recumbency (anesthesia).
- Vaginoscopy—identify strictures, adhesions, septa, diverticula, masses, and foreign bodies; may use a variety of specula; a long (16–20 cm), hollow, rigid-type (e.g., infant proctoscope) with either a fiber-optic or halogen light source recommended; match the speculum's diameter to size of the patient; post-cervical fold (normal) obscures visualization of the external os of the cervix; rigid cystoscopes (used for transcervical insemination) adequate for many anomalies, need vaginal distension (under general anesthesia) with saline or air to visualize some anomalies or lesions.
- Imaging—when results of previous procedures suggest an anatomic abnormality; vaginography and/or ultrasonography.

PATHOLOGIC FINDINGS

Congenital

- Imperforate hymen—thin fenestrated membrane, dorsoventral band(s), or a thick membrane at the vestibulovaginal junction;

(CONTINUED)

VAGINAL MALFORMATIONS AND ACQUIRED LESIONS

simplest, most common defect; remainder of the genital tract normal. • Dorsoventral septum—oriented dorsoventrally in the vagina, cranial to the vestibulovaginal junction; may note a double cervix (most common variant); double vagina, or divided uterine fundus (rare). • Hymenal constriction or vestibulovaginal stenosis—moderate to severe constriction at the vestibulovaginal junction. • Vaginal hypoplasia, or vaginal aplasia—vagina, cervix, uterus, vulva may be absent or hypoplastic.

Acquired

- Strictures and adhesions—may be identified anywhere in the vagina or vestibule; result of prior trauma and/or inflammation; persistent vaginitis, refusal to mate, dystocia, or problems with micturition are common sequelae. • Vaginal hyperplasia and prolapse.
- Vaginal neoplasia—usually leiomyoma, usually extraluminal in the wall of the vestibule; leiomyosarcomas; transmissible venereal tumors; lipomas; mast cell tumors; epidermoid carcinomas; squamous cell carcinomas; fibromas; fibrosarcomas; and invasive urinary tract carcinomas reported.
- Foreign bodies—plant material, sticks, and swabs occasionally found.

TREATMENT

APPROPRIATE HEALTH CARE

- Usually outpatient, until nature of the defect is ascertained. • Inpatient—for positive contrast vaginography.

NURSING CARE

Manual dilation (bougienage)—digitally or with a smooth rigid object; may attempt in patients that have an imperforate hymen or mild vestibulovaginal stenosis; may be performed in a sedated patient gradually over a course of several treatments; may be performed in an anesthetized patient at one time to maximal dilation; variable success; typically leads to reduction, but not complete resolution, of clinical signs; unlikely to resolve moderate or severe stenoses.

SURGICAL CONSIDERATIONS

- Resection, transection, excision—many minor congenital (e.g., imperforate hymen, small dorsoventral septa) and acquired lesions (small strictures or adhesions in the caudal portion of the vagina or masses).
- Episiotomy—usually required for adequate surgical access. • T-shaped vaginoplasty—described for vestibulovaginal stenoses; resection appears to provide the best odds of resolution, although results are variable.
- Complete ring resection—vaginal stenosis.
- Vulvoplasty—excessive vulvar fold (redundant perivulvar skin fold) with or

without increased perivulvar fat deposition; recessed vulva; reserved for patients with concurrent chronic vaginitis, vaginovulvar discharge, perivulvar dermatitis.

- Transendoscopic laser ablation—one report for correcting a dorsoventral septum in an English bulldog that subsequently bred and delivered four pups vaginally.
- Ovariohysterectomy—patient has no breeding value; exhibits signs only during estrus. • Vaginal ablation (vaginectomy cranial to the external urethral orifice) and ovariohysterectomy—patient has no breeding value; concurrent severe, refractory vaginitis at all stages of the estrous cycle; severe vaginal stenosis; broad-based vaginal tumors.

MEDICATIONS

DRUG(S) OF CHOICE

- Concurrent vaginitis—common; usually resolves with correction of the anatomic defect; for severe condition, hasten resolution with appropriate local and antibiotic therapy (see Vaginitis). • Stenotic lesions—corticosteroids (prednisone: 1 mg/kg PO q 24h) used in conjunction with manual dilation in an attempt to prevent recurrence; high recurrence rates with or without steroids.

FOLLOW-UP

PREVENTION/AVOIDANCE

Congenital lesions—possibly inherited, but not confirmed; for a familial line with a high number of affected individuals, recommend sterilization of affected individuals and their sire and dam.

POSSIBLE COMPLICATIONS

- Dystocia, urinary tract infections, incontinence, and vaginitis—with vaginal malformations; with patients that fail to respond to treatment. • Strictures and adhesions—may be postoperative complications of surgical procedures aimed at correcting abnormalities.

EXPECTED COURSE AND PROGNOSIS

- Depends on the severity of the lesion and the degree of inflammation after treatment.
- Prognosis after treatment for imperforate hymens, short dorsoventral bands, or caudal strictures or adhesions—fair to good for improvement of clinical signs; fair to guarded for complete resolution of signs and normal fertility. • Prognosis for hymenal constrictions, vaginal hypoplasia or severe cranial strictures or adhesions—guarded to poor for complete resolution of signs and normal fertility; with concurrent severe

vaginitis, the best recommendation is vaginal ablation.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Urinary tract infections • Vaginitis
- Urinary incontinence

AGE-RELATED FACTORS

- Congenital—more likely in young bitches of any ovarian status. • Vaginal hyperplasia—more likely in young intact bitches.
- Neoplasia of the vagina or vestibule—more likely in old bitches of any ovarian status.

PREGNANCY/FERTILITY/BREEDING

- Some patients may be bred by artificial insemination; the possibility for a vaginal delivery is unlikely without correction of the anomaly. • Warn owner that an elective cesarean section may be required.

SEE ALSO

- Breeding, Timing • Transmissible Venereal Tumor • Vaginal Discharge • Vaginal Hyperplasia and Prolapse • Vaginal Tumors • Vaginitis

Author Sara K. Lyle

Consulting Editor Sara K. Lyle

VAGINAL TUMORS

BASICS

OVERVIEW

- Second most common reproductive tumor, comprising 2.4–3% of all tumors in dogs.
- Dogs—86% benign smooth muscle tumors, often pedunculated (e.g., leiomyoma, fibroleiomyoma, and fibroma); lipoma, transmissible venereal tumor, mast cell tumor, squamous cell carcinoma, leiomyosarcoma, hemangiosarcoma, osteosarcoma, or extension of primary urinary tract carcinomas also reported.
- Dogs—may be an incidental finding at necropsy.
- Cats—extremely rare; usually of smooth muscle origin.
- Hormonal influence—may play a role in the development of leiomyomas, fibromas, or polypoid tumors.

SIGNALMENT

- Dog—mean age, 10.2–11.2 years, boxers, nulliparous bitches.
- Cat—no data available.

SIGNS

Dogs

- Extraluminal—slow-growing perineal mass; vulvar discharge; dysuria; pollakiuria; vulvar licking; dystocia.
- Intraluminal—mass protruding from the vulva (often at estrus); vulvar discharge; stranguria; dysuria; tenesmus.

Cats

- Firm mass
- Constipation

CAUSES & RISK FACTORS

- Intact sexual status (hormonal influence)
- Nulliparous bitches more commonly affected

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vaginal prolapse
- Urethral neoplasia
- Uterine prolapse
- Clitoral hypertrophy
- Vaginal polyp
- Vaginal abscess/granuloma
- Vaginal hematoma

CBC/BIOCHEMISTRY/URINALYSIS

No consistent abnormalities

OTHER LABORATORY TESTS

N/A

IMAGING

- Thoracic radiography—recommended; assess for pulmonary metastatic disease.
- Abdominal radiography—may detect cranial extension of a mass.
- Ultrasonography, vaginography, and urethrocystography—may help delineate mass.
- CT/MRI—definitive delineation of tumor, assess for surgical feasibility, assess for metastatic disease.

DIAGNOSTIC PROCEDURES

- Vaginoscopy with cytologic examination of an aspirate—may help determine cell type.
- Biopsy with histopathologic examination—often necessary for definitive diagnosis.

PATHOLOGIC FINDINGS

- Intraluminal—vestibular wall; protruding into the vulva; may occur singularly or as multiple masses.
- Extraluminal—vestibular roof; causing a bulging of the perineum.

TREATMENT

- Surgical excision and concurrent ovariohysterectomy—treatment of choice.
- Postoperative radiotherapy—may be of benefit for sarcoma and incompletely resected benign tumors.

MEDICATIONS

DRUG(S)

- Postoperative therapy—no standard established.
- Doxorubicin, cisplatin, or carboplatin—rational choice to palliate malignant or metastatic disease.
- Piroxicam may be useful especially for those dogs with primary urinary tumors extending into the vagina and carcinomas.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Doxorubicin—carefully monitor with underlying cardiac disease; consider pretreatment and serial echocardiograms and ECG.
- Cisplatin—do not use in cats (fatal); do not use in dogs with renal disease; always use appropriate and concurrent diuresis.
- Chemotherapy may be toxic; seek advice if you are unfamiliar with chemotherapeutic drugs.

- Piroxicam should not be used with other NSAIDs or prednisone and should be avoided in animals with underlying renal or hepatic disease. Should not be used in conjunction with cisplatin.

FOLLOW-UP

PATIENT MONITORING

- Thoracic and abdominal radiography—consider every 3 months if tumor is malignant.
- CBC (doxorubicin, cisplatin, carboplatin), biochemical profile (cisplatin, piroxicam), urinalysis (cisplatin, piroxicam)—perform before each chemotherapy treatment.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—good with complete excision; guarded if incomplete excision; poor with metastatic disease; poor with carcinoma or squamous cell tumor.
- Recurrence—15% (leiomyoma) without concurrent ovariohysterectomy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Cats—reported concurrent cystic ovaries and mammary gland adenocarcinoma.

ABBREVIATIONS

- CT = computed tomography
- ECG = electrocardiogram
- MRI = magnetic resonance imaging
- NSAID = nonsteroidal anti-inflammatory drug

VAGINITIS

BASICS

DEFINITION

Inflammation of the vagina

PATHOPHYSIOLOGY

- Juvenile vaginitis: unknown, possibly due to imbalances of juvenile vaginal mucosal glandular epithelium.
- Primary adult-onset vaginitis: *Brucella canis* or canine herpesvirus.
- Secondary adult-onset vaginitis: sequela to congenital anomaly, vaginal atrophy post-OHE, drug therapy, foreign body, neoplasia, urinary tract infection, urinary incontinence, systemic disease such as diabetes mellitus.

SYSTEMS AFFECTED

Reproductive

INCIDENCE/PREVALENCE

- 0.7% incidence in one study
- Primary vaginitis—very rare

SIGNALMENT

Species

Primarily dog

Mean Age and Range

- Juvenile vaginitis: less than 1 year of age, ranging from 8 weeks to 1 year, prepubertal animals.
- Adult-onset vaginitis: over 1 year of age, ranging from 1 to 16 years of age.

SIGNS

Historical Findings

Juvenile Vaginitis

- May have no significant history
- Vulvar discharge—seen most often following urination
- Vaginal irritation
- Crusting of the hair coat in the vulvar region
- Scooting
- Excessive vulvar licking
- Perivulvar pruritus
- Inability to housetrain

Adult-Onset Vaginitis

- Vulvar discharge
- Excessive vulvar licking
- Pollakiuria
- Pain during urination
- PU/PD
- Pruritus
- Urinary incontinence
- Infertility

Physical Examination Findings

- Vulvar discharge: mucoid to purulent, scant to copious.
- Vulvar hyperemia.
- Vestibular hyperemia.
- Perivulvar dermatitis.
- Digital examination—strictures and hymens identified at vaginovestibular junction, granular irregularity of mucosa, especially wall opposite urethral papilla.
- Vaginoscopy—diffuse hyperemia of vaginal and vestibular mucosa, prominent lymphoid follicles, luminal exudates, erythema of the urethral papilla or clitoral fossa; presence of foreign body, neoplasia, or congenital abnormalities.

CAUSES

- Prepubertal vagina.
- Infantile vulva.
- Urinary tract infection.
- Urinary or fecal incontinence.
- Foreign body.
- Neoplasia—TVT, leiomyoma
- Bacterial: *Brucella canis*, *E. coli*, *Streptococcus* spp., *Staphylococcus intermedius*, *Pasteurella* spp., *Chlamydia*, *Pseudomonas* spp., *Mycoplasma* spp.

E. coli, *Streptococcus* spp., *Staphylococcus intermedius*, *Pasteurella* spp., *Chlamydia*, *Pseudomonas* spp., *Mycoplasma* spp.

- Viral—canine herpesvirus.
- Congenital anomalies including vaginovestibular strictures, inverted vulva.
- Vaginal trauma.
- Vaginal hematoma.
- Vaginal abscess.
- Systemic disease—diabetes mellitus.
- Zinc toxicity.
- Exogenous or endogenous androgens.

RISK FACTORS

- Alteration of normal vaginal flora by exogenous antibiotic administration.
- Clitoral hypertrophy secondary to exogenous or endogenous (hermaphrodites) androgens.
- Inverted or recessed vulva.
- Obesity.
- Abnormal conformation.
- Vaginal trauma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Normal—hemorrhagic or serosanguinous discharge during proestrus and may continue into estrus.
- Normal—slight purulent exudates may be normal in early diestrus; neutrophils and non-cornified epithelial cells seen on cytologic examination.
- Normal mucus discharge during pregnancy.
- Normal—postpartum discharge for up to 6–8 weeks; odorless dark brown or hemorrhagic discharge; substantial amounts are normal for up to 4 weeks.
- Subinvolution of the placental sites—hemorrhagic discharge lasting longer than ≥ 8 weeks postpartum.
- Cystourethritis.
- Foreign body.
- Pyometra.
- Metritis.
- Retained placenta(s).
- Clitoral hypertrophy.
- Embryonic or fetal death.
- Urine or feces contamination secondary to congenital anomaly or acquired condition.
- Perivulvar dermatitis.
- Urine contamination with ectopic ureter.
- Incontinence secondary to “hypoestrogenism.”
- Sexual differentiation disorder.
- Vaginal neoplasia.
- Vaginal trauma.
- Vaginal hematoma.
- Vaginal abscess.
- Ovarian neoplasia.
- Zinc toxicity.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually within normal limits.
- Adult onset: may indicate urinary tract infection, hematuria, or systemic disease such as diabetes mellitus to pinpoint underlying cause.
- Urinalysis may indicate dilute urine in young puppies (normal finding).

OTHER LABORATORY TESTS

- *Brucella canis* serology: rapid slide agglutination test (D-Tec CB; Zoetis, (888) 963-8471); agar gel immunodiffusion test (Cornell University Diagnostic Laboratory, (607) 253-3900); bacterial culture of whole blood or lymph node aspirate.
- Serum progesterone concentration—to determine if patient is in estrus or in the luteal phase (≥ 2 ng/mL).

patient is in estrus or in the luteal phase (≥ 2 ng/mL).

IMAGING

Ultrasonography

- Rule-out uterus as source of any vaginal discharge.
- Detection of masses: neoplasia, granuloma, or foreign body; saline distention of the vagina may help visualization.

Contrast Radiography—Vaginogram /Urethrogram/Cystogram/IVP

- Identify abnormal conformation or structure (e.g., neoplasia or foreign body) within the vagina.
- Rule-out vestibulovaginal strictures, rectovaginal and urethrovaginal fistulas.
- Rule-out differentials and help localize the problem.

DIAGNOSTIC PROCEDURES

Vaginal Culture and Sensitivity

- Performed prior to other diagnostic procedures.
- Use guarded swab to sample cranial vagina.
- 74% of adult-onset cases positive for bacterial growth, of which 64% were pure cultures.
- Most common organisms are *E. coli*, *Streptococcus* spp., and *Staphylococcus intermedius*.
- Other organisms include *Mycoplasma*, *Pasteurella*, *Pseudomonas* spp., *Chlamydia*.
- Reminder: the vagina is not a sterile environment and culture of normal bitches results in growth of normal vaginal flora; use of vaginal cytology and other diagnostic tools is essential for interpretation of culture results.

Vaginal Cytology

- Always performed in conjunction with vaginal culture.
- Juvenile vaginitis: usually polymorphonuclear leukocytes ± bacteria.
- Adult-onset vaginitis: usually indicative of septic inflammation.
- Evaluate epithelial cells for cornification—cornification present under the influence of estrogen.
- Determine nature of discharge—inflammatory, blood, presence of fecal material.

Vaginoscopy

- Rigid cystourethroscope, ureteroscope, pediatric gastroscope, proctoscope, or flexible endoscope used to visualize vagina.
- Visualization of anomalies: persistent hymen, neoplasia, foreign body, trauma, abscess, and evaluation of the vaginal mucosa.
- Identify source of vaginal discharge—uterine, vaginal, vestibular, or urethral.
- Removal of foreign body or biopsy of vaginal mass.
- The vaginal wall can be thin in ovariectomized bitches—exercise care when using rigid cystourethroscope and ureteroscope.

Other

- Digital vaginal examination—may be best diagnostic tool for identifying strictures in posterior tract.
- Biopsy and histopathology of vaginal mass.
- Urine culture and sensitivity—identify ascending/concurrent infections.

VAGINITIS

TREATMENT

APPROPRIATE HEALTH CARE

- Correction/removal of underlying cause.
- Most often treated as outpatient. • Surgical management may be necessary to remove foreign bodies or masses or for correction of structural anomalies. • Prevention of self mutilation—use of Elizabethan collars.

ACTIVITY

Not altered

DIET

Not altered

CLIENT EDUCATION

General

- *Brucella canis*—positive patients should be isolated. Euthanasia recommended due to zoonotic potential and lack of effective treatment. • Exogenous estrogens and androgens must be removed from the environment.

Juvenile Vaginitis

- Generally resolves without treatment. Advise patience. • Should resolve after first estrous cycle, if not before. Patient may need to go through one estrous cycle prior to elective OHE.

Adult-Onset Vaginitis

- Usually occurs secondary to underlying cause. • Generally resolves after correction of inciting cause. • If no primary cause can be identified, high likelihood of spontaneous recovery without treatment.

SURGICAL CONSIDERATIONS

- Correction of structural anomaly • Removal of foreign body • Removal of vaginal mass
- Episiotomy • Vaginectomy may be performed in refractory cases.

MEDICATIONS

DRUG(S) OF CHOICE

Juvenile Vaginitis

- No treatment for bitches in uncomplicated cases. • Antibiotic therapy warranted in patients with excessive discomfort (pain or excessive vulvar licking) and/or urinary tract infections. • Antibiotic selection based on culture and sensitivity.

Adult-Onset Vaginitis

- Systemic antibiotic selection based on positive cranial vaginal culture and sensitivity; treat for 4 weeks. • NSAIDs may be used to help decrease inflammation.
- Anti-inflammatory dose of corticosteroids may be helpful in decreasing inflammation and discomfort, but side effects are less desirable and may result in subsequent infection. • DES—for idiopathic or recurrent

vaginitis in spayed bitches; helps to reestablish normal mucosal integrity, increases vaginal epithelial cornification, normalization of vaginal vault, use lowest effective dose; 0.5 mg PO for dogs less < 9 kg or 1 mg PO for dogs > 9 kg q24h for 7 days, then taper dose over 2–4 weeks and maintain at lowest effective dose for potential lifelong therapy.

CONTRAINDICATIONS

- Antibiotic therapy in patients may result in alteration of normal flora and development of infection secondary to treatment. • Vaginal douches with antibiotic/antiseptic agents may be irritating to the vaginal mucosa and worsen the condition. • Corticosteroid administration may worsen concurrent urinary tract infection.

PRECAUTIONS

Estrogen administration may increase risk of pyometra in intact animals.

POSSIBLE INTERACTIONS

Effects of hydrocortisone may be potentiated with concurrent estrogen therapy.

ALTERNATIVE DRUG(S)

- Juvenile vaginitis may be treated with DES to induce estrus in refractory cases, but long-term effects are not documented.
- Moist towelettes/baby wipes may be used to clean the perivulvar area.

FOLLOW-UP

PATIENT MONITORING

Juvenile Vaginitis

- Reevaluate if symptoms become more severe or intolerable. • Reevaluate after first estrous cycle.

Adult-Onset Vaginitis

- Recheck if symptoms do not resolve after removal of underlying cause. • Reculture 5–7 days after cessation of antibiotic therapy or if symptoms continue despite therapy.

PREVENTION/AVOIDANCE

- Delay elective OHE until after first estrous cycle in juvenile vaginitis cases • Avoid using antibiotics in unwarranted cases • Maintain good body weight and condition • Avoid vaginal douching • Avoid exogenous androgen therapy.

EXPECTED COURSE AND PROGNOSIS

- Juvenile vaginitis—onset at 6 weeks to 6–12 months of age; duration of days to months but typically intermittent; usually resolves with time or after first estrous cycle.
- Adult-onset—normally resolves after removal/treatment of inciting cause; antibiotic therapy may hasten resolution in warranted cases, NSAIDs may help resolve inflammation.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Perivulvar dermatitis

AGE-RELATED FACTORS

Juvenile vaginitis may be present in prepubertal dogs, usually < 1 year of age.

ZOONOTIC POTENTIAL

Brucella canis—uncommon cause of vaginitis but should be ruled out.

PREGNANCY/FERTILITY/BREEDING

- Vaginitis during pregnancy is rare but may result in ascending infection and subsequent abortion. Resolution of vaginitis should result in a good prognosis for fertility if underlying cause does not affect fertility prognosis.
- Structural anomalies such as persistent hymen may prevent natural matings to occur, or could predispose to a dystocia if artificially inseminated. • Scarring secondary to trauma may result in excessive fibrous tissue and decreased distensibility of the vagina.

SEE ALSO

- Brucellosis • Metritis • Pyometra
- Retained Placenta • Sexual Development Disorders • Subinvolution of Placental Sites
- Vaginal Malformations and Acquired Lesions

ABBREVIATIONS

- DES = diethylstilbestrol • OHE = ovariohysterectomy • NSAID = nonsteroidal anti-inflammatory drug • PU/PD = polyuria/polydipsia • TVT = transmissible venereal tumor • UTI = urinary tract infection

VASCULAR RING ANOMALIES

BASICS

OVERVIEW

Right Aortic Arch

- Entrapment of the esophagus by a persistent right fourth aortic arch on the right and dorsally, the base of the heart and pulmonary artery ventrally, and ductus or ligamentum arteriosum on the left and dorsally.
- Causes megaesophagus cranial to the obstruction at the base of the heart.

Double Aortic Arch

- Entrapment of the esophagus by a functional aortic arch on the right, an atretic aortic arch on the left, the base of the heart and pulmonary artery ventrally, and ductus or ligamentum arteriosum on the left and dorsally.
- Causes megaesophagus cranial to the obstruction at the base of the heart; also causes some tracheal compression.

SIGNALMENT

- Dogs and cats
- Seen most commonly in German shepherds, Irish setters, Great Dane, and Boston terriers

SIGNS

- Regurgitation of undigested solid food in animals < 6 months old.
- Malnourishment in many animals.
- Time between eating and regurgitation varies.
- Signs of aspiration pneumonia (e.g., cough, tachypnea or dyspnea) in some animals.

CAUSES & RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congenital megaesophagus
- Stricture, diverticulum, or esophageal foreign body
- Esophageal motility disorder in Shar-Peis

CBC/BIOCHEMISTRY/URINALYSIS

- Results usually normal
- High white blood cells in some animals with aspiration pneumonia

OTHER LABORATORY TESTS

N/A

IMAGING

- Thoracic radiography—shows food-filled cranial esophagus or signs of aspiration pneumonia in some animals.
- Contrast esophagography—confirms megaesophagus extending to the heart base.
- Fluoroscopy—may be used to differentiate esophageal motility disorders.
- Angiography—may be needed to differentiate between specific vascular ring anomalies.

OTHER DIAGNOSTIC PROCEDURES

Esophagoscopy can be used to differentiate esophageal motility disorders.

TREATMENT

- Surgical correction of the vascular entrapment is indicated—can be performed thoroscopically in some cases.
- Medical management of concurrent aspiration pneumonia may be necessary.
- Feeding procedures for megaesophagus may also be necessary for a prolonged period.
- Supportive care with oxygen may be needed in animal with aspiration pneumonia.

MEDICATIONS

DRUG(S)

Broad-spectrum antibiotics, such as enrofloxacin (2.5 mg/kg q12h) and amoxicillin (10–15 mg/kg q12h) should be instituted in animals with aspiration pneumonia.

CONTRAINdicATIONS/POSSIBLE

INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Prognosis for resolution of the problem, even after surgery, is guarded although some can have resolution of clinical signs.
- Complications of malnourishment and aspiration pneumonia are common and severe.
- Esophageal function is often permanently compromised.

VASCULITIS, CUTANEOUS

BASICS

DEFINITION

Inflammation of blood vessel walls

PATHOPHYSIOLOGY

Primarily type III (immune complex), but type I and type II reactions possible.

SYSTEMS AFFECTED

- Skin/Exocrine
- Renal/Urologic—some greyhounds

GENETICS

- Familial pyogranuloma and vasculitis of Scottish terriers possibly autosomal dominant
- Proliferative arteritis in St. Bernards; unknown mode of inheritance

SIGNALMENT

Species

Dog and cat (rare)

Breed Predilections

Any age breed or sex may be affected; Chinese Shar-Pei, dachshund, collie, Shetland sheepdog, German shepherd dog, and rottweiler predisposed

SIGNS

Historical Findings

Anorexia, depression, pyrexia possible

Physical Examination Findings

- Focal alopecia with scarring and scaling (especially vaccine-induced/lesions over location of vaccination).
- Necrosis and punctate ulcers, palpable purpura, hemorrhagic bullae or urticaria.
- Acrocyanosis.
- Extremities (paws, pinnae, lips, tail, and oral mucosa) may be painful.
- Pitting edema of the extremities, polyarthropathy, and myopathy possible.

CAUSES

- Idiopathic
- Drug-induced
- Vaccine-induced
- Adverse food reaction
- Tick-borne diseases (e.g., *Rickettsia rickettsii*)
- Infectious
- Underlying metabolic process (e.g., diabetes)
- Auto-immune
- Neoplasia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- See "Causes"
- Deep pyoderma
- Ear margin seborrhea
- Chemical and thermal burn
- Hypersensitivity reaction
- Dermatomyositis
- Cryoglobulinemia
- Toxic epidermal necrolysis
- Erythema multiforme
- Eosinophilic dermatitis
- Systemic lupus erythematosus
- Bullous pemphigoid
- Pemphigus vulgaris
- Sepsis

CBC/BIOCHEMISTRY/URINALYSIS

Normal unless due to underlying metabolic process or infection.

OTHER LABORATORY TESTS

- Serologic testing for parasitic and infectious disease in high-risk areas.
- Immunodiagnostic—ANA titer, Coombs' test, and cold agglutinin tests.

DIAGNOSTIC PROCEDURES

- Skin scrapings—demodicosis.
- Biopsy of early lesion—submit to a dermatopathologist; findings depend on the underlying cause but usually include neutrophilic (leukocytoclastic/non-leukocytoclastic), lymphocytic, eosinophilic, or granulomatous mixed cells in and around the vessels; vascular necrosis and fibrin thrombi may be prominent; perivascular hemorrhage and edema may occur.
- Representative cultures (e.g., blood, urine, skin) if suspicious of infectious issues.
- Titers for rickettsial infections.
- Immunoassay for fungal organisms.

PATHOLOGIC FINDINGS

- May vary according with stage and etiology.
- Intramural inflammation of vessels, endothelial cell swelling, pale collagen, faded hair follicles, hemorrhage, and edema of surrounding tissue.

TREATMENT

APPROPRIATE HEALTH CARE

- Underlying disease—first priority in clinical management.
- No systemic abnormalities—treat as outpatient.
- Systemic disease—inpatient care recommended.

NURSING CARE

Adequate wound care may be necessary for cases with severe and extensive ulceration.

ACTIVITY

- No limitation unless infectious agent suspected.
- Isolate if contagious or zoonotic agent suspected.

CLIENT EDUCATION

- Inform client that the prognosis is guarded until a cause is found.

SURGICAL CONSIDERATIONS

Individual (focal) lesions may be surgically excised. Otherwise, dependent on underlying etiology.

MEDICATIONS

DRUG(S) OF CHOICE

- The underlying disease process should be identified and appropriately treated; if drugs or drug-like substances are suspected, they should be discontinued.
- First-line therapy while awaiting histopathology results, if no drug reaction is suspected—antibiotics.
- Immune-mediated disease with concurrent vasculitis—prednisolone (0.5–4 mg/kg q24h and taper according to response).
- Pentoxifylline 10–20 mg/kg PO q8h.

- Cyclosporine may be considered.

- Tetracycline and niacinamide each 500 mg q8h for dogs > 10 kg or 250 mg PO q8h for dogs < 10 kg or doxycycline 5 mg/kg PO q12h with niacinamide as with tetracycline.

PRECAUTIONS

- Do not use any medications suspected of causing hypersensitivity.
- Do not administer tetracycline/doxycycline to pregnant or young animals.

ALTERNATIVE DRUGS

- Chlorambucil 0.1–0.2 mg/kg every 1–2 days PO initially and taper according to response.
- Azathioprine 1–2 mg/kg every 1–2 days PO initially and taper according to response.
- Dapsone (1 mg/kg PO q24h) or sulfasalazine (15–22 mg/kg PO q8–12h).

FOLLOW-UP

PATIENT MONITORING

- Monitor appropriately during treatment of specific etiology.
- Pentoxifylline—may decrease blood pressure; may cause excitation; monitor blood pressure if concerned.
- Doxycycline or tetracycline—possible increased liver enzymes, possible esophageal strictures in cats (doxycycline); monitor liver chemistries.
- Patients receiving prednisolone, azathioprine, chlorambucil, sulfasalazine, or dapsone—monitor appropriately with CBC, chemistry screen, and urinalysis.
- Sulfasalazine or dapsone—may decrease tear formation; Schirmer tear test every 2 weeks initially and then routinely.
- Immuno-suppressive therapies should be reduced to the lowest possible therapeutic dose.

POSSIBLE COMPLICATIONS

Sepsis and death from primary cause and/or sequelae if severe.

EXPECTED COURSE AND PROGNOSIS

If no underlying disease is found, vasculitis may be difficult to treat and the prognosis is guarded.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- Corticosteroids, sulfasalazine, tetracycline/doxycycline, and dapsone—do not use in pregnant animals.
- All drugs should be used with caution in pregnant and breeding animals.

ABBREVIATION

ANA = antinuclear antibody

Suggested Reading

Innara, M. Cutaneous vasculitis. Vet Clin North Am Small Anim Pract 2013, 43:113–134.

Author Karen A. Kuhl

Consulting Editor Alexander H. Werner

VASCULITIS, SYSTEMIC

BASICS

OVERVIEW

- Blood vessel inflammation caused by endothelial injury or extension of adjacent inflammation or infection.
- Endothelial damage by infectious agent, parasite infestation, endotoxin, or immune complex deposition initiates local inflammation, neutrophil accumulation, and complement activation. Neutrophils release lysosomal enzymes, leading to necrosis of vessel wall, thrombosis, and hemorrhage. In humans and dogs with polyarteritis nodosa, intimal proliferation and vessel wall degeneration and necrosis predominate and lead to hemorrhage, thrombosis, and necrosis of involved vessels and adjacent tissues in most patients.
- Non-dermal vasculitis (e.g., renal, hepatic, and serosal surfaces of body cavities) may be the mechanism leading to development of clinically apparent signs of systemic disease (e.g., polyarthritis and proteinuria) without causing obvious external lesions.

SIGNALMENT

Dog and cat

SIGNS

Historical Findings

- Provocative drug (e.g., penicillin, sulfonamides, streptomycin, and hydralazine) given to sensitized animal.
- Recent vaccination history.
- Exposure to ticks.
- Poor dirofilariasis prophylaxis in endemic area.

Physical Examination Findings

- Swelling.
- Ulceration.
- Necrosis of affected skin, especially mucous membranes, mucocutaneous junctions, pinnae edges, and footpads.
- Systemic signs reflecting organ involvement (e.g., hepatic, renal, and CNS).
- Systemic signs of illness (e.g., lethargy, lymphadenopathy, pyrexia, vague signs of pain, and weight loss).
- Juvenile polyarteritis in beagles characterized by recurring episodes of fever ($> 40^{\circ}\text{C}$) and neck pain persisting for 3–7 days.
- Cutaneous lesions of polyarteritis nodosa (subcutaneous nodules—less common in dogs than in people).
- Signs associated with underlying infectious or immune-related disease (e.g., thrombocytopenia and polyarthropathy).
- Ophthalmologic examination—anterior uveitis, sclera injection, hyphema.

CAUSES & RISK FACTORS

Infectious

- Parasitic—*Dirofilaria immitis*, *Angiostrongylus vasorum*, *Leishmania* spp., *Babesia gibsoni*.
- Viral—e.g., feline infectious peritonitis and canine coronavirus infection.
- Rickettsial—e.g., Rocky Mountain spotted fever and ehrlichiosis.
- Bacterial—sepsis

Immune-Related

- Systemic lupus erythematosus
- Rheumatoid arthritis-like arthropathy
- Lupus-like drug reaction
- Type III hypersensitivities (e.g., to food, sulfonamides, fenbendazole, and penicillin)
- Juvenile polyarteritis in beagles
- Wegener's granulomatosis (rare)
- Polyarteritis nodosa
- Neoplasia
- Uremia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cutaneous signs developing after administration of medication implicate drug reaction (usually not immediate, may develop after days or weeks).
- Vasculitis associated with polyarthropathy and pyrexia implicates immune or infectious cause.
- Cold hemagglutinin disease suggested by distribution of cyanotic or necrotic lesions (nose, ears, toes, tail tip, prepuce) and history of exposure to cold.

CBC/BIOCHEMISTRY/URINALYSIS

Results depend on underlying disease.

OTHER LABORATORY TESTS

- Serologic tests may aid diagnosis of infectious (i.e., rickettsial, *Leishmania*) disease.
- ANA titer positive in patients with SLE, may also be positive in patients with other systemic illnesses.
- Occult heartworm test positive in patient with dirofilariasis.
- Angiostrongylus* infestation diagnosed by fecal examination and cytologic examination of tracheal wash.

IMAGING

Radiographs help diagnose dirofilariasis and *Angiostrongylus* infection.

DIAGNOSTIC PROCEDURES

- Skin biopsy specimen from edge of developing lesion may be diagnostic for vasculitis but may not reveal cause.
- Immunofluorescence test of skin biopsy specimen may rule-out pemphigus and pemphigoid diseases.
- If allergic response is suspected, resolution of signs upon discontinuation of suspect medication or food supports diagnosis.

TREATMENT

- Usually resolution of underlying condition and supportive care.
- If untreatable or unknown underlying condition—glucocorticoid, immunosuppressive (e.g., cyclophosphamide, azathioprine), and other drugs (e.g., dapsone and sulfasalazine) are occasionally effective, but clinical trials of efficacy have not been reported in animals.

MEDICATIONS

DRUG(S)

- Infectious or immune-related—treat underlying disease (see specific condition); supportive care.
- Lupus-like drug reactions—discontinue drug; supportive care.
- Type III hypersensitivity—discontinue drug; supportive care.
- Polyarteritis nodosa—glucocorticoids and cyclophosphamide (unknown value).
- "Idiopathic" vasculitis—if other causes have been ruled-out, administer dapsone (1 mg/kg PO q8h for 14 days, then 1 mg/kg PO q12h for 14 days, then 1 mg/kg PO q24h; may eventually be decreased to q48h to maintain remission); alternative—sulfasalazine (45 mg/kg PO q8h). Neither drug's effectiveness is well documented. Pentoxifylline has been used in limited numbers of cases at doses of 25–35 mg/kg PO q12h. Immunosuppressive doses of corticosteroids may be helpful in idiopathic cases.

CONTRAINdicATIONS/POSSIBLE INTERACTIONS

- Do not administer sulfasalazine to patients sensitive to sulfonamides.
- Pentoxifylline is a methylxanthine derivative and may reduce blood pressure.

FOLLOW-UP

- Patients undergoing treatment with dapsone—monitor CBC and liver enzymes for side effects (e.g., hemolytic anemia, methemoglobinemia, and hepatopathy).
- Patients undergoing treatment with sulfasalazine—monitor for keratoconjunctivitis sicca, blood dyscrasias, and hepatopathy.

VENTRICULAR ARRHYTHMIAS/SUDDEN DEATH IN GERMAN SHEPHERDS

BASICS

OVERVIEW

Inherited disorder resulting in ventricular arrhythmias in otherwise healthy young German shepherd dogs. The phenotypic spectrum is wide with some affected dogs having infrequent single premature ventricular complexes while other dogs have frequent and rapid ventricular tachycardia that is associated with sudden death. The pattern of inheritance is complex, depending heavily on background genetics. Siblings of German shepherd dogs that have died suddenly should be tested for this disorder.

SIGNALMENT

- Most dogs develop arrhythmias at approximately 12 weeks of age (identified as young as 6 weeks of age). The number and severity of the arrhythmias tend to peak between the ages of 5 and 9 months of age. By approximately 18–24 months of age most dogs have only a few arrhythmias. • Male and female dogs are afflicted equally.

SIGNS

- Signs are very rare (e.g., in > 500 dogs examined only 1 had syncope) because the dangerous ventricular tachycardia is non-sustained until in some dogs it degenerates into ventricular fibrillation resulting in death (usually between 5 and 9 months of age).
- Arrhythmias often detected during routine examination before neutering. • Death is associated with sleep, rest after exercise, or excitement after sleep particularly in the early morning.

CAUSES & RISK FACTORS

- The genetic mutation(s) responsible for this disorder has not been identified. • Multiple electrophysiologic abnormalities have been identified—early and delayed afterdepolarizations, heterogeneous and altered action potential duration, ion channel current density, calcium cycling, and sympathetic innervation have been documented. • Ventricular tachycardia tends to be most frequent with slow heart rates (drug-induced [e.g., phenylephrine, fentanyl] or during sleep).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Rule out myocarditis.

CBC/BIOCHEMISTRY/URINALYSIS

Results of routine laboratory tests are within normal ranges.

OTHER LABORATORY TESTS

Troponin concentration—to rule out myocarditis. Dogs with inherited arrhythmias have normal troponin levels.

IMAGING

- Thoracic radiographs normal.
- Echocardiography—echocardiograms of individual dogs are usually normal.

DIAGNOSTIC PROCEDURES

24-Hour Ambulatory Electrocardiogram (Holter Recording)

- Required for diagnosis and classification of the severity. • Arrhythmias identified most commonly are polymorphic ventricular tachycardia that is rapid (rates > 400 bpm) with single premature complexes that are most commonly of a left ventricular origin pattern (negative in lead II). Although non-sustained rapid polymorphic ventricular tachycardia is the most characteristic, approximately 15% of dogs will have monomorphic slower and more sustained ventricular tachycardia. • Some dogs will have thousands of singles with no ventricular tachycardia; extensive periods of ventricular bigeminy have been found in others. • After 6 months of age, the runs of ventricular tachycardia are more common after pauses.

PATHOLOGIC FINDINGS

- Routine gross and histopathologic examination is within normal limits.

TREATMENT

- Limited studies have shown that pacing the heart to keep the heart rate higher than 120 bpm decreased the frequency of the arrhythmias; however, it did not prevent sudden death. • Implantation of cardioverter defibrillators might be helpful, but the proper programming of these devices in young dogs is complicated. • Avoid drugs that slow the heart rate. • Anesthesia is not contraindicated in these dogs so long as anticholinergic drugs are used to prevent bradycardia during the age range when the arrhythmias exist. • Treatment is required only for dogs with ventricular tachycardia. Afflicted dogs with only premature ventricular complexes do not die. However, if a young dog is identified with this disorder, repeated Holter monitoring is advised to be sure that the phenotype of that particular dog does not include ventricular tachycardia (e.g., the peak affectedness of that dog has not yet occurred).

MEDICATIONS

DRUG(S)

- The ventricular arrhythmias usually are easily suppressed with lidocaine at 2 mg/kg IV. • Control of the arrhythmias with oral medication is more problematic. • Sotalol alone can be proarrhythmic and should not be used alone. • Sotalol at 2–3 mg/kg PO q12h combined with mexiletine at 4–8 mg/kg PO q8h suppresses the ventricular

arrhythmias, but the response in individual dogs is highly variable.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Avoid drugs that slow the heart rate until the dogs are older than 18–24 months of age.
- Drugs that slow or prolong the action potential duration such as sotalol, phenylephrine, or fentanyl are proarrhythmic.

FOLLOW-UP

PATIENT MONITORING

- Repeat Holter monitoring to assess drug efficacy is highly advised. • After 18–24 months of age the Holter monitoring is again repeated. If the number of ventricular ectopic complexes is < 2,000 singles with no ventricular tachycardia, the dog's risk of death is very low and the medications may be stopped. • Although an occasional dog will have a dramatic drop in the arrhythmia count and severity during treatment, most do not. Therefore, the absence of arrhythmias on Holter recordings after 18–24 months of age indicates a change in the disorder rather than an antiarrhythmic effect. • Lifelong treatment is not required.

EXPECTED COURSE AND PROGNOSIS

- Approximately 50% of affected dogs with > 10 runs of ventricular tachycardia/24 hours will die suddenly before 1 year of age. If a dog does not have ventricular tachycardia identified by 24-hour electrocardiographic monitoring, the probability of death is very low. • If a young German shepherd dog with frequent ventricular tachycardia does not die, it will live. Although this statement is ironic at best, even severely affected dogs that have reached the age of 2 years with documented absence of arrhythmia have lived a normal lifespan > 12 years.

MISCELLANEOUS

AGE-RELATED FACTORS

Because identification of affected dogs depends on the determination of arrhythmias before the age of 1 (ideally 4–9 months) to 2 years (at most), afflicted dogs can easily be missed because the only clinical sign is sudden death with no evidence of a cause found on routine post-mortem examination.

VENTRICULAR FIBRILLATION

**BASICS****DEFINITION**

Ventricular rhythm associated with loss of organized ventricular activity resulting in cardiac muscle fibrillation.

ECG Features

- Rapid, chaotic, irregular rhythm with bizarre waves or oscillations. Oscillations may be large (coarse fibrillation) or small (fine fibrillation).
- No P waves.
- No QRS complexes.

PATHOPHYSIOLOGY

Loss of organized ventricular activity results in acute and profound drop in cardiac output, usually followed by death.

SYSTEMS AFFECTED

- Cardiovascular
- All organ systems affected by loss of perfusion

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

SIGNALMENT**Species**

Dog and cat

Breed Predilections

None

Mean Age and Range

Unknown, but probably more common in old animals

SIGNS**Historical Findings**

- Severe systemic illness or cardiac disease in many patients
- Previous cardiac arrhythmias in some patients

Physical Examination Findings

- Cardiac arrest
- Collapse
- Death

CAUSES

- Anoxia
- Aortic stenosis
- Autonomic imbalances, especially high sympathetic tone or administration of catecholamines
- Cardiac surgery
- Drug reactions—e.g., anesthetic agents, especially halothane and ultrashort-acting barbiturates, digoxin
- Electrical shock
- Electrolyte and acid-base imbalances
- Hypothermia
- Myocardial injury
- Myocarditis
- Shock

RISK FACTORS

Any severe systemic illness or heart disease

**DIAGNOSIS****DIFFERENTIAL DIAGNOSIS**

Rule out ECG artifact. Reapply ECG clips and ensure good skin contact and adequate alcohol applied to leads. Check pulse.

CBC/BIOCHEMISTRY/URINALYSIS

Abnormalities generally relate to the underlying metabolic problem that causes ventricular fibrillation.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

PATHOLOGIC FINDINGS

N/A

**TREATMENT****APPROPRIATE HEALTH CARE**

- Rapidly fatal rhythm requiring immediate, aggressive treatment.
- Patient will probably die without electrical cardioversion.

Direct Current Defibrillation

- Immediate defibrillation is recommended when the duration of cardiopulmonary arrest caused by ventricular fibrillation is 4 minutes or less; otherwise, a 2-minute cycle of chest compressions before defibrillation is recommended. The dose of energy for initial defibrillation is 2–4 J/kg (biphasic defibrillator) or 4–6 J/kg (monophasic defibrillator).
- If an initial shock is not successful, CPR is resumed for 2 minutes before defibrillation is attempted again. A 50% escalation in the energy delivered may be considered for subsequent defibrillation attempts.
- If no access to electrical defibrillator, administer a precordial thump. Apply a sharp blow with your open fist to the chest wall over the heart. Rarely successful, but you have nothing to lose.

NURSING CARE

Treat any problems such as hypothermia, hyperkalemia, and acid-base disorders.

CLIENT EDUCATION

If the patient is converted back to a sinus rhythm, warn the owner that the patient is at high risk for recurrence of the arrhythmia in the immediate post-resuscitation period.

SURGICAL CONSIDERATIONS

N/A

**MEDICATIONS****DRUG(S) OF CHOICE**

- Institute CPR.
- Epinephrine—the low dose (0.01 mg/kg) of epinephrine is recommended because high-dose therapy has not been associated with increased survival. A shortcut to calculate low-dose epinephrine volume for administration is 0.1 mL/10 kg. The dose may be repeated at 3- to 5-minute intervals.
- Vasopressin—there is evidence that this drug may be equivalent to or even superior to epinephrine in some situations. The dose of vasopressin is 0.8 units/kg (dogs and cats), and the dose may be repeated at 3- to 5-minute intervals.
- Once animal is successfully converted, administer intravenous lidocaine or amiodarone to lower the risk of refibrillation or development of ventricular tachycardia.
- Lidocaine—the dose of lidocaine is 2 mg/kg (dogs, IV, IO, IT), and a shortcut to calculate

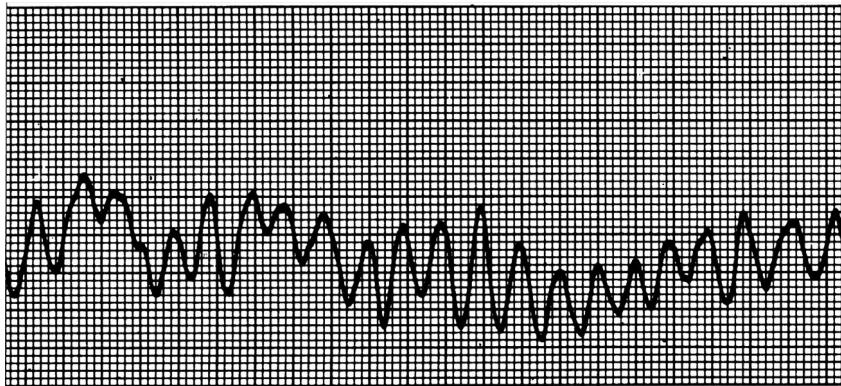

Figure 1.

Coarse ventricular fibrillation. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

VENTRICULAR FIBRILLATION

(CONTINUED)

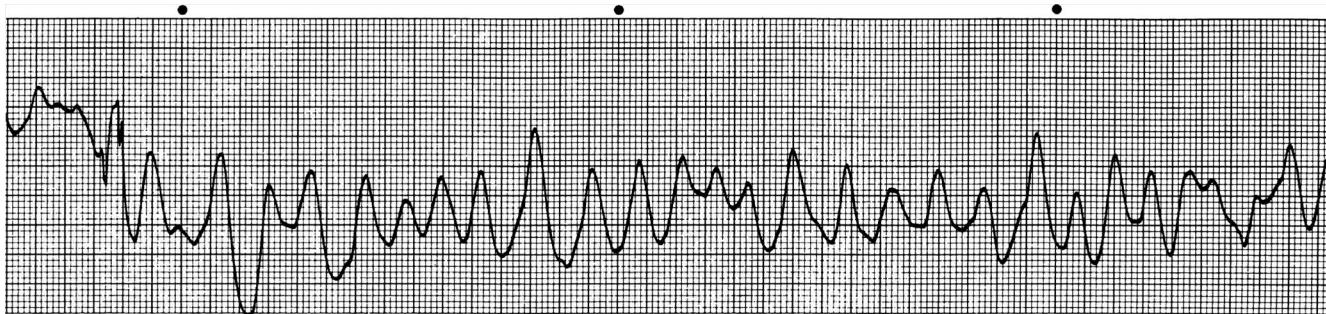

Figure 2.

Ventricular flutter-fibrillation in a cat with severe myocardial damage from an 11-story fall. The complexes are very wide, bizarre, tall, and rapid. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

the dose for the 2% (20 mg/mL) solution is 1 mL/10 kg.

- Amiodarone—the dose of amiodarone is 5–10 mg/kg (dogs, IV), and it is diluted in 5% dextrose before administration.

Hypotension is a common occurrence during amiodarone administration.

PRECAUTIONS

Lidocaine raises the fibrillation threshold but makes defibrillation more difficult.

ALTERNATIVE DRUG(S)

Chemical conversion can be attempted if no access to electrical defibrillator. Administer 1 mEq potassium/kg and 6 mg acetylcholine/kg IC; rarely successful.

FOLLOW-UP

PATIENT MONITORING

- CBC, urinalysis, biochemistry profile, arterial blood gases, and acid-base status.
- If primary cardiac disease is suspected—echocardiogram and thoracic radiographs.
- Monitor ECG closely and frequently.

PREVENTION/AVOIDANCE

Careful monitoring of critically ill patients to prevent and correct acid-base disturbances, hypotension, and hypoxemia.

POSSIBLE COMPLICATIONS

- Death
- DIC and multiorgan failure

EXPECTED COURSE AND PROGNOSIS

Most patients die because of either the arrhythmia or the underlying disease.

VENTRICULAR PREMATURE COMPLEXES

BASICS

DEFINITION

Single cardiac impulse initiated within the ventricles instead of the sinus node.

ECG Features

- QRS complexes typically wide and bizarre
- P waves dissociated from the QRS complexes

PATHOPHYSIOLOGY

Mechanisms include increased automaticity, reentry, and delayed afterdepolarizations.

SYSTEMS AFFECTED

Cardiovascular—secondary effects on other systems because of poor perfusion.

GENETICS

Polygenic in German shepherd dogs—inherited ventricular arrhythmia.

INCIDENCE/PREVALENCE

Unknown

SIGNALMENT

Species

Dog and cat

Breed Predilections

- Common in large-breed dogs with cardiomyopathy, especially boxers (arrhythmogenic right ventricular cardiomyopathy) and Doberman pinschers.
- Inherited ventricular arrhythmia in German shepherds.
- Common in cats with cardiomyopathy; occasionally seen in cats with hyperthyroidism.

Mean Age and Range

Seen in all age groups

SIGNS

Historical Findings

- Weakness
- Exercise intolerance
- Syncope
- Sudden death
- Often asymptomatic

Physical Examination Findings

- Irregular rhythm associated with pulse deficits; may auscult splitting of the first or second heart sound.
- May be normal if arrhythmia is intermittent and absent during examination.
- May observe signs of CHF (e.g., cough, dyspnea) or murmur, depending on the cause of arrhythmia.

CAUSES

- Cardiomyopathy
- Congenital defects (especially subaortic stenosis)
- Chronic valve disease
- Gastric dilation and volvulus
- Traumatic myocarditis (dogs)
- Digitalis toxicity
- Hyperthyroidism (cats)
- Cardiac neoplasia
- Myocarditis
- Pancreatitis

RISK FACTORS

- Hypokalemia
- Hypomagnesemia
- Acid-base disturbances
- Hypoxia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Supraventricular premature beats with bundle branch block.
- Look for P waves associated with the wide QRS complexes; an atrial premature complex with aberrant conduction has an associated P wave.
- An atrial premature complex is usually followed by a non-compensatory pause in which the R-R interval of the two sinus complexes enclosing an APC is less than the R-R interval of three consecutive sinus complexes.
- A ventricular premature complex is usually followed by a compensatory pause in which the R-R interval of two sinus complexes enclosing a VPC is greater than or equal to the R-R interval of three consecutive sinus complexes.

CBC/BIOCHEMISTRY/URINALYSIS

- Hypokalemia and hypomagnesemia predispose animals to ventricular arrhythmias and blunt the response to class I antiarrhythmic drugs (e.g., lidocaine, procainamide, mexiletine, and quinidine).
- High amylase and lipase if condition is secondary to pancreatitis.

OTHER LABORATORY TESTS

- High T₄ (cats) if condition is secondary to hyperthyroidism.
- Increased cardiac troponin I, a biomarker for possible acute myocardial injury may suggest an underlying cardiac condition.

IMAGING

Echocardiography may reveal structural heart disease.

DIAGNOSTIC PROCEDURES

Long-term ambulatory (Holter) recording of the ECG to detect transient ventricular arrhythmias in patients with unexplained syncope or weakness.

PATHOLOGIC FINDINGS

Vary with underlying cause

TREATMENT

APPROPRIATE HEALTH CARE

Generally outpatient basis

ACTIVITY

Restrict if the arrhythmia is accompanied by clinical signs or evidence of structural heart disease.

CLIENT EDUCATION

Alert owner to potential for the arrhythmia worsening and syncope or sudden death.

SURGICAL CONSIDERATIONS

- Continuous ECG monitoring recommended while anesthetized.

- Premedicating the patient with acepromazine (0.02–0.05 mg/kg) raises the threshold for ventricular fibrillation.
- Mask inductions not recommended; sympathetic release during mask induction can aggravate arrhythmia.
- Avoid anticholinergics unless bradycardia develops.

MEDICATIONS

DRUG(S) OF CHOICE

General Comments

- Correct any hypokalemia or hypomagnesemia.
- Drug therapy in the absence of clinical signs—controversial; studies in humans with asymptomatic VPCs and myocardial infarction demonstrated a high incidence of sudden death when treatment was initiated with class I antiarrhythmic agents; no similar studies have been conducted in veterinary patients.
- The author generally does not prescribe antiarrhythmic drugs unless there is evidence of clinical signs of low cardiac output (e.g., episodic weakness or syncope) or the belief that the patient is at high risk of sudden death, based on presence of R on T phenomenon or breed association with VPCs and sudden death (e.g., boxers and Doberman pinschers).
- If antiarrhythmic therapy is initiated in an attempt to lower the risk of sudden death, the author usually chooses a beta-blocker or sotalol; no studies have been done to confirm efficacy of beta-blockers for prevention of sudden death in dogs or cats.

Dogs

- Patient not in CHF or hypotensive—initiate therapy with a beta-blocker such as propranolol (0.2–1 mg/kg PO q8h), atenolol (0.2–1 mg/kg q12h), or metoprolol (0.2–1 mg/kg PO q8–12h) or class III agent sotalol (1–3.5 mg/kg PO q12h).
- Patient in CHF or hypotensive—initiate therapy with a class I antiarrhythmic agent such as mexiletine (5–8 mg/kg PO q8h) or procainamide (8–20 mg/kg PO q6–8h).
- Combine a class I antiarrhythmic drug with a beta-blocker or sotalol if arrhythmia persists; especially in boxers.
- Sotalol monotherapy may have proarrhythmic effect in German shepherds.

Cats

Atenolol (6.25–12.5 mg PO q12h)

V

CONTRAINDICATIONS

Avoid atropine, catecholamines (e.g., epinephrine and dopamine) until arrhythmia is controlled.

PRECAUTIONS

- Use beta-blockers cautiously in animals with CHF; they initially depress myocardial contractility.
- Use digoxin cautiously; it can potentially aggravate ventricular arrhythmias.

VENTRICULAR PREMATURE COMPLEXES

(CONTINUED)

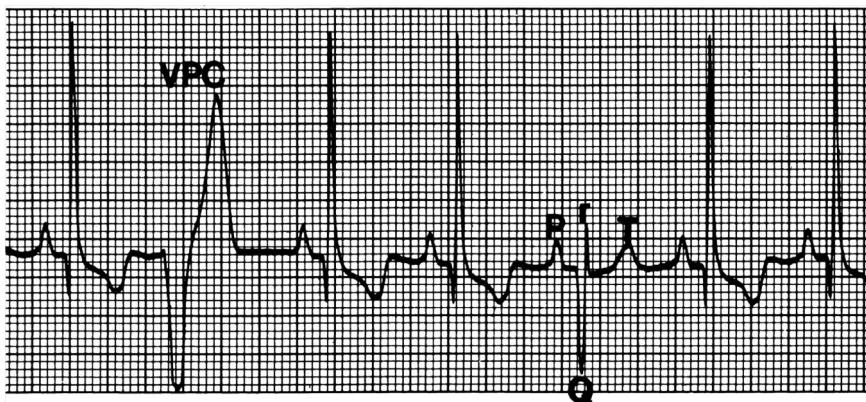

Figure 1.

VPC and a fusion complex (fifth complex) in a dog with myocarditis from pancreatitis. A fusion complex is the simultaneous activation of the ventricle by impulses coming from the SA node and the ventricular ectopic foci. The QRS complex is intermediate in form. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

- Drugs that prolong the action potential (e.g., sotalol) may worsen arrhythmia in German shepherds with inherited ventricular arrhythmia.

POSSIBLE INTERACTIONS

Quinidine and amiodarone raise serum digoxin levels.

ALTERNATIVE DRUG(S)

- Consider amiodarone (5–10 mg/kg PO q12h) for refractory arrhythmias in dogs (generally reserved for ventricular tachycardia); may not want to use in Doberman pinschers.
- Consider sotalol (10–20 mg/cat PO q12h) or procainamide (3–8 mg/kg PO q6–8h) for cats that do not tolerate beta-blockers.

**FOLLOW-UP****PATIENT MONITORING**

- Holter monitoring preferred for monitoring severity of the arrhythmia and efficacy of antiarrhythmic therapy; the goal of antiarrhythmic therapy is to reduce the frequency of ventricular ectopy by > 85%.
- Serial ECGs are not as useful as Holter monitoring—VPCs and paroxysmal ventricular tachycardia can occur sporadically through the day.
- Serum digoxin levels in patients receiving that medication.

PREVENTION/AVOIDANCE

Correct predisposing factors such as hypokalemia, hypomagnesemia, myocardial hypoxia, and digoxin toxicity.

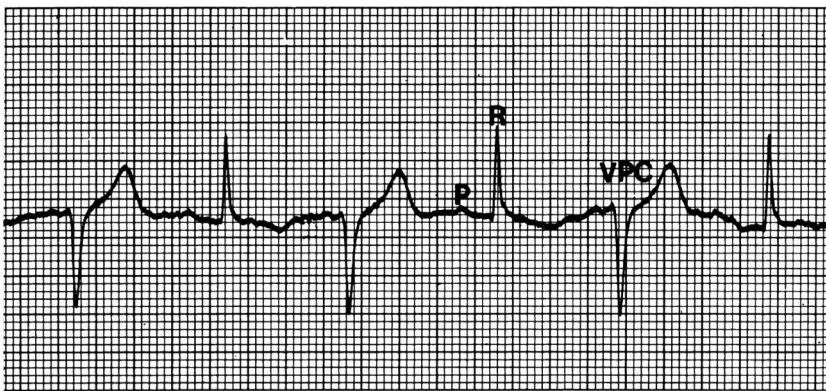

Figure 2.

Ventricular bigeminy. Every other complex is a VPC from the same focus. Each is coupled (interval the same between it and the adjacent sinus complex) to the preceding normal complex. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

POSSIBLE COMPLICATIONS

Syncope, sudden death

EXPECTED COURSE AND PROGNOSIS

- If cause is metabolic—condition may resolve with good prognosis.
- If condition is associated with cardiac disease—prognosis is guarded; VPCs may increase the risk of sudden death.

**MISCELLANEOUS****SEE ALSO**

- Chagas Disease (American Trypanosomiasis)
- Digoxin Toxicity
- Myocarditis
- Ventricular Tachycardia

ABBREVIATIONS

- APC = atrial premature complex
- CHF = congestive heart failure
- ECG = electrocardiogram
- T4 = thyroxine
- VPC = ventricular premature complex

VENTRICULAR SEPTAL DEFECT

BASICS

DEFINITION

An anomalous communication between the two ventricles. The defect may be in the inlet, outlet, muscular, or membranous septum. Most VSDs in small animals are perimembranous, such that the defect is subaortic and has a right ventricular orifice that is beneath the septal leaflet of the tricuspid valve.

PATHOPHYSIOLOGY

- A VSD results in a pulmonary systemic shunt—direction and volume of the shunt are determined by the size of the defect, the relationship of the pulmonary and systemic vascular resistances, and the presence of other anomalies.
- Most VSDs in dogs and cats are small and therefore restrictive (i.e., sufficiently small that the difference between left and right ventricular pressures is maintained). Moderate-sized VSDs are only partially restrictive and result in various degrees of right ventricular hypertension. Large VSDs have an area that is as large as or larger than the open aortic valve; they are non-restrictive, so that left and right ventricular pressures are necessarily equal. Only moderate and large defects impose a pressure load upon the right ventricle.
- In a patient with normal resistance to right ventricular ejection, the direction of the shunt is left to right, which increases pulmonary venous return and imposes a volume load on the left atrium and ventricle. With large shunts, left ventricular congestive failure can develop.
- Unless the defect is of moderate size or large, the right ventricle is spared.

SYSTEMS AFFECTED

- Respiratory—if pulmonary edema develops.
- Cardiovascular—a large shunt can result in pulmonary vascular disease, pulmonary hypertension, and shunt reversal (i.e., Eisenmenger's syndrome). This is uncommon in small animals; if shunt reversal occurs, it usually does so early in life.

GENETICS

Breed predispositions recognized; genetic transmission has not been established.

INCIDENCE/PREVALENCE

One of the most common congenital cardiac malformations in cats, comprising 15% of cases with congenital cardiac defects in one study. Less common in dogs, occurring in 10% of cases with congenital cardiac defects in one study.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog and cat

Breed Predilections

English bulldog, English springer spaniel, basset hound, Akita, West Highland white terrier, Lakeland terrier

Mean Age and Range

Most defects detected during routine examination of puppies and kittens.

Predominant Sex

N/A

SIGNS

Historical Findings

- Usually asymptomatic.
- Clinical signs of left ventricular failure include dyspnea, exercise intolerance, syncope, and cough.

Physical Examination Findings

- A restrictive VSD results in a systolic murmur that typically is loud, band-shaped, and heard best over the right hemithorax. There may be a softer, midsystolic murmur of functional pulmonic stenosis heard over the left heart base. A diastolic decrescendo murmur results if the VSD undermines anatomic support of the aortic valve, causing aortic regurgitation. Patients with right-to-left shunts generally do not have murmurs.
- Split-second heart sound in some patients.
- Femoral pulses usually normal.
- Mucous membranes—pink, unless pulmonary hypertension causes a right-to-left shunt and arterial hypoxemia.
- Tachycardia, dyspnea, and crackles may be evident if left ventricular failure occurs.

CAUSES

Congenital; may have a genetic basis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other congenital cardiac malformations that cause systolic murmurs include atrioventricular valve dysplasia, aortic or pulmonary stenosis, and complex malformations such as tetralogy of Fallot.
- The “to-and-fro” murmur that results when aortic valve regurgitation complicates a VSD must be distinguished from the continuous murmur of patent ductus arteriosus.
- Generally, diagnosis of congenital cardiac malformations requires echocardiographic evaluation including Doppler studies.

CBC/BIOCHEMISTRY/URINALYSIS

- Results usually normal.
- Uncommon right-to-left shunting results in compensatory erythrocytosis.
- Patients with severe CHF may have prerenal azotemia.

OTHER LABORATORY TESTS

N/A

OTHER LABORATORY TESTS

Thoracic Radiography

- Radiographic appearance is determined by the size and direction of the shunt. Thoracic

radiographs may be normal if the VSD is small. Larger defects cause various degrees of left or even generalized cardiac enlargement. Pulmonary hyperperfusion with prominence of the main pulmonary artery segment may be apparent. CHF is manifest as pulmonary edema.

- Patients with right-to-left shunts have right-sided cardiomegaly; the pulmonary arteries are large proximally but distally attenuated, and the pulmonary veins are small because of reduced pulmonary perfusion.

Echocardiography

- Two-dimensional echocardiographic study may demonstrate left atrial enlargement with left ventricular dilation and hypertrophy. Systolic myocardial function is usually preserved. Right ventricular hypertrophy is apparent only if the defect is moderate-sized or large or if the VSD is one aspect of a complex malformation such as tetralogy of Fallot. Careful study usually demonstrates the defect. Evaluate echocardiographic images critically; the artifact of “septal drop-out” is very common.
- The diagnosis is confirmed by Doppler interrogation of the interventricular septum. If the defect is restrictive, spectral Doppler reveals a high-velocity systolic jet. The shunt may be seen directly by color-flow Doppler. Contrast echocardiography may help in the diagnosis of a right-to-left VSD.
- Infrequently, VSDs spontaneously close. The mechanism of closure is usually adherence of a part of the septal tricuspid valve leaflet to the interventricular septum resulting in the echocardiographic appearance of “septal aneurysm.” Spontaneous closure of VSDs has been documented. Occasionally, a “septal aneurysm” is an incidental echocardiographic finding.

Cardiac Catheterization

Selective cardiac catheterization allows visualization of the defect by contrast angiography and calculation of the shunt fraction (QP/QS) and pulmonary vascular resistance.

OTHER DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

- Evidence of left atrial enlargement, left ventricular hypertrophy, or even right ventricular hypertrophy in some animals.
- Right ventricular enlargement pattern in most animals that have a right-to-left shunt because of pulmonary vascular disease or pulmonic stenosis.

V

PATHOLOGIC FINDINGS

Size of the defect determines the degree of chamber enlargement and hypertrophy; pulmonary edema and possibly ascites are seen in patients with CHF.

VENTRICULAR SEPTAL DEFECT

(CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

Clinical signs are related to CHF; most patients can be treated as outpatients.

NURSING CARE

N/A

ACTIVITY

Restrict if animal has CHF; need not restrict asymptomatic patients with small defects.

DIET

Moderate sodium restriction recommended for patients with CHF.

CLIENT EDUCATION

Definitive surgical correction is not widely available; if CHF develops, it is terminal, even with palliative care.

SURGICAL CONSIDERATIONS

- Only a minority of VSDs are sufficiently large to warrant repair.
- Consider definitive surgical repair of the defect during cardiopulmonary bypass for defects associated with large shunt. Cardiopulmonary bypass is presently performed at a small number of veterinary centers. Consider pulmonary artery banding as a palliative procedure for patients with moderate or large shunts and CHF.
- Some VSDs are amenable to transcatheter closure using purpose-designed metallic occluder devices.

MEDICATIONS

DRUG(S) OF CHOICE

Furosemide, enalapril, pimobendan, and, in some circumstances, digoxin—recommended for animals with CHF (see Congestive Heart Failure, Left-Sided).

CONTRAINDICATIONS

Vasodilators—contraindicated or used only with great caution in patients with complex malformations that include stenotic lesions.

PRECAUTIONS

ACE inhibitors and digoxin must be used cautiously if patient has renal dysfunction.

FOLLOW-UP

PATIENT MONITORING

Periodic echocardiographic or radiographic evaluation suggested for patients without clinical signs.

PREVENTION/AVOIDANCE

Breeding affected animals is not recommended.

POSSIBLE COMPLICATIONS

- Left ventricular congestive failure
- Bacterial endocarditis • Pulmonary hypertension • Arrhythmias

EXPECTED COURSE AND PROGNOSIS

- Patients with small shunts may have a normal lifespan; isolated, restrictive VSDs usually do not cause clinical signs.
- Concurrent anomalies such as pulmonic stenosis or aortic insufficiency worsen the prognosis.
- Patients with overt CHF may live 6–18 months with medical treatment.
- The development of pulmonary hypertension and shunt reversal is uncommon but generally associated with a poor prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- VSD may be one component of complex malformations such as tetralogy of Fallot.
- Most VSDs are perimembranous and subaortic. Therefore, aortic valve insufficiency resulting from a poorly supported aortic valve complicates the condition in some patients.
- In cats, VSD may be associated with an atrial septal defect and atrioventricular valve abnormalities as part of a complete atrioventricular septal defect (endocardial cushion defect).

AGE-RELATED FACTORS

The murmur of VSD becomes apparent shortly after birth, when pulmonary vascular resistance drops.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

High risk in patients with large defects; breeding affected animals is not recommended.

VENTRICULAR STANDBY (ASYSTOLE)

BASICS

DEFINITION

Absence of ventricular complexes on the ECG or absence of ventricular activity (electrical-mechanical dissociation).

ECG Features

- Ventricular asystole can result from severe sinoatrial block or arrest or by third-degree AV block without a junctional or ventricular escape rhythm; ECG features include:
- P waves present if patient has complete AV block (Figure 1)
- P waves absent during asystole if patient has severe sinoatrial block or arrest
- No QRS complexes
- Electrical-mechanical dissociation—a recorded ECG cardiac rhythm (P-QRS-T) and no effective cardiac output or palpable femoral pulse.

PATOPHYSIOLOGY

Ventricular asystole represents cardiac arrest; if the ventricular rhythm is not restored in 3–4 minutes, irreversible brain injury can occur.

SYSTEMS AFFECTED

- Cardiovascular
- All organ systems affected by loss of perfusion

GENETICS

DRUG(S) OF CHOICE

- Institute cardiopulmonary resuscitation.
- Epinephrine 0.2 mg/kg IV, IT, or IL (double the dose for IT administration and deliver with equal volume of saline).
- Atropine 0.05 mg/kg IV, IT, or IL (double the dose for IT administration and deliver with equal volume of saline).
- Sodium bicarbonate 1 mEq/kg IV for each 10 minutes of cardiac arrest.
- Dexamethasone and dopamine may be helpful in patients with electrical-mechanical dissociation.

V

Figure 1.

Ventricular asystole in a dog with severe complete AV block. Only P waves (atrial activity) are present; there is no ventricular activity. (Lead II, 50 mm/second, 1 cm = 1 mV.) (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

VENTRICULAR STANDSTILL (ASYSTOLE)

(CONTINUED)

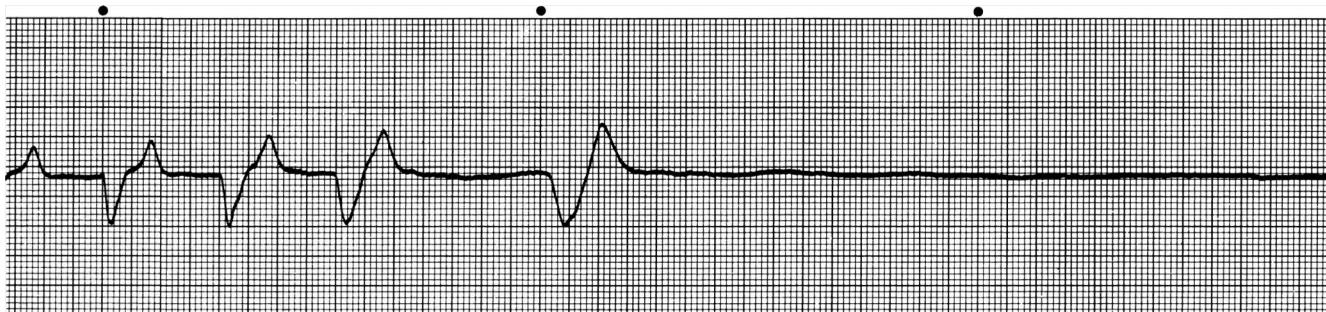

Figure 2.

Ventricular asystole in a cat with severe hyperkalemia (11 mEq/L) from urethral obstruction. No P waves or QRS complexes are seen after four wide and bizarre QRS complexes (atrial standstill with delayed ventricular conduction). (Lead II, 50 mm/sec, 1 cm = 1 mV.) (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

CONTRAINdications

Drugs that depress sinus node or AV node conduction in patients with sinus arrest or heart block (e.g., beta-blockers, calcium channel blockers, digoxin).

PRECAUTIONS

None

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

Calcium gluconate—patients with ventricular standstill and hyperkalemia.

**FOLLOW-UP****PATIENT MONITORING**

- If animal is resuscitated—evaluate CBC, biochemical analysis, and urinalysis.
- If animal survives and primary cardiac disease is suspected—an echocardiogram and thoracic radiographs.
- ECG—closely and frequently.

PREVENTION/AVOIDANCE

Careful monitoring of critically ill patients to prevent and correct acid-base disturbances, hypotension, and hypoxemia.

POSSIBLE COMPLICATIONS

- Death
- DIC and multiorgan failure

EXPECTED COURSE AND PROGNOSIS

Usually die. If sinus rhythm reestablished, prognosis still usually guarded to poor as not uncommon to arrest again.

VENTRICULAR TACHYCARDIA

BASICS

OVERVIEW

Ventricular tachycardia may occur in structurally normal hearts (hereditary arrhythmias) or may occur due to myocardial abnormalities associated with cardiomyopathy, significant valvular disease, or myocarditis. To date, there is no medical therapy available that is known to prevent sudden death in animals afflicted with ventricular tachyarrhythmias.

ECG Features

- Three or more ventricular premature contractions in a row.
- May be intermittent (paroxysmal) or sustained; heart rate usually > 150 bpm with a regular or irregular rhythm.
- QRS complexes—typically wide and bizarre.
- If P waves visible—dissociated from the QRS complexes.
- Breed-specific ECG changes—VT in boxers is characteristically positive in the ventrocaudal leads (leads II, III, and aVF) or display a “left bundle branch block pattern.” VT in Doberman pinschers and German shepherds has both polymorphic and monomorphic characteristics.

PATHOPHYSIOLOGY

Potentially life-threatening arrhythmia because it can degenerate into ventricular fibrillation, resulting in sudden death. Usually signifies underlying myocardial disease or metabolic/electrolyte derangement; mechanisms include increased automaticity, reentry, and triggered activity.

SYSTEMS AFFECTED

Cardiovascular system, with secondary effects on other systems because of poor perfusion.

GENETICS

- Arrhythmogenic right ventricular cardiomyopathy (ARVC) in boxer dogs and dilated cardiomyopathy with VT in Doberman pinschers are both inherited as autosomal dominant traits.
- There is an association with a striatin mutation with the development of DCM in boxers. Striatin is desmosomal protein (scaffolding protein) that has been associated with ARVC in humans. In addition, the Wnt signaling pathway is now implicated in boxer dogs with ARVC. In brief, Wnt signaling pathways play essential roles in cell behavior, survival, and proliferation.
- There is a mutation in Doberman pinschers in the *PDK4* gene. However, there are more than 20 different mutations in humans that can cause DCM.
- Ventricular arrhythmias and sudden cardiac death are hereditary in German shepherd dogs; mode of inheritance is polygenic due to

an abnormality in a major gene with modifiers.

- In the Maine Coon and Ragdoll cat a mutation in the myosin binding protein C (MYBPC3) has been identified. However, the Ragdoll mutation is different from the Maine Coon mutation as it is located in a different region of the gene.
- Testing positive for the genetic defect does not mean all animals will express the phenotype of the disease.

INCIDENCE/PREVALENCE

Common arrhythmia in dogs; uncommon in cats

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dogs and cats

Breed Predilections

Commonly seen in large-breed dogs with cardiomyopathy, especially boxers and Doberman pinschers. German shepherd dogs with sudden cardiac death.

Mean Age and Range

- All age groups if not breed-specific VT.
- Boxers with arrhythmogenic cardiomyopathy usually present at 4–6 years of age, frequency and severity of the arrhythmia usually increases over time.
- Doberman pinschers with occult cardiomyopathy typically develop ventricular arrhythmias beginning at 3–6 years of age, but it also can occur much later in life; frequency and severity of the arrhythmia usually increases over time.
- German shepherds develop ventricular arrhythmias at 12–16 weeks of age and the frequency and severity of the arrhythmias increases until 24–30 weeks of age. After 8 months of age the arrhythmia severity stabilizes or starts to decrease.

SIGNS

Historical Findings

- Syncope
- Weakness
- Exercise intolerance
- Sudden death
- May be asymptomatic

Physical Examination Findings

- May be normal if arrhythmia is paroxysmal and absent during examination.
- Paroxysmal or sustained tachycardia may be auscultated.
- Femoral pulses may have variable pulse intensity or are weak during runs of VT.
- Signs of congestive heart failure or murmur may be present, depending on cause of arrhythmia.

CAUSES

- Cardiomyopathy
- Congenital defects (especially subaortic stenosis)

- Chronic degenerative valve disease
- Traumatic or infectious myocarditis
- Cardiac neoplasia
- Gastric dilation and volvulus
- Splenic neoplasia/ hemorrhage
- Hyperthyroidism (cats)
- Digitalis toxicity
- Pancreatitis

RISK FACTORS

- Hypokalemia, hyperkalemia
- Hypomagnesemia
- Acid-base disturbances
- Hypoxemia
- Neoplasia (e.g., cardiac or splenic hemangiosarcoma)
- Anemia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Supraventricular tachycardia with bundle branch block. If P waves can be identified, look for association between P waves and QRS complexes. If there is a consistent PR interval, then the rhythm is supraventricular with bundle branch block. If there is no association between P waves and QRS complexes, the rhythm is probably ventricular tachycardia. If P waves cannot be identified due to a fast rate (P buried in preceding T wave), lidocaine administration may result in slowing of the VT rate and P waves may be identified if present. Termination of a tachyarrhythmia after administration of lidocaine supports diagnosis of ventricular tachycardia. If no effect with lidocaine, esmolol administration may result in slowing of a supraventricular tachycardia with bundle branch block, so that P waves associated with QRS complexes can be identified.

CBC/BIOCHEMISTRY/URINALYSIS

- Hypokalemia and hypomagnesemia predispose animal to ventricular tachycardia and blunt response to class I antiarrhythmic drugs (e.g., lidocaine, procainamide, mexiletine, and quinidine).
- High amylase and lipase if arrhythmia is secondary to pancreatitis.
- Inflammatory changes may occur on CBC such as increased neutrophil count if arrhythmias secondary to myocarditis.

OTHER LABORATORY TESTS

- Increased troponin (cTnI) with myocarditis. Cardiac troponin is a highly sensitive and specific biomarker of myocardial injury.
- High T₄ (cats) if arrhythmia is secondary to hyperthyroidism.
- Lyme or tick titers in myocarditis.
- Genetic testing if suspect DCM as the cause for VT:
 - Striatin mutation can be tested for in boxers.
 - There is one genetic mutation that can be

VENTRICULAR TACHYCARDIA

(CONTINUED)

tested for in Doberman pinschers—mutation in the *PDK4* gene.

- Genetic testing if suspect HCM in cats:
 - In the Maine Coon and Ragdoll genetic testing can be performed. There is a mutation in the cardiac myosin binding protein C gene (*MYBPC3*).
- Increased TLI (trypsin-like immunoreactivity) and PLI (pancreatic lipase immunoreactivity) if suspect pancreatitis is a cause for the VT.

IMAGING

Echocardiography may reveal presence of underlying structural heart disease.

DIAGNOSTIC PROCEDURES

ECG

Long-term ambulatory (Holter) or event recording of the ECG—for detection of intermittent ventricular arrhythmias in patients with unexplained syncope or weakness.

PATHOLOGIC FINDINGS

Vary with underlying cause

TREATMENT

APPROPRIATE HEALTH CARE

- Most patients with intermittent VT can safely be evaluated for underlying diseases (echocardiogram, lab work) and it is ideal to establish a true baseline of the arrhythmia quantity and quality by a 24-hour Holter prior to initiating therapy.
- If an animal is unstable (lateral recumbent, weak, or has frequent syncope), immediate intravenous treatment in a hospital setting with continuous ECG monitoring may be required. Once the arrhythmia is controlled and patient is hemodynamically stable, oral medication should be instituted. A follow-up 24-hour Holter is required to test efficacy and possible pro-arrhythmic effects of antiarrhythmic therapy.

NURSING CARE

Varies with underlying cause

ACTIVITY

- Generally speaking, there is no known benefit to exercise restriction.
- Boxer dogs tend to have an increased incidence of VT during excitement, so in some cases owners should know what specific situations to avoid.

DIET

N/A

CLIENT EDUCATION

Alert the owner to the potential for sudden death.

SURGICAL CONSIDERATIONS

- When possible, determine the cause of the arrhythmia and treat it prior to inducing general anesthesia.

- Assess if VT is correctable with a test dose of lidocaine; if it is, treat as necessary with lidocaine, either using IV boluses or CRI.
- Premedication with acepromazine (0.02–0.05 mg/kg) raises the threshold for ventricular fibrillation.
- Avoid pro-arrhythmic drugs such as alpha-2 agonists (xylazine and medetomidine) and thiopental.
- Mask inductions are not recommended in inadequately sedated patients with ventricular arrhythmias because increased sympathetic tone during mask induction will aggravate the arrhythmia.
- Continuous ECG monitoring while animal is anesthetized.

MEDICATIONS

DRUG(S) OF CHOICE

Correct any hypokalemia or hypomagnesemia, if possible, prior to instituting medical therapy.

Dogs

Acute Life-Threatening VT

- Administer lidocaine slowly in 2 mg/kg IV boluses (up to 8 mg/kg total) to convert to sinus rhythm; follow with lidocaine CRI, 30–80 µg/kg/minute.
- If lidocaine fails—administer procainamide slowly in 2 mg/kg IV boluses (up to 20 mg/kg total) to convert to sinus rhythm; follow with procainamide infusion at 20–50 µg/kg/minute or 8–20 mg/kg IM q6h.
- In cases of refractory VT lidocaine and procainamide CRIs can be combined.
- If the patient does not respond to lidocaine or procainamide, administer slow IV boluses of esmolol (a short-acting beta-blocker) at 0.05–0.1 mg/kg q5 minutes to a cumulative dose of 0.5 mg/kg, or as a 50–200 µg/kg/minute CRI.
- Combination of esmolol with procainamide may cause a significant drop in cardiac output and hypotension.

Chronic VT in a Stable Patient

- Sotalol (1–2 mg/kg PO q12h).
- Mexiletine monotherapy is not very effective, but combination of mexiletine (5–8 mg/kg PO q8h) with a beta-blocker such as atenolol (0.25–0.5 mg/kg PO q12h) or sotalol (1–2 mg/kg PO q12h) may be more effective for refractory VT, especially in boxer dogs.
- In German shepherd dogs the combination of mexiletine and sotalol is the most effective. Sotalol monotherapy should be avoided due to its proarrhythmic effects in this breed.

Cats

- Use lidocaine cautiously and only for sustained ventricular tachycardia; neurotoxicity (seizures) is common in cats. Use one-tenth of the dosage used for dogs.

- Atenolol (6.25–12.5 mg PO q12h) is preferred in cats.

CONTRAINdications

Avoid atropine, catecholamines (e.g., epinephrine, dopamine), until arrhythmia is controlled.

PRECAUTIONS

- Use beta-blockers cautiously in animals with CHF. Monitoring by echocardiogram is recommended to check for worsening of myocardial function due to beta blockade.
- Sotalol when used as a sole agent and other drugs that prolong the action potential duration may worsen VT in German shepherd dogs with inherited ventricular arrhythmias.

POSSIBLE INTERACTIONS

Quinidine and amiodarone raise digoxin levels.

ALTERNATIVE DRUG(S)

- For extremely refractory life-threatening VT in dogs consider amiodarone, 10 mg/kg q12h for 1 week (loading dose), then 5 mg/kg q24h (maintenance dose). Although amiodarone is a potent antiarrhythmic drug, its benefits must be balanced against its slow onset to action and adverse effects, which include hepatic toxicity, gastrointestinal disturbances, and blood dyscrasias in dogs. Caution is advised when considering amiodarone therapy because of its adverse effects. Signs of toxicity include anorexia, vomiting, lethargy, and hepatic enzyme elevation. Amiodarone hepatopathy is reversible after reduction of dosage or discontinuation of the drug. Overt clinical signs of toxicity resolve within a few days of stopping amiodarone. Hepatic enzyme activity gradually returns to normal within 3 months after amiodarone is discontinued or the dosage is reduced.
- Monitoring of serial serum chemistries is recommended, since increases in liver enzyme activities usually precede the onset of clinical signs of amiodarone toxicity. Liver enzymes should be measured after 7 days of drug loading and once monthly during maintenance therapy.
- Consider sotalol (10–20 mg/cat q12h) for refractory arrhythmias in cats.

FOLLOW-UP

PATIENT MONITORING

- Holter monitoring is preferred for monitoring severity of the arrhythmia and efficacy of antiarrhythmic therapy; the goal of antiarrhythmic therapy is to reduce the frequency of ventricular ectopy by > 85%.
- Serial ECGs and telemetry can be used cautiously—not as useful as Holter monitoring because ventricular premature complexes and paroxysmal ventricular

(CONTINUED)

VENTRICULAR TACHYCARDIA

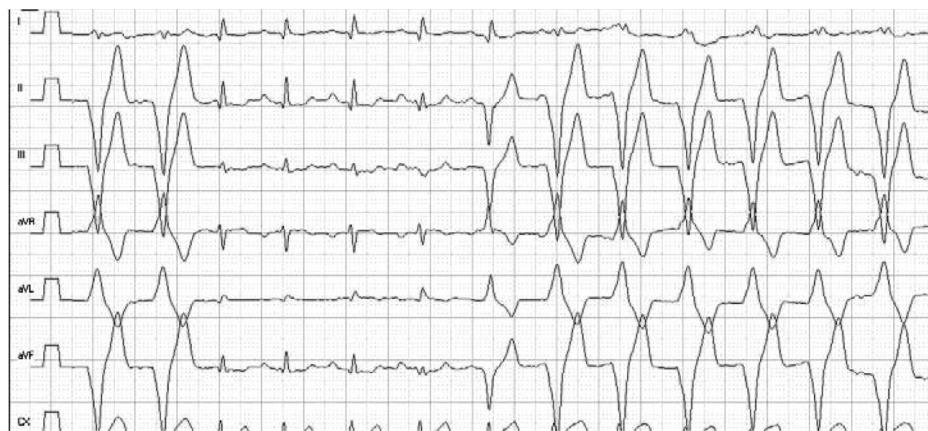

Figure 1.

Ventricular tachycardia. 6-lead ECG demonstrating the wide and bizarre QRS complexes that occur at the beginning and end of the ECG. Ventricular tachycardia should be treated as soon as possible. Acid-base and electrolyte abnormalities should always be corrected.

tachycardia can occur sporadically through the day.

- To avoid digoxin toxicity, serum digoxin levels should be measured after 1 week, 8–10 hours post-pill in patients receiving that medication due to its narrow therapeutic range (0.5–1.5 ng/mL).

PREVENTION/AVOIDANCE

- Correct predisposing factors such as hypokalemia, hypomagnesemia, myocardial hypoxia, and digoxin toxicity.
- In boxer dogs, limit significant stress or excitement as the increase in sympathetic tone may exacerbate the arrhythmia.

POSSIBLE COMPLICATIONS

- Syncope
- Sudden death

EXPECTED COURSE AND PROGNOSIS

- If cause is metabolic—condition may resolve with a good prognosis.
- If condition is associated with cardiac disease—prognosis is guarded because the underlying heart disease is likely chronic and progressive and therefore the arrhythmias may also worsen over time; presence of significant VT increases the risk of sudden death.
- If VT associated with hemangiosarcoma (cardiac or splenic)—the long-term outcome is grave due to the poor prognosis of the underlying disease.
- Approximately 50% of German shepherds with more than 10 runs of ventricular tachycardia/24 hours die suddenly.
- If German shepherd dogs reach the age of 18 months, the probability of sudden death decreases.
- Unlike boxers with ARVC, Doberman pinschers with VT and DCM may die suddenly during their first syncopal episode.

VERTEBRAL COLUMN TRAUMA

BASICS

DEFINITION

- Vertebral column trauma is caused by the application of exogenous forces to vertebrae, intervertebral discs, tendons and ligamentous support structures, and the spinal cord.
- The clinical signs may include hyperesthesia, limb paresis and/or general proprioceptive ataxia, para- or tetraplegia, loss of nociception, urinary retention, and fecal incontinence.

PATHOPHYSIOLOGY

- In the normal vertebral column, passive (bones, ligaments), active (tendons, muscles), and neural systems are responsible for stability.
- Compression, lateral bending, torsion, and sheer forces may result in failure of these systems, leading to vertebral column fracture or subluxation.
- In some instances, significant spinal cord injury can be present without instability or fracture. Traumatic disc herniation, penetrating injuries associated with the vertebral canal, and post-traumatic vascular myopathy are scenarios by which this may occur.
- Most commonly, animals are evaluated after vertebral column trauma due to the presence of SCI.
- SCI occurs because of primary and secondary mechanisms.
- Primary injury results from mechanical events such as spinal cord compression and contusion.
- Secondary injury is the biochemical cascade that follows primary events, which consist of oxidative stress, inflammation, excitotoxicity, vascular injury, and other processes.

SYSTEMS AFFECTED

- Nervous
- Musculoskeletal
- Others possible due to exogenous trauma

INCIDENCE/PREVALENCE

- Vertebral fractures and luxations represented 6% of all feline myelopathies and 7% of all canine neurology cases in two single center studies.
- The incidence of traumatic SCI without fracture/luxation is unknown.

GEOGRAPHIC DISTRIBUTION

Data not available

SIGNALMENT

Species

Dog and cat

Breed Predilections

Limited data on vertebral fracture/luxation suggest medium- and large-breed dogs are commonly affected.

Mean Age and Range

One retrospective report on vertebral trauma indicated that affected dogs and cats were young (median 2 years of age; range 0.25–15 years).

Predominant Sex

Males appear overrepresented.

SIGNS

General Comments

- The majority of dogs with vertebral column trauma have SCI.
- Concurrent peripheral (e.g., brachial plexus trauma) or central nervous system injuries (e.g., head trauma) can occur.
- Abnormalities associated with other body systems are frequently identified.

Historical Findings

- Acute onset paresis and ataxia or para-/tetraplegia.
- Clinical signs suggestive of hyperesthesia (vocalization, reluctance to move, arched back).
- Lethargy and poor appetite.

Neurologic Examination Abnormalities

- SCI is usually classified as C1–C5, C6–T2, T3–L3, L4–Cd5, multifocal, or diffuse based on neurologic examination.
- Focal SCI is most common.
- Gait abnormalities—in > 90% of animals; may include general proprioceptive ataxia, paresis, and loss of voluntary movement.
- Abnormalities in spinal reflexes and postural reactions are common and reflect the spinal cord segment(s) injured.
- Regional hyperesthesia.
- Animals with severe SCI may have absent nociception.
- The absence of deep nociception is a negative prognostic indicator, with the proportion of animals ambulating following thoracolumbar vertebral fracture/luxation traditionally placed at < 5%.

Physical Examination Abnormalities

- Pulmonary contusions and rib fractures
- Pelvic and appendicular bone fractures
- Cutaneous wounds
- Traumatic brain injury
- Abdominal organ injury

CAUSES

- Automobile accident is the most common cause of vertebral column trauma.
- Other etiologies include fall (frequent in cats), animal bites and gunshot wounds.

RISK FACTORS

Animals housed outdoors, those walked off lead, and those unsecured in the cabs of pickup trucks are likely overrepresented.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other neurologic diseases such as disc herniation, fibrocartilagenous embolic myopathy, meningo(myelitis, discospondylitis, and vertebral column neoplasia, should be considered.
- Orthopedic injuries such as appendicular fracture or ligamentous injuries may occasionally be mistaken for vertebral column trauma.

CBC/BIOCHEMISTRY/URINALYSIS

- Abnormalities may be present if significant injury has occurred to other body systems.
- Anemia, findings consistent with

dehydration, elevated creatinine kinase, and hematuria are all commonly seen.

IMAGING

Radiography

- 70% sensitive and highly specific for detecting vertebral fracture/luxation.
- Vertebral radiographs do not permit visualization of the spinal cord and have poor soft tissue detail.

Myelography

- Can define extradural spinal cord compression; has been used in decision making for surgical approaches after SCI.
- Invasive, does not allow direct visualization of spinal cord parenchyma, and lacks the tissue detail of advanced imaging studies.
- May not detect lateralized spinal cord compression as effectively as advanced imaging modalities.

Advanced Imaging

- CT—gold standard for evaluating the bones of the vertebral column and may also be used to visualize mineralized disc material and extradural hemorrhage.
- MRI—can be utilized to visualize the bony vertebral column, but provides more soft tissue detail than CT; it is the only means to exclude certain differential diagnoses, such as fibrocartilagenous embolic myopathy, and provides prognostic information concerning recovery.

DIAGNOSTIC PROCEDURES

- CSF—often unremarkable; in some severe cases, CSF total protein, nucleated count, and red blood cell count may be increased.
- CSF abnormalities with SCI are not etiology-specific.
- CSF is collected as an adjunct and not as a substitute to advanced imaging.

PATHOLOGIC FINDINGS

- Gross findings may include evidence of vertebral luxation/fracture, extradural hemorrhage, disc extrusion, spinal cord swelling, dural/subarachnoid erythema/hemorrhage, and myelomalacia.
- Histopathologic abnormalities within the spinal cord may include necrosis, demyelination, zones of spinal cord infarction, parenchymal hemorrhage, and axonal spheroids.

TREATMENT

APPROPRIATE HEALTH CARE

- Emergency intensive care management is recommended for all animals immediately following injury.
- Surgical management may be needed if imaging suggests significant spinal cord compression or vertebral column instability.
- Medical management may be selected for animals that lack evidence of instability/compression.

(CONTINUED)

VERTEBRAL COLUMN TRAUMA

NURSING CARE

- Prior to imaging, animals should be immobilized on a back board.
- Animals with imaging that suggests vertebral column instability should be immobilized until surgical stabilization.
- Non-ambulatory dogs require padded bedding, frequent turning, and urinary bladder evacuation.
- Fluid therapy is required in the event of dehydration.
- Physical rehabilitation consisting of range of motion exercises, electrical muscle stimulation, active weight bearing, and underwater treadmill may be beneficial. Physical rehabilitation that involves significant mobilization should only be performed after vertebral column instability is addressed.

ACTIVITY

- Strict exercise restriction for 4 weeks for all animals that have received vertebral column surgery. Animals with fractures and instability may require 6–8 weeks of rest.
- Animals that are medically managed and lack vertebral column instability/fracture may require shorter periods of rest.

CLIENT EDUCATION

Outcome is generally believed to be good for animals that have traumatic SCI with intact nociception, so long as appropriate therapy is selected.

SURGICAL CONSIDERATIONS

- Surgery is recommended for animals with advanced imaging that supports significant spinal cord compression or vertebral column instability (e.g., subluxation, violation of multiple vertebral unit compartments).
- Spinal stapling, pins and methylmethacrylate, and various plates can be used to stabilize the vertebral column.
- Decompression may be needed with or without stabilization in cases where there is significant extradural hemorrhage or disc material.

**MEDICATIONS****DRUG(S) OF CHOICE**

- *Opioid analgesics* are commonly used to relieve hyperesthesia associated with trauma (tramadol 3–5 mg/kg PO q8–6h).
- *Nonsteroidal anti-inflammatory drugs* provide analgesia and anti-inflammatory effects, which may be beneficial. Carprofen is commonly used at 2.2 mg/kg PO q12h.
- *Alpha receptor antagonists* can relax the internal urethral sphincter and facilitate urinary voiding in upper and lower motor neuron bladder dysfunction. Prazosin can be administered at 1 mg/15 kg PO q8–12h.
- *Muscarinic agonists* stimulate detrusor contractility and may permit urine voiding in dogs with lower motor neuron bladder. Bethanechol chloride is delivered at 5–15 mg/dog PO q8–12h.

CONTRAINDICATIONS

- *Glucocorticoids* continue to be commonly used in veterinary medicine for vertebral column trauma. While high-dose methylprednisolone sodium succinate provided within 8 hours of injury has been shown to be beneficial in some human SCI clinical trials, most human SCI centers have ceased providing this intervention as it is fraught with adverse events and does not robustly enhance recovery.
- MPSS and other glucocorticoids have not been shown to be beneficial in dogs with SCI, although research has been largely retrospective. Adverse effects are commonly recognized in the setting of canine disc-associated SCI.

PRECAUTIONS

- NSAIDs may result in gastric ulcers in animals that have SCI.
- Glucocorticoids may cause gastric ulceration, vomiting, colonic ulceration, and urinary tract infections (especially dexamethasone).
- Alpha-antagonists may result in hypotension and gastrointestinal signs.
- Muscarinic agonism is not suggested in animals with upper motor neuron bladder dysfunction that are not receiving alpha blockade. Muscarinic agonists can result in excessive salivation, defecation, urination, and bradycardia.

POSSIBLE INTERACTIONS

Glucocorticoids and NSAIDs should not be combined as this increases the risk of gastrointestinal adverse effects.

ALTERNATIVE DRUG(S)

- Experimental medical strategies for SCI work via many mechanisms, including neuroprotection, induction of plasticity, and regeneration.
- Clinical trials evaluating small molecules and cellular therapies are ongoing.

**FOLLOW-UP****PATIENT MONITORING**

- Daily physical examination-based scoring of SCI with a validated scale is strongly suggested to monitor progression.
- The modified Frankel scale, Texas Spinal Cord Injury Scale, and 14-point pelvic limb motor score are three validated systems used in dogs.

PREVENTION/AVOIDANCE

Indoor animals have lower risk of exogenous SCI.

POSSIBLE COMPLICATIONS

- Chronic ataxia/paresis as well as failure to regain voluntary ambulation are possible.
- Some animals may have urinary/fecal incontinence, especially if they are non-ambulatory.
- Non-ambulatory animals are at risk for skin ulcers and urinary tract infection.

EXPECTED COURSE AND PROGNOSIS

- Animals with intact nociception have a good prognosis for ambulatory recovery if appropriate treatment is undertaken.
- Animals with absent nociception that have vertebral fracture or luxation have a very poor prognosis for regaining voluntary ambulation (< 5%), but literature on this topic is limited.
- Dogs without fracture/luxation that lack nociception may have poorer outcome than dogs with non-traumatic disc herniation, but data limited on this subset of dogs with traumatic SCI.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Animals that have traumatic SCI often have injury to other body systems.

AGE-RELATED FACTORS

Younger animals appear more commonly affected.

PREGNANCY/FERTILITY/BREEDING

SCI may affect ability to achieve pregnancy and carry fetuses to term.

V

VESICOURACHAL DIVERTICULA

BASICS

OVERVIEW

- A common congenital anomaly of the urinary bladder that occurs when a portion of the urachus (i.e., a fetal conduit that allows passage of urine from the bladder to the placenta) located at the bladder vertex fails to close; the result is a blind diverticulum of variable size that protrudes from the bladder vertex.
- Other characteristics include congenital microscopic diverticula (microscopic lumens that may persist at the bladder vertex).
- Acquired macroscopic diverticula develop after the onset of concurrent but unrelated acquired lower urinary tract diseases; presumably, urethral obstruction or detrusor hyperactivity induced by inflammation causes high intraluminal pressure and subsequent enlargement of microscopic diverticula.
- Congenital macroscopic diverticula, most likely caused by impaired urine outflow, develop before or soon after birth and persist indefinitely.

SIGNALMENT

- Dog and cat.
- Frequently encountered in cats with acquired lower urinary tract diseases; twice as common in male cats as in female cats.
- No breed or age predisposition.

SIGNS

- Depend on concomitant disorders predisposing to formation of macroscopic vesicourachal diverticula.
- Hematuria, dysuria, pollakiuria, or signs of urethral obstruction in some patients with concurrent acquired lower urinary tract diseases.

CAUSES & RISK FACTORS

- Persistent congenital microscopic diverticula—cause unknown.
- Congenital microscopic diverticula—risk factors for acquired macroscopic diverticula.
- Diseases associated with increased bladder intraluminal pressure (e.g., bacterial urinary tract infection, uroliths, urethral plugs, and idiopathic disease)—risk factors for acquired macroscopic diverticula.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Persistent (or patent) urachus; very uncommon)—characterized by inappropriate

loss of urine through the umbilicus.

- Persistent urachal ligaments are non-patent fibrous remnants of the urachus, connecting the bladder vertex to the umbilicus.
- Urachal cysts are focal accumulations of fluid in isolated segments of the urachus. They may be aseptic or septic.

CBC/BIOCHEMISTRY/URINALYSIS

- Abnormal findings are related to the underlying disorder that causes vesicourachal diverticula, unless complicated by concurrent acquired lower urinary tract diseases.
- Abnormal findings related to secondary urinary tract infection.

IMAGING

- Congenital and acquired macroscopic diverticula—best identified by positive-contrast urothrocystography.
- Radiographs obtained with the bladder completely then partially distended with contrast medium may facilitate detection of small diverticula.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Extramural macroscopic diverticula appear as convex or conical luminal projections from the bladder vertex.
- Intramural microscopic diverticula appear as transitional epithelium-lined lumens persisting at the bladder vertex from the level of the submucosa to subserosa.

TREATMENT

- Many macroscopic diverticula in cats (and probably dogs) are acquired and self-limiting if the underlying disease is eliminated.
- Direct treatment efforts toward eliminating underlying cause(s) of lower urinary tract disease.
- Consider diverticulectomy if a macroscopic diverticulum persists in a patient with persistent or recurrent bacterial urinary tract infection despite appropriate antimicrobial therapy.

MEDICATIONS

DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

If bacterial urinary tract infection persists or recurs despite proper antimicrobial therapy, the status of the diverticulum should be reevaluated by contrast radiography.

PREVENTION/AVOIDANCE

Avoid diagnostic procedures or treatments that alter normal host urinary tract defenses and predispose to urinary tract infection.

POSSIBLE COMPLICATIONS

Persistent congenital macroscopic diverticula are risk factors for recurrent bacterial urinary tract infection.

EXPECTED COURSE AND PROGNOSIS

- Congenital microscopic diverticula are usually clinically silent unless complicated by concurrent lower urinary tract disease.
- Acquired macroscopic diverticula typically heal in 2–3 weeks after amelioration of clinical signs of lower urinary tract disease.
- Diverticulectomy and appropriate antimicrobial therapy usually associated with resolution of recurrent urinary tract infections in patients with persistent congenital macroscopic diverticula.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Persistent congenital macroscopic diverticula are potential risk factors for recurrent bacterial urinary tract infections.
- Acquired macroscopic diverticula are typically encountered in patients with concurrent lower urinary tract diseases.

SEE ALSO

- Feline Idiopathic Lower Urinary Tract Disease
- Lower Urinary Tract Infection chapters

Osborne

Consulting Editor Carl A. Osborne

VESTIBULAR DISEASE, GERIATRIC—DOGS

BASICS

DEFINITION

Acute onset non-progressive disturbance of the peripheral vestibular system in older dogs.

PATHOPHYSIOLOGY

- Unknown.
- Suspected abnormal flow of the endolymphatic fluid in the semicircular canals of the inner ear secondary to disturbance in production, circulation, or absorption of the fluid.
- Possible intoxication of the vestibular receptors or inflammation of the vestibular portion of the vestibulocochlear nerve (cranial nerve VIII).
- Often incorrectly referred to as a stroke, geriatric vestibular disease is neither central in location nor suspected to be vascular or ischemic in origin.

SYSTEMS AFFECTED

Nervous—peripheral vestibular system

GENETICS

N/A

INCIDENCE/PREVALENCE

Common, sporadic, acquired disease of older dogs

SIGNALMENT

Species

Dog

Breed Predilections

- None reported
- Seems to occur more frequently in medium to large breeds

Mean Age and Range

Geriatric; patients usually > 8 years old

Predominant Sex

N/A

SIGNS

General Comments

- Signs of acute onset peripheral vestibular dysfunction usually unilateral but occasionally bilateral.
- If vestibular signs are severe, do not incorrectly attribute the signs (especially the gait) to a central (i.e., CNS) location.

Historical Findings

- Sudden onset of imbalance, disorientation, reluctance to stand, and (usually) head tilt and irregular eye movements.
- May be preceded or accompanied by nausea and vomiting.

Physical Examination Findings

- Head tilt—mild to marked; directed toward the side of the lesion; occasionally disease is bilateral with erratic side-to-side head movements either without a head tilt or with a mild tilt in direction of the more severely affected side.

- Abnormal (resting) nystagmus common in early stages; either horizontal or rotatory with the fast phase always in the direction opposite to the head tilt; with bilateral disease, abnormal nystagmus usually mild or not present and physiologic nystagmus or conjugate eye movements diminished to absent.

- Mild to marked disorientation and vestibular ataxia with tendency to lean or fall in the direction of the head tilt.
- Strength and proprioception normal; with severe disease, patient may be reluctant to stand and may have other issues (e.g. hip dysplasia), making assessment of gait difficult; with bilateral disease, may have base-wide stance.

CAUSES

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primarily distinguished from other causes of vestibular deficits by the acute onset and usually rapid improvement without specific treatment.
- Otitis media and interna—may have concurrent ipsilateral facial nerve (cranial nerve VII) paresis or paralysis, deafness, and/or Horner's syndrome; otitis externa with ruptured tympanic membrane may be present with otitis media and interna.
- Ototoxic drugs—eliminated by history.
- Trauma—may cause similar acute changes; differentiated by history, results of physical examination.
- Hypothyroid neuropathy—usually not as acute in onset or as severe; may be associated with clinical signs of hypothyroidism and possible cranial nerve VII deficit.

CBC/BIOCHEMISTRY/URINALYSIS

- Generally normal.
- Hemoconcentration secondary to dehydration may be present.
- Unrelated concurrent disorders (e.g., renal and hepatic disease) associated with geriatric state may cause laboratory abnormalities.

OTHER LABORATORY TESTS

N/A

IMAGING

- Usually none required.
- Radiographs of tympanic bullae: normal radiographs do not rule out bulla disease.
- CT or MRI (preferred over radiographs)—may be required to rule out other causes such as otitis media and interna.

DIAGNOSTIC PROCEDURES

- Brainstem auditory evoked response—to assess cochlear portion of cranial nerve VIII; may help to evaluate for otitis media and interna since only the vestibular portion of

cranial nerve VIII is affected with geriatric vestibular disease.

- Deafness may, however, be present as an unrelated aging change.

PATHOLOGIC FINDINGS

None reported

TREATMENT

APPROPRIATE HEALTH CARE

- Mild disease—usually can manage as outpatient.
- Severe disease—patients that cannot ambulate or require intravenous fluid support should be hospitalized during the initial stages.

NURSING CARE

- Treatment supportive, including rehydration by intravenous fluids if required.
- Keep recumbent patients warm and dry using soft, absorbent bedding and, if required, urinary catheter.
- Severe disease—physical therapy, including passive manipulation of limbs and moving body to alternate sides, may be required initially.

ACTIVITY

Restrict activity as required by the degree of disorientation and vestibular ataxia.

DIET

- No modification usually required.
- Nausea, vomiting, and severe disorientation—initially withhold oral intake then supervised feeding.

CLIENT EDUCATION

Reassure client that although the initial signs can be alarming and incapacitating, the prognosis for rapid improvement and recovery is excellent.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

- Sedatives—for severe disorientation and ataxia; diazepam (2–10 mg/dog PO or IV q8h), acepromazine (0.02–0.05 mg/kg IM, SC, IV to maximum of 2 mg).
- Antiemetic drugs or drugs against motion sickness—questionable benefit; dimenhydrinate (4–8 mg/kg PO, IM, IV q8h), meclizine HCl (25 mg PO q24h).
- Glucocorticoids—not recommended since do not alter the course of the disease; may exacerbate concurrent issues (e.g., dehydration).
- Antibiotics—recommended when otitis media and interna cannot be ruled-out; trimethoprim-sulfa (15 mg/kg PO q12h or

VESTIBULAR DISEASE, GERIATRIC—DOGS

(CONTINUED)

30 mg/kg PO q12–24h); first-generation cephalosporin (e.g., cephalexin 10–30 mg/kg PO q6–12h); amoxicillin/clavulanic acid (12.5 mg/kg PO q12h).

CONTRAINDICATIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Neurologic examination of outpatient—repeat 2–3 days later to confirm stabilization and initial improvement.
- Discharge inpatient when able to ambulate and resume eating and drinking.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Fluid and electrolyte imbalances and decompensation of renal insufficiency (if exists) may follow vomiting and/or insufficient fluid and food intake.
- Pressure sores/abrasions.

EXPECTED COURSE AND PROGNOSIS

- Improvement of clinical signs usually starts within 72 hours with resolution of vomiting

and improvement of nystagmus and vestibular ataxia.

- Head tilt and ataxia—significant improvement usually occurs over 7–10 days; if no improvement other causes of peripheral vestibular disease should be pursued; mild head tilt may persist.
- Most patients return to normal within 2–3 weeks.
- Recurrence—repeat episodes of geriatric vestibular disease can occur on the same or opposite side but are uncommon; brief return of signs may occur with stress (e.g., anesthesia).

Any age; rare in cats < 1 year of age

SIGNS

General Comments

Limited to signs associated with peripheral vestibular disturbance.

Historical Findings

Sudden onset of severe disorientation, falling, rolling, leaning, vocalizing, and crouched posture; tendency to panic when picked up.

Physical Examination Findings

- Head tilt—always toward the side of the lesion; occasionally disease is bilateral with wide, side-to-side excursions of the head either without a head tilt or with a mild tilt toward the more severely affected side.
- Resting nystagmus—usually horizontal, but may be rotatory with the fast phase always in direction opposite to the head tilt; with bilateral disease, the abnormal nystagmus is usually mild or not present, and physiologic nystagmus or conjugate eye movements are diminished to absent.
- Vestibular ataxia with tendency to roll and fall toward the side of the head tilt.
- Preservation of strength and normal proprioception; with bilateral disease, patient may be reluctant to ambulate, preferring to stay in a crouched posture and possible wide-based stance.

CAUSES

- Unknown.
- Previous upper respiratory tract infection—suspected in some patients; relationship not confirmed; in limited necropsy data no evidence of inflammation.

RISK FACTORS

May be an increase in cases in the summer and early fall, possibly after outbreaks of upper respiratory disease; disease can occur throughout the year.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diagnosis made on the basis of acute onset peripheral vestibular signs that improve rapidly without specific treatment.
- Otitis media and interna (e.g., bacterial, parasitic)—may have concurrent ipsilateral facial nerve (cranial nerve VII) paresis or paralysis, Horner's syndrome, deafness, ruptured tympanic membrane, otitis externa, and/or radiographic changes in tympanic bulla; signs usually not self-limiting.
- Nasopharyngeal polyp(s)—may cause unilateral or, much less commonly, bilateral peripheral vestibular signs; may have concurrent tympanic bulla involvement; signs usually not as acute and severe at onset and are not self-limiting.
- Blue-tailed lizard ingestion—southeastern United States; thought to produce a similar acute, unilateral, peripheral vestibular syndrome; vomiting, salivation, irritability, and trembling also noted; most patients recover without specific treatment.
- Aminoglycoside toxicity, especially streptomycin—may cause acute unilateral or bilateral peripheral vestibular syndrome and/or hearing loss; differentiated by history of drug use.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

IMAGING

- None usually necessary.
- Radiographs of tympanic bullae: normal radiographs do not rule-out bulla disease.
- CT or MRI—occasionally required to rule out other causes such as otitis media and interna and nasopharyngeal polyp(s).

DIAGNOSTIC PROCEDURES

Brainstem auditory evoked response—may help rule-out other causes (e.g., otitis media and interna; nasopharyngeal polyp); with idiopathic vestibular disease hearing not

affected since disease limited to the vestibular portion of cranial nerve VIII.

PATHOLOGIC FINDINGS

None reported

TREATMENT

APPROPRIATE HEALTH CARE

- Usually outpatient.
- Inpatient—severely affected patient may require hospitalization for supportive care.

NURSING CARE

- Mild disease—treatment supportive only.
- Severe disease—may require intravenous or subcutaneous fluids; maintain patient in quiet, well-padded cage.

ACTIVITY

Restricted according to the degree of disorientation and ataxia.

DIET

Patient may initially be reluctant to eat and drink because of disorientation and/or nausea.

CLIENT EDUCATION

Reassure client that, despite initial alarming and often incapacitating signs, the prognosis for rapid and complete recovery is excellent.

MEDICATIONS

DRUG(S) OF CHOICE

- Sedatives—for severe disorientation and rolling; diazepam (1–5 mg/cat PO q8–12h) and acepromazine (0.02–0.05 mg/kg IM, SC, IV).
- Antiemetic drugs and drugs against motion sickness—questionable benefit; e.g., meclizine HCl 12.5 mg PO q24h.
- Glucocorticoids—not recommended since do not alter course of the disease.
- Antibiotics—recommended if otitis media and interna cannot be ruled out; trimethoprim-sulfa (15 mg/kg PO q12h); first-generation cephalosporin (e.g., cephalexin 10–30 mg/kg PO q6–12h); amoxicillin/clavulanic acid (Clavamox 62.5 mg/cat PO q12h, Clavaseptin 12.5 mg/kg PO q12h).

FOLLOW-UP

PATIENT MONITORING

- Neurologic examination of outpatient—repeat in approximately 72 hours to confirm stabilization and initial improvement.

VESTIBULAR DISEASE, IDIOPATHIC—CATS

(CONTINUED)

- Inpatient—discharge patient when able to ambulate and resume eating and drinking.

EXPECTED COURSE AND PROGNOSIS

- Marked improvement, especially in resting nystagmus within 72 hours, with progressive improvement of gait and head tilt.
- Patients usually normal within 2–3 weeks.
- Head tilt—final sign to resolve; mild residual tilt may remain.

- If signs do not improve rapidly, other causes of vestibular disease should be pursued.
- Rarely recurs.

**MISCELLANEOUS****ABBREVIATIONS**

- CT = computed tomography
- MRI: magnetic resonance imaging

VITAMIN D TOXICOSIS

BASICS

DEFINITION

Hypercalcemic disorder resulting from ingestion of vitamin D rodenticide preparations, excessive dietary and vitamin supplementation, ingestion of congeners of vitamin D metabolites used for treatment of psoriasis and other immune-mediated human disorders, or diets high in vitamin D.

PATOPHYSIOLOGY

- Cholecalciferol is metabolized to 25-hydroxycholecalciferol in the liver. 25-hydroxycholecalciferol is metabolized to several metabolites in the kidney, including calcitriol, the most potent metabolite in terms of enhancing calcium absorption from the gut and calcium resorption from bones under physiologic conditions.
- 1,25-Dihydroxycholecalciferol is the active metabolite of cholecalciferol under physiologic conditions. • Under toxic conditions, 25-hydroxycholecalciferol is the predominant circulating and active metabolite. • Calcipotriol (Dovonex), a congener of calcitriol, does not require activation; has immediate but limited action due to a short half-life (100 minutes).
- 25-Hydroxycholecalciferol, calcitriol, and calcipotriol increase absorption of calcium from the gut, stimulate bone resorption, and enhance calcium absorption in renal distal tubules, resulting in hypercalcemia (serum calcium > 12.5 mg/dL). • Serum phosphorus is also increased (> 8 mg/dL). • The outcome is metastatic and dystrophic mineralization of soft tissues, resulting in pathophysiology of the affected organs.

SYSTEMS AFFECTED

- Cardiovascular—mineralization, arrhythmias. • Gastrointestinal—anorexia; mineralization; emesis; hematemesis; constipation; increased gastric acid secretion.
- Musculoskeletal—demineralization; muscle tremors. • Nervous—seizures or depression.
- Renal/Urologic—calcification, proximal tubular necrosis, and renal failure.
- Respiratory—mineralization; dyspnea.

INCIDENCE/PREVALENCE

- Cholecalciferol rodenticide toxicosis—most common cause of vitamin D poisoning in dogs and cats. • Vitamin D₃ poisoning from excessive vitamin D₃ in a commercial dog food in January of 2000, April of 2006, and October of 2010 led to pet food recalls.
- Calcipotriol ointment (Dovonex; 50 µg calcipotriol/g) antipsoriasis medication—leading cause of vitamin D congener toxicity in dogs. • Suckling pups and kittens can be poisoned through milk. • Overall incidence of vitamin D toxicity is unknown.

SIGNALMENT

Species

- Dogs and cats • Other species, particularly exotics

Mean Age and Range

All ages affected; younger dogs (< 6 months) and cats are the most sensitive.

SIGNS

General Comments

- Calcipotriol (Dovonex)—signs develop within 6–12 hours post-ingestion
- Cholecalciferol rodenticides—signs develop within 12–36 hours post-ingestion

Historical Findings

- Inactivity • Vomiting • CNS depression
- Weakness • Anorexia • Polydipsia
- Polyuria • Diarrhea • Melena
- Hematemesis • Loss in body weight
- Constipation • Seizures • Muscle tremors

Physical Examination Findings

- Depression • Vomiting • Diarrhea
- Hematemesis • Hematochezia • Polyuria
- Polydipsia • Renal pain on palpation
- Gastrointestinal hemorrhage • Abdominal pain • Hypersalivation • Oropharyngeal erosive lesions • Bradycardia; ventricular premature contractions • Dyspnea

CAUSES

- Cholecalciferol rodenticides (0.075%)—Quintox, Rampage, Ortho Rat-B-Gone, Ortho Mouse-B-Gone, others; clinically normal dogs and cats have developed hypercalcemia at 0.5 mg/kg bw; signs have occurred in dogs and cats at 0.1 mg/kg bw.
- Calcipotriol: Ingesting 1.8–3.6 µg/kg BW is toxic to dogs. • Diet: In dogs, daily ingestion of vitamin D₃ in excess of the recommended dietary maximum of 1.43 kIU/1,000 kcal of ME causes chronic toxicosis. • In cats, chronic intake of diets containing more than the recommended maximum vitamin D₃ concentrations of 2.5 kIU/1,000 kcal ME is toxic. • In the 2006 dog food outbreak, dietary concentrations of vitamin D₃ were found between 1.51 and 2.67 kIU/1,000 kcal ME.

RISK FACTORS

- Preexisting renal, gastrointestinal, cardiac, lung, or CNS diseases • Dehydration
- Neoplasia • Primary hyperparathyroidism
- Hypoadrenocorticism • Granulomatous diseases (e.g., blastomycosis) • Juvenile hypercalcemia • Age—young animals are most susceptible • Feline idiopathic hypercalcemia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other hypercalcemic disorders, including lymphosarcoma and other malignancies, hypoadrenocorticism, chronic renal failure, primary hyperparathyroidism, and

granulomatous lesions in soft tissues. Vitamin D and congener toxicosis can be differentiated from these diseases because it suppresses intact parathyroid hormone. In other conditions, iPTH is either normal or increased. • Juvenile hypercalcemia.

- Anticoagulant rodenticide and NSAID toxicity—due to hematemesis and melena.

CBC/BIOCHEMISTRY/URINALYSIS

- Calcium—hypercalcemia (total serum calcium > 12.5 mg/dL, ionized calcium > 6.0 mg/dL). Hypercalcemia is immediate (2–3 hours) and transient (will decline to normal within 24 hours post-ingestion) with calcipotriol ingestion. In cholecalciferol rodenticide toxicity, hypercalcemia is evident 12 hours post-ingestion and persists for weeks if not treated. • Hyperphosphatemia (> 8 mg/dL), may precede hypercalcemia.
- Hypokalemia. • Azotemia. • Hyposthenuria, proteinuria, and glucosuria. • Metabolic acidosis. • Calcipotriol—other abnormalities include hypoalbuminemia, increased ALP, ALT, and AST activity, thrombocytopenia, prolonged APTT, and increased fibrinogen concentration.

OTHER LABORATORY TESTS

- Currently there are no confirmatory tests for calcipotriol intoxication. Serum 25-hydroxy vitamin D and calcitriol are normal. • In acute, one-time ingestions, serum 25-hydroxy vitamin D concentration is increased at least 10 times normal (normal ranges: dogs, 60–215 nmol/L; cats, 65–170 nmol/L) in cholecalciferol toxicosis. • In chronic intoxications, serum 25-hydroxy vitamin D concentrations can increase from 1.5 to 5 times above normal values. • Serum 1,25 dihydroxy vitamin D is only transiently increased and is of limited diagnostic value.
- The total calcium-to-total phosphorus ratio in renal cortex of deceased dogs is in the range of 0.4–0.9 for all vitamin D-related intoxications. • Renal cortical 25-hydroxy vitamin D concentration > 80 nmol/L supports a diagnosis of cholecalciferol toxicosis. • Biliary 25-hydroxy vitamin D concentration > 100 nmol/L supports a diagnosis of cholecalciferol toxicosis.
- Decreased iPTH (normal in dogs is 3–17 pmol/L and for cats is 0–4 pmol/L).
- Normal Na/K ratio.

IMAGING

Ultrasonography—renal, gastric wall, lung hyperechogenicity

V

DIAGNOSTIC PROCEDURES

- ECG—may show bradycardia, sinus tachycardia, ventricular premature complexes.
- Endoscopy—may reveal erosive/hemorrhagic gastric mucosa.

PATHOLOGIC FINDINGS

- Diffuse mineralization of gastric wall and intestines; hemorrhage in gastric mucosa; mineralization of the soft palate, salivary

VITAMIN D TOXICOSIS

(CONTINUED)

glands, other soft tissues. • Necrosis and mineralization of myocardium (especially the atria) and large blood vessels; myocardial degeneration. • Mineralization of glomerular mesangium and capsule, and renal tubular basement membranes. • Tubular necrosis. • Mineralization of lungs.

TREATMENT

APPROPRIATE HEALTH CARE

- Calcipotriol—emergency treatment is recommended; prognosis is guarded, and hospitalization is required.
- Cholecalciferol—once clinical signs show (usually 24–36 hours post-ingestion), gastric decontamination is not worthwhile.
- Hospitalization with close observation in all cases for at least 48 hours post-ingestion.

NURSING CARE

- Correct dehydration and electrolyte imbalances (hypokalemia). • Enhance calciuresis with fluid therapy—strongly recommended for all patients. • Peritoneal dialysis with a calcium-free dialysate—for severe azotemia and hypercalcemia. • Blood transfusion—if anemia is severe or in case of hypovolemia. • Antibiotic therapy—to prevent secondary bacterial infection because of broken defense barrier in gut. • Parenteral alimentation—recommended to rest the gut and to overcome anorexia.

DIET

Offer low-calcium, low-phosphorus diets.

CLIENT EDUCATION

- Caution client to keep all rodenticide products in places that are inaccessible to pets.
- Caution client to secure all medications where pets cannot reach them. • Warn client that vitamin D toxicity is a severe and costly disease to treat with prolonged therapy and hospitalization.

MEDICATIONS

DRUG(S) OF CHOICE

- Pamidronate disodium—to treat hypercalcemia • Salmon calcitonin—to treat hypercalcemia

Decontamination of Gastrointestinal Tract

- Must for calcipotriol ingestions; highly toxic. • Within 2 hours of vitamin D ingestion. • Emetic and activated charcoal followed by osmotic cathartics. • Dogs—apomorphine 0.02–0.04 mg/kg IV, IM, SC, or subconjunctivally. • Cats—xylazine 0.4–0.5 mg/kg IV. • Activated charcoal powder (1–4 g/kg) combined with a saline cathartic (magnesium or sodium sulfate, 250 mg/kg)—PO or by gastric tube.

Hypercalcemia Reduction

- Pamidronate disodium 1.3–2.0 mg/kg in 0.9% sodium chloride slow IV over 2–4 hours; repeat once in 3–4 days for large ingestions; do not combine with salmon calcitonin. • Salmon calcitonin 4–6 IU IM or SC every 6 hours till calcium concentration stabilizes; limited efficacy and patients may become refractory. • Prednisolone—dogs and cats: 2–6 mg/kg IM or PO q12h.
- Furosemide—dogs, 2–6 mg/kg; cats, 1–4 mg/kg SC, IV, or IM q8–12h.

Seizure Control

Diazepam 0.5 mg/kg IV, repeat as necessary

Control of Clinically Significant Ventricular Arrhythmias

Lidocaine—dogs, 2–4 mg/kg IV over 1 minute, repeat up to 8 mg/kg; cats, use cautiously at 0.25–0.5 mg/kg IV slowly.

Gastrointestinal Protection

- Sucralfate 0.25–1 g PO q6–8h.
- Famotidine 0.5–1 mg/kg IV, IM, PO q12h.

Antiemetics

Maropitant 1 mg/kg SQ q24h.

PRECAUTIONS

- Supratherapeutic doses of pamidronate disodium may worsen renal failure. • Salmon calcitonin—associated with side effects: anorexia, anaphylaxis, and emesis. Rarely used. • Xylazine—may aggravate respiratory depression and result in vagal-mediated slowing of the heart rate. • Prolonged prednisolone therapy may result in adrenocortical suppression; taper doses gradually over a 2–4-week treatment period.

FOLLOW-UP

PATIENT MONITORING

- Following pamidronate therapy—serum calcium and BUN at 24, 48, and 72 hours following exposure; if hypercalcemia is present, fluid diuresis is recommended; if hypercalcemia still present, repeat pamidronate infusion 72 or 96 hours after the first infusion and monitor serum calcium and BUN q48h. • Following calcitonin therapy—serum calcium and BUN; monitor q24h and continue adjusting dose until calcium returns to normal (24–48 hours for calcipotriol, or 2–4 weeks for cholecalciferol). • Calcipotriol causes short-term hypercalcemia (24–48 hours) with massive soft tissue mineralization; requires long-term aggressive fluid and supportive therapy.
- Cholecalciferol-induced hypercalcemia is persistent, requiring long-term management and supportive care (2–4 weeks).

PREVENTION/AVOIDANCE

- Keep rodenticides and medications out of reach of pets. • Avoid diets high in vitamin D.

POSSIBLE COMPLICATIONS

- Chronic renal failure—inability to concentrate urine. • Secondary bacterial infection from injury in the gut. • Subclinical renal, cardiovascular, and gastrointestinal injury—due to mineralization.

EXPECTED COURSE AND PROGNOSIS

- Calcipotriol—guarded prognosis unless aggressive therapy is immediate due to peracute nature of condition and associated massive soft tissue mineralization.
- Cholecalciferol—depends on severity and duration of hypercalcemia; if hypercalcemia is unresponsive or severe mineralization occurs before therapy is initiated, prognosis is poor.

MISCELLANEOUS

AGE-RELATED FACTORS

Distinguish from normal juvenile hypercalcemia.

PREGNANCY/FERTILITY/BREEDING

Teratogenic effects—calcipotriol and vitamin D have antiproliferative effects and potential for teratogenesis.

SYNONYMS

- Calcipotriol toxicosis • Cholecalciferol toxicosis • Dovonex toxicosis • Vitamin D congeners toxicosis

ABBREVIATIONS

- ALP = alanine phosphatase • ALT = alanine aminotransferase • APTT = activated partial thromboplastin time • AST = aspartate aminotransferase • CNS = central nervous system • ECG = electrocardiogram • iPTH = intact parathyroid hormone • ME = metabolizable energy • NSAID = nonsteroidal anti-inflammatory drug

Author Wilson K. Rumbeha
Consulting Editor Lynn R. Hovda

VOMITING, ACUTE

BASICS

DEFINITION

- Forceful, neurologically mediated reflex expulsion of gastric contents from the oral cavity.
- Acute vomiting is defined as vomiting of short duration (< 5–7 days) and variable frequency.

PATHOPHYSIOLOGY

• A complex set of reflex activities under central neurologic and hormonal control involving the coordination of GI, abdominal, and respiratory musculature.

- Often preceded by prodromal signs of nausea.
- In the first stage there is increased saliva production with bicarbonate to lubricate the esophagus and neutralize gastric acid.
- This is followed by decreased gastric and esophageal motility and increased retrograde motility of the proximal small intestine.
- Stage 2 consists of retching, which is forceful contractions of the abdominal muscles and diaphragm with a resultant negative intrathoracic pressure and positive intra-abdominal pressure to facilitate moving gastric contents orally.
- In stage 3 the gastric contents are expelled. There is a change in the intrathoracic pressure from negative to positive via the force generated by the abdominal and diaphragm muscles.

Concurrently, respiration is inhibited and the nasopharynx and glottis close to prevent aspiration.

- Stimulation of stretch receptors, chemoreceptors, and osmoreceptors located throughout the GI tract, hepatobiliary system, genitourinary system, peritoneum, and pancreas are examples of neural activation. (Duodenum has the most receptors.)
- The humoral stimuli are mediated through the chemoreceptor trigger zone; with a more permeable blood-brain barrier.
- Cats have poorly developed CTZ dopaminergic receptors and therefore respond poorly to apomorphine or D2 dopaminergic receptor antagonists such as metoclopramide.
- Higher centers can lead to psychogenic vomiting, and input from the vestibular apparatus (e.g. motion sickness, vestibular disease) can stimulate the emetic center.

SYSTEMS AFFECTED

- Cardiovascular—hypovolemia, causing tachycardia, pale mucous membranes, and weak pulses; hypokalemia can cause arrhythmias.
- Gastrointestinal—reflux esophagitis.
- Metabolic—electrolyte and acid-base abnormalities (e.g. hypokalemia, hyponatremia, hypochloremia, metabolic alkalosis), prerenal azotemia, and dehydration.
- Nervous—lethargy.
- Respiratory—aspiration pneumonia, rhinitis from vomitus refluxed into the nasopharynx.

GENETICS

No genetic basis

INCIDENCE/PREVALENCE

Increased incidence in younger animals with dietary indiscretion

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

No age, breed, or sex predisposition

Species

Dog and cat

SIGNS

Historical Findings

- Variable vomiting of food and/or fluid. It is essential to differentiate between vomiting and regurgitation when obtaining the history.
- Ingestion of foreign material.
- Variable lethargy and appetite loss; may see diarrhea and/or melena.

Physical Examination Findings

- May include dehydration, (e.g., dry mucous membranes, reduced skin turgor, sunken eyes, pale mucous membranes, tachycardia, weak pulses), fluid-filled bowel loops, excessive gut sounds, abdominal pain (localized [e.g., foreign body, pancreatitis, pyelonephritis, hepatic disease] vs. diffuse [e.g., peritonitis, severe enteritis]), or abdominal mass (e.g., foreign body, intussusception, torsed viscus).
- May note diarrhea or melena on rectal examination.
- May see fever with infectious and inflammatory causes.
- May be unremarkable.

CAUSES

- Adverse food reactions—most frequent cause of acute vomiting; indiscretions (eating rapidly, ingestion of foreign material); intolerances (e.g. sudden diet change, allergies).
- Drugs—antibiotics, anti-inflammatory drugs (corticosteroids, NSAIDs), chemotherapeutics, digitalis, narcotics, xylazine.
- GI inflammation—*infectious enteritis*: viruses (parvo, distemper, corona virus), bacteria (*Salmonella*, *Campylobacter*, *Helicobacter* spp.); hemorrhagic gastroenteritis.
- Gastroduodenal ulcers.
- GI obstruction—foreign bodies, intussusception, neoplasia, volvulus, ileus, constipation, mucosal hypertrophy.
- Systemic disease—uremia, hepatic failure, sepsis, acidosis, electrolyte imbalance (hypokalemia, hypocalcemia, hypercalcemia).
- Abdominal disorders—pancreatitis, peritonitis, pyometra.
- Endocrine disease—hypoadrenocorticism, diabetic ketoacidosis.
- Neurologic disease—vestibular disturbances, meningitis, encephalitis, CNS trauma.
- Parasitism—ascariids, *Giardia*, *Physaloptera*, *Ollulanus tricuspis* (cats), salmon poisoning (dogs).
- Toxins—lead, ethylene glycol, zinc, mycotoxins, household plants.
- Miscellaneous—anaphylaxis, heat stroke, motion sickness, pain, fear.

RISK FACTORS

- Dietary indiscretion
- Sudden changes to diet

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiating Similar Signs

- Vomiting usually includes hypersalivation, retching, and forceful contractions of the abdominal muscles and diaphragm.
- Must always be differentiated from regurgitation, which is the passive expulsion of fluid or food from the esophagus or pharyngeal cavity, and dysphagia (difficulty in swallowing), which is observed during eating or drinking.
- Animals that are vomiting may have disorders that additionally cause regurgitation, and frequent vomiting can lead to reflux esophagitis and regurgitation.

Differentiating Causes

- If no signs of serious vomiting (e.g., dehydration, lethargy, fever, anorexia, or abdominal pain), can assess with a thorough history and physical examination alone.
- When indications of serious vomiting exist, when frequency intensifies, or when signs do not resolve over 2–3 days, obtain a minimum database (including CBC, biochemical analysis, urinalysis, and survey abdominal radiographs) in an attempt to find the primary cause.

CBC/BIOCHEMISTRY/URINALYSIS

- In non-severe vomiting, the hemogram, biochemical profile, and urinalysis are typically unremarkable unless the animal is dehydrated.
- Anemia with panhypoproteinemia seen with severe gastric ulceration and bleeding.
- Dehydration—may see hemoconcentration (high PCV and total protein).
- May see a stress leukogram.
- Infectious or inflammatory causes—may see an inflammatory leukogram.
- Acute hepatopathies—may see elevated liver enzymes and serum bilirubin.
- Pancreatitis—may see elevated lipase, amylase, and liver enzymes.
- Hyponatremia, hyperkalemia, hypoglycemia, and azotemia suggest hypoadrenocorticism.
- Hyperglycemia with glucosuria and ketonuria indicates ketoacidotic diabetic mellitus.

OTHER LABORATORY TESTS

Additional blood tests for specific diseases when indicated (e.g., blood lead level, ethylene glycol assay, ACTH stimulation testing for hypoadrenocorticism, and canine pancreatic lipase immunoreactivity (cPL) or feline pancreatic lipase immunoreactivity (fPL) testing for pancreatitis).

IMAGING

- Survey abdominal radiographs are often unremarkable, but radiodense foreign bodies, segmental ileus, or gastric distension indicating volvulus or outflow obstruction may be observed; serosal detail may be lost (“ground glass” appearance) with pancreatitis or peritonitis; a mass effect or haziness in the

VOMITING, ACUTE

(CONTINUED)

right cranial quadrant or persistent gas in the descending duodenum may indicate pancreatitis. • Can use contrast radiography to evaluate for radiolucent foreign bodies, obstruction, intussusception, or volvulus. • Can use abdominal ultrasonography to visualize an obstruction, an intussusception, or pancreatitis.

DIAGNOSTIC PROCEDURES

Endoscopy may be useful to assess for gastroduodenal ulceration and gastric and proximal duodenal foreign bodies.

PATHOLOGIC FINDINGS

Dependent on etiology

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient if vomiting non-serious
- Hospitalize if severe vomiting

NURSING CARE

• Fasting the animal is not warranted unless the vomiting is intractable and the risk of aspiration pneumonia is increased. • Patients with frequent episodes of vomiting should be treated initially by keeping the animal NPO and administering intravenous crystalloid fluids.

ACTIVITY

Animals should have limited activity until the vomiting has stopped.

DIET

• If vomiting resolves, initially offer small amounts of water or ice cubes, and if vomiting does not recur, follow with an easily digestible, low-fat, intestinal diet or single-protein and single-carbohydrate-source diet such as non-fat cottage cheese or skinless white chicken and rice in a 1:3 ratio. • If vomiting does not recur, wean the patient back onto the normal diet over 4–5 days.

CLIENT EDUCATION

Owners should be educated on the risks of giving their pet table scraps and to refrain from feeding high-fat treats. They should limit the pet's access to the trash and monitor the pet while it plays with toys to prevent ingestion of foreign bodies.

SURGICAL CONSIDERATIONS

Surgery should be considered for obstructions of any kind as well as for peritonitis or volvulus.

MEDICATIONS

DRUG(S) OF CHOICE

- May use antiemetics in patients with severe vomiting causing electrolyte and/or acid-base disturbances or reflux esophagitis.
- Several antiemetics are available for both

dogs and cats—phenothiazine derivatives that act at the CTZ and emetic center include chlorpromazine (0.5 mg/kg SC q8h) and metoclopramide, a dopamine antagonist and motility modifier that acts at the CTZ and on local receptors in the gut (0.2–0.5 mg/kg PO or SC q6–8h, or 1–2 mg/kg/day as a CRI); H₁-receptor antagonists acting on the CTZ can be used in motion sickness (e.g., diphenhydramine 2–4 mg/kg PO, IM q6–8h) for dogs only; maropitant, a neurokinin-1 antagonist (1 mg/kg SC q24h or 2 mg/kg PO q24h). • Patients with ulceration—can use H₂-receptor antagonists such as ranitidine (1–2 mg/kg PO, SC, IV q12h) and famotidine (0.5–1 mg/kg PO, SC, IV q12h), proton pump inhibitors such as omeprazole (0.7–1 mg/kg PO q12–24h), and/or gastric mucosal protectants such as sucralfate (250 mg/cat PO q6–12h, 250–1,000 mg/dog PO q6–12h) as a slurry. • Fever or mucosal injury (hematemesis, melena)—antibiotics may be indicated (e.g., ampicillin, enrofloxacin).

CONTRAINdications

• Use phenothiazines with caution in dehydrated patients because of possible hypotension from their alpha-receptor antagonist effect; they also may lower the seizure threshold and should be avoided in epileptics. • Do not use anticholinergics; they can cause gastric atony and intestinal ileus, which could exacerbate vomiting. • Do not use prokinetics such as metoclopramide and cisapride in patients with GI obstruction • Maropitant should be used with caution in patients with hepatic disease and preferably for a maximum of 5 days.

PRECAUTIONS

Use antiemetics cautiously; they may suppress vomiting and mask progressive disease or hamper an important means of monitoring response to primary therapy.

POSSIBLE INTERACTIONS

Anticholinergics and opioids may negate the effect of metoclopramide.

ALTERNATIVE DRUG(S)

- Cisapride • Famotidine • Dolasetron
- Pantoprazole

FOLLOW-UP

PATIENT MONITORING

• If frequency of vomiting increases or the animal has systemic evidence of disease: hospitalize for treatment and obtain appropriate diagnostics. • If vomiting persists beyond 7 days despite conservative therapy, pursue appropriate testing for chronic vomiting.

PREVENTION/AVOIDANCE

- Animals should be fed a highly digestible fat-restricted diet. • Owners should attempt

to control indiscriminate eating and monitor for foreign body ingestion.

POSSIBLE COMPLICATIONS

- Aspiration pneumonia • Esophagitis
- Dehydration • See "Systems Affected"

EXPECTED COURSE AND PROGNOSIS

• Recovery from non-serious vomiting is usually rapid and spontaneous. • Feeding of a highly digestible, fat-restricted diet will frequently control non-serious vomiting. • GI foreign bodies have a good prognosis after endoscopic retrieval or surgical removal.

MISCELLANEOUS

ASSOCIATED CONDITIONS

See "Systems Affected"

AGE-RELATED FACTORS

Young animals are more likely to ingest foreign objects and acquire viral, bacterial, and parasitic disease.

ZOONOTIC POTENTIAL

Some species of *Giardia*, *Salmonella*, and *Campylobacter* are zoonotic.

PREGNANCY/FERTILITY/BREEDING

Misoprostol, a synthetic prostaglandin E1 analogue used most often in treatment or prevention of gastric ulceration associated with nonsteroidal anti-inflammatory drugs, is contraindicated in pregnant animals.

SYNONYM

Emesis

SEE ALSO

- Diarrhea, Acute • Gastroduodenal Ulceration/Erosion

ABBREVIATIONS

- ACTH = adrenocorticotrophic hormone
- CNS = central nervous system • CTZ = chemoreceptor trigger zone • GI = gastrointestinal • NSAID = nonsteroidal anti-inflammatory drug • PCV = packed cell volume

VOMITING, CHRONIC

BASICS

DEFINITION

Persistent vomiting lasting longer than 5–7 days or vomiting that occurs intermittently several days/week. This condition is usually non-responsive to symptomatic treatment.

PATHOPHYSIOLOGY

- Vomiting occurs when the vomiting center, located within the medulla oblongata, is activated by the humoral or neural pathway.
- There are four main components to the vomiting reflex: (1) visceral receptors within the GI tract; (2) vagal and sympathetic afferent neurons; (3) CRTZ; and (4) vomiting center.
- The humoral pathway is mediated via activation of the CRTZ and is affected by uremic toxins, liver disease, digoxin toxicity, endotoxemia, apomorphine, and other bloodborne triggers.
- The neural pathway is mediated via activation of the vomiting center and is affected by disorders associated with obstruction, distension, or inflammation of the gastrointestinal tract.
- All causes of vomiting (including the vestibular apparatus and cerebrum) are ultimately mediated via the vomiting center.

SYSTEMS AFFECTED

- Endocrine/Metabolic—dehydration, electrolyte and acid-base imbalances.
- Cardiovascular—hypovolemia or electrolyte and acid-base imbalances can cause arrhythmias.
- Gastrointestinal—gastroesophageal reflux, esophagitis, and subsequent esophageal stricture.
- Respiratory—aspiration pneumonia.
- Neurologic—altered mentation.

SIGNALMENT

- Dog and cat.
- Young animals are more likely to ingest foreign bodies; linear foreign bodies are more common in cats.
- Confirmed or suspected breed predispositions—brachycephalic breeds are prone to pyloric outflow obstruction secondary to mucosal hypertrophy; Basenji, German shepherd, and Shar-Pei are prone to inflammatory bowel disease; rottweiler are prone to eosinophilic IBD; Airedale terrier prone to pancreatic carcinoma; beagle, Bedlington terrier, cocker spaniel, Doberman pinscher, Labrador retriever, Skye terrier, and standard poodle are prone to chronic hepatitis. Yorkshire terrier predisposed to intestinal lymphangiectasia.

SIGNS

Historical Findings

- Vomiting of food, clear or bile-stained fluid, hematemesis, decreased appetite or anorexia,

pica, melena, polydipsia, and abdominal distension are typical of gastric disease.

- Diarrhea and profound weight loss are more characteristic of intestinal disease.
- Signs such as weakness, polyuria, or jaundice relate to other underlying metabolic diseases.

Physical Examination Findings

- Weight loss and poor hair coat may indicate chronic malnutrition.
- Abdominal palpation may reveal abdominal distention, pain, thickened bowel loops, lymphadenopathy, or mass effects.
- Tacky mucous membranes and prolonged skin tenting if dehydration is present; pale membranes if patient is anemic.
- Oral examination may reveal uremic ulcerations or sublingual string foreign bodies.
- Rectal examination may detect diarrhea, hematochezia, or melena.

CAUSES

Esophageal Disease

- Hiatal hernia (more commonly associated with regurgitation)
- Gastroesophageal reflux (more commonly associated with regurgitation)

Infectious Disease

- *Helicobacter*-related gastritis
- Histoplasmosis
- Pythiosis
- Small intestinal bacterial overgrowth
- Gastric parasites—*Physaloptera* spp.
- Intestinal parasitism

Metabolic Diseases

- Renal disease
- Hepatobiliary disease
- Hypoadrenocorticism
- Chronic pancreatitis
- Diabetic ketoacidosis (DKA)
- Metabolic acidosis
- Electrolyte abnormalities—hypo-/hyperkalemia, hyponatremia, hypercalcemia

Inflammatory Bowel Disease

- Lymphocytic, plasmacytic, eosinophilic, or granulomatous
- Gastritis, enteritis, or colitis

Obstructive GI Disease

- Foreign body
- Congenital pyloric stenosis
- Chronic pyloric hypertrophic gastropathy
- Intussusception

Neoplastic Disease

- GI lymphoma, adenocarcinoma, fibrosarcoma, gastrointestinal stromal cell tumor
- Pancreatic adenocarcinoma
- Gastrin-secreting tumor (gastrinoma)
- Systemic mastocytosis

Neurologic

- Cerebral edema
- CNS tumors
- Encephalitis/meningoencephalitis
- Vestibular disease

Motility Disorders

- Post-gastric dilatation
- Post-surgical—gastric, duodenal
- Electrolyte imbalances
- Ileus (see chapter, Ileus, for underlying causes)

Miscellaneous

- Drug-induced (e.g., NSAIDs, glucocorticoids, chemotherapeutics, antibiotics, antifungals)
- Food intolerance/allergy
- Toxicity

Additional Causes in Cats

- Parasitic—dirofilariasis, *Ollulanus tricuspis*
- Inflammatory—cholecystitis, cholangiohepatitis
- Metabolic—hyperthyroidism
- Functional—constipation/obstipation

RISK FACTORS

Breed-associated disease (see "Signalment")

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vomiting must first be differentiated from regurgitation.
- Regurgitation is a passive retrograde movement of fluid or undigested food into the oronasal cavity that has not yet reached the stomach and occurs without an abdominal component, thus localizing disease to the esophagus.
- Vomiting is a centrally mediated reflex often preceded by prodromal signs of restlessness, nausea, salivation, and repeated swallowing.
- Vomiting patients may also regurgitate because of secondary esophagitis.
- Vomit of food or partially digested food is more common with primary gastric disease, while vomitus of bile is more likely intestinal in origin.

CBC/BIOCHEMISTRY/URINALYSIS

- CBCs are often unremarkable with primary gastric disease.
- Chronic GI bleeding can cause a nonregenerative anemia, often with characteristics of iron deficiency (microcytosis, hypochromasia, thrombocytosis).
- Acute GI bleeding can cause either regenerative or nonregenerative anemia, depending on severity and duration.
- Nonregenerative anemia may also occur secondary to chronic metabolic or inflammatory diseases.
- IBD, chronic pancreatitis, cholangiohepatitis, and cholecystitis may cause neutrophilic leukocytosis and monocytosis.
- Eosinophilia can occur from eosinophilic gastroenteritis, adrenocortical insufficiency, and GI parasitism.
- Thrombocytopenia has been reported with IBD.

VOMITING, CHRONIC

(CONTINUED)

- Dehydration increases the packed cell volume and total protein.
- Biochemistry provides diagnostic and therapeutic information; normal results rule-out metabolic disease as the underlying etiology with the exception of hypoadrenocorticism that can have normal electrolytes.
- Electrolyte and acid-base imbalances reflect severity of losses and can help to localize disease.
- Hypochloremic metabolic alkalosis, often with hypokalemia, indicates substantial loss of gastric content, most consistent with a gastric outflow obstruction.
- Hyperkalemia in the vomiting patient suggests hypoadrenocorticism or oliguric/anuric renal failure; occasionally, enteritis caused by trichuriasis or bacterial infection (salmonellosis) mimics hypoadrenocorticism.
- Metabolic acidosis is common in patients with dehydration, renal failure, DKA, and severe gastroenteritis with diarrhea.
- Increased liver enzyme activity, hypoalbuminemia, hyperbilirubinemia, hypoglycemia, or low urea nitrogen concentration indicates hepatic disease.
- Persistent hyperglycemia and glucosuria is consistent with diabetes mellitus.
- Hyperglobulinemia may indicate chronic inflammation or infection.
- Hypoalbuminemia, lymphopenia, and hypomagnesemia occur secondary to a protein-losing enteropathy caused by infiltrative intestinal diseases such as lymphocytic plasmacytic gastroenteritis, neoplasia, histoplasmosis, or primary intestinal lymphangiectasia.
- Hypcholesterolemia may also be seen with lymphangiectasia.
- Urinalysis is used to rule out non-GI causes of chronic vomiting such as renal failure and DKA.
- Acidic urine in the hypokalemic, hypochloremic, alkaliotic patient indicates substantial loss of gastric content as would occur with gastric outflow obstruction.

OTHER LABORATORY TESTS

- ACTH stimulation test is used to confirm hypoadrenocorticism. A resting cortisol test $< 2 \mu\text{g}/\text{dL}$ should be followed with an ACTH stimulation test to confirm hypoadrenocorticism.
- Pancreatic lipase immunoreactivity assay may help confirm pancreatitis together with supportive history and physical exam findings and ultrasound.
- Bile acid concentration (pre- and postprandial) is used to help confirm hepatobiliary dysfunction.
- Fecal testing for gastrointestinal parasitism.

IMAGING

- Survey radiographs of the abdomen help identify foreign bodies, GI distension with fluid or gas, and displacement, malposition,

shape, and/or size changes of abdominal organs.

- Survey radiographs of the thorax are used to evaluate for pulmonary metastases, gross esophageal abnormalities, or infectious disease.
- A gastrogram or upper GI series can be used to identify foreign bodies, GI wall masses or infiltrative disease, mucosal ulceration, delayed gastric emptying, and motility disorders; however, the procedure is relatively insensitive for detection of mucosal ulceration.
- Abdominal ultrasonography helps identify parenchymal abnormalities of the liver, gallbladder, kidneys, pancreas, GI tract, and mesenteric lymph nodes.
- CT and MRI further evaluate for parenchymal abnormalities of abdominal organs.

DIAGNOSTIC PROCEDURES

- Gastroduodenoscopy—allows direct inspection of the gastric and intestinal lumen to identify gross mucosal lesions and foreign bodies and provides a minimally invasive method of biopsy to evaluate for microscopic disease. Limitations of endoscopy include the working length of the endoscope (unable to access the jejunum in large-breed dogs) and depth of the biopsies.
- Laparoscopy or exploratory laparotomy is used for more extensive diagnostic and therapeutic procedures.

TREATMENT

- Specific treatment should be aimed at eliminating the underlying cause in conjunction with supportive therapy.
- If vomiting is intractable, stop oral intake of food and water for 12–24 hours or until the vomiting episodes are better controlled with antiemetics.
- Use crystalloid fluid therapy to replace deficits and to provide for maintenance and ongoing losses.
- If acid-base status is unknown or if hypochloremic metabolic alkalosis is present, use 0.9% sodium chloride.
- If metabolic acidosis is present, use lactated Ringer's solution.
- Supplement potassium if hypokalemia is present; 20 mEq of KCl/L of fluid can be safely added for replacement and maintenance; use higher concentrations if severe hypokalemia is present.
- Debilitated patients and those in poor nutritional condition may need supplemental parenteral or enteral nutrition.
- Dietary therapy for patients with suspected food allergy or with IBD should use an elimination diet containing a single, novel protein source or a hydrolyzed diet.
- Blood transfusion in severely anemic patients with evidence of active GI bleeding.

- Use surgical treatment if uncontrolled hemorrhage, obstruction, or perforation is suspected.

MEDICATIONS

DRUG(S)

- Antisecretory drugs such as H₂-receptor blockers (e.g., famotidine, ranitidine) or proton-pump inhibitors such as omeprazole (more potent)—famotidine 0.5–1 mg/kg PO, IV, or SC q12h; ranitidine 1–2 mg/kg PO, IV q12h; omeprazole 0.7–1.5 mg/kg PO q12–24h.
- Protectants such as sucralfate (0.5–1 g/dog PO q8–12h; 0.25 g/cat PO q8–12h) to accelerate gastric mucosal healing; can be used with antisecretory drugs for patients with evidence of upper GI bleeding (e.g., hematemesis or melena).
- Antibiotics—indicated for treatment of *Helicobacter*-associated gastritis, SIBO, and as an adjunct to corticosteroids in the treatment of IBD.
- Suggested treatment of *Helicobacter*-associated gastritis—amoxicillin 20 mg/kg PO q8h plus omeprazole 0.7–1.5 mg/kg PO q24h and metronidazole 10 mg/kg PO q12h for 21 days; clarithromycin 7.5 mg/kg PO q12h can be used with amoxicillin and metronidazole (as above) as an alternative therapy for cats.
- Metronidazole—may be used at 10 mg/kg PO q12h in conjunction with corticosteroids to treat IBD, although evidence of direct benefit of this approach is currently lacking.
- Antibiotic-responsive enteropathy (tylosin-responsive enteropathy)—tylosin is the drug of choice administered at 5–10 mg/kg q24h for 8–12 weeks. Alternative option is metronidazole (10 mg/kg q12h for 8–12 weeks) although tylosin is felt to be superior for this disorder.
- Use corticosteroids in conjunction with dietary changes to treat biopsy-confirmed IBD; azathioprine, chlorambucil, or cyclosporine can also be used in patients with poor response to corticosteroids alone or to decrease the dosage of steroids required to control symptoms. Avoid the use of more than 2 immunomodulatory drugs given concurrently.
- Prokinetic drugs (e.g., metoclopramide, cisapride or erythromycin) are used to treat delayed gastric emptying not associated with obstructive disease.
- Pyrantel pamoate is effective for *Physaloptera*; fenbendazole is effective for *Ollulanus*.
- Iron supplementation for animals with chronic GI bleeding that develop microcytic hypochromic anemia.
- Surgery and/or chemotherapy for neoplasia, depending on the tumor type and location.
- Paraneoplastic hypersecretion of gastric acid, as occurs with mastocytosis and

(CONTINUED)

VOMITING, CHRONIC

- gastrin-secreting pancreatic tumors, is best treated with antisecretory drugs (e.g., omeprazole) to diminish gastritis, gastric ulcer, and chronic vomiting.
- Reserve antiemetics for patients with persistent vomiting unresponsive to treatment of the underlying disease. Maropitant is a neurokinin-1 receptor antagonist suppressing vomiting at the CRTZ, vomiting center, and vagal afferents; maropitant 1 mg/kg SC q24h, 2 mg/kg PO q24h. Phenothiazines (e.g., chlorpromazine) work at both the CRTZ and vomiting center; chlorpromazine 0.5 mg/kg SC, IM q6–8h.
 - Prokinetic drugs (e.g., metoclopramide)—metoclopramide also blocks the dopaminergic 2 receptors at the CRTZ, but this effect is far weaker in cats compared to dogs; metoclopramide 0.2–0.5 mg/kg IV, IM, PO q6–8h; metoclopramide can also be administered as a continuous rate infusion of 1–2 mg/kg/24h in hospitalized patients.
 - Vomiting caused by chemotherapy is best treated with ondansetron 0.5–1 mg/kg IV, PO given 30 minutes before chemotherapy.

PRECAUTIONS

- Do not give α -adrenergic blockers such as chlorpromazine to dehydrated patients as they can cause hypotension.
- Use antiemetics with caution, as they can mask the underlying problem.
- Metoclopramide can cause lethargy, restlessness, agitation, and other behavioral changes, particularly in cats.
- Corticosteroids are immunosuppressive and are a risk factor for development of GI

ulceration; use caution when treating IBD with corticosteroids at high dosages or for long periods.

- Azathioprine and chlorambucil are myelotoxic; monitor CBCs for neutropenia and thrombocytopenia every 2 weeks for the first month of treatment and monthly thereafter.
- Cyclosporine can exacerbate vomiting and diarrhea when used at high dosages; use with caution in patients with renal disease.
- Do not use anticholinergics as antiemetics, as they can exacerbate vomiting by causing gastric atony and gastric retention.
- Metoclopramide and cisapride are contraindicated in patients with GI obstruction.

POSSIBLE INTERACTIONS

Ranitidine interferes with hepatic metabolism of theophylline, phenytoin, and warfarin, and should not be used concurrently with these drugs. Avoid use of cimetidine because it is a weak H₂-receptor antagonist and is a potent inhibitor of the cytochrome P450 enzyme pathway.

**MISCELLANEOUS****ZOONOTIC POTENTIAL**

Helicobacter heilmannii and *H. felis* may have zoonotic potential; they have been isolated from humans with chronic gastritis, most of whom have had close contact with dogs or cats.

ABBREVIATIONS

- ACTH = adrenocorticotrophic hormone
- CNS = central nervous system
- CRTZ = chemoreceptor trigger zone
- CT = computed tomography
- DKA = diabetic ketoacidosis
- GI = gastrointestinal
- IBD = inflammatory bowel disease
- MRI = magnetic resonance imaging
- NSAID = nonsteroidal anti-inflammatory drug
- SIBO = small intestinal bacterial overgrowth

VON WILLEBRAND DISEASE

BASICS

DEFINITION

- Primary hemostatic defect caused by a quantitative or functional deficiency of vWF.
- Clinical expression varies from a mild to severe bleeding diathesis.

PATHOPHYSIOLOGY

- vWF is an adhesive plasma protein required for normal platelet binding at sites of small vessel injury. In addition, plasma vWF is a carrier protein for coagulation factor VIII.
- A lack of vWF impairs platelet adhesion and aggregation, especially at sites of high shear stress. The largest molecular weight (MW) forms of vWF demonstrate highest reactivity in supporting platelet-collagen interactions.

SYSTEMS AFFECTED

- vWF deficiency may cause spontaneous hemorrhage, prolonged post-traumatic hemorrhage, and ultimately blood loss anemia.
- Spontaneous hemorrhage—typically manifests as bleeding from mucosal surfaces.

GENETICS

- An autosomal trait; both males and females express and transmit the defect with equal frequency.
- Expression pattern of severe forms (Types 2 and 3 vWD) is recessive; milder form (Type 1 vWD) appears to be recessive or incomplete dominant.

INCIDENCE/PREVALENCE

- The most common hereditary hemostatic defect in dogs.
- Rarely reported in cats.

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Breed Predilections

- Three type classifications are found in dogs; a single type predominates within each affected breed.
- Type 1 vWD (mild to moderate signs): quantitative protein deficiency. Low vWF:Ag with proportionate reduction in vWF function. Type 1 is the most common classification.
 - Breeds: Airedale, Akita, basset hound, Bernese mountain dog, dachshund, Doberman pinscher, German shepherd, golden retriever, greyhound, Irish wolfhound, Manchester terrier, miniature pinscher, Pembroke Welsh corgi, poodle, and sporadic cases in any breed and mixed-breed dogs.
- Type 2 vWD (severe signs): quantitative and functional protein defect; low vWF:Ag with disproportionate lack of activity due to absence of high MW multimers.
 - Breeds: German wirehaired and shorthaired pointers.

- Type 3 vWD (severe signs): complete lack of plasma vWF.

- Breeds: Chesapeake Bay retriever, Dutch Kooiker, Scottish terrier, Shetland sheepdog, and sporadic cases in any breed.

Mean Age and Range

- Severe (Types 2 and 3 vWD) typically manifests by 3–6 months of age.
- Milder forms typically demonstrate abnormal bleeding after surgery or trauma, or in association with another condition that impairs hemostasis.

SIGNS

Physical Examination Findings

- Hemorrhage from mucosal surfaces: epistaxis, gastrointestinal hemorrhage, hematuria, vaginal hemorrhage, gingival hemorrhage.
- Prolonged bleeding after surgery or trauma.
- Blood loss anemia if prolonged hemorrhage.

CAUSES

Heredity vWD is caused by mutations that impair vWF synthesis, release, or stability.

RISK FACTORS

Acquired disease conditions or drug therapy that impair platelet function may exacerbate clinical signs of vWD.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Thrombocytopenia (the first rule-out for any patient with abnormal hemorrhage).
- Acquired coagulation factor deficiency (often associated with liver disease, vitamin K deficiency, or DIC).
- Acquired platelet function defects (often associated with drug therapy, uremia, hyperproteinemia).
- Hereditary coagulation factor deficiencies.
- Hereditary platelet function defects.

CBC/BIOCHEMISTRY/URINALYSIS

- Regenerative anemia develops after blood loss.
- Platelet count is normal unless the patient has experienced acute, massive bleeding.

OTHER LABORATORY TESTS

- Coagulation screening tests (ACT, APTT, PT, TCT, fibrinogen)—normal.
- Clinical diagnosis based on specific measurement of plasma vWF concentration (vWF:Ag).
 - vWF:Ag < 50% indicates vWF deficiency, but clinical signs of abnormal bleeding typically develop in animals with vWF:Ag < 25%.
 - Types 1 and 2 vWD are characterized by low vWF:Ag, whereas Type 3 vWD is defined as the complete absence of detectable protein (vWF:Ag < 0.1%).

- Types 1 and 2 vWD are differentiated based on functional and/or structural vWF analyses.

- vWF:CBA is a functional measure of vWF/collagen affinity. Type 2 vWD dogs have a relative lack of vWF:CBA compared to vWF:Ag, resulting in a protein concentration to function ratio > 2:1. Type 1 vWD dogs have proportionate protein concentration and function.

- vWF multimer structure is visualized on Western blots. Type 2 vWD dogs lack the highest MW forms.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- BMBT and the platelet function analyzer-100 are point-of-care screening tests whose endpoints are prolonged in patients with platelet aggregation defects, and vWF deficiency. Prolongation is nonspecific and may accompany severe thrombocytopenia, anemia, or changes in blood viscosity.
- BMBT (expected values 2–4 minutes): typical values for Type 1 vWD = 5–10 minutes, Types 2 and 3 vWD > 12 minutes.
- PFA-100 closure times (expected ADP/collagen closure time < 120 seconds): typical values for Type 1 vWD = 150–300 seconds, Types 2 and 3 vWD > 300 seconds.

PATHOLOGIC FINDINGS

Hemorrhage is the only associated abnormality. Morbidity and mortality are caused by blood loss or hemorrhage into critical sites (i.e., CNS, respiratory tract).

TREATMENT

- Transfusion of fresh whole blood, fresh plasma, fresh frozen plasma, and cryoprecipitate will supply vWF.
- Component therapy (fresh frozen plasma at 10–12 mL/kg) or cryoprecipitate (unit definition and dosage vary by source) is best for surgical prophylaxis and non-anemic patients, to prevent red cell sensitization and volume overload.
- Patients with severe vWD may require repeated transfusion (q6–12h) to control or prevent hemorrhage.

SURGICAL CONSIDERATIONS

- Preoperative transfusion should be given just before the procedure. Peak vWF is obtained immediately after transfusion, with values falling to baseline by 24 hours after a single dose.
- Cage rest and close monitoring (serial Hct and examination of surgical site) for 24 hours after surgery are ideal to confirm adequate hemostasis. Management of severe vWD typically requires at least one postoperative transfusion.

(CONTINUED)

VON WILLEBRAND DISEASE**MEDICATIONS****DRUG(S) OF CHOICE**

- Desmopressin acetate (DDAVP) is a vasopressin analog that can be given preoperatively to dogs with mild to moderate Type 1 vWD to enhance surgical hemostasis. Dosage is 1 µg/kg SC; given 30 minutes before surgery.
- Response is variable; transfusion should be available if DDAVP alone does not prevent bleeding.

CONTRAINDICATIONS

Avoid drugs with anticoagulant or antiplatelet effects: NSAIDs, sulfonamide antibiotics, heparin, coumadin, plasma expanders, estrogen, cytotoxic drugs.

**FOLLOW-UP****PATIENT MONITORING**

Observe closely for hemorrhage associated with trauma or surgical procedures.

PREVENTION

- Screen dogs preoperatively to determine baseline vWF:Ag in breeds or lines with high prevalence of vWD. The risk of abnormal bleeding is greatest for vWF:Ag < 25%.
- Clinically affected dogs should not be bred. Carriers of vWD can be identified based on low vWF:Ag (< 50%); however, values for carrier and clear dogs may overlap at the low end of normal range (50–70% vWF:Ag). At present, commercial tests (VetGen) to detect specific vWF mutations in DNA are available for several breed-variants of vWD. Dogs that are heterozygous for a specific mutation are considered vWD “carriers” and homozygotes are considered vWD “affected.”

- Selective breeding practices can reduce or eliminate vWD from an affected pedigree. Breeding two clear parents is ideal because all offspring are expected to be vWD clear. Breeding one clear and one carrier parent may be acceptable, with the clear pups produced from these matings used for subsequent breeding. Carrier-to-carrier matings are inadvisable because they are most likely to produce clinically affected offspring.

EXPECTED COURSE AND PROGNOSIS

- Most dogs with mild to moderate vWD have good quality of life and require minimal or no special treatment.
- Dogs with more severe forms require transfusion for surgery and should be transfused if supportive care fails to control a spontaneous bleed. Most of these dogs can be maintained comfortably in pet homes.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

- The development of any disease condition that impairs platelet function may exacerbate the bleeding tendency of vWD. Common conditions include thrombocytopenia, endocrinopathy (hypothyroidism, hypocortisolism), hyperproteinemia, and uremia.
- Acquired vWD occurs in humans with aortic stenosis, and features of Type 2 vWD have been reported in Cavalier King Charles spaniels with mitral valve disease.

PREGNANCY/FERTILITY/BREEDING

See “Prevention” for breeding recommendations.

SYNOMYS

vWF protein was formerly referred to as factor VIII-related antigen.

ABBREVIATIONS

- ACT = activated clotting time
- APTT = activated partial thromboplastin time
- BMBT = buccal mucosal bleeding time
- DDAVP = deamino-8-d-arginine vasopressin
- DIC = disseminated intravascular coagulation
- MW = molecular weight
- NSAID = nonsteroidal anti-inflammatory drug
- PT = prothrombin time
- TCT = thrombin clotting time
- vWF = von Willebrand factor
- vWF:Ag = von Willebrand factor antigen
- vWF:CBA = von Willebrand factor collagen binding assay

WEIGHT LOSS AND CACHEXIA

BASICS

DEFINITION

- *Weight loss* refers to unintended loss of body weight. Relative to prior stable body weight, acute loss of 10% or chronic loss of 15% is considered clinically important.
- *Cachexia* refers to a state of severe weight loss and tissue wasting secondary to underlying disease, such as cancer, heart failure, or severe inflammatory conditions. In addition to fat loss, cachectic patients lose a significant amount of lean body mass, especially skeletal muscle.
- *Sarcopenia* refers to a disproportionate loss of skeletal muscle and LBM. Sarcopenia can occur without loss of body weight. Sarcopenia may occur secondary to disease or may be age-related.
- LBM loss, such as occurs in cachexia and sarcopenia, contributes to debilitation including weakness, fatigue, and shortness of breath.
- In cats and dogs, loss of lean body mass is a significant risk factor for mortality.
- Weight loss or below-normal body condition is associated with shorter survival in cardiac and cancer patients.

PATHOPHYSIOLOGY

Weight Loss

- Weight loss may occur due to decreased intake or increased energy expenditure, including metabolic waste, resulting in negative energy balance.
- Decreased or insufficient intake can be caused by poor appetite secondary to systemic disease, oral disease, or anosmia; or by inadequate access to nutrients that can occur if access to food is restricted.
- Decreased intake of nutrients can be caused by dysphagia, vomiting or regurgitation.
- Malabsorption syndromes are important causes of weight loss.
- Reduced energy intake or absorption in otherwise healthy animals leads to compensatory changes in metabolism, such as reduced energy metabolism and a shift toward lipid-based energy utilization.

Cachexia

- Cachexia, with loss of fat and LBM, occurs secondary to acute or chronic inflammatory diseases, such as cancer, cardiac disease, renal failure, diabetes, sepsis, chronic fever, etc.
- Features that differentiate cachexia from simple weight loss include activation of inflammatory cytokines, activation of the ubiquitin-proteosome system and metabolic dysregulation resulting in increased energy metabolism.
- Cachexia is associated with increases in IL-6, TNF- α , and other pro-inflammatory cytokines; norepinephrine, epinephrine and cortisol; increased oxidative stress; and

decreased anabolic factors such as IGF-1 and DHEA.

- Inflammatory changes result in dysregulation of appetite, insulin resistance, and increased muscle protein breakdown. Inflammatory cytokines activate the ubiquitin-proteosome system and impair tissue synthesis.
- Increased basal metabolic rate and metabolic inefficiencies contribute to tissue wasting. Secondary anorexia or withholding of food aggravates protein-calorie malnutrition.
- Provision of nutrition to cachectic patients without addressing the underlying disease or metabolic dysregulation is rarely successful in correcting the loss of body tissues.

SYSTEMS AFFECTED

- All body systems may be affected by weight loss depending on the underlying disease and severity of illness.
- Cachexia can result in muscle weakness, fatigue and respiratory compromise.

SIGNALMENT

Dog and cat, especially prominent in aging animals.

SIGNS

Historical Findings

- Clinical signs in patients with weight loss may include normal, increased, decreased, or absent appetite, fever, or other signs of systemic illness.
- A comprehensive dietary history is important to determine nutrient intake, dietary type and quantity offered and consumed, and any changes.
- Historical information on patient's daily activity, environment, pregnancy, appetite, or signs of gastrointestinal disease (e.g., vomiting, diarrhea, stool color/consistency, dysphagia, regurgitation) can help assess calorie expenditure or indicate malabsorption.
- Other historical findings may be indicative of underlying diseases, such as polyuria, polydipsia, changes in attitude, lameness or exercise intolerance.

Physical Examination Findings

- Physical examination must include body weight, a body condition score and an assessment of muscle wasting.
- In obese animals, loss of LBM may occur despite excess body fat so these should be evaluated separately.
- Body weight should be compared against historical data to determine percent weight change.
- BCS is a semiquantitative assessment of body composition and correlates well with body fat.
- Muscle wasting is assessed by palpating over the scapulae, skull, and wings of the ilia, as well as palpation of the gluteal and vastus muscles. This is usually scored subjectively on a 4-point scale.
- Additional evaluation should be aimed at detecting any abnormality that may be

associated with an underlying disease (see "Causes").

CAUSES

Dietary Causes

- Insufficient quantity or quality of food
- Low-calorie or low-protein diet
- Competition in a multi-pet household

Anorexia/Pseudoanorexia

- Inability to smell, prehend, or chew food
- Dysphagia
- Nausea
- Regurgitation
- Vomiting

Maldigestive and Malabsorptive Disorders

- Inflammatory bowel disease
- Intestinal neoplasia (lymphoma, carcinoma, sarcoma)
- Lymphangiectasia
- Severe intestinal parasitism
- Age related decreases in digestive function
- Exocrine pancreatic insufficiency

Metabolic Disorders

- Organ failure—cardiac, hepatic, or renal failure
- Hypoadrenocorticism
- Hyperthyroidism (especially cats)
- Cancer
- Increased catabolism—fever, infection, inflammation, cancer

Excessive Nutrient Loss

- Protein-losing enteropathy
- Protein-losing nephropathy
- Diabetes mellitus
- Extensive skin lesions (e.g., burns)

Neuromuscular Disease

- Lower motor neuron disease
- CNS disease—usually associated with anorexia or pseudoanorexia

Physiologic Increased Use of Calories

- Increased physical activity
- Prolonged or extreme cold environment
- Pregnancy or lactation

RISK FACTORS

- Age
- See "Causes"

DIAGNOSIS

- Diagnosis is by evaluation of BCS and muscle wasting. Loss of LBM can occur without significant weight change (sarcopenia).
- Body weight should be compared to historic weight if available after adjusting for under- or over-hydration.
- Once loss of weight or LBM is confirmed, seek underlying cause.

DIFFERENTIAL DIAGNOSIS

- See "Causes."
- Determine if weight loss is associated with increased, normal or decreased calorie intake and absorption of nutrients.

(CONTINUED)

- Determine what the patient's appetite was at the onset of weight loss as any condition can lead to anorexia if it persists long enough for the patient to become debilitated.
- Fever suggests an underlying infectious or inflammatory cause.
- Absence of fever is more consistent with metabolic causes of weight loss such as cardiac, renal, or hepatic failure.

CBC/BIOCHEMISTRY/URINALYSIS

- Laboratory tests may be indicative of underlying disease.
- No laboratory tests reliably measure protein/calorie malnutrition, but the following may be observed:
 - Low hematocrit, elevated alkaline phosphatase, and/or low urea nitrogen with normal to elevated serum creatinine.

OTHER LABORATORY TESTS

- Determined by most likely differential diagnoses on the basis of findings of the history, physical examination, and initial database.
- Perform serologic FeLV and FIV tests in cats with weight loss of unknown cause.
- Measure serum T₄ concentration in any cat > 5 years old with weight loss of unknown cause.
- Examine serial fecal centrifugation flotations and direct smears to exclude intestinal parasitism.
- In endemic areas, or in pets with a history of travel, rule-out infectious (parasitic, protozoal, viral, and fungal) diseases.
- Specific organ function tests as indicated by historical, physical examination, and initial database findings. Examples include serum TLI for exocrine pancreatic insufficiency; ACTH stimulation test for hypoadrenocorticism; pre- and postprandial serum bile acids for hepatobiliary disease; and urine protein:creatinine ratio if protein-losing nephropathy is suspected.

IMAGING

Thoracic, abdominal, or other radiographs, ultrasound, or echocardiography may be indicated, depending on other clinical findings and suspected underlying causes.

DIAGNOSTIC PROCEDURES

- Vary depending on initial diagnostic findings and the suspected underlying cause of weight loss. See chapter(s) for specific diseases.
- If indications for exploratory laparotomy exist—consider placing a feeding tube at that time.

**TREATMENT**

- The most important treatment principles are to treat the underlying cause of the weight loss and provide appropriate nutritional support.
- Inadequate calorie and protein intake is common among hospitalized patients.

- Calorie needs should be calculated at resting energy requirements ($70\text{Kcal} \cdot \text{kg}^{0.75}$). When feeding is initiated, begin by delivering 25% of RER on day 1 and gradually increase over 3–5 days to achieve RER. Monitor body weight and response, and gradually increase as tolerated. While animals do need to increase their body weight, overfeeding too quickly can result in metabolic problems associated with refeeding syndrome.
- Unless contraindicated, protein intake should be increased above maintenance levels to encourage retention or restoration of LBM.

ORAL NUTRITION

- If the patient is physically able to ingest, digest and absorb nutrients, this is the preferred route.*
- To increase voluntary food intake, offer palatable food several times daily; offer the patient's usual food; offer moist food unless the patient prefers dry food; offer food warmed to body temperature.
- Unless contraindications exist, consider using diets formulated to be high in protein and fat calories. Examples include "critical care" therapeutic diets as well as performance and growth diets. Kitten foods may be suitable for adult cats, and cat foods may be suitable for canine patients.
- Long-chain omega-3 fatty acids EPA and DHA can reduce inflammatory mediators. Consider diets enriched with EPA and DHA for cachectic patients, or those with inflammatory conditions. Examples include therapeutic diets for arthritis, dermatologic and neoplastic conditions. Alternatively, supplement with high EPA fish oil capsules at 1 g fish oil/4.5 kg body weight.
- If underweight patients refuse therapeutic diets (e.g., renal diet, cardiac diet), try an alternate brand, add broth or other flavorants, or consider homemade. Adequate intake of a maintenance diet is preferred over inadequate intake of a therapeutic diet.
- Appetite stimulants may be tried on a short-term basis (see "Medications").
- Forced feeding is rarely effective and is not recommended.

ENTERAL NUTRITION

- If the patient is unable or unwilling to ingest food, but can digest and absorb nutrients, this is the preferred route.*
- Enteral feeding as far proximal in the GI tract as the patient can tolerate is preferred.
- Nasoesophageal tubes (5–8Fr) can be used until patients are able to undergo anesthesia for placement of a larger tube. Due to small tube size, only liquid diets can be used.
- Esophagostomy (12–14Fr for cats, 20–24Fr for dogs) or gastrostomy tubes (18–24Fr) can be placed fairly quickly using a choice of techniques.
- Jejunostomy tubes or gastro-jejunostomy tubes (5–8Fr) are more difficult to place and manage, and require liquid diets fed via chronic infusion. These may be appropriate for patients with intractable vomiting or

severe compromise of the esophagus and stomach.

PARENTERAL NUTRITION

- If the patient is unable to tolerate enteral feedings, this is the preferred route.*
- Total (central) parenteral nutrition requires a dedicated central venous access line, which must be placed and maintained aseptically to reduce complications.
- Metabolic complications and refeeding syndromes are more common in catabolic and cachectic patients.
- Protein in parenteral admixtures should provide 15–25% of calories for dogs and 25–35% of calories for cats. The remaining calories may be provided by glucose or a combination of glucose and lipids, with up to 70% of the non-protein calories from lipid. Vitamins and electrolytes can be provided separately.
- Patients should be fed about 50% of RER on the first day, gradually increasing over 2 days to achieve RER. Patients must be monitored carefully for metabolic (hyperglycemia, hyperlipidemia) and electrolyte (hyper- or hypokalemia, hypophosphatemia, hyper- or hyponatremia, hypomagnesemia) complications.

**MEDICATIONS****DRUG(S) OF CHOICE**

- Depend on the underlying cause of the weight loss; see specific chapter for each condition.
- Appetite stimulants may be useful in addition to medications targeted at the underlying condition; adjust selection or dosage based on underlying disease:
 - Benzodiazepines: diazepam (0.1–0.2 mg/kg PO q12–24h in dogs; 0.05–0.10 mg/kg IV q24h dog/cat); oxazepam (1.25–2.5 µg/cat PO q12–24h; 0.3–0.4 g/kg PO q12–24h for dogs); midazolam (2–5 mg/kg IV for cats); flurazepam (0.1–0.2 mg/kg PO q12–24h for cats).
 - Mirtazapine (1.88 mg/cat PO q24–48h to 3.5 mg/cat (1/4 of a 15 mg tablet) PO q72h). The dose in dogs is 3.75 mg q24h in animals weighing < 7 kg; 7.5 mg q24h in dogs weighing 7–14 kg; 15 mg q24h in dogs weighing 14–27 kg; 30 mg q24h in dogs > 27 kg. The drug is available in 15 mg and 30 mg tablets.
 - Propofol (1–2 mg/kg IV for dogs).
 - Anabolic agents: stanozolol (1–2 mg PO q 12–24h); boldenone (5 mg SC or IV).

CONTRAINdicATIONS

See drug label for specifics

PRECAUTIONS

- Appetite stimulants should only be used for a limited period (days). Recognize that appetite stimulants do not treat the

WEIGHT LOSS AND CACHEXIA

(CONTINUED)

underlying cause of the animal's anorexia and may hamper the assessment of the patient's therapeutic response to concurrently administered drugs.

- Monitor food intake to assure adequate intake.

POSSIBLE INTERACTIONS

Many medications used for underlying causes can cause anorexia and/or nausea.

ALTERNATIVE DRUG(S)

- Megestrol acetate to inhibit inflammatory mediators, promote appetite and weight gain.
- Clenbuterol to enhance muscle mass.
- Long chain omega-3 fatty acids to reduce inflammation.

FOLLOW-UP

PATIENT MONITORING

- See specific condition for follow-up regarding underlying cause.
- Monitor body weight and body condition score closely.
- Appetite and food intake should be monitored closely to ensure nutritional needs are being met.

POSSIBLE COMPLICATIONS

- See specific underlying cause.
- If using assisted (tube) feeding: GI intolerance with vomiting and/or diarrhea; tube displacement or regurgitation leading to aspiration; peritonitis; metabolic disturbances including hyperglycemia, hypophosphatemia, hypokalemia or hypomagnesemia.

- If using parenteral feeding: sepsis; thrombosis; thrombophlebitis; metabolic disturbances including hyperglycemia, hyperlipidemia, azotemia, hyperammonemia, hypophosphatemia, hypokalemia, or hypomagnesemia.

WEST NILE VIRUS INFECTION

BASICS

OVERVIEW

- An acute to inapparent viral disease with neurologic manifestations caused by West Nile virus, a member of the family Flaviviridae, genus *Flavivirus*. The geographic distribution of the virus is North, Central, South America, Africa, Asia, southern Europe, and Australia (Kunjin virus).
- Natural route of infection is through the bite of numerous species of mosquitoes depending upon geographic location. Infection produces a low-level viremia that is undetectable by day 6 post-infection. Viremia levels insufficient for dogs to be an amplifying host. Antibody detectable by day 7 post-infection.

SIGNALMENT

- Natural infections not limited by species or age.
- Seroprevalence varies with geographic region (3–38%).

SIGNS

- High percentage of dogs show no clinical signs—no experimentally infected dogs have shown clinical signs.
- Incubation period 2–4 days post-infection.
- Febrile response 40.3–42.2°C (104–108°F) 3–6 days post-infection.
- In the rarely affected dogs, common signs are ataxia, depression, anorexia, tremors, conscious proprioceptive deficits, seizures, weakness, flaccid paralysis.

CAUSES & RISK FACTORS

- Neurologic disease caused by West Nile virus.
- Outdoor dogs much greater odds of being seropositive than indoor dogs. High seroprevalence in coyotes supports outdoor risk factor.
- Stray dogs greater odds of being seropositive than owned dogs.
- Lineage 1 virus more neurovirulent (all North American isolates) than lineage 2 (Africa).
- Yearly fluctuation of infections linked to density of mosquito populations.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- On an individual basis, the signs of WNV-induced neurologic disease are indistinguishable from signs associated with various “arbovirus” infections, e.g., EEE, VEE, La Crosse.
- Other considerations—rabies, canine distemper, neosporosis, toxoplasmosis, pseudorabies, encephalomyocarditis virus.

CBC/BIOCHEMISTRY/URINALYSIS

- Generally normal.
- Serial sampling may show drop in leukocytes but may remain within normal.

IMAGING

Electroencephalogram

DIAGNOSTIC PROCEDURES

- Low viremia levels make detection of agent in acute phase highly unlikely. Test of choice if an attempt is made is RT-PCR for WNV specifically or for arboviruses in general.
- Acute and convalescent serum samples should be collected for IgM ELISA test and/or virus neutralization assays.
- For post-mortem testing—RT-PCR and/or immunohistochemistry.

PATHOLOGIC FINDINGS

- Gross lesions not present in limited number of dogs necropsied (one case with epicarditis).
- Histologic lesions in brain—mild, multifocal, non-suppurative meningoencephalitis (lymphocytic to lymphohistiocytic perivasacular infiltrates predominantly in gray matter).

TREATMENT

Supportive therapy directed at reducing neurologic signs.

MEDICATIONS

- Antiviral drugs have not been tested for efficacy.

- Antipyretics to reduce fever.
- Antiseizure medication.

FOLLOW-UP

PREVENTION/AVOIDANCE

Vaccines although available for equines have not been approved for dogs.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- West Nile virus can infect numerous species including humans; however, the insect vector is generally necessary for transmission. The viremia is too low in infected dogs to serve as host for infecting feeding mosquitoes.
- Care should be taken if necropsy is done, as infectious viral particles may be presented in tissue samples.

RISK TO OTHER ANIMALS

Virus is not transmitted from the infected dog to other animals. Clinical case of WNV should be noted as indicative of infected mosquitoes in the area.

ABBREVIATIONS

- EEE = eastern equine encephalitis
- ELISA = enzyme-linked immunosorbent assay
- RT-PCR = reverse transcriptase polymerase chain reaction
- VEE = Venezuelan equine encephalitis
- WNV = West Nile virus

WHIPWORMS (TRICHURIASIS)

BASICS

OVERVIEW

- The whipworm, *Trichuris*, occurs in the cecum of dogs (*T. vulpis*) and cats (*T. felis*). Feline trichuriasis is rare in the United States.
- Life cycle is direct; infection is acquired by ingestion of larvated eggs; infective eggs can persist in the environment for months to years.
- Infection can be asymptomatic or cause bloody diarrhea and large bowel inflammation.
- Clinical signs can occur before patency, i.e., before eggs are shed in feces; prepatent period is approximately 70–90 days.
- No extra-intestinal migration occurs.

SIGNALMENT

- Dogs, cats of any age, breed, and sex
- Rarely seen in cats in the United States

SIGNS

- Range from asymptomatic to severe.
- Intermittent large bowel diarrhea often containing mucus and fresh blood (hematochezia).
- Bloody diarrhea with dehydration, anemia, and weight loss in severe cases.
- Signs can occur before eggs detectable in feces.
- Acute to chronic debilitation.

CAUSES & RISK FACTORS

- Ingestion of infective (larvated) eggs from environment contaminated with feces of infected dog.
- Eggs accumulate in environment and remain infective for months to years, especially in soil and dirt runs in moist, shady areas.
- Return of dog to an environment contaminated with infective eggs after anthelmintic treatment will result in reinfection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bacterial (spirochaetal) infections of cecum.
- Hookworm infection—identify eggs in feces; signs include anemia, pale mucous

W

membranes, and melena rather than fresh blood in feces.

- Inflammatory bowel disease.
- Gastrointestinal ulcers.
- Dietary indiscretion.
- Capillarid infections (*Pearsonema*, *Eucoleus*)—eggs similar in appearance but smaller with roughened surface; infect urinary or respiratory tracts, respectively, rather than GI tract; usually asymptomatic.
- Secondary pseudohypoaldrenocorticism in severe trichuriasis with metabolic acidosis, hyponatremia, hyperkalemia, and dehydration; normal ACTH stimulation response in trichuriasis.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal; hyponatremia, hyperkalemia, and metabolic acidosis can occur in very severe cases.

OTHER LABORATORY TESTS

ACTH stimulation test in severe cases with electrolyte disturbances to differentiate trichuriasis from hypoadrenocorticism.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Centrifugal flotation of feces in sugar solution (s.g. > 1.2) preferred method.
- Differentiate *Trichuris* eggs (brown, ovoid or lemon-shaped with prominent bipolar plugs, smooth shell, single cell within egg, ~90 × 45 µm) from similar capillarid eggs (smaller, roughened shell surface).

TREATMENT

- Outpatient treatment with anthelmintic for most cases.
- Severe cases with dehydration and electrolyte disturbances require inpatient fluid therapy plus anthelmintic.

MEDICATIONS

DRUG(S)

- Fenbendazole 50 mg/kg PO q24h for 3 days; repeat monthly 3 times; extra-label use in cats.

- Febantel/praziquantel/pyrantel pamoate—label dose PO in dogs.
- Milbemycin oxime 0.5 mg/kg PO q30 days in dogs.
- Moxidectin/imidacloprid, label dose in dogs.

FOLLOW-UP

PATIENT MONITORING

Repeat fecal examination for trichurid eggs and/or retreat with anthelmintic at 3 weeks and at 3 months following initial treatment or once a month for 3 months to detect and eliminate recently matured adults.

PREVENTION/AVOIDANCE

- Prompt removal and disposal of feces to prevent environmental contamination with infective eggs.
- Anthelmintic treatment of infected dogs to prevent shedding of eggs and contamination of environment.

EXPECTED COURSE AND PROGNOSIS

Good prognosis following treatment and implementation of preventive measures.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Relatively rare cases of human infection with *T. vulpis* have been diagnosed based on morphologic differences between eggs of the human whipworm, *T. trichiura*, and those of *T. vulpis*.

ABBREVIATIONS

- ACTH = adrenocorticotropic hormone
- GI = gastrointestinal

WOLFF-PARKINSON-WHITE SYNDROME

BASICS

DEFINITION

- Ventricular preexcitation occurs when impulses originating in the sinoatrial node or atrium activate a portion of the ventricles prematurely through an accessory pathway without going through the AV node; the remainder of the ventricles are activated normally through the usual conduction system.
- WPW syndrome consists of ventricular preexcitation with episodes of paroxysmal supraventricular tachycardia (Figures 1 and 2).

ECG Features of Ventricular Preexcitation

- Normal heart rate and rhythm.
- Normal P waves.
- Short PR interval (dogs, < 0.06 second; cats, < 0.05 second).
- Widened QRS (small dogs, > 0.05 second; large dogs, > 0.06 second; cats, > 0.04 second), often with slurring or notching of the upstroke of the R wave (delta wave).

ECG Features of Ventricular Preexcitation with WPW Syndrome

- Extremely rapid heart rate (dogs, often > 300 bpm; cats, approaching 400–500 bpm).
- P waves may be difficult to recognize.
- QRS complexes may be normal, wide with delta wave, or very wide and bizarre, depending on the circuit.
- Conduction is usually 1:1 (i.e., 1 P wave for every QRS complex).

PATHOPHYSIOLOGY

- Can be associated with congenital or acquired cardiac defects in dogs or cats.
- May be associated with hypertrophic cardiomyopathy in cats.
- Hemodynamic compromise during episodes of supraventricular tachycardia with WPW syndrome.

- WPW syndrome results from a developmental abnormality of the atrioventricular groove. During normal cardiogenesis, direct continuity between the atrial and ventricular myocardium is lost by growth of the annulus fibrosis. Defects in the annulus leave muscular connections called accessory pathways or Kent bundles between the atria and ventricular myocardium. By bypassing the AV node, these pathways can lead to preexcitation of the ventricles.
- The accessory pathways typically have an “all or none” conduction properties. They may only conduct from the atria to the ventricles (called anterograde or antegrade conduction), only from the ventricles to the atria (called retrograde conduction), or in both directions.

SYSTEMS AFFECTED

Cardiovascular

INCIDENCE/PREVALENCE

Unknown

SIGNALMENT

Species

Dog and cat

SIGNS

Historical Findings

- None in patients with ventricular preexcitation
- Syncope in patients with WPW syndrome

Physical Examination Findings

- None in animals with ventricular preexcitation
- Rapid heart rate in animals with WPW syndrome

CAUSES

Congenital Heart Disease

- Congenital defect limited to the conduction system
- Atrial septal defect in dogs or cats
- Tricuspid valvular dysplasia in dogs

Acquired Heart Disease

- Hypertrophic cardiomyopathy in cats

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ventricular preexcitation—differentiate from other causes of short PR intervals (e.g., fever, hyperthyroidism, and anemia); these conditions do not cause delta waves.
- Narrow complex WPW syndrome—differentiate from other supraventricular arrhythmias (e.g., atrial tachycardia, atrial flutter, and atrial fibrillation); WPW syndrome is most easily recognized after conversion to normal heart rate and rhythm.
- Alternating WPW syndrome should not be confused with ventricular bigeminy.
- Wide complex WPW syndrome must be differentiated from ventricular tachycardia.
- Short PR interval may be correlated with a normal QRS complex if the anomalous pathway bypasses the AV node and connects to the bundle of His (i.e., Lown-Ganong-Levine syndrome).

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

Normal

IMAGING

Echocardiography may show structural heart disease

DIAGNOSTIC PROCEDURES

Electrocardiography

PATHOLOGIC FINDINGS

- Pathologic findings vary with underlying cause
- Possibility of no organic heart lesions

CV₆LU

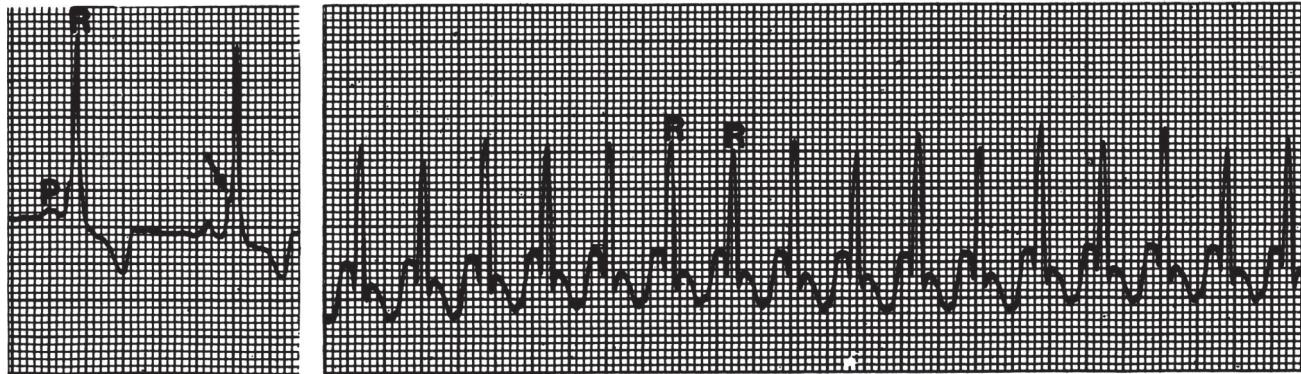

Figure 1.

Wolff-Parkinson-White syndrome (canine). Ventricular preexcitation represented by the short PR interval, wide QRS complex, and delta wave (arrow) in CV₆LU. Paroxysms of supraventricular tachycardia are represented in the long lead II rhythm strip. (From: Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

WOLFF-PARKINSON-WHITE SYNDROME

(CONTINUED)

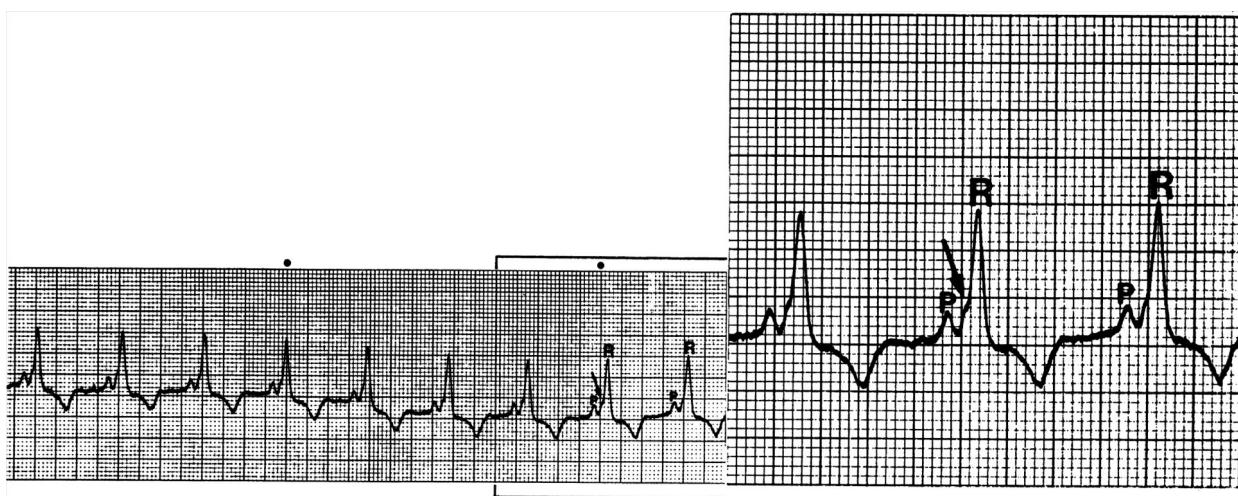

Figure 2.

Ventricular preexcitation in a cat with episodes of fainting. The P waves are normal, the PR interval is short, and the QRS complex is wide; delta waves (arrow) are present. (From: Tilley LP Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992, with permission.)

TREATMENT

APPROPRIATE HEALTH CARE

- Ventricular preexcitation without tachycardia—no treatment needed.
- WPW syndrome requires conversion by ocular or carotid sinus pressure, direct current shock (the most effective treatment), or drugs.

ACTIVITY

May need to be limited with WPW until supraventricular tachycardias are controlled.

CLIENT EDUCATION

WPW—explain the need to identify and treat the underlying cause in addition to therapy for supraventricular tachycardia.

SURGICAL CONSIDERATIONS

Catheter ablation with radiofrequency current—a relatively recent technique that allows accessory pathways to be destroyed or ablated by a transvenous catheter positioned at the site of the pathway; can be preferred alternative to lifelong therapy with drugs.

MEDICATIONS

DRUG(S) OF CHOICE

- A variety of drugs are used in humans; opinions differ on agents of choice.
- Lidocaine IV bolus (2 mg/kg) followed by IV drip (25–75 mg/kg/min CRI—dogs only).
- Esmolol (dogs and cats, 50–100 mg/kg bolus; 50–200 mg/kg/min CRI).
- Propranolol (cats, 2.5–5 mg PO q8–12h; dogs, 0.2–1 mg/kg PO q8h) or atenolol (cats, 6.2–12.5 mg PO q24h; dogs, 0.25–1 mg/kg PO q12h).

W

- Diltiazem may be effective (cats, 1–2.5 mg/kg PO q8h; dogs, 0.5–1.5 mg/kg PO q8h).
- Procainamide IV may be used acutely because it decreases conduction over the accessory pathway and is safe if anterograde accessory pathway conduction is present in atrial fibrillation.

CONTRAINDICATIONS

- Digitalis, verapamil, and propranolol may be contraindicated—by slowing conduction through the AV node, these drugs may favor conduction through the anomalous pathways.
- Cats—propranolol and atenolol are the drugs of choice.

FOLLOW-UP

PATIENT MONITORING

Serial ECG

POSSIBLE COMPLICATIONS

None expected

EXPECTED COURSE AND PROGNOSIS

Depends on severity of the underlying cause; most WPW patients respond to therapy for supraventricular tachycardia—favorable prognosis.

XYLITOL TOXICOSIS

BASICS

OVERVIEW

- Xylitol—a 5-carbon sugar alcohol used as a sweetener; present in some sugar-free gums, candies, toothpastes, mouthwashes, vitamins, liquid medications, and baked goods. It is also available as a granulated powder for cooking and baking.
- Ingestion by dogs can cause vomiting, weakness, ataxia, seizures, hypokalemia, hypophosphatemia/hyperphosphatemia, and hypoglycemia due to excess insulin release.
- Mild to moderate elevations of ALT can be seen within 4 hours of ingestion.
- Hepatic failure with high liver enzymes, hyperbilirubinemia, and coagulopathy may occur at dosages > 0.5 g/kg.
- Dosages of > 0.075–0.1 g/kg of xylitol may cause hypoglycemia.

SIGNALMENT

- Dogs—no breed, age, or sex predilection
- Cats—toxicity not established

SIGNS

- May develop within 15–30 minutes of exposure; with sugar-free gums, hypoglycemia may be delayed up to 12 hours.
- Vomiting common.
- Progressive lethargy, weakness, ataxia, collapse, and seizures.
- Hepatic failure may be accompanied by vomiting and widespread hemorrhage including petechiae, ecchymosis, and gastrointestinal and abdominal bleeding.
- Clinical signs of hypoglycemia may not be evident prior to onset of hepatic failure.

CAUSES & RISK FACTORS

Ingestion of xylitol or xylitol-containing products

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Hypoglycemia

- Insulin overdose
- Sulfonylurea antihyperglycemic agents
- Insulinoma (pancreatic β -cell tumor)

Acute Hepatic Failure

- Acetaminophen
- Aflatoxin
- Blue-green algae
- Amanita and similar hepatotoxic mushrooms
- Iron
- Sago palms (*Cycad* spp.)
- Leptospirosis

CBC/BIOCHEMISTRY/URINALYSIS

- Hypoglycemia
- Hypokalemia
- Hypophosphatemia or hyperphosphatemia
- Increased ALT, AST, SAP—may be delayed up to 24–48 hours
- Bilirubinemia
- Thrombocytopenia

OTHER LABORATORY TESTS

- Prolonged PT/PTT
- Increased FDP, D-dimers and/or decreased fibrinogen

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Severe hepatic necrosis
- Widespread hemorrhage

TREATMENT

- Decontamination—emesis if patient is asymptomatic; activated charcoal not likely to be beneficial.
- Monitor at 1–2-hour intervals for hypoglycemia and hypokalemia and correct as needed.
- Monitor for hepatic changes.

MEDICATIONS

DRUG(S)

- Dextrose—0.5–1 g/kg IV followed by a 2.5–5% CRI—consider starting with dosages of > 0.1 g/kg.
- Potassium chloride—supplement in fluids if potassium value < 2.5 mmol/L.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None

FOLLOW-UP

- Monitor glucose levels for at least 24 hours.
- Monitor hepatic enzymes, bilirubin, PT/PTT, and platelets for at least 72 hours.
- Prognosis good for uncomplicated hypoglycemia with mild-to-moderate elevations of ALT; guarded to poor if severe hepatic necrosis occurs especially if hyperphosphatemia is present.

MISCELLANEOUS

SEE ALSO

Consulting Editor Lynn R. Hovda

ZINC TOXICOSIS

BASICS

OVERVIEW

- Toxicity results from the ingestion of zinc-containing material.
- Causes gastrointestinal inflammation and hemolytic anemia; may cause multiple organ failure (e.g., renal, hepatic, pancreatic, and cardiac), DIC, and cardiopulmonary arrest.

SIGNALMENT

Most frequently reported in young, small-sized dogs (i.e., < 12 kg); can occur in all species of all sizes.

SIGNS

- Anorexia
- Vomiting
- Diarrhea
- Lethargy
- Pale or icteric mucous membranes
- Hemoglobinemia
- Hemoglobinuria
- Orange-tinted feces
- Tachycardia

CAUSES & RISK FACTORS

- There are a variety of zinc compounds with different bioavailabilities: zinc carbonate and zinc gluconate (dietary supplements), zinc chloride (deodorants), zinc pyrithione (shampoos), zinc acetate (throat lozenges), zinc oxide (sunblock, Desitin, calamine lotion), zinc sulfide (paints), metallic zinc (coins).
- Toxic doses have not been well defined.
- Brass: alloy of copper and zinc.
- Toxicities result from ingestion of zinc-containing material: U.S. pennies minted after 1982 (most common source), nuts, bolts, staples, galvanized metal (e.g., nails), pieces from board games, zippers, miscellaneous toys, jewelry.
- Organic forms of zinc (e.g., zinc oxide) generally cause only gastrointestinal inflammation.
- Acidic environment within the stomach promotes rapid leaching of zinc from the ingested substance, allowing for zinc to be absorbed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Numerous causes of gastrointestinal upset: viral, bacterial, parasitic, immune mediated.
- Numerous causes of hemolysis: immune-mediated hemolytic anemia, Babesia, onion and garlic toxicosis, mothball toxicosis (naphthalene), caval syndrome, acetaminophen, coral snake venom, pit viper venom, brown recluse spider venom, mushrooms, overhydration, skunk spray.

CBC/BIOCHEMISTRY/URINALYSIS

- Hemolytic anemia, with possible Heinz body formation.
- Regeneration will occur if there is enough time: high nucleated RBC counts, basophilic stippling, polychromasia, elevated reticulocytes.
- Target cells.
- Spherocytosis—mild and often inconsistent.
- Leukocytosis with a neutrophilia.

- Hemoglobinemia.
- Bilirubinemia.
- High liver enzymes AST, ALP; less common are elevations in GGT and ALT.
- Elevated pancreatic enzymes—amylase and lipase—may indicate multiple organ failure.
- Proteinuria.
- Pigmenturia (hemoglobin, bilirubin).
- Azotemia (high BUN and creatinine)—not common.

OTHER LABORATORY TESTS

- Serum zinc levels often exceed 5 ppm (approximate normal range: 0.70–2 ppm for dogs and cats).
- Blood must be collected in non-zinc-contaminated blood tubes.
- Coagulation panel—may indicate DIC (prolonged PT and PTT, hypofibrinogenemia, thrombocytopenia, and high FDPs).
- Frequent monitoring of PCV is indicated because the decline in PCV can be rapid.

IMAGING

- Abdominal imaging—*may* reveal metallic object(s) in the gastrointestinal tract.
- Often the zinc object has passed (via vomit or feces) by the time the patient is admitted.

DIAGNOSTIC PROCEDURES

ECG—may reveal arrhythmias and ST-segment abnormalities.

TREATMENT

- Rapid removal of the zinc object by endoscopy or laparotomy/gastrotomy—imperative.
- Intravenous fluid therapy—maintain hydration and diuresis—acute renal failure is a serious sequela.
- Severe intravascular hemolysis—may require blood transfusion(s)/packed RBCs, oxygen-carrying substances (Oxyglobin).
- Inform client about the hazards of ingesting zinc-containing objects (especially US pennies minted after 1982).

MEDICATIONS

DRUG(S)

- Chelation therapy may *not* be warranted once the source of the excess zinc is removed—zinc levels drop fairly rapidly (over a few to several days) via excretion into bile, pancreatic secretions, and urine.
- CaEDTA—100 mg/kg diluted in 5% dextrose SC, divided into 4 doses per day (treatment as for lead poisoning) if clinical improvement or reduced blood zinc is not accomplished by removal of zinc objects.
- Penicillamine—110 mg/kg/day PO divided 6–8h for 5–14 days (treatment as for lead poisoning)—generally less frequently used than CaEDTA.
- Heparin—150 U/kg SC q6h; for DIC.
- H2-receptor antagonists (e.g., cimetidine, ranitidine, famotidine), proton pump inhibitors (e.g., omeprazole), and

antacids used alone or in combination—may help reduce stomach acidity and the rate of release of zinc.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid aminoglycoside antibiotics and other potential nephrotoxins—risk of acute renal failure.

FOLLOW-UP

PATIENT MONITORING

- ECG—monitor for evidence of arrhythmias and ST-segment alterations.
- Coagulation profile, PCV, RBC, amylase, lipase, BUN, creatinine, ALP, AST, and ALT—monitor for the first 72 hours after zinc removal.
- Monitor serum zinc levels.

EXPECTED COURSE AND PROGNOSIS

- Multiple organ failure (e.g., kidney, liver), DIC, pancreatic disease, cardiopulmonary arrest—potential outcomes.
- Rapid removal of the source of zinc may provide progressive improvement over 48–72 hours; complete recovery possible.

MISCELLANEOUS

SEE ALSO

Poisoning (Intoxication) Therapy

ABBREVIATIONS

- ALP = alkaline phosphatase
- ALT = alanine aminotransferase
- AST = aspartate aminotransferase
- DIC = disseminated intravascular coagulation
- ECG = electrocardiogram
- GGT = gamma-glutamyltransferase
- PCV = packed cell volume
- PT = prothrombin time
- PTT = partial thromboplastin time
- RBC = red blood cells

APPENDIX II

ENDOCRINE TESTING

Table II-A

Endocrine function testing protocols	
ADRENAL GLAND DISORDERS	
ACTH STIMULATION TEST	
Dogs	
Administer 20 IU ACTH gel IM or 0.25 mg synthetic ACTH IV or IM (Cortrosyn, Organon Pharmaceuticals, West Orange, NJ). ACTH Gel	This pattern suggests that the animal does not have Cushing's disease. <i>Escape from Suppression</i> Cortisol value falls below 1 $\mu\text{g}/\text{dL}$ (30 nmol/L) at 4 hours and rises above 1 $\mu\text{g}/\text{dL}$ at 8 hours. This pattern is consistent with pituitary-dependent Cushing's disease. <i>High-Dose Dexamethasone Suppression Test (HDDST)</i> Administer 1 mg/kg dexamethasone (Azium) IV or IM. Obtain serum samples before and 4 and 8 hours after injection of dexamethasone for cortisol assay.
Synthetic ACTH	<i>Interpretation</i> Any cortisol determination that falls below 1.5 $\mu\text{g}/\text{dL}$ (45 nmol/L) at any point during the 8-hour testing period is considered suppression. Suppression after a high dose of dexamethasone is consistent with pituitary-dependent Cushing's disease. Lack of suppression (all cortisol values remain above 1.5 $\mu\text{g}/\text{dL}$) is diagnostic of a pituitary or adrenal tumor.
Cats	
Administer 0.125 mg synthetic ACTH IV. Serum samples should be obtained before and 1 hour after injection of ACTH for cortisol assay.	
Interpretation	
<i>Screening for Cushing's Disease</i>	
An exaggerated response to ACTH is consistent with Cushing's disease. High normal cut-off values differ slightly between laboratories.	
<i>Screening for Hypoadrenocorticism</i>	
Pre- and post-cortisol determinations <1 $\mu\text{g}/\text{dL}$ (30 nmol/L) are consistent with hypoadrenocorticism.	
Monitoring Mitotane or Ketoconazole.	
<i>Therapy for Cushing's Disease</i>	
Pre- and post-cortisol determinations should be within the normal basal cortisol range.	
LOW-DOSE DEXAMETHASONE SUPPRESSION TEST (LDDST)	
Dogs	
Administer 0.015 mg/kg dexamethasone (Azium, Schering-Plough, Union, NJ) IV or IM. Obtain serum samples before and 4 and 8 hours after injection of dexamethasone for cortisol assay.	
Cats	
Administer 0.1 mg/kg dexamethasone (Azium) IV or IM. Obtain serum sample before and 4 and 8 hours after injection of dexamethasone for cortisol assay.	
Interpretation	
Three basic patterns.	
<i>Lack of Suppression</i>	
All cortisol values remain above 1 $\mu\text{g}/\text{dL}$ (30 nmol/L). This pattern is consistent with Cushing's disease.	
<i>Suppression</i>	
Cortisol values fall below 1 $\mu\text{g}/\text{dL}$ (30 nmol/L) at 4 and 8 hours.	
INTERPRETATION	
Serum T_4 concentration after administration of $T_3 > 1.5 \mu\text{g}/\text{dL}$ (20 nmol/L) is consistent with hyperthyroidism.	
GASTRINOMA	
SECRETIN STIMULATION TEST	
Administer 2 units of secretin/kg IV. Take blood samples before administration of secretin and then 2, 5, 10, 15, and 30 minutes later. Assay the samples for gastrin.	
Interpretation	
Dogs with gastrinomas have a rise in gastrin levels after the injection of secretin. In three reported cases, two dogs had a rise in gastrin levels 2 times baseline 5 minutes after secretin injection, and one dog had a rise in gastrin levels 1.4 times baseline 5 minutes after secretin injection. Normal dogs have a decline in gastrin levels after administration of secretin.	
CALCIUM CHALLENGE TEST	
Administer 2 mg/kg of calcium gluconate IV over a 1-minute period or administer 5 mg/kg of calcium gluconate as an IV infusion over several hours.	
Obtain a blood sample before calcium administration and then 15, 30, 60, 90, and 120 minutes after calcium administration. Assay the samples for gastrin.	
Interpretation	
Two reported patients with gastrinoma had a doubling of the gastrin level 60 minutes after the calcium infusion.	
SEX HORMONE DISORDERS	
GNRH STIMULATION TEST	
Administer 0.5–1.0 μg of GnRH/kg IM. Obtain blood samples before GnRH administration and 1 hour later. Assay blood samples for testosterone.	
Interpretation	
Normal dogs have baseline testosterone levels between 0.5 and 5 ng/mL, and after administration of GnRH the testosterone levels rise above 5 ng/mL. Animals with hypoandrogenism have lower values.	
HCG STIMULATION TEST	
Administer 44 IU of hCG/kg IM. Obtain blood samples before hCG administration and 4 hours later. Assay blood samples for testosterone.	

(Continued)

ENDOCRINE TESTING (CONTINUED)

Table II-A

Endocrine function testing protocols (<i>continued</i>)	
Interpretation	
Normal dogs have baseline testosterone levels between 0.5 and 5 ng/mL, and after administration of hCG, the testosterone levels rise above 5 ng/mL. Animals with hypoandrogenism have lower values.	Day 1 130–165 mL/kg/day Day 2 100–125 mL/kg/day Day 3 65–70 mL/kg/day (normal maintenance requirement)
DIABETES INSIPIDUS	The morning of the fourth day, discontinue food and water. Start the test. Weigh the patient and empty the bladder. Weigh at 1- to 2-hour intervals. Monitor carefully for dehydration and depression. When 5% of body weight is lost or azotemia develops, empty the bladder and check urine specific gravity. Consider plasma vasopressin determination at this point.
MODIFIED WATER DEPRIVATION TEST	Interpretation If the urine specific gravity is > 1.025 (dogs) or > 1.030 (cats), stop the test. The patient does not have diabetes insipidus. If the urine specific gravity is not > 1.025 (dogs) or > 1.030 (cats), administer 0.55 U/kg aqueous vasopressin IM (maximum dose 5 U). Empty the bladder and check urine specific gravity at 30, 60, and 120 minutes post-administration. If urine specific gravity increases < 10%, nephrogenic diabetes insipidus is indicated; if it increases 10–50%, partial central diabetes insipidus is indicated; if it increases 50–800%, complete central diabetes insipidus is indicated.
Rule-out other causes of polyuria and polydipsia (especially hyperadrenocorticism). Begin water restriction 3 days before abrupt water deprivation.	

Table II-B

Tests of the endocrine system*			
Hormone	Unit	Dogs	Cats
Adrenocorticotropic hormone, basal (ACTH, plasma)	pmol/L	2–15	1–20
Aldosterone [†] (plasma)	pmol/L	14–957	194–388
Basal	pmol/L	197–2103	277–721
Post-ACTH	pmol/L		
Cortisol (serum or plasma, urine)	nmol/L	25–125	15–150
Basal	nmol/L	200–550	130–450
Post-ACTH	nmol/L	≤ 40	≤ 40
Post-low-dose dexamethasone (0.01 or 0.015 mg/kg)	nmol/L	≤ 40	≤ 40
Post-high-dose dexamethasone (0.1 or 1.0 mg/kg) [‡]	nmol/L	—	—
Urinary cortisol-creatinine ratio	× 10 ⁻⁶	8–24, [†] 10 [§]	35–200
Insulin, basal (serum)	pmol/L	35–200	0–4
Intact parathormone [†] (serum)	pmol/L	2–13	≤ 3.0 in anestrus, proestrus
Progesterone (serum or plasma, female)	mmol/L	50–220 in diestrus, pregnancy	50–220 in diestrus, pregnancy
Testosterone (serum or plasma, male)	nmol/L	1–20	1–20
Thyroxine (T ₄ , serum)	nmol/L	12–50	10–50
Basal	nmol/L	> 45	> 45
Post-thyroxine-stimulating hormone (TSH)	nmol/L	—	≤ 20
Triiodothyronine (T ₃) suppression*	nmol/L	0.7–2.3	0.5–2.0
Triiodothyronine, basal (T ₃ , serum)	nmol/L		

*Prepared with the assistance of ME Peterson, The Animal Medical Center, New York, NY. Unless indicated otherwise, values in this table are adapted from Kemppainen RJ, Zerbe CA. Common endocrine diagnostic tests: normal values and interpretations. In: Kirk RW, ed., Current Veterinary Therapy X. Philadelphia: Saunders, 1989, pp. 961–968. Hormone determinations are variable between laboratories. The laboratory performing the analysis should provide reference values. Before submitting samples for hormone determinations, consult the laboratory for sample specifications, use of anticoagulants, and sample preservation. General sampling conditions are discussed in Reimers TJ. Guidelines for collection, storage, and transport of samples for hormone assay. In: Kirk RW, ed., Current Veterinary Therapy X. Philadelphia: Saunders, 1989, pp. 968–973. Factors that affect serum thyroid and adrenocortical hormone concentrations in dogs are discussed in Reimers TJ, Lawler DF, Sutaria PM, et al. Effects of age, sex, and body size on serum concentrations of thyroid and adrenocortical hormones in dogs. Am J Vet Res 1990, 51:454.

[†]Provided by RF Nachreiner, Animal Health Diagnostic Laboratory, Endocrine Diagnostic Section, Michigan State University.

[‡]This test is used after adrenocortical hyperfunction has been confirmed. It is used to differentiate adrenal tumor (where no suppression is seen) from pituitary-dependent cases (where suppression occurs but is variable).

APPENDIX III

APPROXIMATE NORMAL RANGES FOR COMMON MEASUREMENTS IN DOGS AND CATS

	Dog	Cat
Heart rate (bpm)	60–180	140–220
Capillary refill time	< 2 sec	< 2 sec
Body temperature	99.5–102.5°F 37.5–39.2°C	100.5–102.5°F 38.1–39.2°C
Mean arterial pressure (mm Hg)	90–120	100–150
Blood volume (mL/kg)	75–90	47–66
Cardiac output (mL/kg/min) (L/M ² /min)	100–200 4.72 ± 1.09	167 ± 39
Systemic resistance (mm Hg/mL/kg/min) (dynes/sec/cm)	0.64 ± 0.16 2162 ± 458	
Mean pulmonary arterial pressure (mm Hg)	14 ± 3	
Central venous pressure (cm H ₂ O)	3 ± 4	
Pulmonary artery occlusion pressure (mm Hg)	5 ± 2	
Urine output	1–2 mL/kg/hr	1–2 mL/kg/hr
Breathing rate (breaths/min)	10–30	24–42
Minute ventilation (mL/kg/min)	170–350	200–350
Oxygen delivery (mL/kg/min) (mL/M ² /min)	29 ± 8 815 ± 234	
Oxygen consumption (mL/kg/min) (mL/M ² /min)	4–11 198 ± 53	3–8
Arterial Po ₂ (mm Hg)	85–105	100–115
Arterial So ₂	> 95	> 95
Arterial Pco ₂ (mm Hg)	30–44	28–35
Arterial pH	7.36–7.46	7.34–7.43
Bicarbonate (mEq/L)	20–25	17–21
Base deficit (mEq/L)	0 to –4	–1 to –8
Total plasma proteins (g/dL)	6.0–8.0	6.8–8.3
Albumin (g/dL)	2.5–3.5	1.9–3.9
Packed cell volume (%)	37–55	29–48
Hemoglobin (g/dL)	12–18	9–15.1
Sodium (mEq/L)	145–154	151–158
Potassium (mEq/L)	4.1–5.3	3.6–4.9
Chloride (mEq/L)	105–116	113–121
Total CO ₂ (mEq/L)	16–26	15–21

Modified from Aldrich J, Haskins SC. Monitoring the critically ill patient. In: Current Veterinary Therapy XII. Philadelphia: Saunders, 1995, pp. 98–105 (with permission).

APPENDIX IV**NORMAL VALUES FOR THE CANINE AND FELINE ELECTROCARDIOGRAM**

Rate		
Dog	60–140 beats/min for giant breeds 70–160 beats/min for adult dogs Up to 180 beats/min for toy breeds Up to 220 beats/min for puppies	
Cat	Range: 120–240 beats/min Mean: 197 beats/min	
Rhythm		
Dog	Normal sinus rhythm Sinus arrhythmia Wandering sinoatrial pacemaker	
Cat	Normal sinus rhythm Sinus tachycardia (physiologic reaction to excitement)	
<i>Measurements (lead II, 50 mm/sec, 1 cm = 1 mV)</i>		
Dog	P wave	Width: maximum, 0.04 second; 0.05 second in giant breeds Height: maximum, 0.4 mV
	PR interval	Width: 0.06–0.13 second
	QRS complex	Width: maximum, 0.05 second in small breeds maximum, 0.06 second in large breeds Height of R wave*: maximum, 3.0 mV in large breeds maximum, 2.5 mV in small breeds
	ST segment	No depression: not more than 0.2 mV No elevation: not more than 0.15 mV
	T wave	Can be positive, negative, or biphasic Not greater than one-fourth amplitude of R wave Amplitude range \pm 0.05–1.0 mV in any lead
	Q-T interval	Width: 0.15–0.25 second at normal heart rate; varies with heart rate (faster rates have shorter Q-T intervals and vice versa)
Cat	P wave	Width: maximum, 0.04 second Height: maximum, 0.2 mV
	PR interval	Width: 0.05–0.09 second
	QRS complex	Width: maximum, 0.04 second Height of R wave: maximum, 0.9 mV
	ST segment	No depression or elevation
	T wave	Can be positive, negative, or biphasic—most often positive Maximum amplitude: 0.3 mV
	Q-T interval	Width: 0.12–0.18 second at normal heart rate (range 0.07–0.20 second); varies with heart rate (faster rates have shorter Q-T intervals and vice versa)
<i>Mean Electrical Axis (frontal plane)</i>		
Dog	+40 to +100 degrees	
Cat	0 to + 160 degrees (not valid in many cats)	
<i>Precordial Chest Leads (values of special importance)</i>		
Dog	CV_5 RL (rV_2): T wave positive, R wave not greater than 3.0 mV CV_6 LL (V_2): S wave not greater than 0.8 mV, R wave not greater than 3.0 mV* CV_6 LU (V_4): S wave not greater than 0.7 mV, R wave not greater than 3.0 mV* V_{10} : negative QRS complex, T wave negative except in Chihuahuas	
Cat	CV_6 LL (V_2): R wave not greater than 1.0 mV CV_6 LU (V_4): R wave not greater than 1.0 mV $V10$: T wave negative, R/Q not greater than 1.0 mV	

*Not valid for thin, deep-chested dogs under 2 years of age.

APPENDIX V

ANTIDOTES AND USEFUL DRUGS: METHODS OF TREATMENT

Antidotes and Useful Drugs		
Drugs	Toxicant/Indication for Use	Dosage
Acepromazine	Amphetamine and other stimulant drugs with agitation and excitation; serotonin syndrome	Dogs and cats: 0.02–0.1 mg/kg IV, IM, SC. May cause hypotension.
Antivenin, crotalids	<i>Crotalus</i> and <i>Sistrurus</i> (rattlesnake); <i>Agkistrodon</i> (cottonmouth and copperhead) venom	Several products available. Follow the manufacturer's guidelines for dilution and administration. Dose varies from 1 to 5 vials IV depending on severity of symptoms. 95% of cases controlled with a single vial.
Antivenin, elapids	<i>Micruurus fulvius</i> , <i>Micruurus tenere</i> , <i>Micruroides euryxanthus</i> (coral snakes) venom	Extremely limited availability. The manufacturer's guidelines for dilution and administration should be followed closely.
Atipamezole	Medetomidine, dexmedetomidine reversal. Used off-label to reverse other alpha-2-adrenergic agonists, including amitraz, clonidine, and xylazine	Dogs: 50–100 µg/kg IM Cats: 25–50 µg/kg IM or IV (slow)
Atropine	Anticholinesterase pesticide muscarinic signs (OPs and carbamates); also cholinergic agents and clitocybe and inocybe (muscarinic) mushrooms	Dogs and cats: 0.2–2 mg/kg. One quarter of the dose should be given IV and the remainder IM or SQ. The dose will likely need to be repeated; heart rate and secretions should be used to guide redosing.
Barbiturates	Strychnine and other seizure-producing drugs	Dogs: Phenobarbital at 5–8 mg/kg IV q4–6h. Cats: Phenobarbital at 3 mg/kg IV, repeat every 20 minutes to maximum of 24 mg/kg/24 hours. 4–6 IU/kg, SQ q8–12h. Rarely used. Calcium gluconate 10% 0.54–1.61 mL/kg IV slowly; calcium chloride 10% 0.18–0.56 mL/kg IV slowly.
Calcitonin salmon	Hypercalcemia; vitamin D and analogs	
Calcium gluconate or chloride	Fluoride and hydrofluoric acid; oxalic acid and oxalates; beta and calcium channel antagonists; others	
Calcium disodium EDTA (CaEDTA or calcium disodium versenate)	Heavy metals, primarily lead and zinc. Also chelates cadmium, chromium, copper, cobalt, iron, manganese, nickel, plutonium, thorium, uranium, yttrium, and vanadium	Dilute product in 5% dextrose to a final concentration of 2–4 mg/mL prior to use. Give 25 mg/kg IV or SQ q6h. Maximum recommended daily dose of 2 g/day. Treat for 5 days; rest for 5–7 days; and repeat if needed. Do not use if metal still present in GIT.
Cyproheptadine	Drugs that cause serotonin syndrome (selective serotonin reuptake inhibitors, tricyclic antidepressants, 5-hydroxytryptophan)	Dogs: 1.1 mg/kg PO or rectally q4–8h PRN. Cats: 2–4 mg total dose PO or rectally q4–8h PRN.
D-penicillamine	Heavy metals, primarily lead; but also cadmium, copper, inorganic mercury, and zinc	
Dantrolene	Hops (<i>Humulus lupulus</i>) intoxication and black widow spider envenomation (<i>Latrodectus mactans</i>)	Dogs (home therapy after CaNa ₂ EDTA lead treatment): 110 mg/kg/day PO divided q6–8h for 1–2 weeks. Cats (home therapy after CaNa ₂ EDTA lead treatment and in the presence of elevated blood levels): 125 mg total dose, PO q12h for 5 days. Do not use if metal still present in GI tract.
Deferoxamine	Iron	Dogs: Black widow spider: 1 mg/kg IV followed by 1 mg/kg PO q4h as needed. Hops: 2–3 mg/kg IV or 3.5 mg/kg PO. Dogs and cats: 40 mg/kg IM q4–8h. In critical situations, an IV infusion of 15 mg/kg/hour can be used, but the cardiovascular system must be monitored closely during this time. The excreted complex turns the urine pink or salmon colored and is sometimes referred to as the "vin rose" of iron poisoning. Continue treatment until the urine is clear or serum iron levels are within normal limits.
Digoxin immune Fab fragments	Digoxin, <i>Rhinella</i> sp. (<i>Bufo</i>) toad toxins, and some cardiac glycoside-containing plants	If serum digoxin level is available: number of vials = serum digoxin level (ng/mL) × BW (kg)/100. If serum digoxin level is not available or if treating a <i>Rhinella</i> (<i>Bufo</i>) toad or cardiac glycoside-containing plant toxicosis, start therapy with 1–2 vials and reassess as needed.

ANTIDOTES AND USEFUL DRUGS: METHODS OF TREATMENT (CONTINUED)

<i>Antidotes and Useful Drugs</i>	<i>Toxicant/Indication for Use</i>	<i>Dosage</i>
Dimercaprol (BAL)	Heavy metals, primarily arsenic. Also used to chelated lead and mercury	Arsenic toxicosis: 5 mg/kg IM × one dose followed by 2.5 mg/kg IM q4h for 2 days, q8h for 1 day, and q12h until recovered. Lead toxicosis: 2.5–5 mg/kg IM as 10% solution q4h on days 1 and 2, then q6h on day 3. Preferred method: using 7% ethanol (70 mg/mL), load with 8.6 mL/kg (600 mg/kg) slow IV × 1 dose and follow with 1.43 mL/kg/hour (100 mg/kg/hour) IV CRI for 24–36 hours or until ethylene glycol (EG) test is negative.
Ethanol	Ethylene glycol	Dogs and cats: 0.01 mg/kg IV. Short half-life and may need to repeat in 1–3 hours. Doses 10–20× labeled dose have been used in some animals but there is currently no scientific data to support them.
Flumazenil	Benzodiazepine (clonazepam, diazepam, lorazepam, others); CNS depression or coma	Dogs: 20 mg/kg IV over 15–20 minutes as loading dose; 15 mg/kg IV at 12 and 24 hours; 5 mg/kg IV at 36 hours. Repeat EG test. If positive, continue 5 mg/kg IV every 12 hours until negative.
Fomepizole	Ethylene glycol	Cats: 125 mg/kg slow IV as a loading dose; 31.25 mg/kg IV at 12, 24, and 36 hours. 50 ng/kg IV bolus in 0.9% sodium chloride followed by 10–15 ng/kg/min CRI. May need to increase up to 40 ng/kg/min to maintain euglycemia.
Glucagon	Insulin and oral hypoglycemic agent-induced hypoglycemia; beta and calcium channel blockers and tricyclic antidepressants bradycardia, AV block, and hypotension.	75–150 mg/kg IV
Hydroxycobalamin (vitamin B12a; B12 precursor)	Cyanide	Standard protocol: 1.5 mL/kg IV bolus of 20% solution over 5–15 minutes, followed immediately with CRI of 0.25 mL/kg/min over 1–2 hours. May repeat dose in several hours if signs of toxicity return and serum is not lipemic. Suggested protocol: 1.5–4 mL/kg IV bolus of 20% over 1 minute, followed by CRI of 0.25 mL/kg/min over 30–60 min. Individual boluses may be repeated as needed up to 7 mL/kg.
Intravenous lipid emulsion (ILE); also referred to as intravenous fat emulsion (IFE)	Some lipophilic (fat-soluble) drugs including baclofen, barbiturates, ivermectin and moxidectin, propranolol, tricyclic antidepressants, verapamil, and others.	Dogs and cats: Methotrexate: Varies depending on methotrexate serum concentrations (25–200 mg/m ² IV, IM q6h for up to 8 doses). Pyrimethamine, trimethoprim: 0.1–0.3 mg/kg PO q24h. Dogs: 55–220 mg/kg slow IV. Labeled not to exceed 330 mg/kg/day but higher doses may be used in severe poisonings as long as the dog is monitored for CNS and respiratory depression. Cats: 44 mg/kg slow IV, up to 330 mg/kg/day. Labeled not to exceed 330 mg/kg/day but higher doses may be needed in severe poisonings. Monitor for CNS and respiratory depression when using high doses.
Leucovorin	Methotrexate; pyrimethamine trimethoprim, ormetoprim, others	Cats: Use with extreme caution or not at all. Dogs: 1–1.5 mg/kg as 1% solution IV over several minutes; may be repeated once in 30 min.
Methocarbamol	Metaldehyde, permethrin, strychnine, tremorgenic mycotoxins, other toxicants that cause tremors	Dogs and cats: 140 mg/kg IV or PO × 1 dose, then 70 mg/kg IV or PO q 6 hours for 7 doses. The product should be diluted to a 5% solution prior to use. IV administration preferred in cats due to low oral bioavailability (20%). A variety of other doses have been suggested; most based on extrapolation from human literature. Some recommend higher doses (280 mg/kg) and others additional doses (up to 17 doses) for massive ingestions. Emesis frequently occurs with oral dosing, especially after the initial dose, and an antiemetic may be required prior to starting NAC therapy.
Methylene blue	Aniline dyes, local anesthetics, naphthalene, nitrates and nitrites-induced methemoglobinemia	
N-acetylcysteine (NAC)	Acetaminophen; less often <i>Amanita phalloides</i> mushroom, sago palm, and xylitol intoxication	

ANTIDOTES AND USEFUL DRUGS: METHODS OF TREATMENT (CONTINUED)

<i>Antidotes and Useful Drugs</i>	<i>Toxicant/Indication for Use</i>	<i>Dosage</i>
Pamidronate	Cholecalciferol, calcipotriene, and calcitriol-induced hypercalcemia and hyperphosphatemia	Dogs and cats: 1.3–2 mg/kg diluted in 250–500 mL 0.9% NaCl, IV slowly over several hours. Monitor serum calcium levels q12–24h and adjust ancillary treatment as needed. If hypercalcemia is still present, a repeated dose of pamidronate may be necessary 5–7 days after the initial dose. Very large overdoses of cholecalciferol may require a second dose in 3–4 days.
Naloxone	Opioid and opiate-induced respiratory and CNS depression	Dogs and cat: 0.01–0.04 mg/kg, IV, IM, SQ; may need to use 0.04 mg/kg with larger overdoses. IM and SQ route result in slower onset of action (5 minutes). Short half-life and may need to repeat in 1–3 hours.
Phytanadione (vitamin K1)	Anticoagulant rodenticides, warfarin tablets	2–5 mg/kg PO q24h or divided twice a day.
Pralidoxime (2-PAM)	Organophosphates (nicotinic signs)	Dose (dogs and cats): 20 mg/kg IM or slow IV (over 30 min) for first dose. Repeat dose q8–12h, IM or SQ. Rapid IV administration has resulted in tachycardia, neuromuscular blockade, laryngospasm, muscle rigidity, and death.
Protamine sulfate	Heparin	Dogs and cats: 1 mg protamine sulfate IV per 100 units heparin to be inactivated. Give slowly, no faster than 50 mg per over 10 minutes. Decrease amount of protamine sulfate by 50% for every 30–60 minutes that has passed since heparin overdose given. 0.01–0.03 mg/kg/hour CRI. Longer half-life than other similar drugs.
Pyridostigmine	Anticholinergic plants (<i>Cestrum</i> spp., <i>Datura</i> spp., <i>Solanum</i> spp, etc.), atropine, avermectin and ivermectin, botulism, some elapid snake bites, and nondepolarizing neuromuscular blocking agents (curare, pancuronium, etc.)	
Pyridoxine	Isoniazid	71 mg/kg as 5–10% infusion over 30–60 minutes; if total amount of isoniazid consumed is known can give on a mg per mg (1:1) ratio.
Succimer (2-3 dimer-captosuccinic acid)	Lead	Dogs and cats: 10 mg/kg PO or rectal q8h × 10 days; retreat only if clinical signs are present. Monitor renal values closely in cats.
Trentine (TETA)	Copper hepatopathy in dogs	Dogs: 10–15 mg/kg PO 1–2 hours before meals. Useful in dogs unable tolerate vomiting associated with D-penicillamine.
Yohimbine	Xylazine and other alpha-2-adrenergic agonists (amitraz, clonidine, xylazine)	Dogs and cats: 0.11 mg/kg IV slowly. Shorter half-life than atipamezole.

Abbreviations: Standard**Comments:**

Specific antidotes are not free of side effects and should be used with knowledge and forethought. Many toxicants lack a true antidote, and symptomatic and supportive care, including many of the useful drugs found in this table, is imperative for survival of the poisoned patient. Other drugs may be needed and the reader is directed to the references below for further information.

APPENDIX VI

GARY D. OSWEILER AND LYNN R. HOVDA

TOXIC HOME AND GARDEN HAZARDS FOR PETS

Table VI-A

Toxic plants and their clinical signs—antidotes and treatment		
Plant and Characteristics	Clinical Signs	Antidotes and/or Treatment
Air plant, Cathedral bells (<i>Kalanchoe</i> spp.) Bright red-orange to pink blooms; umbel flower pattern. Plant contains cardiotoxins similar to azalea and rhododendrons, concentrated mainly in flowers.	Cardiac glycoside causes acute signs 1–3 hours after ingestion. Signs include depression, salivation, diarrhea, bradycardia, heart block, tachypnea, ataxia, tremors, and paralysis.	Preventive emesis and/or activated charcoal early after ingestion. Treat as a cardiac glycoside. (See chapter, Cardiac Glycoside Plant Toxicosis.)
Aloe, Octopus plant, Candelabra plant (<i>Aloe</i> spp.) Succulent plant, used in folk and herbal medicine. Toxic fraction is anthraquinone glycoside; disrupts water and electrolyte balance in large intestine.	Anorexia, depression, vomiting, colic, diarrhea, tremors (uncommon), and change in urine color. Generally mild in nature.	Drugs for abdominal pain/diarrhea. Protect airway, treat locally for pharyngitis associated with oxalate crystals (rare).
Autumn crocus (<i>Colchicum autumnale</i>) Houseplant, garden plant. Typically blooms in fall, different from most other bulbs. Dosages above 6 g/kg BW considered lethal. Although the whole plant is toxic, the toxin (colchicine) is highest in bulbs.	Acute onset 2–12 hours post ingestion. Initial signs are nausea, salivation, vomiting, colic, diarrhea, incoordination, and weakness. Multiple organ systems (heart, lungs, and kidneys) also may be involved. Potential for coagulopathy and elevated serum enzymes.	Induce emesis if not vomiting. Activated charcoal if early. Evaluate CBC and serum chemistries, including prothrombin, LDH, CK, IV fluids, analgesics, anticonvulsants as needed.
Baneberry, Doll's eye, Cohosh (<i>Actaea</i> spp.) Toxic principal is protoanemonin glycoside, as well as irritant essential oils.	Clinical response ranges from dermatitis and blistering of skin to oral irritation, drooling, pawing at face or mouth, emesis, diarrhea, and hematuria. Neurologic and cardiovascular signs are occasionally reported. Nausea, vomiting, diarrhea, hypotension, depression. Oxalate crystals can cause direct pharyngeal irritation.	Cleanse mouth thoroughly with water; apply appropriate local demulcents; control emesis and diarrhea as necessary; monitor for organ dysfunction, especially renal damage.
Belladonna lily (<i>Amaryllis</i> spp.) Potted plant, bulbs are most toxic. Contains both lycorine alkaloid (systemic effects) and insoluble oxalates (local pharyngitis).	Gastric irritation, vomiting, diarrhea.	Gastric lavage, activated charcoal, fluids, and supportive treatment.
Bittersweet (<i>Celastrus</i> spp.) Weed, vine with red berries. Immature fruits are toxic. Toxins are sesquiterpene alkaloids (celaphanine, celastrine, paniculatine).		Fluids, supportive care as needed.
Bleeding heart (<i>Dicentra</i> spp.) Garden, woods, potted plant. Roots more toxic than leaves. Toxins are isoquinoline alkaloids (apomorphine, cularine, protoberberine).	Vomiting, diarrhea, muscle tremors, convulsions or paralysis.	Fluids and seizure control.
Castor bean (<i>Ricinus communis</i>) Garden shrub or ornamental grows to 2 meters. Seeds are 1 cm, dark and light mottled, and highly toxic; chewing the seed greatly increases toxicity. Toxin is ricin.	Severe, dangerous if seeds chewed before swallowing. Latent period 6–48 hours. Emesis, severe and hemorrhagic diarrhea, colic, muscle tremors, sudden collapse. Dehydration, hypotension, hemolysis and/or hemoglobinuria.	Emesis for recent exposure: sorbitol if diarrhea not present; charcoal, fluids, and electrolytes. Monitor electrolytes, liver, kidney, adrenal function up to 6 days; H ₂ blockers for GI signs; diazepam for seizures; Antibiotics, lactulose, SAM-e for liver damage.

(Continued)

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-A

Toxic plants and their clinical signs—antidotes and treatment (continued)		
Plant and Characteristics	Clinical Signs	Antidotes and/or Treatment
Chinaberry tree (<i>Melia azedarach</i>) Other common names are Persian lilac, white cedar, Texas umbrella tree. Ornamental tree in temperate to subtropical areas: southern coastal states, Mexican border. Berry is most toxic. Toxins are meliatoxins.	Salivation, anorexia, vomiting, diarrhea. May be followed by weakness, ataxia, excitement or seizures. Fatalities have occurred, generally within two days post-ingestion.	Early emesis, GI lavage and charcoal are considered beneficial. Fluid and electrolyte replacement, anticonvulsants, and supportive care
Christmas rose (<i>Helleborus niger</i>) House and garden plant; entire plant is toxic, but fruits are most dangerous. Small amounts considered dangerous. Contains several toxins including ranunculin that is converted to protoanemonin when chewed, cardenolides, and bufadienolides.	Hypersalivation, vomiting, anorexia, diarrhea followed by cardiac arrhythmias, heart block with premature beats, premature beats, slow irregular pulse. Potent cardenolide action is greatest risk.	Gastric lavage or emesis; activated charcoal or saline cathartics to decontaminate the GI tract. Atropine may be helpful as for other cardenolide plants such as <i>Digitalis</i> spp.
Daphne (<i>Daphne mezereum</i>) Landscape shrub; evergreen or deciduous. Entire plant is toxic. Bitter or acid taste discourages consumption, may reduce toxic effects. Toxins are tricyclic daphnane and diterpenes.	Vesication and edema of the lips and oral cavity associated with ingestion. Signs progress to salivation, thirst, abdominal pain, emesis, hemorrhagic diarrhea.	Analgesics to control pain. General GI detoxification, medical treatment for vomiting and diarrhea. Fluid and electrolyte replacement as needed. Monitor body fluids and electrolytes.
Delphinium/Larkspur (<i>Delphinium</i> spp.) and Pheasant's eye, Yellow oxeye (<i>Adonis</i> spp.) Outdoor perennial, gardens, mountains; tall with blue, purple, or pinkish flowers. Seeds more toxic than leaves. Toxin is a diterpenoid alkaloid.	Small animal poisoning unlikely unless by access to seeds. Early signs are vomiting, colic and diarrhea. May progress to trembling, ataxia, weakness, lateral recumbency.	GI detoxification; demulcents and anti-diarrheal for GI signs; physostigmine to treat muscarinic signs.
English holly (<i>Ilex</i> spp.) Landscape plant; glossy green leaves with marginal spicules. Fruit (drupe) white, yellow, black, red, orange. Occurs in forested areas of eastern N. America; elsewhere as an ornamental. Fruit is most likely portion consumed. Fruit and leaves contain potentially toxic saponins.	Nausea, vomiting, diarrhea most common from consumption of berries. Some animals may be depressed. Clinical response most often mild/moderate and transient.	Relief of digestive distress, activated charcoal may be helpful. Fluid and electrolyte replacement as needed.
English ivy (<i>Hedera helix</i>), also known as Atlantic ivy, Irish ivy, Common ivy Houseplant, or in mild climates used as a ground cover. Occurs as a woody, climbing or creeping vine. Commonly grown throughout North America. Toxins are triterpenoid saponins.	Salivation, thirst, emesis, gastroenteritis, diarrhea, dermatitis. Relatively few reported cases, most are moderate GI irritation. Often moderate or mild.	Symptomatic relief of GI distress; supportive care for vomiting and diarrhea.
Golden angel's trumpet (<i>Brugmansia</i> spp.) Non-native ornamental, similar to Jimsonweed. Large pendulous flowers, similar to Angel's trumpet. Toxin similar to Jimsonweed (tropine alkaloid scopolamine) causes anticholinergic effects.	Typical anticholinergic effects are restlessness, dilated pupils, tachycardia, dyspnea, dry mouth, GI atony, rarely seizures. Rarely lethal.	Treat similar to <i>Datura</i> spp. (See Thorn apple below.)

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-A

Toxic plants and their clinical signs—antidotes and treatment (continued)		
Plant and Characteristics	Clinical Signs	Antidotes and/or Treatment
Horse chestnut or Ohio buckeye (<i>Aesculus</i> spp.) Landscape or forest tree; palmate leaves. Native range is Midwest, east to Appalachian mountains, south into Texas. Planted as ornamental/landscape tree as well. Nuts and twigs most toxic; very early green foliage in spring. Horse chestnut highly toxic; Ohio buckeye very low toxicity. Contain several toxins including saponins, anthraquinones, and a coumarin glycoside.	Gastroenteritis, diarrhea, dehydration, electrolyte imbalance. Neurologic signs possible, including incoordination, hypermetria, staggering. Usually transient, rarely fatal. Recovery usual within 24–48 hours.	Fluid and electrolyte replacement, demulcents, and therapy for gastroenteritis. Confine animals during neurologic phase.
Iris or Blue or yellow flag (<i>Iris</i> spp.) Perennial garden flower, very commonly available. Rootstock (rhizome) most toxic; most risk at transplantation. Close to soil surface, may be dug up by dogs. Advise clients of potential risk. Rootstock contains purgative toxin known as irisin.	Hypersalivation, vomiting, colic, diarrhea which may be hemorrhagic. Occasionally irritation of the lips and muzzle.	GI decontamination early. Fluid and electrolyte therapy as needed.
Irish potato (<i>Solanum tuberosum</i>) Vegetable garden plant. Vines, green skin, and sprouts are toxic. Toxins vary but are solanine and other glycoalkaloids.	Vomiting, diarrhea, depression, rapid heart rate, mydriasis, muscle tremors. Signs may vary from atropine like to cholinesterase inhibition. Use antidotes accordingly and with caution.	GI decontamination. If atropine-like signs predominate: use physostigmine. If salivation and diarrhea are present: use atropine cautiously.
Jerusalem cherry, Winter cherry (<i>Solanum pseudocapsicum</i>) Common ornamental houseplant. Toxin is the glycoalkaloid solanine, similar to other plants of the nightshade (<i>Solanaceae</i>) family.	Severe GI irritation characterized by drooling, vomiting, diarrhea, ulceration, depression, and sometimes seizures.	GI decontamination if exposure is recent. If salivation and diarrhea are present and severe, use atropine cautiously. Provide fluid therapy based on condition of patient and results of laboratory tests.
Lantana (<i>Lantana camara</i>) Occurs wild and in gardens in mild temperate to tropical areas. Naturalized in southeastern coastal states of the USA. Bright orange, yellow, red, purple, or pink flowers. Foliage and immature berries are most toxic. Toxins are pentacyclic triterpenoid lantadenes A, B, and C.	Weakness, lethargy, vomiting, diarrhea, mydriasis, dyspnea. Continued ingestion can lead to chronic disease. Advanced signs: cholestasis, hyperbilirubinemia. Liver changes predispose to photosensitization.	GI decontamination, activated charcoal for acute exposures. Provide fluids and respiratory support. Protect from sunlight and treat for hepatic insufficiency.
Lily of the valley (<i>Convallaria majalis</i>) Ornamental garden plant. Prefers moist, shaded areas. Blossoms nodding/drooping on stem. Toxic principal (cardenolides) persists in dried plants; highest concentration in roots.	Multi-organ failure. Tremors, thirst, vomiting, diarrhea, cardiac arrhythmia/bradycardia, weakness, shock. Monitor for cardiac arrhythmias, shock and hyperkalemia.	Emesis or gastric lavage. Control dehydration, maintain electrolytes; control diarrhea; monitor ECG and serum potassium.

(Continued)

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-A

Toxic plants and their clinical signs—antidotes and treatment (continued)		
Plant and Characteristics	Clinical Signs	Antidotes and/or Treatment
Lupine, Bluebonnet (<i>Lupinus</i> spp.) Common garden ornamental throughout USA; wild plants abundant in some regions, primarily western USA. Seeds more toxic than leaves, but plant, seeds, and pods are toxic. Toxin is lupine.	Signs begin 1–24 hours post exposure. Salivation, ataxia, mydriasis, depression or seizures, disorientation, dyspnea. Liver and kidney damage may develop from continued ingestion. Lupines are teratogenic in ruminants. Risk in small animals is not well known. Chewing on the plant releases oxalate spicules into mouth, tongue and lips.	GI decontamination with activated charcoal for acute exposure. Anticonvulsants may be needed if neurologic signs are severe.
Mexican breadfruit, Swiss cheese plant, Hurricane plant (<i>Monstera deliciosa</i>) Stems and leaves contain insoluble calcium oxalate spicules (raphides).	Response is immediate irritation, pain, salivation, and inflammation. Signs include pawing at face, drooling, and vomiting; potential interference with upper airway. Vomiting, GI pain, diarrhea; ataxia, hypotension, occasional seizures, cardiovascular failure.	Cleanse mouth thoroughly with water. Apply local and/or systemic anti-inflammatory agents based on clinical condition of patient.
Mistletoe (<i>Phoradendron</i> spp.) Access to pets in homes at holiday time. Oval evergreen leaves with white berries. Leaves, stems, and berries are moderately toxic, contain toxic amines and proteins.	Vomiting, GI pain, diarrhea; ataxia, hypotension, occasional seizures, cardiovascular failure. Principal risk may be from use during holiday season.	Fluid and electrolyte replacement; demulcents for gastroenteritis.
Monkshood (<i>Aconitum</i> spp.) Perennial garden ornamental. Entire plant is toxic, contains diterpene alkaloids that are primarily neurotoxic.	Interferes with inactivation of Na^+ channels in nerves. Salivation, vomiting, diarrhea. Muscle tremors, weakness, cardiac arrhythmia and/or heart failure; respiratory depression.	GI decontamination, fluid and electrolyte replacement. Manage similar to digitalis glycoside overdose, with caution for potassium administration.
Morning glory (<i>Ipomoea purpurea</i> and <i>Ipomoea tricolor</i>) Garden annual, potted plant. Seeds most toxic. Increased risk when seeds are pre-soaked, consumed by dogs. Indole alkaloid toxin similar to ergot alkaloids; abused as hallucinogen.	Nausea, mydriasis, ataxia, muscle tremors, hallucinations, decreased reflexes, diarrhea, hypotension.	Dark, quiet surroundings; tranquilization as needed. GI decontamination is not routinely recommended.
Mountain laurel (<i>Kalmia</i> spp.) Native of eastern and southeastern woods, mountains. Both leaves and flowers are toxic. Honey from nectar also toxic. Toxins are diterpenoids, in particular grayanotoxins I and II.	Oral irritation, salivation, projectile vomiting, diarrhea, weakness, impaired vision, bradycardia, hypotension, AV block.	Activated charcoal, fluid replacement, and respiratory support as needed.
Narcissus, Daffodil, Jonquil (<i>Narcissus</i> spp.) Garden ornamental bulb. Bulb is most toxic. Contains lycorine alkaloid.	Nausea, vomiting, salivation, hypotension, diarrhea. Prolonged signs may cause dehydration.	Gastric lavage, activated charcoal, fluid replacement, supportive treatment for gastroenteritis.
Nettle (<i>Urtica</i> spp.) Garden or waste area weed. Hairs on leaves contain toxin that enters skin on contact. Most common in hunting or outdoor free-roaming dogs. Toxins are biogenic amines (acetylcholine, histamine, etc.).	Oral irritation and pain, hypersalivation, swelling and edema of nose and periocular areas or other areas of skin contact	Antihistamines and analgesics. Local or systemic anti-inflammatory supportive therapy to treat affected contact areas.

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-A

Toxic plants and their clinical signs—antidotes and treatment (continued)		
Plant and Characteristics	Clinical Signs	Antidotes and/or Treatment
Persian violet, Sowbread (<i>Cyclamen persicum</i>) Popular florists' plant; widely available. Irritant saponins in all parts of the plant, especially tubers or roots.	Chewing plant parts causes oral irritation with drooling, vomiting and diarrhea. Occasional hemoglobinuria may color urine red-brown. Large amounts may cause cardiac arrhythmias, seizures and rarely mortality.	Control vomiting and diarrhea if severe; administer fluids as needed. Monitor urine for color and/or hemoglobin. Control seizures and cardiac arrhythmias as needed.
Philodendron spp. Very common indoor ornamental vine. Toxic principal is insoluble oxalate.	Chewing on the plant releases oxalate spicules into mouth, tongue and lips. Response is immediate irritation, pain, salivation, and inflammation. Signs include pawing at face, drooling, and vomiting; also potential interference with upper airway. Irritation of mouth: may cause vomiting, diarrhea, and dermatitis. Usually transient and not life-threatening.	Cleanse mouth thoroughly with water. Apply local and/or systemic anti-inflammatory agents based on clinical condition of patient.
Poinsettia (<i>Euphorbia pulcherrima</i>) Garden or potted plant, especially during Holiday season. Sap of stem and leaves mild irritant. Contains a variety of diterpenoid euphorbol esters.		Demulcents for local lesions; fluids to prevent dehydration.
Rosary pea, Precatory bean (<i>Abrus precatorius</i>) Native of Caribbean islands. Seeds (when broken or chewed) are highly toxic. Seeds used in ornamental jewelry in some countries. Illegal to import into USA. Toxin is abrin.	Signs may be delayed up to 2 days after ingestion. Early signs are nausea, vomiting, diarrhea (often hemorrhagic) followed by weakness, tachycardia, possible renal failure, coma, death.	Emesis or lavage followed by activated charcoal, demulcents, fluids, and electrolytes. Early and thorough detoxication is important for survival.
Thorn apple, Jimsonweed (<i>Datura stramonium</i>) Annual weed, some species are ornamental (<i>Datura metel</i>). Entire plant is toxic, but seeds are most toxic and available. Toxins are tropane alkaloids (hyoscyamine and scopolamine) with effects similar to atropine.	Thirst, disturbances of vision, delirium, mydriasis, tachycardia, hyperthermia, GI atony/constipation. Commonly described as "Hot as a pistol, blind as a bat, red as a beet, mad as a hatter."	GI decontamination if early after ingestion. Parasympathomimetic drug (e.g., physostigmine).
Tulip (<i>Tulipa spp.</i>) and Hyacinth (<i>Hyacinthus spp.</i>) Poisoning usually occurs when dogs consume available bulbs or dig up freshly planted bulbs. Toxic principal includes allergenic lactones and similar alkaloids.	Signs reflect direct irritation and include drooling, nausea, vomiting, diarrhea, dyspnea, tachycardia, and hyperpnea.	GI decontamination if early after ingestion. Apply local and/or systemic anti-inflammatory agents based on clinical condition of patient. Monitor and control gastrointestinal effects; medicate as needed for tachycardia and dyspnea.
Tobacco (<i>Nicotiana tabacum</i>) Garden plant, weed, cigarettes. Entire plant toxic. Nicotine alkaloid is toxic principal.	Rapid onset of salivation, nausea, emesis, tremors, incoordination, ataxia, collapse and respiratory failure.	Assist ventilation, provide vascular support. Gastric lavage with activated charcoal.

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-A

Toxic plants and their clinical signs—antidotes and treatment (continued)		
Plant and Characteristics	Clinical Signs	Antidotes and/or Treatment
Wisteria (<i>Wisteria</i> spp.) Woody vine or shrub with bluish purple to white legume flowers. Entire plant is toxic. Toxin is a glycoprotein lectin.	Nausea, abdominal pain, prolonged vomiting; diarrhea. Signs may persist 2–3 days.	Antiemetics and fluid replacement therapy.
Yellow Jessamine (<i>Gelsemium sempervirens</i>) Mild temperate to subtropical climates; mainly SE United States. Yellow trumpet-shaped flowers grow on evergreen vines. Neurotoxic alkaloids and sempervirine, an indole, are toxins.	Weakness, ataxia, clonic/tonic seizures, paralysis, respiratory failure.	GI decontamination early in course of toxicosis. Symptomatic and supportive therapy for respiration. Fluid replacement therapy as needed.

APPENDIX VI

COLEEN M. ALMGREN

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-B

Herbal toxicities						
Class	Toxic Principle	Genus Species	Common Names	Clinical Signs	Treatment Overview	Popular Usage
Sympathomimetics	Ephedrine, pseudoephedrine, synephrine	<i>Ephedra sinica</i> , <i>Sida cordifolia</i> , <i>Citrus aurantium</i>	Ma huang, Indian common mallow, bitter orange	Hyperthermia, hypertension, tachycardia, tremors, seizures, hallucinations, agitation, serotonin syndrome	Decontamination, monitor CV, CNS. Acepromazine for agitation, Cyproheptadine for serotonin syndrome. Beta blockers for tachycardia.	Weight loss, Weight lifting, Herbal “ecstasy,” decongestants
Methylxanthines	Caffeine, theobromine	<i>Camellia sinensis</i> , <i>Paullinia cupana</i> , <i>Cola acuminata</i> , <i>Theobroma cacao</i>	Epigallocatechin gallate or ECGC (green tea), guarana, cocoa, cola, kola nut, chocolate	Agitation, hyperactivity, polyuria, polydipsia, cardiac arrhythmias, tremors, seizures	Decontamination, fluid diuresis, monitor CV and CNS, manage arrhythmias, tremors, seizures, symptomatic supportive care.	Weight loss, herbal “NoDoz”
Hypoglyemics	Alpha lipoic acid, cinnamon, xylitol	Alpha lipoic acid (ALA), <i>Cinnamomum cassia</i>	Thioctic acid, cinnamon, xylitol	Hypersalivation, vomiting, hypoglycemia, increased liver or renal enzymes, death (ALA)	Monitor blood glucose, manage hypoglycemia, monitor liver enzymes.	Diabetic treatment, sugar substitute, amanita mushroom poisoning (ALA)
Serotonin syndrome	5-hydroxytryptophan (5-HTP)	<i>Griffonia simplicifolia</i>	5-HTP	Vomiting, diarrhea, tremors, seizures, ataxia, hyperesthesia, depression	Decontamination, Methocarbamol for tremors. Phenobarbital or propofol for seizures. Avoid benzodiazepines.	Depression, headaches, insomnia, obesity
Allergenic	Arabinogalactan	<i>Echinacea purpurea</i>	Purple coneflower	Vomiting, diarrhea	Cyproheptadine is a specific antagonist.	
Anticoagulant	Hydroxycoumarin, bisabolol	<i>Matricaria recutita</i> , <i>Chamaemelum nobile</i>	Chamomile	Vomiting, diarrhea, lethargy, rarely epistaxis, hematoma (cats)	Symptomatic/supportive care. Monitor coagulation, symptomatic and supportive care, very rarely blood transfusion.	Cold and flu support, immune stimulant Sedative, gastrointestinal ulcers
MAO inhibitor	Hypericin	<i>Hypericum perforatum</i>	St. John's wort	Depression, vomiting, diarrhea, rarely tremors, seizures	Decontamination, symptomatic and supportive care, cyproheptadine for serotonin syndrome.	Antidepressant, insomnia

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-B

Herbal toxicities (continued)						
Class	Toxic Principle	Genus Species	Common Names	Clinical Signs	Treatment Overview	Popular Usage
Sedative	Valpotriates	<i>Valeriana officianalis</i>	Valerian	Lethargy, sedation	Generally home care, prevent injury.	Sedative, sleep aid
Essential oil	Melaleuca oil, pulegone, menthofuran	<i>Melaleuca alternifolia</i> , <i>Mentha pulegium</i>	Tea tree oil, pennyroyal oil	Orally: vomiting, diarrhea, CNS depression, hepatotoxicity, aspiration pneumonia. Dermally (as a spot-on): transient paresis	Dermal—bath. Oral—fluids, N-acetylcysteine, monitor liver enzymes for pennroyal ingestions. Pain control, thermoregulation as needed.	Germicidal, fungal infections, antiseptic, flea control
Polysulfated glycosaminoglycan (PSGAG)	PSGAG	Glucosamine, chondroitin sulfate	Adequan and many other brands	Oral: vomiting, diarrhea, polydipsia, hepatopathy. IM: transient	Manage vomiting and diarrhea, baseline liver enzymes if large ingestion.	Arthritis, chondroprotective
Cationic detergents	Quaternary ammonium compounds	<i>Citrus X paradisi</i>	Grapefruit seed extract (GSE)	dose-dependent prolongation of PT, aPTT, reduced platelet aggregation, diathesis	Coagulopathies only expected with injectable overdoses, monitor clotting parameters.	Disinfectant, antifungal
Alpha 2-adrenergic blocking agent	Alpha 2-adrenergic blocking agent	<i>Pausinystalia yohimbine</i>	Yohimbine	Drooling, vomiting ± blood, weakness, anorexia, hyperthermia,	Dilution, carafate slurries, H2 blocker, fluids, nutritional support, broad-spectrum antibiotic, pain control.	
Salicylates	Methyl salicylate	<i>Gaultheria procumbens</i>	Wintergreen extract	oral/esophageal ulceration or irritation, dermal erythema, pain, ulceration	Hyperactivity, agitation, tremors, seizures, vomiting, diarrhea, abdominal pain, hypotension	Monitor glucose, blood pressure, control agitation, tremors, seizures. Fluids and dextrose PRN.
					GI upset, GI ulcers, hyperthermia, hepatotoxicity, coagulopathies, coma	Hypertension, angina, "herbal Viagra"

APPENDIX VI

LYNN R. HOVDA

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-C

Household cleaners, disinfectants, and solvents—products, clinical signs and treatment		
Products	Toxicity and Clinical Signs	Treatment
SOAPs, DETERGENTS, AND CLEANING AGENTS		
Soaps (fatty acid salts)—includes commercial bar soaps, some liquid hand soaps, laundry bar soaps, homemade soaps, some baby and infant products.	Low order toxicity	Generally dilution with water and observation is all that is required. Fluids and electrolytes should be used to replace fluid loss from excessive vomiting and diarrhea. If vomiting has not yet occurred, emesis should be induced in noncorrosive bar soap ingestions > 20 g soap/kg body weight (BW). Eyes should be irrigated with tepid water or isotonic saline for 10–15 minutes and observed for signs of irritation. Any exposed skin and hair coat should be washed well to prevent re exposure.
Anionic Detergents (sulfonated or phosphorylated straight chain hydrocarbons)—includes most laundry detergents, some automatic dishwashing detergents, and some shampoos. Common detergents include alkyl sodium sulfate, alkyl sodium sulfonate, dioctyl sodium sulfosuccinate, sodium lauryl sulfate, others. Hard water "boosters" or "builders" such as sodium carbonate, sodium phosphate, and sodium silicate are often added.	Generally slight to moderate toxicity with high alkaline and potentially corrosive automatic dishwashing detergents, including pods or complete packs, the exception. Irritation to the gastrointestinal tract (GIT) with discomfort, vomiting, and diarrhea the most common signs. Absorption occurs through the GIT and irritated skin; IV hemolysis has been reported. Repeated dermal exposure may result in irritation. Ocular exposure may cause conjunctivitis and irritation; ocular exposure to automatic dishwashing detergents may result in corneal erosion and opacity. Laundry pods or complete packs have caused more serious problems than expected based on the ingredients. The reason is unknown but may be related to increased amounts ingested due to a concentrated product packaged in a small, colorful pod.	Depends on specific product and amount ingested. With most products, dilution with water or milk and replacement of fluid and electrolyte losses secondary to vomiting and diarrhea are all that are required. Serum should be monitored for hemolysis. Skin and hair coat should be washed well with tepid water to prevent exposure, especially those animals that are known to self-groom. Eyes should be irrigated well for 10–15 minutes with tepid water or isotonic saline and monitored closely for irritation. Animals exposed in any manner to automatic dishwashing detergents or laundry pods should be examined and monitored for corrosive type injuries.
Cationic Detergents (quaternary ammonium compounds with aryl or alkyl substituent groups, often a very long hydrophobic carbon chain with a halogen such as chloride or iodide is attached)—includes fabric softeners, sanitizers, germicides. Compounds such as benzethonium chloride, benzalkonium chloride, and cetyl pyridinium chloride are used as cationic detergents. Liquid potpourris, covered elsewhere, are also in this group.	Highly toxic compounds. Effects are concentration dependent with 1% concentrations causing irritation and damage to mucous membranes and 7.5% concentrations resulting in corrosive burns to the mouth, tongue, pharynx, and esophagus. Salivation is profuse and vomiting ± blood may occur. Other signs include shock at any stage of exposure, muscle weakness, fever, CNS and respiratory depression, seizures, collapse and coma. Dermal effects are concentration dependent. Hair loss and skin ulceration are frequently seen in cats and inflammatory lesions on the paws in dogs. Ocular signs after exposure are concentration dependent and range from irritation and discomfort to corneal damage and ulceration.	Depends on the concentration of the product and route of exposure. Animals ingesting the product should be given water or another diluent such as milk. Vomiting should not be induced, especially when the concentration is greater than 7.5%. Activated charcoal may be administered in asymptomatic animals but the use is controversial. The mouth and oropharynx should be examined for lesions and those animals with continued profuse salivation, stridor, or dysphagia should undergo endoscopic examination for analysis of mucosal damage. Supportive care includes IV fluids as needed, attention to respiratory effort, adequate caloric intake, seizure medication as needed, and close monitoring for shock. Exposed skin and hair coat should be washed with tepid water and mild soap for 10–25 minutes and monitored for irritation and ulceration. The eyes should be thoroughly evaluated and irrigated with isotonic saline for 20 minutes followed by a slit lamp examination. Further treatment depends on the examination results.

(Continued)

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-C

Household cleaners, disinfectants, and solvents—products, clinical signs and treatment (continued)		
Products	Toxicity and Clinical Signs	Treatment
Nonionic Detergents (uncharged aqueous solutions)—includes hand dishwashing detergents, shampoos, few laundry detergents. Alkyl ethoxylate, alkylphenoxy polyethoxy ethanol (alcohol ethoxylates), and polyethylene glycol stearate are examples.	Primarily of low toxicity after ingestion. Ocular exposure may result in irritation.	Dilution with water and observation normally all that is required. IV fluids and electrolytes may be used to replace fluid losses from excessive vomiting and diarrhea. Eyes should be irrigated with tepid water or isotonic saline for 10–15 minutes and observed for signs of continued irritation. Any exposed skin and hair coat should be washed well to prevent re-exposure.
CORROSIVES Acids (pH < 7; strong acids pH < 2.5–3)—includes rust removers, drain and toilet bowl cleaners, gun barrel cleaning fluids and other metal cleaners, swimming pool cleaning agents. Hydrochloric acid (muriatic acid), sulfuric acid, nitric acid, oxalic acid, phosphoric acid, and sodium bisulfite (sodium acid sulfate) are all acid corrosives. Hydrofluoric acid, a rust remover product, carries a special warning.	<p>Signs are concentration and time dependent although in general these are highly toxic substances. Acids typically have a localized necrotic effect and rarely cause full-thickness mucous membrane lesions. Exposure in animals results in immediate, intense pain which typically limits further exposure.</p> <p>Corrosive mucous membranes burns are initially gray to milky white, turning black as an eschar forms. Stricture formation may follow in several weeks. The animal may vocalize or become lethargic; excessive panting may indicate pain and inability to swallow may be noted. Other effects are hematemesis, abdominal pain, polydipsia, epiglottal edema with secondary respiratory distress, and shock. Secondary pneumonitis results from aspiration or exposure to acid vapors.</p> <p>Serious burns result from ocular or dermal exposure. Pain is severe. Acids tend to penetrate the eye more slowly than bases and may result in a delayed corneal damage including corneal and conjunctiva necrosis.</p> <p><i>Hydrofluoric acid (HF)</i> penetrates tissues and poisoning can occur through ingestion, inhalation, or skin or eye exposure. Signs are often delayed and pain may not be immediately evident. Once systemic, HF binds with calcium ions producing insoluble calcium fluoride. Severe pain and swelling as well as hypocalcemia result. In severe exposures death from cardiac arrest may occur.</p>	<p>All exposures should be diluted immediately with water or milk. Attempts to neutralize the burn with other chemicals are contraindicated as is emesis or gastric lavage. Activated charcoal is ineffective in binding acid corrosives and should not be administered. Supportive care including IV fluids is indicated. Therapy for shock may be required as uncorrected circulatory collapse can lead to renal failure, ischemic lesions in vital organs, and acute death. The presence of severe pharyngeal edema indicates the need for an endotracheal or tracheostomy tube. Esophageal complications are less common with acid exposures than alkali ingestions. If necessary, endoscopy should be carefully performed 12–24 hours after exposure to determine the extent of injury. The procedure should be stopped at the first sign of mucosal damage. Radiographic examination is another alternative.</p> <p>Affected skin and hair coat should be irrigated for 15–20 minutes with copious amounts of tepid water and monitored for lesions.</p> <p>Affected eyes should be irrigated for 20–30 minutes with isotonic saline followed by an examination with a slit lamp. Further treatment depends on the result of the examination.</p> <p>Any deterioration in the animal's signs necessitates a second examination.</p> <p><i>Hydrofluoric acid</i> exposures require immediate attention even though they may not show any signs. Caretakers should take precautions to protect themselves when bathing or applying medications. Exposed areas should be washed well with cool water and ice packs applied to slow diffusion of the fluoride ion. Calcium gluconate gel applied liberally to the affected area will help bind fluoride. If calcium gluconate gel is not readily available the area can be soaked in any magnesium hydroxide containing antacid product until the gel is located.</p>

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-C

Household cleaners, disinfectants, and solvents—products, clinical signs and treatment (<i>continued</i>)		
Products	Toxicity and Clinical Signs	Treatment
Bases (pH >7; strong base pH >11.5–12; some references state >10)—includes drain and oven cleaners, cleaning agents, toilet bowl cleaners, washing products. Lye (sodium or potassium hydroxide or caustic soda), sodium carbonate (washing soda or soda ash), sodium metasilicate, and ammonium hydroxide are alkaline ingredients present in many of these products.	Rapid liquefaction necrosis on contact with deep, penetrating ulcers. Ingestion may result in full thickness esophageal burns with secondary stricture formation. Little pain on contact so animals are not repelled and significant exposure may occur. The remaining signs are similar to those found under corrosive acids.	All exposures should be diluted immediately with water or milk. Attempts to neutralize with other chemicals are contraindicated as is emesis or gastric lavage. Activated charcoal is ineffective in binding and should not be administered. Supportive care includes IV fluids, analgesics, and adequate nutrition. Corticosteroids have been recommended to decrease stricture formation but their use is controversial. Antibiotics should be used in animals with known perforations or infections. Therapy for shock may be required as uncorrected circulatory collapse can lead to renal failure, ischemic lesions in vital organs, and acute death. The presence of severe pharyngeal edema indicates the need for an endotracheal or tracheostomy tube. Endoscopy should be carefully performed 12–24 hours after exposure to determine the extent of injury. The procedure should be stopped at the first sign of mucosal damage. Radiographic examination is another alternative. Affected skin and hair coat should be flushed for 15–20 minutes with copious amounts of tepid water and monitored for lesions.
DISINFECTANTS		Affected eyes should be irrigated for 20–30 minutes with isotonic saline followed by an examination with a slit lamp. Further treatment depends on the results of the examination.
Bleaches —includes common household bleach (3 to 6% sodium hypochlorite); industrial or swimming pool bleach (up to 50% sodium hypochlorite); powdered bleach (calcium hypochlorite, sodium dichloroisocyanurate), non-chlorine or colorfast bleach (sodium carbonate peroxide, hydrogen peroxide, sodium perborate).	The toxicity of chlorine bleach depends on the pH and concentration of the hypochlorite ion. Exposed animals may smell like chlorine and their exposed hair coat bleached. Household chlorine bleach products are mild to moderate irritants and generally not associated with significant tissue destruction. Common clinical signs secondary to ingestion include oral irritation, salivation, abdominal pain, and vomiting. Inhalation of fumes may result in coughing, gagging and retching. Systemic reactions are rare. Oral, pharyngeal, esophageal, and gastric burns have been reported from household chlorine bleach ingestions but are rare. The more concentrated hypochlorite solutions and bleach powders can produce corrosive effects. Non-chlorine bleach products are of low order toxicity with gastric irritation and vomiting the most commonly reported signs. Borate containing products decompose to peroxide and borate resulting in a more alkaline and potentially irritating product.	Any deterioration in the animal's signs necessitates a second examination. All oral exposures should be diluted with water or another appropriate diluent. Exposed skin and hair coat should be washed with a mild soap and copious amounts of water; eyes should be irrigated with isotonic saline for 10–15 minutes. Animals inhaling chlorine bleach fumes should be moved to fresh air. The incidence of esophageal damage is low so endoscopy is not routinely recommended. Animals with dysphagia, dyspnea, or severe oropharyngeal burns should undergo careful endoscopic examination and treated as needed for corrosive injuries.

(Continued)

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-C

Products	Toxicity and Clinical Signs	Treatment
Phenols (coal tar derived aromatic alcohols)—chlorophenols, phenylphenols in a variety of concentrations and products; some concentrated commercial products contain up to 50% pure phenol.	<p>Considered highly toxic and a medical emergency due to rapid absorption by inhalation, ingestion, or dermal exposure. Cats are more sensitive than dogs. The oral LD₅₀ in dogs is 0.5g/kg BW. Concentrations >1% have caused dermal burns and >5% oral burns.</p> <p>Oral exposure causes burns to the mouth, oropharynx, and esophagus. Hypersalivation, panting, agitation, and vomiting progress to tremors, cardiac arrhythmias, shock, and coma. Methemoglobinemia, respiratory alkalosis, and renal and hepatic damage may develop.</p> <p>Dermal and ocular exposure results in a short period of intense pain followed by local anesthesia. Necrotic skin areas are white followed in a few days by a dry, grey black eschar. Ocular exposure results in severe corneal burns and erosions.</p>	<p>Dilution with water is considered controversial as it may increase systemic absorption; milk is preferred and small amounts should be administered at home prior to obtaining veterinary care. Emesis is contraindicated. The mouth and oropharynx should be examined carefully for evidence of mucosal damage prior to gastric lavage. If present gastric lavage is contraindicated. If there is no mucosal damage, activated charcoal with a cathartic may be administered. Further care is supportive and includes monitoring of renal and hepatic function, acid-base status, and respiratory effort. Shock and respiratory depression are complicating factors. N-acetylcysteine (NAC) may be used to limit hepatic and renal toxicity.</p> <p>Individuals treating dermal exposures should protect themselves prior to animal treatment. Polyethylene glycol (PEG) or glycerol is recommended for the initial dilution and removal of phenolic compounds followed by washing with a mild soap and water. Oil based creams and ointments should be avoided as they may increase phenol absorption.</p>
Pine Oils (terpene alcohols) and Turpentine (mixture of terpenes derived from pine oil)—Concentration of pine oil in disinfectants varies from 0.3% to 60%. Turpentine is used to thin oil-based paints.	<p>The oral LD₅₀ of pine oil varies from 1 to 2.7 mL/kg BW but much lower doses may result in severe toxicosis. Cats are more susceptible than dogs. Pine oil products are direct irritants to mucous membranes resulting in erythema in contact areas (mouth, oropharynx, skin).</p> <p>Ingestion results in profuse salivation, abdominal pain, and vomiting ± blood. Systemic effects include respiratory depression, CNS depression, weakness, ataxia, and hypotension. Aspiration during ingestion or emesis or chemical pneumonitis secondary to systemic absorption results in pulmonary toxicity. Myoglobinuria and acute renal may develop with massive ingestions.</p> <p>Dermal exposure causes redness and irritation. Ocular signs include photosensitivity, blepharospasm, epiphora, and conjunctival and scleral erythema.</p>	<p>Affected eyes should be irrigated for 20–30 minutes with isotonic saline and a slit lamp examination performed. Medications and further therapy depend on exam results.</p> <p>All oral exposures should be diluted with water or milk. Induction of emesis is contraindicated and gastric lavage carries a risk. Activated charcoal with a cathartic should be administered after dilution. Further treatment is symptomatic and includes close monitoring of renal perfusion, electrolytes, and acid base status.</p> <p>Affected skin should be washed well with a mild soap and copious amounts of water.</p> <p>Ocular exposures should be irrigated for 10–15 minutes with isotonic saline and monitored for further signs.</p>

TOXIC HOME AND GARDEN HAZARDS FOR PETS (CONTINUED)

Table VI-C

<i>Products</i>	<i>Toxicity and Clinical Signs</i>	<i>Treatment</i>
SOLVENTS AND ALCOHOLS		
Acetone —found in nail polish remover, glues and rubber cement, paint thinner, varnish.	The oral LD ₅₀ in dogs is 8 mL/kg BW but doses as low as 2–3 mL/kg BW may be toxic. The odor of acetone and presence of elevated urinary ketones indicate exposure. Clinical signs associated with a mild exposure include CNS depression, ataxia, and vomiting; stupor and coma occur with larger amounts. Hyperglycemia and ketonemia may be present.	Emesis followed by activated charcoal with a cathartic has been suggested but is controversial due to rapid absorption of acetone and poor binding of activated charcoal. It may be useful if performed within 15–30 minutes of ingestion. Further therapy is symptomatic and supportive and may need to be continued for several days due to the long plasma half-life.
Isopropanol —found in perfume, cologne, hand sanitizers, fuel additives.	The toxic dose of 70% isopropanol is 1 mL/kg BW but doses as low as 0.5 mL/kg BW may be toxic. Signs occur rapidly, generally within 30–60 minutes, and include vomiting ± blood, stupor, and ataxia which may progress to CNS and respiratory depression, severe hypotension, and coma. Mild acidosis may occur.	The rapid onset of signs prevents most forms of decontamination. Emesis may be induced in asymptomatic animals if the ingestion occurred with 15–30 minutes. Activated charcoal is not recommended as it does not readily bind alcohols. Further treatment includes IV fluids and monitoring of acid-base and electrolyte status. Hemodialysis may be useful in animals with severe hypotension and coma.
Methanol (methyl or wood alcohol, "denatured alcohol")—found in windshield wiper solutions, antifreeze products for door locks.	The lethal dose of oral methanol in dogs is 4–8 mL/kg BW. Clinical signs include CNS and respiratory depression, ataxia, hypothermia, and coma. Blindness and severe acidosis do NOT occur in dogs and cats.	Treatment is similar to isopropanol toxicosis.

LEIGH A. LAMONT, KURT A. GRIMM, AND WILLIAM J. TRANQUILLI

PAIN MANAGEMENT

Table VII-A

Recommended parenteral opioid dosages and indications			
Opioid	Dose/Route/Duration	Indications	Comments
Butorphanol (injectable)	Dog: 0.2–0.4 mg/kg IM, IV, or SC Cat: 0.2–0.4 mg/kg IM, IV, or SC Duration: 1–3 h	Mild to moderate pain	Mild or no sedation; mild ventilatory depression.
Buprenorphine (injectable)	Dog: 0.005–0.03 mg/kg IM, IV Cat: 0.005–0.03 mg/kg IM, IV or transmucosal Duration: 3–8 h Cat: 0.24 mg/kg SC once daily for up to 3 days for post-operative pain (SIMBADOL) Duration: 24 h	Mild to moderate pain	May be difficult to antagonize, onset of effect 15–30 minutes.
Morphine (injectable)	Dog: 0.2–1.0 mg/kg IM or SC; 0.05–0.5 mg/kg IV Cat: 0.05–0.2 mg/kg IM or SC Duration: 3–6 h	Moderate to severe pain	Sedation; respiratory depression; bradycardia; nausea; hypothermia; dysphoria in cats without pain or with large dosage; rapid IV injection may cause histamine release.
Methadone (injectable)	Dog: 0.25–0.5 mg/kg IV, IM or SC Cat: 0.1–0.25 mg/kg IV, IM or SC Duration 3–4 h	Moderate to severe pain	Sedation; dysphoria, vomiting, and constipation are reportedly less than with morphine.
Hydromorphone (injectable)	Dog: 0.05–0.2 mg/kg IM, IV, or SC Cat: 0.05–0.2 mg/kg IM, IV, or SC Duration: 3–6 h	Moderate to severe pain	Similar side effects as those observed with morphine, but less vomiting and minimal histamine release. May be associated with hyperthermia in cats.
Fentanyl (injectable)	Dog: 0.002–0.01 mg/kg IV or IM Cat: 0.001–0.005 mg/kg IV or IM Duration: 0.5–2 h	Moderate to severe pain; CRI necessary for long-term analgesia	Sedation; respiratory depression; bradycardia; nausea; inadequate duration of analgesia from single IV bolus or IM injection.
Fentanyl (topical)	Dog: 1.3–2.7 mg/kg applied topically to the dorsal scapular area 2–4 h prior to surgery (RECUVYRA) Duration: 4 days	Severe pain	Sedation, decreased food and water intake: RECUVYRA Risk Minimization Action Plan (RiskMAP) training required to minimize risk of human exposure.

CRI = constant rate infusion.

Table VII-B

Recommended dispensable opioid dosages and indications			
Opioid	Dose/Route/Duration	Indications	Comments
Codeine (tablets)	Dog: 1.0–2.0 mg/kg PO Cat: 0.1–1.0 mg/kg PO Duration: 4–8 h	Mild to moderate pain	Minimal side effects; when dosed with acetaminophen, avoid in dogs with liver disease or Heinz body anemia; do not use in combination with acetaminophen in cats.
Butorphanol (tablets)	Dog: 0.5–1.0 mg/kg PO Cat: 0.5–1.0 mg/kg PO Duration: 2–4 h	Mild to moderate pain	Mild or no sedation; mild ventilatory depression.
Tramadol (immediate-release tablets)	Dog: 2–5 mg/kg PO q8–12h Cat: 2–5 mg/kg PO q8–12h	Mild to moderate pain	Sedation, anxiety, urinary retention.

PAIN MANAGEMENT (CONTINUED)

Table VII–C

Recommended parenteral NSAID dosages and indications			
NSAID	Dose/Route/Duration	Indications	Comments
Carprofen (injectable)	Dog: 2–4 mg/kg IV, SC q24h Cat: 1.0 mg/kg SC only once	Mild to moderate pain	Primarily used perioperatively before switching to oral formulation; GI irritation and altered renal function.
Meloxicam (injectable)	Dog: 0.2 mg/kg initially IM, IV, or SC; 0.1 mg/kg thereafter SC Cat: 0.1–0.2 mg/kg initially IM, SC (single dose only per label) Duration: 24 h	Mild to moderate pain	Can be mixed with food; GI irritation and altered renal function.
Ketoprofen (injectable)	Dog: 1.0–2.0 mg/kg initially IM, IV, or SC; 0.5–1.0 mg/kg thereafter SC Cat: 1.0–2.0 mg/kg initially IM, IV, or SC; 0.5–1.0 mg/kg thereafter SC Duration: 24 h	Mild to moderate pain; approved in Canada for dogs and cats and in the United States for horses	GI irritation and altered renal function. Dosing should not exceed 5 days for dogs and 3 days for cats.
Robenacoxib (injectable)	Dog: 2.0 mg/kg SC once prior to surgery; PO administration as per Table VII–D thereafter		

GI = gastrointestinal; NSAID = nonsteroidal anti-inflammatory drug.

Table VII–D

Recommended dispensable NSAID dosages and indications			
NSAID	Dosage/Route/Duration	Indications	Comments
Carprofen (tablets and chewables)	Dog: 4.4 mg/kg PO q24h or divided q12h Cat: 1.0 mg/kg PO (1 dose only) Duration: 12–24 h	Mild to moderate pain; approved for use in dogs with osteoarthritis or perioperative pain	Toxicity associated with chronic use in cats due to variable half-life; may cause GI irritation and altered renal function in some patients.
Deracoxib (chewable tablets)	Dog (post-operative pain): 3.0–4.0 mg/kg PO q24 h as needed for 7 days Dog (osteoarthritis): 1–2 mg/kg PO q24 h for long-term treatment over 7 days Duration: 24 h	Pain and inflammation associated with osteoarthritis. Post-operative pain and inflammation associated with orthopedic surgery in dogs with osteoarthritis.	GI irritation and altered renal function.
Firocoxib (chewable tablets)	Dog: 5 mg/kg PO q24 h	Pain and inflammation associated with osteoarthritis and perioperative pain	GI irritation and altered renal function.
Etodolac (tablets)	Dog: 10–15 mg/kg PO Cat: not used Duration: 24 h	Mild to moderate pain	Hypoproteinemia; GI irritation and altered renal function. Associated with KCS in a small number of dogs.
Aspirin (tablets)	Dog: 10–25 mg/kg PO Cat: 10–15 mg/kg PO Duration: 8–12 h for dogs, 24–72 h for cats	Mild to moderate pain and inflammation	GI irritation and altered renal function; more likely at higher doses.

(Continued)

PAIN MANAGEMENT (CONTINUED)

Table VII-D

Recommended dispensable NSAID dosages and indications (continued)			
NSAID	Dosage/Route/Duration	Indications	Comments
Meloxicam (oral liquid suspension, tablets)	Dog: 0.2 mg/kg initially PO; 0.1 mg/kg thereafter PO Cat: 0.1–0.2 mg/kg initially PO; 0.05–0.1 mg/kg thereafter PO (reduce to minimum effective dose) Duration: 24 h	Mild to moderate pain	GI irritation and altered renal function; can be mixed with food. Cats should not be given meloxicam for > 5 days.
Robenacoxib (oral tablets)	Dog: 1 mg/kg PO q24h for up to 12 days Cat: 1 mg/kg PO q24h for up to 3 days Duration: 24 h	Mild to moderate pain; not approved for dogs in US	GI irritation and altered renal function.
Ketoprofen (tablets)	Dog: 1.0–2.0 mg/kg initially PO; 0.5–1.0 mg/kg thereafter PO Cat: 1.0–2.0 mg/kg initially PO; 0.5–1.0 mg/kg thereafter PO Duration: 24 h	Mild to moderate pain; approved in Canada for dogs and cats and in the United States for horses	GI irritation and altered renal functions. Limit administration to 5 days for both dogs and cats.
Acetaminophen (tablets and oral liquid suspension)	Dog: 10–15 mg/kg PO Cat: contraindicated Duration (in dogs): 8–12 h	Mild to moderate pain; low anti-inflammatory action	Toxic to cats; often given in combination with codeine to dogs (see oral analgesic preparations).

GI = gastrointestinal; NSAID = nonsteroidal anti-inflammatory drug; KCS = keratoconjunctivitis sicca.

Table VII-E

Dosages and indications for selected drugs used to treat neuropathic pain			
Drug	Dosage/Route	Duration (PO)	Comments
Ketamine (NMDA antagonist)	Dog: 0.1–1.0 mg/kg IM, SC, or PO Cat: 0.1–1.0 mg/kg IM or SC	4–6 h 4–6 h	Low doses potentiate postoperative analgesics. Do not use with intracranial hypertension.
Amantadine (NMDA antagonist)	Dog: 3.0–5.0 mg/kg PO Cat: 3.0–5.0 mg/kg PO	24 h 24 h	Used to potentiate or prolong analgesia. Efficacious when combined with an NSAID for management of osteoarthritis-associated pain in dogs.
Amitriptyline (tricyclic antidepressant)	Dog: 1.0 mg/kg PO Cat: 2.5–10.0 mg/cat PO	12–24 h 24 h	Used to potentiate or prolong analgesia.
Gabapentin (antiepileptic)	Dog: 2–10 mg/kg PO q8–12h; dose can be titrated up to 20 mg/kg q8–12h if necessary Cat: 1–8 mg/kg PO q8–12h	24 h 24 h	Usually associated with few side effects other than sedation, and, occasional ataxia in cats. Has shown good results in human and animal studies.

To select and administer an adjuvant analgesic properly, the veterinarian should be aware of the drug's clinical pharmacology. The following information about the drug is necessary: (1) approved indication, (2) unapproved indication (e.g., as an analgesic) widely accepted in veterinary medical practice, (3) common side effects and potentially serious adverse effects, (4) pharmacokinetic features, and (5) specific dosing guidelines for pain.

NMDA = *N*-methyl-D-aspartate.

APPENDIX VIII

CHRISTOPHER L. MARIANI

GLOSSARY OF TERMINOLOGY FOR SEIZURES AND EPILEPTIC DISORDERS

GLOSSARY OF TERMINOLOGY FOR SEIZURES AND EPILEPTIC DISORDERS

There is no formally approved classification system for seizures or epilepsy in veterinary medicine and authors proposing such systems in the past have largely adapted human classification schemes (1–5). This proposed glossary is no different and is based mainly on publications sanctioned by the International League Against Epilepsy (ILAE) (6–11). Terms have been added, changed or eliminated to better reflect the seizure types seen in veterinary patients and the challenges inherent with the interpretation of such events in animals. This glossary is adapted from a more detailed proposal of terminology for veterinary patients (12), and interested readers are referred to this work for more details on seizure description and semiology, background on ILAE classification and adaptations for animals, and rationale for the currently proposed terms.

GENERAL TERMS AND DEFINITIONS

Seizure: a discrete episode suspected to be epileptic in origin. Synonym: ictus.

Epileptic seizure: manifestation(s) of excessive and/or hypersynchronous activity of neurons in the brain; usually self-limiting.

Epilepsy: a chronic neurologic condition characterized by recurrent seizures; has an intracranial origin.

Focal seizure: a seizure whose initial signs indicate, or are consistent with, initial activation of only part of one cerebral hemisphere. Synonym: partial.

Generalized seizure: a seizure whose initial signs indicate, or are consistent with, more than minimal involvement of both cerebral hemispheres.

CLASSIFICATION OF EPILEPTIC SEIZURES

1. Motor Seizures: involving somatic musculature in any form. May consist of an increase (positive) or decrease (negative) in muscle contraction to produce a movement.

1A. Elementary Motor: a single type of contraction of a muscle or group of muscles that is usually stereotyped.

• **Tonic:** a sustained increase in muscle contraction lasting a few seconds to minutes.

• **Myoclonic:** sudden, brief (< 100 ms), involuntary single or multiple contractions of muscles or muscle groups of variable topography (axial, proximal limb, distal limb, facial).

◦ **Clonic:** myoclonus that is regularly repetitive, involves the same muscle groups,

at a frequency of approximately 2–3 per second, and is prolonged.

• **Tonic-clonic:** a sequence consisting of a tonic followed by a clonic phase.

◦ **Generalized tonic-clonic seizure:** bilateral symmetric tonic contraction and then bilateral clonic contractions of somatic muscles, usually associated with autonomic phenomena and loss of consciousness. Synonyms: grand mal seizure, bilateral tonic-clonic seizure, major motor seizure.

• **Atonic:** sudden loss or diminution of muscle tone without an apparent preceding myoclonic or tonic event lasting greater than 1–2 seconds and involving the head, trunk, jaw or limb musculature.

• **Astatic:** loss of erect posture that results from an atonic, myoclonic or tonic mechanism. Synonym: drop attack.

1B. Automatism: a more or less coordinated, repetitive, motor activity usually occurring when cognition is impaired. Often resembles a voluntary movement. Examples might include chewing, licking, aimless running, or vocal utterances (e.g., barking, meowing, whining or growling).

2. Non-motor Seizures

Aura: an ictal phenomenon that may precede an observable seizure or if occurring alone, constitutes a sensory seizure.

Sensory seizure: a perceptual experience not caused by appropriate stimuli in the external world.

Note: Although sensory seizures almost certainly occur in animals, documenting their existence is obviously very difficult without the ability of the patient to describe sensory phenomena. Therefore, we are left to observe the behavior that the suspected sensory seizure produces. Some potential sensory phenomena include visual events (e.g., flashing or flickering lights, or other objects or patterns; the animal may bite or snap in response (“fly biting”)), somatosensory events (tingling, numbness or electric-shock sensations; the animal may bite or lick itself or run frantically during episode), auditory, olfactory, gustatory and affective events (e.g., fear, depression, joy or anger; the animal may become aggressive towards people or other animals).

Dyscognitive seizure: events in which disturbance of cognition is the predominant or most apparent feature.

Note: In the ILAE glossary, cognition is composed of perception, attention, emotion, memory and executive function (which includes decision making and initiation of motor activity) (8). In animals,

without a description from the patient it may again be difficult to prove that certain dyscognitive seizure types exist or differentiate them from sensory seizures. However, certain examples (e.g., events where animals suddenly stop what they are doing and stare into space, often with a lack of appropriate responsiveness to external stimuli (“behavioral arrest”)) might be best classified here.

3. Autonomic Seizures: an objectively documented and distinct alteration of autonomic nervous system function involving cardiovascular, pupillary, gastrointestinal, sudomotor, vasomotor, and thermoregulatory functions.

MODIFIERS AND DESCRIPTORS OF SEIZURE TIMING

Duration: time between the beginning of initial seizure manifestations and the cessation of observed seizure activity. Does not include prodrome or postictal states but might include aura.

Cluster seizures: two or more seizures within a 24-hour period. Synonyms: acute repetitive seizures, serial seizures

Status epilepticus: 1) a seizure that persists for greater than 5 minutes or 2) recurrent seizures without interictal resumption of baseline central nervous system function.

Prodrome: a pre-ictal phenomenon. A subjective or objective clinical alteration (e.g., agitation, attention-seeking) that heralds the onset of an epileptic seizure but does not form part of it.

Note: It may be quite challenging or impossible to differentiate a prodrome (pre-ictal period) from an aura (start of ictus) in many veterinary patients although videotaping of the episodes, close observation and/or ictal electroencephalography may be helpful in this regard.

Postictal phenomenon: a transient clinical abnormality of central nervous system function that appears or becomes accentuated when clinical signs of the ictus have ended. May manifest as impaired mentation, altered behavior or motor or sensory deficits.

Provocative factor: transient and sporadic endogenous or exogenous element capable of augmenting seizure incidence in animals with chronic epilepsy or evoking seizures in susceptible individuals without epilepsy.

• **Reactive:** occurring in association with transient systemic perturbation or illness such as some metabolic conditions (e.g., hypoglycemia, electrolyte disorders) or intoxications.

• **Reflex:** objectively and consistently demonstrated to be evoked by a specific

(Continued)

afferent stimulus or by activity of the patient. Examples include stimuli such as light flashes, certain noises or startling and activities such as specific motor movements or more complex behaviors.

CLASSIFICATION OF EPILEPSY

Epilepsy is defined here as a chronic neurologic disorder that causes recurrent seizure activity, and that has an intracranial etiology. As stated by the ILAE Classification Core Group in 2006, “the diagnosis of epilepsy implies a persistent epileptogenic abnormality of the brain that is able to spontaneously generate paroxysmal activity. This is in contrast to a brain that has an acute seizure as a natural response to a transient insult or loss of homeostasis” (10). Thus, seizures caused by extracranial disorders such as metabolic conditions (e.g., hypoglycemia, electrolyte abnormalities) or toxins are not considered to be epilepsy, even when repetitive seizures occur over time (e.g., with hypoglycemia secondary to an insulinoma). These seizures are termed reactive seizures (see definition under “provocative factor” above).

Note however that such a disorder might secondarily cause structural damage to a previously normal brain (e.g., through necrosis or excitotoxicity) and result in true epilepsy. An explanation of the term “idiopathic epilepsy” is also warranted here, as veterinarians use the word “idiopathic” in various ways. Some use this term to imply epilepsy of genetic or heritable origin (as it was originally intended for use in humans), while others use “idiopathic” to mean “cause unknown.” The following classification is proposed to replace those previously used in veterinary medicine and has been adapted from a 2010 ILAE report (11).

Genetic epilepsy: Epilepsy as a direct result of a known or strongly suspected genetic defect or defects in which seizures are the core

sign of the disorder. Generally, genetic epilepsies have no identifiable structural brain lesion or other neurologic signs, and have an age-dependent onset. Synonyms: Primary, inherited, idiopathic (for some).

Structural epilepsy: Epilepsy as a result of one or more identifiable structural lesions of the brain. Synonyms: Symptomatic, secondary. Structural epilepsies include disorders such as brain tumors, encephalitis, and cerebrovascular accidents. Note that some disorders that may have a genetic cause or that are strongly heritable may still be best classified here; these include anomalous disorders such as hydrocephalus, lissencephaly, degenerative disorders such as ceroid lipofuscinosis, and others.

Unknown epilepsy: The underlying cause of the epilepsy is unknown. This may be the result of a subtle structural lesion that is undetectable with currently available diagnostic technologies or an as yet unrecognized genetic disorder. Synonyms: Cryptogenic, probably symptomatic, idiopathic (for some).

APPENDIX IX

MARK G. PAPICH

Blackwell's Five-Minute Consult Drug Formulary

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Acepromazine (PromAce and many generic brands)	Phenothiazine tranquilizer. Inhibits action of dopamine as neurotransmitter. Used for sedation and preanesthetic purposes.	Phenothiazines can cause sedation as a common side effect. May cause α -adrenergic blockade. Produces extrapyramidal side effects in some individuals.	Usually used as preanesthetic in combination with other drugs. When used as preanesthetic, dose is ordinarily 0.02–0.2 mg/kg IM, SC, IV.	5, 10, 25 mg tablet and 10 mg/mL injection	Dog: Sedation 0.5–2.2 mg/kg PO q6–8h, or 0.02–0.1 mg/kg IV, IM, SC in a single dose. Do not exceed 3 mg total dose in dogs Cat: Sedation 1.13–2.25 mg/kg PO q6–8h, or 0.02–0.1 mg/kg IM, SC, IV in a single dose
Acetaminophen (Tylenol and many generic brands)	Analgesic agent. Exact mechanism of action is not known. <i>Not a prostaglandin synthesis inhibitor.</i>	Well tolerated in dogs at doses listed. High doses have caused liver toxicity. <i>Do not administer to cats.</i>	Many OTC formulations available. Acetaminophen with codeine may have synergistic analgesic efficacy in some animals.	120, 160, 325, 500 mg tablets	Dog: 15 mg/kg PO q8h Cat: not recommended
Acetaminophen with codeine (Tylenol with codeine and many generic brands)	Same as above, except the opiate codeine is added to enhance analgesia	See Codeine and Acetaminophen.	See Codeine and Acetaminophen.	Oral solution and tablets. Many forms, for example: 300 mg acetaminophen plus either 15, 30, or 60 mg codeine	Dog: Follow dosing recommendations for codeine Cat: Contraindicated
Acetazolamide (Diamox)	Glaucoma, Ca inhibitor	Can potentially produce hypokalemia in some patients. Significant bicarbonate loss can occur with repeated administration. In dogs, possible respiratory acidosis.	In combination with other agents, is usually used to decrease intraocular pressure in treatment of glaucoma. Has been used to produce alkaline urine to prevent formation of some urinary calculi.	125, 250 mg tablets	5–10 mg/kg PO q8–12h (glaucoma); 4–8 mg/kg PO q8–12h (other diuretic uses)
Acetylcysteine (Mucomyst)	Decreases viscosity of secretions. Used as mucolytic agent in eyes and in bronchial nebulizing solutions. However, as a donator of sulphydryl group, used as antidote for intoxications (e.g., acetaminophen toxicosis in cats).	May cause sensitization with prolonged topical administration. May react with certain materials in nebulizing equipment.	Available as agent for decreasing viscosity of respiratory secretions, but most common use is as a treatment for intoxications	20% solution	Antidote: 140 mg/kg (loading dose), then 70 mg/kg q4h IV or PO for 5 doses Eye: 2% solution topically q2h
Acetylsalicylic acid	See Aspirin.				

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
ACTH	See Corticotropin.				
Activated charcoal	See Charcoal, activated.				
Adequan	See Polysulfated glycosaminoglycan (PSGAG).				
Albendazole (Valbazen)	Benzimidazole antiparasitic drug. Inhibits glucose uptake in parasites.	At approved doses, there is a wide margin of safety. Adverse effects can include anorexia, lethargy, and bone marrow toxicity. At high doses, has been associated with bone marrow toxicity. Adverse effects are possible when administered for longer than 5 days.	Used primarily as antihelmintic, but also has demonstrated efficacy for giardiasis	113.6 mg/mL suspension and 300 mg/mL paste	25–50 mg/kg q12h PO × 3 days For <i>Giardia</i> , use 25 mg/kg q12h × 2 days For respiratory parasites, use 50 mg/kg q24h PO × 10–14 days
Albuterol (Proventil, Ventolin)	β_2 -adrenergic agonist. Bronchodilator. Stimulates β_2 receptors to relax bronchial smooth muscle. May also inhibit release of inflammatory mediators, especially from mast cells.	Causes excessive β -adrenergic stimulation at high doses (tachycardia, tremors). Arrhythmias occur at toxic doses. Avoid use in pregnant animals.	Doses are primarily derived from extrapolation of human dose. Well-controlled efficacy studies in veterinary medicine are not available. Onset of action is 15–30 min; duration of action may be as long as 8 h.	2, 4, 5 mg tablets; 2 mg/5 mL syrup	20–50 μ g/kg q6–8h; or up maximum of 100 μ g/kg q6h
Allopurinol (Lopurin, Zylorprim)	Decreases production of uric acid by inhibiting enzymes responsible for uric acid synthesis. Also used for leishmaniasis	May cause skin reactions (hypersensitivity)	Used in people primarily for treating gout. In animals, used to decrease formation of uric acid uroliths.	100, 300 mg tablets	For urate urolith, 10 mg/kg q8h, then reduce to 10 mg/kg q24h, PO For leishmaniasis, use 10 mg/kg q12h PO for at least 4 months
Alprazolam (Xanax)	Tranquilizer Benzodiazepine	Excess sedation; paradoxical excitement	Often combined with other sedatives and anesthetics	0.25, 0.5, 1, and 2 mg tablets	Dog: 0.025–0.1 mg/kg q8h, PO Cat: 0.125 mg per cat, PO q8h
Alumunium carbonate gel (Basaljel)	Antacid (neutralizes stomach acid), and phosphate binder in intestine	Generally safe. May interact with other drugs administered orally.	Antacid doses are designed to neutralize stomach acid, but duration of acid suppression is short.	Capsules (equivalent to 500 mg aluminum hydroxide)	10–30 mg/kg PO q8h (with meals)
Aluminium hydroxide gel (Amphojel)	Antacid (neutralizes stomach acid), and phosphate binder in intestine	Generally safe. May interact with other drugs administered orally.	Antacid doses are designed to neutralize stomach acid, but duration of acid suppression is short.	64 mg/mL oral suspension; 600 mg tablet	10–30 mg/kg PO q8h (with meals)

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Amikacin (Amiglyde-V [veterinary] and Amikin [human])	Aminoglycoside antibacterial drug (inhibits protein synthesis). Mechanism is similar to other aminoglycosides (see Gentamicin sulfate), but may be more active than gentamicin.	May cause nephrotoxicosis with high doses or prolonged therapy. May also cause ototoxicity and vestibulotoxicity.	Once-daily doses are designed to maximize peak minimum inhibitory concentration (MIC) ratio.	50, 250 mg/mL injection	Dog: 15–30 mg/kg q24h IV, IM, SC Cat: 10–14 mg/kg q24h IV, IM, SC
Aminopentamide (Centrine)	Antidiarrheal drug. Anticholinergic (blocks acetylcholine at parasympathetic synapse).	Use cautiously in animals with GI stasis or when anticholinergic drugs are contraindicated (e.g., glaucoma).	Dosing guidelines based on manufacturer's recommendation	0.2 mg tablets; 0.5 mg/mL injection	Dog: 0.01–0.03 mg/kg q8–12h IM, SC, PO Cat: 0.1 mg/cat q8–12h IM, SC, PO
6-Aminosalicylic acid	See Mesalamine, Olsalazine.				
Amiodarone (Cordarone)	Class III antiarrhythmic agent with potassium-channel blocking properties; indicated for severe refractory atrial and ventricular arrhythmias	Most common effect in dogs is decreased appetite. Prolonged QT interval is a concern. Other adverse effects include: bradycardia, chronic heart failure (CHF), hypotension, atrioventricular (AV) block, thyroid dysfunction, pulmonary fibrosis, and hepatotoxicity. Acute cardiac toxicity has been observed in dogs.	Use for recurrent hemodynamically unstable ventricular tachycardia; takes weeks to achieve therapeutic levels. Typically, loading doses are administered, followed by maintenance dose. Safe doses for injection have not been established.	100, 200, 300, 400 mg tablets; 50 mg/mL injection	Dog: start with 10–15 mg/kg q12h PO for 1 week, then 5–7 mg/kg q12h for 2 weeks Maintenance doses are 7.5 mg/kg q24h, PO Cat: no safe dose established
Amitraz (Mitaban)	Antiparasitic drug for ectoparasites. Used for treatment of mites, including <i>Demodex</i> . Inhibits monoamine oxidase in mites.	Causes sedation in dogs (α 2-agonist), which may be reversed by yohimbine or atipamezole. When high doses are used, other side effects reported include pruritus, polyuria and polydipsia (PU/PD), bradycardia, hypothermia, hyperglycemia, and (rarely) seizures.	Manufacturer's dose should be used initially. But, for refractory cases, this dose has been exceeded to produce increased efficacy.	10.6 mL concentrated dip (19.9%)	10.6 mL per 7.5 L water (0.025% solution). Apply 3–6 topical treatments q14d. For refractory cases, this dose has been exceeded to produce increased efficacy. Doses that have been used include: 0.025, 0.05, and 0.1% concentration applied 1–2× per week In extreme cases 0.125% solution applied to one-half of the body alternating side the next day, every day for 4 weeks to 5 months

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Amitriptyline hydrochloride (Elavil)	Tricyclic antidepressant drug. Action is via inhibition of uptake of serotonin and other transmitters at presynaptic nerve terminals. Used in animals to treat variety of behavioral disorders, such as anxiety. Used in cats for chronic idiopathic cystitis.	Multiple side effects are associated with tricyclic antidepressants, such as antimuscarinic effects (dry mouth, rapid heart rate) and antihistamine effects (sedation). High doses can produce life-threatening cardiotoxicity. In cats, reduced grooming, weight gain, and sedation are possible.	Doses are primarily based on empiricism. There are no controlled efficacy trials available for animals. There is evidence for success treating idiopathic cystitis in cats. Clomipramine is preferred for behavior problems.	10, 25, 50, 75, 100, 150 mg tablets	Dog: 1–2 mg/kg PO q12–24h Cat: 2–4 mg per cat/day PO (0.5–1.0 mg/kg PO/day. May be divided into 12h intervals.); cystitis: 2 mg/kg/day PO (2.5–7.5 mg/cat/day)
Amlodipine besylate (Norvasc)	Calcium channel-blocking drug of the dihydropyridine class. Decreases calcium influx in cardiac and vascular smooth muscle. Its greatest effect is as a vasodilator. In cats and dogs, it is used to treat hypertension.	Can cause hypotension and bradycardia. Use cautiously with other vasodilators.	In cats, efficacy has been established at 0.625 mg/cat once daily. If cats are large size (> 4.5 kg) or refractory, increase to higher dose (J Vet Int Med 12:157–162, 1998).	2.5, 5, and 10 mg tablets	Dog: 2.5 mg/dog, or 0.1 mg/kg once daily PO Cat: 0.625 mg/cat initially, PO once daily, and increase if needed to 1.25 mg/cat (average is 0.18 mg/kg, once daily for hypertension)
Ammonium chloride (generic)	Urine acidifier	Do not use in patients with systemic acidemia. May be unpalatable when added to some animals' food.	Doses are designed to maximize urine acidifying effect.	Available as crystals	Dog: 100 mg/kg q12h PO Cat: 800 mg/cat (approximately 1/3 to 1/4 tsp) mixed with food daily
Amoxicillin (Amoxi-Tabs, Biomox, and other brands. [Omnipen, Principen, Totacillin are human forms])	β -lactam antibiotic. Inhibits bacterial: cell wall synthesis. Generally broad-spectrum activity. Used for a variety of infections in all species.	Usually well tolerated. Allergic reactions are possible. Diarrhea is possible with oral doses.	Dose recommendations vary depending on the susceptibility of bacteria and location of infection.	50, 100, 150, 200, 400 mg tablets; 250 and 500 mg capsules; 50 mg/mL oral suspension (human forms)	6.6–20 mg/kg q8–12h PO
Amoxicillin + clavulanate potassium (Clavamox)	β -lactam antibiotic + β -lactamase inhibitor (clavulanate/clavulanic acid)	Same as for amoxicillin	Same as for amoxicillin	62.5, 125, 250, 375 mg tablets and 62.5 mg/mL suspension	Dog: 12.5–25 mg/kg q12h PO Cat: 62.5 mg/cat q12h PO.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Amphotericin B (Fungizone)	Antifungal drug. Fungicidal for systemic fungi, by damaging fungal membranes.	Produces a dose-related nephrotoxicosis. Also produces fever, phlebitis, and tremors.	Administer IV via slow infusion diluted in fluids, and monitor renal function closely. When preparing IV solution, do not mix with electrolyte solutions (use D-5-W, for example); administer NaCl fluid loading before therapy.	50 mg injectable vial	Dog: 0.5 mg/kg IV (slow infusion) q48h to a cumulative dose of 4–8 mg/kg Cat: 0.25 mg/kg IV (slow infusion) q48h
Amphotericin B, liposomal formulation (ABLC, Abelcet)	Same indications as for conventional amphotericin B. Liposomal formulations may be used at higher doses, and safety margin is increased. Expense is much higher than for conventional formulations.	Renal toxicity is the most dose-limiting effect.	Higher doses can be used compared to conventional formulation of amphotericin B. Dilute in 5% dextrose in water to 1 mg/mL, and administer IV over 1–2 hours.	100 mg/20 mL in lipid formulation	Dog: 2–3 mg/kg IV 3 times/week for 9–12 treatments to a cumulative dose of 24–27 mg/kg Cat: 1 mg/kg IV 3 times/week for up to 12 treatments
Ampicillin (Omnipen, Principen, others [human forms])	β -lactam antibiotic. Inhibits bacterial cell wall synthesis.	Use cautiously in animals allergic to penicillin-like drugs.	Dose requirements vary depending on susceptibility of bacteria. Absorbed approximately 50% less, compared with amoxicillin, when administered orally.	250, 500 mg capsules; 125, 250, 500 mg vials of ampicillin sodium. Ampicillin trihydrate: 10 and 25 g vials for injection	Ampicillin sodium: 10–20 mg/kg q6–8h IV, IM, SC or 20–40 mg/kg q8h PO Ampicillin trihydrate: Dog: 10–50 mg/kg q12–24h IM, SC Cat: 10–20 mg/kg q12–24h IM, SC
Ampicillin + sulbactam (Unasyn)	Ampicillin plus a β -lactamase inhibitor (sulbactam). Sulbactam has similar activity as clavulanate.	Same as for ampicillin	Same as for amoxicillin + clavulanate.	2:1 combination for injection. 1.5 and 3 g vials	10–20 mg/kg IV, IM q8h
Ampicillin trihydrate (Polyflex)	β -lactam antibiotic. Inhibits bacterial cell wall synthesis.	Use cautiously in animals allergic to penicillin-like drugs.	Absorption is slow and may not be sufficient for acute serious infection.	10, 25 mg vials for injection	Dog: 10–50 mg/kg q12–24h IM, SC Cat: 10–20 mg/kg q12–24h IM, SC
Amprolium (Corid)	Enteric coccidiostat	Toxicity observed only at high doses. CNS signs are caused by thiamin deficiency, which may be reversed by adding thiamin to the diet.	Used to control and treat coccidiosis in puppies. It is administered orally, often mixed with food.	9.6% (9.6 g/dL) oral solution; soluble powder	1.25 g of 20% amprolium powder to daily feed, or 30 mL of 9.6% amprolium solution to 3.8 L of drinking water for 7 days

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Antacid drugs	See Aluminum hydroxide, Magnesium hydroxide, Calcium carbonate.				
Apomorphine hydrochloride (generic)	Emetic drug. Causes emesis via dopamine release or direct effects on chemoreceptor trigger zone	Produces emesis before serious adverse effects occur. Use cautiously in cats that may be sensitive to opiates.	Consult local poison center or pharmacist for availability. Not as effective in cats as dogs.	6 mg tablets 10 mg/mL ampule or 3 mL preloaded syringes	0.03–0.05 mg/kg IV IM, 0.1 mg/kg SC, or instill 0.25 mg in conjunctiva of eye (dissolve 6 mg tablet in 1–2 mL of saline)
Ascorbic acid (Vitamin C)	Vitamin. Used as acidifier.	Toxicity only at very high doses	Primarily used as nutritional supplement, but high doses have been used for treatment of certain diseases.	Various forms, including 250 mg/ml sodium ascorbate	100–500 mg/animal/day (diet supplement), or 100 mg/animal q8h (urine acidification)
L-Asparaginase (Elspar)	Anticancer agent. Purified enzyme from <i>E. coli</i> . Used in lymphoma protocols. Depletes cancer cells of asparagine and interferes with protein synthesis.	Hypersensitivity, allergic reactions	Usually used in combination with other drugs in cancer chemotherapy protocols	10,000 U per vial for injection	Dog: 400 U/kg IM weekly or 10,000 U/m ² weekly × 3 weeks Cat: 400 U/kg SC weekly
Aspirin (many generic and brand names [Bufferin, Ascriptin])	Nonsteroidal anti-inflammatory drug (NSAID). Anti-inflammatory action is generally considered to be caused by inhibition of prostaglandins. Used as analgesic, anti-inflammatory, and antiplatelet drug.	Narrow therapeutic index. High doses frequently cause vomiting. Other GI effects can include ulceration and bleeding. Cats susceptible to salicylate intoxication because of slow clearance. Use cautiously in patients with coagulopathies because of platelet inhibition.	Analgesic and anti-inflammatory doses have primarily been derived from empiricism. Antiplatelet doses are lower because of prolonged effect of aspirin on platelets.	81, 325 mg tablets	Mild analgesia: (dog) 10 mg/kg q12h PO Anti-inflammatory: Dog: 20–25 mg/kg q12h PO Cat: 10–20 mg/kg q48h PO Antiplatelet: Dog: 5–10 mg/kg q24–48h PO Cat: 81 mg/cat q48–72h PO
Atenolol (Tenormin)	β-adrenergic blocker. Relatively selective for β ₁ -receptor. Used primarily as an antiarrhythmic or for other cardiovascular conditions to slow sinus rate.	Bradycardia and heart block are possible. May produce bronchospasm in sensitive patients.	Dosing precautions are similar to other β-blocking drugs. Atenolol is reported to be less affected by changes in hepatic metabolism than other β-blockers.	25, 50, 100 mg tablets	Dog: 6.25–12.5 mg/dog q12–24h (or 0.25–1.0 mg/kg q12–24h), PO Cat: 6.25–12.5 mg per cat q12h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Atipamezole (Antisedan)	α_2 -antagonist. Used to reverse α_2 -agonists, such as dexmedetomidine and xylazine.	Can cause some initial excitement in some animals shortly after reversal.	When used to reverse dexmedetomidine, inject same volume as used for dexmedetomidine.	5 mg/mL injection	Inject same volume as used for dexmedetomidine. Range of doses = 0.32 mg/kg for small animals to 0.14 mg/kg for large dogs
Atovaquone (Mepron)	In animals, it has been used, often in combination with azithromycin, to treat refractory protozoan diseases and bloodborne pathogens. In dogs, it has been used to treat Babesia gibsoni.	Adverse effects have not been reported in animals. In people, adverse reactions consist of skin rash, cough, and diarrhea.	There has been only limited experience for treatment of infections in animals. A few clinical trials have shown efficacy when combined with azithromycin for treatment of protozoa infections.	750 mg/5 mL liquid oral suspension (150 mg/mL)	Dog: 13.3 mg/kg q8h, PO for 10 days, usually in combination with azithromycin (10 mg/kg q24h, PO) Cat: 15 mg/kg q8h, PO, in combination with azithromycin (10 mg/kg q24h)
Atracurium (Tracrium)	Neuromuscular blocking agent (nondepolarizing). Competes with acetylcholine at neuromuscular end plate. Used primarily during anesthesia or other conditions in which it is necessary to inhibit muscle contractions.	Produces respiratory depression and paralysis. Neuromuscular blocking drugs have no effect on analgesia.	Administer only in situations in which careful control of respiration is possible. Doses may need to be individualized for optimum effect. Do not mix with alkalinizing solutions or lactated Ringer's solution.	10 mg/mL injection	0.2 mg/kg IV initially, then 0.15 mg/kg every 30 min (or IV infusion at 4–9 μ g/kg/min)
Atropine (many generic brands)	Anticholinergic agent (blocks acetylcholine effect at muscarinic receptor), parasympatholytic. Used primarily as adjunct to anesthesia or other procedures to increase heart rate and decrease respiratory and gastrointestinal secretion. Also used as antidote for organophosphate intoxication.	Potent anticholinergic agent. Do not use in patients with glaucoma, intestinal ileus, gastroparesis, or tachycardia. Side effects of therapy include xerostomia, ileus, constipation, tachycardia, urine retention.	Used ordinarily as adjunct with anesthesia or other procedures. Do not mix with alkaline solutions.	400, 500, 540 μ g/mL injection; 15 mg/mL injection	0.02–0.04 mg/kg q6–8h IV, IM, SC; 0.2–0.5 mg/kg IV, IM (as needed) for organophosphate and carbamate toxicosis

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Azathioprine (Imuran)	Thiopurine immunosuppressive drug. Acts to inhibit T cell lymphocyte function. This drug is metabolized to 6-mercaptopurine, which may account for immunosuppressive effects. Used to treat various immune-mediated disease.	Bone marrow suppression is most serious concern. Cats particularly are susceptible. There has been some association with development of pancreatitis when administered with corticosteroids.	Usually used in combination with other immunosuppressive drugs (such as corticosteroids) to treat immune-mediated disease. Doses of 2.2 mg/kg in cats have produced toxicity.	25, 50, 75, and 100 mg tablets; 10 mg/mL for injection	Dog: 2 mg/kg q24h PO initially then 0.5–1 mg/kg q48h Cat (use cautiously): 0.3 mg/kg q24h PO initially, then q48h, with careful monitoring (will require compounding)
Azithromycin (Zithromax)	Azalide antibiotic. Similar mechanism of action as macrolides (erythromycin), which is to inhibit bacteria protein synthesis via inhibition of ribosome. Spectrum is primarily gram-positive.	Vomiting is likely with high doses. Diarrhea may occur in some patients.	Azithromycin may be better tolerated than erythromycin. Primary difference from other antibiotics is the high intracellular concentrations achieved.	250 mg capsules, 250 and 600 mg tablets, 100 or 200 mg/5 mL oral suspension, and 500 mg vials for injection	Dog: 5–10 mg/kg PO once daily for 5–7 days then tapering to q48h Cat: 5–10 mg/kg PO once daily for 7 days, then tapering to q48h; upper respiratory infection: 15 mg/kg q72h PO
AZT (Azidothymidine)	See Zidovudine.				
BAL (British antilewisite)	See Dimercaprol.				
Benazepril (Lotensin)	Angiotensin-converting enzyme (ACE) inhibitor. Used for hypertension and heart failure. Action is similar to enalapril and captopril	Similar to those for captopril and enalapril	Dose is based on approved use in dogs in Europe and Canada. Monitor renal function and electrolytes 3–7 days after initiating therapy and periodically thereafter.	5, 10, 20, 40 mg tablets	Dog: 0.25–0.5 mg/kg q24h PO, may be increased to 1 mg/kg in dogs that are not responsive. Cat (systemic hypertension and renal disease): 0.5–1 mg/kg q24h PO, or 2.5 mg/cat per day up to maximum of 5 mg/cat per day PO
Bethanechol chloride (Urecholine)	Muscarinic, cholinergic agonist. Parasympathomimetic. Stimulates gastric and intestinal motility, but primarily used to increase contraction of urinary bladder.	High doses of cholinergic agonists will increase motility of GI tract and cause abdominal discomfort and diarrhea. Can cause circulatory depression in sensitive animals.	Administer injection SC only, <i>not</i> IV. Doses are derived from extrapolation of human doses or via empiricism. There are no well-controlled efficacy studies available for veterinary species.	No longer commercially available. However, available through compounding pharmacies	Dog: 5–15 mg/dog q8h PO Cat: 1.25–5 mg/cat q8h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Bisacodyl (Dulcolax)	Laxative/cathartic. Acts via local stimulation of GI motility, most likely by irritation of bowel. Used primarily as laxative or for procedures in which bowel evacuation is necessary.	Avoid use in patients with renal disease. Avoid overuse.	Available as OTC tablet. Doses are derived from extrapolation of human doses or via empiricism. There are no well-controlled efficacy studies available for veterinary species. Onset of action is approx. 1 h.	5 mg tablets	Dog: 5 mg/animal q8–24h PO Cat: 5 mg/cat q24h PO
Bismuth subsalicylate (Pepto-Bismol)	Antidiarrhea agent and GI protectant. Anti-prostaglandin action of salicylate component may be beneficial for enteritis. Bismuth component is efficacious or treating infections caused by spirochete bacteria (<i>Helicobacter gastritis</i>).	Adverse effects are uncommon; however, salicylate component is absorbed systemically, and overuse should be avoided in animals that cannot tolerate salicylates (such as cats and animals allergic to aspirin). Owners should be warned that bismuth will discolor stools.	Available as OTC product. Doses are derived from extrapolation of human doses or via empiricism. There are no well-controlled efficacy studies available for veterinary species.	Oral suspension: 262 mg/15 mL, or 525 mg/mL in extra strength formulation; 262 mg tablets	1–3 mL/kg/day (in divided doses) PO
Bleomycin (Blenoxane)	Anticancer, antibiotic agent. Used for treatment of various sarcomas and carcinomas. Exact mechanism of action is unknown, but may bind to DNA and prevent synthesis.	Causes local reaction at site of injection. Causes pulmonary toxicity in people as well as fever and chills, but side effects are not well documented in veterinary species.	Injectable solution usually used in combination with other anticancer agents. Consult anticancer protocols for details regarding use.	15 U vials for injection	Dog: 10 U/m ² IV or SC q24h for 3 days, then 10 U/m ² weekly (maximum cumulative dose 200 U/m ²)
Budesonide (Entocort)	Corticosteroid. Budesonide is a locally-acting corticosteroid. It is designed to release locally – in the intestine – after oral administration. Only a small fraction is absorbed systemically. Budesonide is used to treat inflammatory bowel disease.	No serious adverse effects are reported. However, some systemic absorption may cause glucocorticoid effects in animals (such as adrenal suppression).	The capsules are designed for human use. When administering to animals, do not disrupt the coating on the drug or the intestinal release may be compromised.	1, 3 mg capsule	0.125 mg/kg q6–8h, PO. Dose interval may be increased to every 12 hours when condition improves

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Bunamidine hydrochloride (Scolaban)	Used as anticestodal agent. Primarily to treat tapeworm infections in dogs and cats. Mechanism of action is to damage integrity of protective integument on parasite.	Vomiting and diarrhea have occurred after use. Avoid use in young animals.	Do not break tablets. Administer tablets on empty stomach. Do not feed for 3 h after administration.	100, 200, 400 mg tablets	20–50 mg/kg once PO
Bupivacaine hydrochloride (Marcaine, and generics)	Local anesthetic. Inhibits nerve conduction via sodium channel blockade. Longer-acting and more potent than lidocaine or other local anesthetics.	Adverse effects rare with local infiltration. High doses absorbed systemically can cause nervous system signs (tremors and convulsions). After epidural administration, respiratory paralysis is possible with high doses.	Used for local infiltration or infusion into epidural space. One may admix 0.1 mEq sodium bicarbonate per 10 mL solution to increase pH, decrease pain from injection, and increase onset. Use immediately after mixing with bicarbonate.	2.5 and 5 mg/mL solution injection	1 mL of 0.5% solution per 10 cm for an epidural
Buprenorphine hydrochloride (Buprenex [Vetergesic in the UK]) Simbadol	Opioid analgesic. Partial μ -receptor agonist, κ -receptor antagonist. 25–50 \times more potent than morphine. Buprenorphine may cause less respiratory depression than other opiates.	Adverse effects are similar to other opiate agonists, except there may be less respiratory depression. Dependency from chronic use may be less than with pure agonists.	Used for analgesia, often in combination with other analgesics or in conjunction with general anesthesia. Longer acting than morphine. Only partially reversed by naloxone	0.324 mg/mL solution, 1.8 mg/mL solution for SC administration in cats. For people, transdermal patches and buccal tablets also are available.	Dog: 0.02 mg/kg IV, IM, SC q4–8h Cat: 0.01–0.02 mg/kg IV, IM, q4–8h Buccal administration in cat: 0.02–0.04 mg/kg q8h, SC administration to cats using Symbadol 1.8 mg/mL solution: 0.24 mg/kg q24h, SC.
Buspirone (BuSpar)	Antianxiety agent. Acts by binding to serotonin receptors. In veterinary medicine, has been primarily used for treatment of urine spraying in cats.	Some cats show increased aggression; some cats show increased affection to owners.	Some efficacy trials suggest effectiveness for treating urine spraying in cats. There may be a lower relapse rate compared to other drugs.	5, 10, 15, and 30 mg tablets	Dog: 2.5–10 mg/dog q12–24h PO or 1 mg/kg q12h PO Cat: 2.5–5 mg/cat q12–24h PO (may be increased to 5–7.5 mg per cat twice daily for some cats)
Busulfan (Myleran)	Anticancer agent. Bifunctional alkylating agent and acts to disrupt DNA of tumor cells. Used primarily for lymphoreticular neoplasia.	Leukopenia is most severe side effect.	Usually used in combination with other anticancer agents. Consult specific protocol for details.	2 mg tablets	3–4 mg/m ² q24h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Butorphanol tartrate (Torbutrol, Torbugesic)	Opioid analgesic. κ -receptor agonist and weak μ -receptor antagonist. Butorphanol is used for perioperative analgesia, chronic pain, and as an antitussive agent.	Adverse effects are similar to other opioid analgesic drugs. Sedation is common at analgesic doses. Respiratory depression can occur with high doses. Dysphoric effects have been observed with some agonist/antagonist drugs.	Often used in combination with anesthetic agents or in conjunction with other analgesic drugs.	1, 5, 10 mg tablets; 0.5 or 10 mg/mL injection	Dog: (antitussive) 0.055 mg/kg q6–12h SC or 0.55–1 mg/kg q6–12h PO; (preanesthetic) 0.2–0.4 mg/kg IV, IM, SC (with acepromazine); (analgesic) 0.2–0.4 mg/kg q2–4h IV, IM, SC Cat (analgesic): 0.2–0.4 mg/kg q2–6h, IV, SC or 1.5 mg/kg PO q4–8h
Calcitriol (Rocaltrol, Calcijex)	Used to treat calcium deficiency and diseases such as hypocalcemia associated with hypoparathyroidism. Also used to lower parathyroid levels in patients with renal secondary hyperparathyroidism. Not indicated as vitamin D supplement. Action is to increase calcium absorption in intestine.	Overdose can result in hypercalcemia.	Doses should be adjusted in each patient according to response and monitoring of calcium plasma concentration, (hypoparathyroidism) or parathyroid levels (renal secondary hyperparathyroidism).	Available as injection (Calcijex) and capsules (Rocaltrol); 0.25, 0.5 μ g capsules, 1 or 2 μ g/mL injection, and 1 μ g/mL oral solution (Rocaltrol)	Dog: 2.5–3.5 ng/kg PO q24h Cat: 0.25 μ g/cat q48h PO Renal secondary hyperparathyroidism: 2.5–3.5 ng/kg PO q24h
Calcium carbonate (many brands available: Titrалac, Tums, generic)	Used as oral calcium supplement for hypocalcemia. Used as antacid to treat gastric hyperacidity and GI ulcers. Neutralizes stomach acid. Also used as intestinal phosphate binder for hyperphosphatemia.	Few side effects. Increased calcium concentrations are possible. <i>Drug interactions:</i> Avoid use with oral fluoroquinolones (e.g., ciprofloxacin, enrofloxacin) as it may decrease their absorption.	Doses are primarily derived from extrapolation of human doses. When used as calcium supplement, doses should be adjusted according to serum calcium concentrations.	Many tablets or oral suspension, e.g., 650 mg tablets (contain 260 mg calcium ion)	Phosphate binder: 60–100 mg/kg/day in divided doses PO with food Calcium supplementation: 70–180 mg/kg/day with food
Calcium chloride (generic)	Calcium supplement. Used in acute situations to supplement as electrolyte replacement or as a cardiotonic.	Overdose with calcium is possible. Do not administer IV solution SC or IM because it may cause tissue necrosis.	Injection is 27.2 mg of calcium ion (1.36 mEq) per mL. Usually used in emergency situations. Intracardiac administration has been performed, but avoid injections into the myocardium.	10% (100 mg/mL) solution	0.1–0.3 mL/kg IV (slowly)

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Calcium citrate (Citracal [OTC])	Calcium supplement. Used in treatment of hypocalcemia, such as with hypoparathyroidism.	Hypercalcemia possible with oversupplementation.	Doses should be adjusted according to serum calcium concentration.	950 mg tablets (contain 200 mg calcium ion)	Dog: 20 mg/kg/day PO (with meals) Cat: 10–30 mg/kg q8h PO (with meals)
Calcium disodium EDTA	See Eddetate calcium disodium.				
Calcium gluconate (Kalcinate and generic)	Calcium supplement. Used in treatment of hypocalcemia, such as with hypoparathyroidism. Used in electrolyte deficiency.	Hypercalcemia possible with over supplementation.	Injection is 97 mg (9.5 mg of calcium ion [0.47 mEq]) per mL. 500 mg tablets contain 45 mg of calcium ion. Avoid administration of IV solution IM or SC because it will cause tissue necrosis.	10% (100 mg/mL) injection	50–200 mg/kg IV (slowly)
Calcium lactate (generic)	Calcium supplement	Hypercalcemia possible with over supplementation.	Calcium lactate contains 130 mg of calcium ion per gram.	325 mg, 650 mg OTC tablets	Dog: 0.5 g/dog/day PO (in divided doses) Cat: 0.2–0.5 g/cat/day PO (in divided doses)
Captopril (Capoten)	ACE inhibitor. Inhibits conversion of angiotensin I to angiotensin II. Generally used to treat hypertension and congestive heart failure.	Hypotension possible with excessive doses. May cause azotemia in some patients, especially when administered with potent diuretics (furosemide). <i>Drug interactions:</i> Use cautiously with diuretics, potassium supplements. NSAIDs may diminish antihypertensive effect.	Monitor patients carefully to avoid hypotension. With all ACE inhibitors, monitor electrolytes and renal function 3–7 days after initiating therapy and periodically thereafter. Use of captopril has been replaced by enalapril and benazepril in dogs and cats.	25 mg tablet	Dog: 0.5–2 mg/kg q8–12h PO Cat: 3.12–6.25 mg/cat q8h PO
Carbimazole (Neomercazole)	Antithyroid drug converted to methimazole for activity.	Similar to methimazole, with perhaps fewer GI effects.	Used in Europe. Clinical experience in US is limited.	Available in Europe, but not US	Cat: 5 mg/cat q8h PO (induction), followed by 5 mg/cat q12h PO
Carboplatin (Paraplatin)	Anticancer agent. Used for treating various carcinomas. Interrupts replication of DNA in tumor cells by cross-linking. Used for squamous cell carcinoma and other carcinomas, melanoma, osteosarcomas, and other sarcomas. Action is similar to cisplatin.	Dose-limiting toxicosis is myelosuppression. May cause anemia, leukopenia, or thrombocytopenia. Carboplatin may induce renal toxicity. Compared to cisplatin, carboplatin is less emetogenic and less nephrotoxic. In cats, causes a dose-limiting neutropenia and thrombocytopenia with a nadir at 17 days.	Available for reconstitution for injection. Do not use with administration sets containing aluminum, because of incompatibility. Usually administered in specific anticancer protocols.	50 and 150 mg vial for injection	Dog: 300 mg/m ² every 3–4 weeks IV Cat: 200–227 mg/m ² every 4 weeks IV × 4 treatments

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Carprofen (Rimadyl; Zenecarp in the UK) Novox (generic)	NSAID. Used for treatment of pain and inflammation, particularly pain and inflammation associated with osteoarthritis. Shown to be safe and effective for perioperative use for surgical pain either by injection or PO. Carprofen's action may be via cyclooxygenase inhibition but is relatively COX-1 sparing.	Most common adverse effects in clinical patients have been GI (vomiting, nausea, diarrhea). Other adverse effects are more rare and include idiosyncratic hepatotoxicosis. If they occur, signs of hepatotoxicosis appear 2–3 weeks after beginning therapy. Perioperative use has not adversely affected renal function or bleeding times. Avoid use with other NSAIDs or with corticosteroids.	Doses are based on manufacturer's field trials and US registration data. Clinical trials conducted with canine patients with osteoarthritis and surgical patients. Injectable carprofen administered for surgery may be given 2 hours prior to the procedure.	25, 75, 100 mg tablets (regular and chewable); 50 mg/mL injectable solution	Dog: 4.4 mg/kg/day PO, administered either once a day or divided into 2.2 mg/kg q12h; 4.4 mg/kg/day SC, administered once daily or 2.2 mg/kg q12h Cat: 4 mg/kg one-time injection
Carvedilol (Coreg)	Nonselective β -blocker with α -blocking and antioxidant properties; indicated for systemic hypertension and upregulation of β -receptors in animals with myocardial failure.	Bradycardia, CHF due to initial myocardial depression. Adverse effects from nonselective β -blockade are possible, including weakness and bronchospasm.	Typical starting dose is 0.2 mg/kg q12h, then gradually titrate the dose upward to 0.4 mg/kg. If signs of heart failure worsen at higher doses, lower to the previously well-tolerated dose. Oral absorption highly variable in dogs.	3.125, 6.25, 12.5, 25 mg tablets	Dog: 0.2–0.4 mg/kg q12h PO. If not in heart failure, the dose could cautiously be titrated to 1.5 mg/kg q12h PO based on pharmacokinetic studies. Cat: no dose established
Cascara sagrada (many brands [e.g., Nature's Remedy])	Stimulant cathartic. Action is believed to be by local stimulation of bowel motility. Used as laxative to treat constipation or evacuate bowel for procedures.	Overuse can cause electrolyte losses.	Available in various OTC products.	100 and 325 mg tablets and oral liquid	Dog: 1–5 mg/kg/day PO Cat: 1–2 mg/cat/day PO
Castor oil (generic)	Stimulant cathartic. Action is believed to be by local stimulation of bowel motility. Used as laxative to treat constipation or evacuate bowel for procedures.	Overuse can cause electrolyte losses. Castor oil has been known to stimulate premature labor in pregnancy.	Available as OTC product	Oral liquid (100%)	Dog: 8–30 mL/day PO Cat: 4–10 mL/day PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Cefadroxil (Cefa-Tabs, Cefa-Drops)	Cefadroxil is a 1st-generation cephalosporin antibiotic.	Cefadroxil has been known to cause vomiting after oral administration in dogs.	Spectrum of cefadroxil is similar to other 1st-generation cephalosporins. For susceptibility test, use cephalothin as test drug.	50 mg/mL oral suspension; 50, 100, 200, 1000 mg tablet. Availability of some oral formulations is inconsistent.	Dog: 22 mg/kg q12h, up to 30 mg/kg q12h PO Cat: 22 mg/kg q24h PO
Cefazolin sodium (Ancef, Kefzol, and generic)	Cefazolin is a 1st-generation cephalosporin antibiotic.	Adverse effects uncommon.	Commonly used 1st-generation cephalosporin as injectable drug for prophylaxis for surgery as well as for acute therapy for serious infections.	50 and 100 mg/50 mL for injection	20–35 mg/kg q8h IV, IM. For perisurgical use: 22 mg/kg q2h IV during surgery.
Cefepime (Maxipime)	4th-generation cephalosporin with broader spectrum than other classes.	Similar adverse effects as other cephalosporins.	Dosing regimens are based on pharmacokinetic studies in dogs.	500 mg; 2 g vials for injection	Dog: 40 mg/kg q6h IM or IV
Cefotaxime sodium (Claforan)	Cefotaxime is a 3rd-generation cephalosporin. Cefotaxime is used when resistance is encountered to other antibiotics or when infection is in central nervous system.	Similar to those of other cephalosporins.	3rd-generation cephalosporin used when resistance encountered to 1st- and 2nd-generation cephalosporins.	500 mg; 1, 2, and 10 g vials for injection	Dog: 50 mg/kg IV, IM, SC q12h Cat: 20–80 mg/kg q6h IV, IM
Cefovecin (Convenia)	3rd-generation cephalosporin for injection in dogs and cats. Very long half-life compared to other cephalosporins.	Adverse effects may include transient GI problems.	Dose intervals are usually q14d in dogs and cats, or a single injection.	80 mg/mL vial for injection	Dog and Cat: 8 mg/kg SC every 14 days, injections may be repeated
Cefoxitin sodium (Mefoxin)	Cefoxitin is a 2nd-generation cephalosporin. May have increased activity against anaerobic bacteria.	Similar to those of other cephalosporins.	2nd-generation cephalosporin, which is often used when activity against anaerobic bacteria is desired.	1, 2, and 10 g vials for injection (20 or 40 mg/mL)	30 mg/kg q6–8h IV, IM, presurgical use: 22 mg/kg IV
Cefpodoxime proxetil (Simplicef)	Oral 3rd-generation cephalosporin. Activity includes gram-negative bacilli and staphylococcus.	Vomiting and diarrhea are the most common adverse effects.	Approved for skin and soft-tissue infections in dogs.	100, 200 mg tablets	Dog: 5–10 mg/kg PO q24h Cat: dose not established
Ceftazidime (Fortaz, Ceptaz, Tazicef)	3rd-generation cephalosporin. Ceftazidime has more activity than other cephalosporins against <i>Pseudomonas aeruginosa</i> .	Similar to those of other cephalosporins.	3rd-generation cephalosporin. May be reconstituted with 1% lidocaine for IM injection.	Vials (0.5, 1, 2, 6 g) reconstituted to 280 mg/mL	Dog and Cat: 30 mg/kg q6h IV, IM Dog: 30 mg/kg q4–6h SC

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Ceftiofur (Naxcel [ceftiofur sodium]; Excenel [ceftiofur HCl]).	Ceftiofur spectrum resembles many of the 3rd-generation cephalosporins.	Similar to those of other cephalosporins. Do not substitute the crystalline free acid (Excede) for Naxcel.	Available as powder for reconstitution prior to injection. After reconstitution, stable for 7 days when refrigerated or 12 h at room temperature, or frozen for 8 weeks.	50 mg/mL injection	2.2–4.4 mg/kg SC q24h (for urinary tract infections)
Cephalexin (Keflex and generic forms)	Cephalexin is a 1st-generation cephalosporin.	Similar to those of other cephalosporins.	Veterinary approved chewable formulations and human generic formulations are both used in veterinary medicine.	250, 500 mg capsules; 250, 500 mg tablets; 100 mg/mL oral suspension, and 125, 250 mg/5 mL oral suspension	Dog: 22–25 mg/kg q12h, PO Cat: 15–20 mg/kg q12h PO
Cetirizine (Zyrtec)	Antihistamine (H-1 blocker). It acts by blocking the histamine type-1 receptor (H1) and suppressing inflammatory reactions caused by histamine. The H1-blockers have been used to control pruritus and skin inflammation, rhinorrhea, and airway inflammation. Cetirizine is considered a 2nd-generation antihistamine, which may be associated with less sedation than older drugs.	No adverse effects have been reported in dogs or cats.	There are no studies published that demonstrate clinical efficacy in dogs and cats. Clinical use is based on experimental animals.	1 mg/mL oral syrup; 5 and 10 mg tablets	Dog: 2 mg/kg, q12h, PO Cat: 1 mg/kg per day, PO
Charcoal, activated (Acta-Char, Charcodote, Toxiban, generic)	Adsorbent. Used primarily to adsorb drugs and toxins in intestine to prevent their absorption	Not absorbed systemically. Safe for administration	Available in variety of forms; usually used as treatment of poisoning. Many commercial preparations contain sorbitol, which acts as flavoring agent and promotes intestinal catharsis.	Oral suspension and granules	1–4 g/kg PO (granules); 6–12 mL/kg (suspension)
Chlorambucil (Leukeran)	Cytotoxic agent. Acts in similar manner as cyclophosphamide as alkylating agent. Used for treatment of various tumors and immunosuppressive therapy.	Myelosuppression is possible.	Consult anticancer drug protocol for specific regimens.	2 mg tablets	Dog: 2–6 mg/m ² q24h initially, then q48h PO Cat: 0.1–0.2 mg/kg q24h initially, then q48h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Chloramphenicol and chloramphenicol palmitate (Chloromycetin, generic forms)	Antibacterial drug. Mechanism of action is inhibition of protein synthesis via binding to ribosome. Broad spectrum of activity.	Bone marrow suppression is possible with high doses or prolonged treatment (especially in cats). Avoid use in pregnant or neonatal animals. Drug interactions with other drugs (e.g., barbiturates) possible because chloramphenicol will inhibit hepatic microsomal enzymes.	Chloramphenicol palmitate requires active enzymes and should not be administered to fasted (or anorectic) animals. Note: Some forms of chloramphenicol are no longer available in the US.	30 mg/mL oral suspension (palmitate), 250 mg capsules, and 100, 250, and 500 mg tablets	Dog: 50 mg/kg q8h PO Cat: 50 mg/cat q12h PO or 12.5–20 mg/kg q12h PO
Chlorothiazide (Diuril)	Thiazide diuretic. Inhibits sodium reabsorption in distal renal tubules. Used as diuretic and antihypertensive. Since it decreases renal excretion of calcium, it also has been used to treat calcium-containing uroliths.	Do not use in patient with elevated calcium. May cause electrolyte imbalance, such as hypokalemia	Not as effective as high-ceiling diuretics (such as furosemide).	250 and 500 mg tablets, 50 mg/mL oral suspension, and injection vials of 500 mg	20–40 mg/kg q12h PO
Chlorpheniramine maleate (Chlor-Trimeton, Phenetron, and others)	Antihistamine (H ₁ -blocker). Blocks action of histamine on receptors. Also may have direct anti-inflammatory action. Used most often to prevent allergic reactions. Used for pruritus therapy in dogs and cats.	Sedation is most common side effect. Antimuscarinic effects (atropine-like effects) also are common.	Chlorpheniramine is included as ingredient in many OTC cough/cold and allergy medications.	4, 8 mg tablets, 2 mg/5 mL syrup, and 2 mg chewable tablets	Dog: 4–8 mg/dog q12h PO (up to a maximum of 0.5 mg/kg q12h) Cat: 2 mg/cat q12h PO
Chlorpromazine (Thorazine)	Phenothiazine tranquilizer/antiemetic. Inhibits action of dopamine as neurotransmitter. Most often used as central antiemetic. Also used for sedation and preanesthetic purposes.	Causes sedation. May cause α-adrenergic blockade. Produces extrapyramidal side effects in some individuals.	Used for vomiting caused by toxins, drugs, or GI disease. Higher doses than listed in dose section have been used with cancer chemotherapy (2 mg/kg q3h SC).	25 mg/mL injection solution	Dog: 0.5 mg/kg q6–8h IM, SC Cat: 0.2–0.4 mg/kg q6–8h IM, SC
Chorionic gonadotropin	See Gonadotropin, chorionic.				

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Cimetidine (Tagamet [OTC and prescription])	Histamine-2 antagonist (H ₂ -blocker). Blocks histamine stimulation of gastric parietal cells to decrease gastric acid secretion. Used to treat ulcers and gastritis.	Adverse effects usually seen only with decreased renal clearance. In people, CNS signs may occur with high doses. <i>Drug interactions:</i> May increase concentrations of other drugs used concurrently (e.g., theophylline) because of inhibition of hepatic enzymes.	Precise doses needed to treat ulcers have not been established.	100, 200, 300, 400, 800 mg tablets; 60 mg/mL oral solution; 6 mg/mL injection	10 mg/kg q6–8h IV, IM, PO
Ciprofloxacin (Cipro) and generic	Fluoroquinolone antibacterial. Acts to inhibit DNA gyrase and inhibit cell DNA and RNA synthesis. Bactericidal. Broad antimicrobial activity	Avoid use in dogs 4 weeks to 7 months of age. High concentrations may cause CNS toxicity, especially in animals with renal failure. Causes occasional vomiting. IV solution should be given slowly.	Efficacy studies have not been performed in dogs or cats. Ciprofloxacin is not absorbed orally as well as enrofloxacin.	250, 500, 750 mg tablets; 2 mg/mL injection	Dog: 20–25 mg/kg, PO, q24h 10–15 mg/kg IV, q24h Cat: 20 mg/kg, PO, q24h 10 mg/kg, IV, q24h
Cisapride	Prokinetic agent. Stimulates gastric and intestinal motility by either acetylcholine action, activity on serotonin receptors, or direct effect on smooth muscle. Used for gastric reflux, gastroparesis, ileus, constipation.	Contraindicated in patients with GI obstruction	Doses are based on extrapolation from human doses, experimental studies, and anecdotal evidence. Efficacy studies have not been performed in dogs or cats.	No longer commercially available. However, available through compounding pharmacies.	Dog: 0.1–0.5 mg/kg q8–12h PO (as high as 0.5–1.0 mg/kg q8h) Cat: 2.5–5 mg/cat q8–12h PO (as high as 1 mg/kg q8h)
Cisplatin (Platinol)	Anticancer agent. Used for treating various solid tumors, including osteosarcoma. Action is believed to be similar to bifunctional alkylating agents and interrupts replication of DNA in tumor cells.	Nephrotoxicity is the most limiting factor to cisplatin therapy. In cats, causes a dose-related, species-specific, primary pulmonary toxicosis. Vomiting may occur in dogs with administration. Transient thrombocytopenia may occur in dogs.	To avoid toxicity, fluid loading before administration using sodium chloride should be performed. Antiemetic agents are often administered before therapy to decrease vomiting.	1 mg/mL injection	Dog: 60–70 mg/m ² every 3–4 weeks IV (administer fluid for diuresis with therapy) Cat: Do not administer to cats

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Clarithromycin (Biaxin)	Macrolide antibiotic with bacteriostatic activity. Spectrum includes primarily gram-positive bacteria. Resistance is expected for most gram-negative bacteria. Efficacy is not established for animals. Most common use in people is for treatment of <i>Helicobacter</i> gastritis, and respiratory infections.	Well tolerated in animals. Most common side effects are vomiting, nausea, and diarrhea.	Doses are not established for animals due to lack of clinical trials. Dose recommendations are extrapolated from human or empirical use.	250, 500 mg tablets; 25 and 50 mg/mL oral suspension	7.5 mg/kg q12h PO
Clavamox	See Amoxicillin/clavulanate potassium.				
Clemastine (Tavist, Contac 12 Hour Allergy, and generic)	Antihistamine (H_1 -blocker). Blocks action of histamine on tissues. Used primarily for treatment of allergy. Some evidence suggests that clemastine is more effective than other antihistamines for pruritus in dogs.	Sedation is most common side effect.	Used for short-term treatment of pruritus in dogs. May be more efficacious when combined with other anti-inflammatory drugs. Tavist syrup contains 5.5% alcohol.	1.34 mg tablets (OTC), 2.64 mg tablets (Rx), and 0.134 mg/mL syrup	Dog: 0.05–0.1 mg/kg q12h PO
Clindamycin (Antirobe [veterinary], Cleocin [human])	Antibacterial drug of the lincosamide class (similar in action to macrolides). Inhibits bacterial protein synthesis via inhibition of bacterial ribosome. Primarily bacteriostatic, with spectrum of activity primarily against gram-positive bacteria and anaerobes.	Generally well tolerated in dogs and cats. Oral liquid product may be unpalatable to cats. Lincomycin and clindamycin may alter bacterial population in intestine and cause diarrhea; for this reason, do not administer to rodents or rabbits.	Most doses are based on manufacturer's drug approval data and efficacy trials. See dosing column for specific guidelines for different infections.	Oral liquid 25 mg/mL; 25, 75, 150, and 300 mg capsules, and 150 mg/mL injection (Cleocin)	Dog: 11–33 mg/kg q12h PO; for periodontal and soft tissue infection, 5.5–33 mg/kg q12h PO Cat: 11–33 mg/kg q24h PO; for skin and anaerobic infections, 11 mg/kg q12h PO; for toxoplasmosis, 12.5–25 mg/kg PO q12h
Clofazimine (Lamprene)	Antimicrobial agent used to treat feline leprosy. Slow bactericidal effect on <i>Mycobacterium leprae</i> .	Adverse effects have not been reported in cats. In people, the most serious adverse effects are GI.	Doses based on empiricism or extrapolation of human studies	50 and 100 mg capsules	Cat: 1 mg/kg up to a maximum 4 mg/kg/day PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Clomipramine (Clomicalm [veterinary]; Anafranil [human])	Tricyclic antidepressant (TCA) drug. Used in people to treat anxiety and depression. Used in animals to treat variety of behavioral disorders, including obsessive-compulsive disorders and separation anxiety. Action is via inhibition of uptake of serotonin at presynaptic nerve terminals.	Reported adverse effects include sedation, reduced appetite. Other side effects associated with TCAs are antimuscarinic effects (dry mouth, rapid heart rate) and antihistamine effects (sedation). Overdoses can produce life-threatening cardiotoxicity.	When adjusting doses, one may initiate therapy with low dose and increase gradually. There may be a 2–4 week delay after initiation of therapy before beneficial effects are seen.	5, 20, 80 mg tablets (veterinary); 10, 25, 50 mg tablets (human)	Dog: 1–2 mg/kg q12h PO Cat: 1–5 mg per cat q12–24h PO
Clonazepam (Klonopin)	Benzodiazepine. Action is to enhance inhibitory effects of γ -aminobutyric acid (GABA) in CNS. Used for antiseizure action, sedation, and treatment of some behavioral disorders.	Side effects include sedation and polyphagia. Some animals may experience paradoxical excitement.	Doses are based primarily on reports from human medicine, empiricism, or experimental studies. No clinical efficacy studies have been performed in dogs or cats.	0.5, 1, and 2 mg tablets	Dog: 0.5 mg/kg q8–12h PO Cat: 0.1–0.2 mg/kg q12–24h PO
Clopidogrel (Plavix)	Clopidogrel is used to inhibit platelets in patients that are prone to forming blood clots. In cats, clopidogrel has been recommended to prevent cardiogenic arterial thromboembolism associated with heart disease and atrial enlargement.	Bleeding complications can occur.	Administer with or without aspirin in patients prone to thrombi and emboli. The dose of 19 mg is approximately 1/4 of a human tablet.	75 mg tablets	Dog: 0.5–1 mg/kg q24h PO Oral loading dose of 2–4 mg/kg may be followed with 1 mg/kg q24h. Cat: 19 mg per cat (1/4 tablet), q24h PO
Clorazepate dipotassium (Tranxene)	Benzodiazepine. Action is to enhance inhibitory effects of GABA in CNS. Used for antiseizure action, sedation, and treatment of some behavioral disorders.	Side effects include sedation and polyphagia. Some animals may experience paradoxical excitement.	Doses are based primarily on reports from human medicine, empiricism, or experimental studies. No clinical efficacy studies have been performed in dogs or cats. Clorazepate tablets degrade quickly in presence of light, heat, or moisture. Keep in original packaging or in tightly sealed container.	3.75, 7.5, 11.25, 15 mg tablets	Dog: 0.5–2 mg/kg q8–12h, PO, but as frequently as q4h Cat: 0.2–0.4 mg/kg q12–24h PO (up to 0.5–2 mg/kg) q12h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Codeine (generic)	Opiate agonist. Mechanism is similar to morphine, except with approximately 1/10 potency of morphine. Poorly absorbed in dogs.	Primary adverse effect is sedation.	Available as codeine phosphate and codeine sulfate oral tablets. Doses listed for analgesia are considered initial doses; individual patients may need higher doses, depending on degree of tolerance or pain threshold.	15, 30, 60 mg tablets, 5 mg/mL syrup, 3 mg/mL oral solution	Dog: (analgesia) 0.5–1 mg/kg q4–6h PO; (antitussive) 0.1–0.3 mg/kg q4–6h PO Cat: (analgesia) 0.5 mg/kg q6h PO; (antitussive) 0.1 mg/kg q6h PO
Colchicine (generic)	Anti-inflammatory agent. Used primarily to treat gout. In animals, used to decrease fibrosis and development of hepatic failure (possibly by inhibiting formation of collagen)	Do not administer to pregnant animals. Adverse effects are not well documented in animals. Colchicine may cause dermatitis in people.	Doses based on empiricism. There are no well controlled efficacy studies in veterinary species.	600 µg tablets	0.01–0.03 mg/kg q24h PO
Colony-stimulating factor: Sargramostim (Leukine) and Filgrastim (Neupogen)	Stimulates granulocyte development in bone marrow. Used primarily to regenerate blood cells to recover from cancer chemotherapy or other therapy.	Pain from injection	Doses based on limited experimental information performed in dogs. Leukine: reconstitute with 1 mL sterile water to make solution of 250 or 500 µg/mL. Gently swirl, do not shake; then further dilute with sterile 0.9% saline to concentration less than 10 µg/mL for IV infusion.	300 µg/mL (Neupogen) and 250–500 µg/mL (Leukine)	Leukine: 0.25 mg/m ² q12h SC or IV infusion over 2h Neupogen: 0.005 mg/kg q24h SC × 2 weeks
Corticotropin (ACTH) (Acthar)	Used for diagnostic purposes to evaluate adrenal gland function. Stimulates normal synthesis of cortisol from adrenal gland.	Adverse effects unlikely when used as single injection for diagnostic purposes.	Doses established by measuring normal adrenal response in animals.	80 U/mL gel	Response test: Collect pre-ACTH sample and inject 2.2 IU/kg IM. Collect post-ACTH sample at 2 h in dogs and at 1 and 2 h in cats.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Cosyntropin (Cortrosyn)	Cosyntropin is a synthetic form of corticotropin (ACTH) used for diagnostic purposes only. In humans, it is preferred over corticotropin because it is less allergenic.	Same as for corticotropin	Use for diagnostic purposes only; not intended for treatment of hypoadrenocorticism. Maximum dosage for dog should be 250 µg. Frozen preparations can be stored for up to 6 months.	250 µg per vial	ACTH response test: collect pre-ACTH sample and inject 5 µg/kg IV or IM (dog) or 125 µg (0.125 mg) IM (cat) Cat: collect sample at 60 and 90 min after IV administration or 30 and 60 min after IM administration Dog: Collect post sample at 30 and 60 min
Cyanocobalamin (Vitamin B ₁₂) (many) and Cobalamin	Vitamin B ₁₂ analogue	Adverse effects rare except in high overdoses.	Adjust dose by monitoring. See Vitamin B ₁₂ for more information.	1000 µg/mL (= 1 mg/mL) injection; 25–100 µg tablets	Dog: 100–200 µg/day PO Cat: 50–100 µg/day PO, or 250 µg IM or SC weekly
Cyclophosphamide (Cytoxan, Neosar)	Cytotoxic agent. Bifunctional alkylating agent. Disrupts base-pairing and inhibits DNA and RNA synthesis. Cytotoxic for tumor cells and other rapidly dividing cells. Used primarily as adjunct for cancer chemotherapy and as immunosuppressive therapy	Bone marrow suppression is most common adverse effect. Can produce severe neutropenia (that usually is reversible). Vomiting and diarrhea may occur in some patients. Dogs are susceptible to bladder toxicity (sterile hemorrhagic cystitis). May cause hair loss when used in some chemotherapeutic protocols	Cyclophosphamide is usually administered with other drugs (other cancer drugs in cancer protocols or corticosteroids) when used for immunosuppressive therapy. Consult specific anticancer protocols for specific regimens.	25 mg/mL injection; 25, 50 mg tablet	Dog: Anticancer: 50 mg/m ² once daily 4 days/week PO, or 150–300 mg/m ² IV, and repeat in 21 days Immunosuppressive therapy: 50 mg/m ² (approx. 2.2 mg/kg) q48h PO, or 2.2 mg/kg once daily for 4 days/week Cat: 6.25–12.5 mg/cat once daily 4 days/week
Cyclosporine (Neoral [human], Atopica [veterinary], Optimmune [ophthalmic]. Other name for cyclosporine is cyclosporin A).	Immunosuppressive drug. Suppresses induction of T cell lymphocytes. Used for atopic dermatitis and treatment of immune-mediated diseases.	Can cause vomiting, diarrhea, anorexia. In comparison to other immunosuppressive drugs, does not cause myelosuppression. <i>Drug interactions:</i> erythromycin, or ketoconazole may increase cyclosporine concentrations when used concurrently.	Neoral oral products are the same formulation as Atopica. Topical cyclosporine has been used successfully as treatment for keratoconjunctivitis sicca.	10, 25, 50, and 100 mg capsules, 100 mg/mL oral solution	Dog: 5 mg/kg PO, once daily. Higher doses may be needed for some immune-mediated diseases. Cat: 7.5 mg/kg, PO, once daily.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Cyproheptadine hydrochloride (Periactin)	Phenothiazine with antihistamine and antiserotonin properties. Used as appetite stimulant (probably by altering serotonin activity in appetite center)	May cause increased appetite and weight gain	Clinical studies have not been performed in veterinary medicine. Use is based primarily on empiricism and extrapolation from human results. Syrup contains 5% alcohol.	4 mg tablet; 2 mg/5 mL syrup	Antihistamine: 0.5–1.1 mg/kg q8–12h PO Appetite stimulant: 2 mg/cat PO Feline asthma: 1–2 mg/cat q12h PO
Cytarabine (cytosine arabinoside) (Cytosar)	Anticancer agent. Exact mechanism is not known. Probably inhibits DNA synthesis. Used for lymphoma and leukemia protocols. Also used for meningoencephalitis.	Bone marrow suppression. Causes vomiting and nausea	Consult anticancer protocols for precise dosing regimens.	100 mg vial	Dog (lymphoma): 100–150 mg/m ² once daily, or 50 mg/m ² twice daily for 4 days IV, SC, or 600 mg/m ² IV, SC single dose Dog (meningoencephalitis): 50 mg/m ² twice daily for 2 days and repeated every 3 weeks SC Continuous rate intravenous (CRI) administration at 25 mg/m ² for 8 hours Cat: 100 mg/m ² once daily for 2 days
Dacarbazine (DTIC)	Anticancer agent. Monofunctional alkylating agent. Used for melanoma.	Leukopenia, nausea, vomiting, diarrhea. Do not use in cats.	Consult anticancer protocol for specific regimens.	200 mg vial for injection	Dog: 200 mg/m ² for 5 days every 3 weeks IV; or 800–1000 mg/m ² every 3 weeks IV
Dalteparin sodium (Fragmin)	Low molecular weight heparin (LMWH); anticoagulant; indicated for prevention of thromboembolism in at-risk patients. Anti-Xa: anti-IIa ratio: 2.7:1	May increase risk of bleeding.	No need to monitor clotting times as with conventional (unfractionated) heparin when dalteparin is used at recommended dosages. Dosages extrapolated from humans may not apply to dogs and cats.	16 mg (2500 U)/0.2 mL; 32 mg (5000 U)/0.2 mL prefilled syringes for injection; 64 mg (10,000 U) mL multidose vials for injection	Dogs: 150–175 U/kg, q8h, SC Cats: 150 U/kg, q4h, to 180 U/kg q6h, SC
Danazol (Danocrine)	Gonadotropin inhibitor. Suppresses luteinizing hormone (LH) and follicle-stimulating hormone (FSH) and estrogen synthesis. In humans, used for endometriosis. May reduce destruction of platelets or RBC in immune-mediated disease.	May cause signs similar to other androgenic drugs. Adverse effects have not been reported in animals.	When used to treat autoimmune disease, usually used in conjunction with other drugs (e.g., corticosteroids). Efficacy has not been evaluated.	50, 100, 200 mg capsules	5–10 mg/kg q12h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Dantrolene sodium (Dantrium)	Muscle relaxant. Inhibits calcium leakage from sarcoplasmic reticulum. In addition to muscle relaxation, it has been used for malignant hyperthermia. Also has been used to relax urethral muscle in cats.	Muscle relaxants can cause weakness in some animals.	Doses have been primarily extrapolated from experimental studies or extrapolation of human studies. No clinical trials available in veterinary medicine. Studies in which dantrolene relaxed urethra in cats used 1 mg/kg IV.	100 mg capsule and 0.33 mg/mL injection	For prevention of malignant hyperthermia: 2–3 mg/kg IV For muscle relaxation: Dog: 1–5 mg/kg q8h PO Cat: 0.5–2 mg/kg q12h PO
Dapsone (generic)	Antimicrobial drug used primarily for treatment of mycobacterium. May have some immunosuppressive properties or inhibit function of inflammatory cells. Used primarily for dermatologic diseases in dogs and cats.	Hepatitis and blood dyscrasias may occur. Toxic dermatologic reactions have been seen in people. <i>Drug interactions:</i> Do not administer with trimethoprim (may increase blood concentrations). Do not administer to cats.	Doses are derived from extrapolation of human doses or empiricism. No well-controlled clinical studies have been performed in veterinary medicine.	25 and 100 mg tablets	Dog: 1.1 mg/kg q8–12h PO Cat: do not use
Deferoxamine mesylate (Desferal)	Chelating agent with strong affinity for trivalent cations. Used to treat acute iron toxicosis. Indicated in cases of severe poisoning. Deferoxamine also has been used to chelate aluminum and facilitate removal.	Adverse effects have not been reported in animals. Allergic reactions and hearing problems have occurred in people.	100 mg of deferoxamine binds 8.5 mg of ferric iron. Monitor serum iron concentrations to determine severity of intoxication and success of therapy. Contact local poison control center for guidance. Successful therapy is indicated by monitoring urine color (orange-rose color change to urine indicates chelated iron is being eliminated).	500 mg vial for injection	10 mg/kg IV, IM q2h for 2 doses, then 10 mg/kg q8h for 24 h
Deprenyl (L-deprenyl)	See Selegiline.				

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Deracoxib (Deramaxx)	NSAID of the coxib class; high COX-1: COX-2 in vitro inhibitory ratio. Indicated for the control of postoperative pain and inflammation associated with orthopedic surgery and pain and inflammation associated with osteoarthritis.	Most common adverse effect from clinical trials has been GI (vomiting and diarrhea).	Recommended doses are for dogs weighing > 1.8 kg (4 lb). Safety has not been established for dogs under 4 months of age, dogs used for breeding, pregnant or lactating dogs, or for cats.	25, 100 mg tablets; chewable tablets	Dog (postoperative pain): 3.0–4.0 mg/kg q24h PO as needed for 7 days Dog (osteoarthritis): 1–2 mg/kg PO q24h for long-term treatment over 7 days Cat: 1 mg/kg PO, single dose
DES	See Diethylstilbestrol.				
Desmopressin acetate (DDAVP)	Synthetic peptide similar to antidiuretic hormone (ADH). Used as replacement therapy for patients with diabetes insipidus. Desmopressin also has been used for treatment of patients with mild to moderate von Willebrand disease prior to surgery or other procedure that may cause bleeding.	No side effects reported. In people, it rarely has caused thrombotic events.	Desmopressin is used only for central diabetes insipidus. Duration of effect is variable (8–20 h). It is ineffective for treatment of nephrogenic diabetes insipidus or polyuria from other causes. Intranasal product has been administered as eye drops in dogs. Onset of effect is within 1 h.	4 µg/mL injection and desmopressin acetate nasal solution 100 µg/mL (0.01%) metered spray. Tablets 0.1 and 0.2 mg.	Diabetes insipidus: 2–4 drops (2 µg) q12–24h intranasally or in eye. 0.05–0.1 mg q12h PO as needed. von Willebrand disease treatment: 1 µg/kg (0.01 mL/kg) SC, IV, diluted in 20 mL of saline administered over 10 min
Desoxycorticosterone pivalate (Percorten-V, DOCP, or DOCA pivalate)	Mineralocorticoid. Used for adrenocortico-insufficiency (hypoadrenocorticism). No glucocorticoid activity.	Excessive mineralocorticoid effects with high doses.	Initial dose based on studies performed in clinical patients. Individual doses may be based on monitoring electrolytes in patients. Actual interval between doses may range from 14–35 days.	25 mg/mL Injection	1.5–2.2 mg/kg every 25 days IM
Dexamethasone (Dexamethasone solution and dexamethasone sodium phosphate) (Azium, Decaject SP, Dexavet, and Dexasone. Tablets include Decadron and generic)	Corticosteroid. Dexamethasone has approximately 30× potency of cortisol. Multiple anti-inflammatory effects.	Corticosteroids produce multiple systemic side effects and adverse effects from chronic therapy.	Doses based on severity of underlying disease. Dexamethasone is used for testing hyperadrenocorticism. Low-dose dexamethasone suppression test: dogs 0.01 mg/kg IV, cats 0.1 mg/kg IV, and collect sample at 0, 4, and 8 hours. For high-dose dexamethasone suppression test: dogs 0.1 mg/kg IV, cats 1.0 mg/kg IV.	Azium solution, 2 mg/mL. Sodium phosphate forms are 3.33 mg/mL. 0.25, 0.5, 0.75, 1, 1.5, 2, 4, 6 mg tablets, 0.1 and 1 mg/mL oral solution	Anti-inflammatory: 0.07–0.15 mg/kg q12–24h IV, IM, PO Dexamethasone 21-isonicotinate 0.03–0.05 mg/kg IM

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Dexmedetomidine (Dexdomitor)	Alpha-2 agonist; similar to medetomidine, except it is more specific because it is the active isomer. Used for sedation, analgesia, and anesthesia; may be used with other anesthetics and sedatives.	Vomiting may occur. Use cautiously in animals with heart disease.	Doses may vary depending on degree of sedation desired. Reverse with equal volume of atipamezole (Antisedan).	0.5 mg/mL injection, and a lower concentration of 0.1 mg/mL in sterile vials	Dog: 125 µg/m ² IM (3–9 µg/kg) 375 µg/m ² IV or 500 µg/m ² IM for deeper anesthesia. Cat: 40 µg/kg IM, lower doses of 10 µg/kg for short-term sedation.
Dextran (Dextran 70, Gentrant 70)	Synthetic colloid used for volume expansion. High molecular weight fluid replacement. Primarily used for acute hypovolemia and shock.	Only limited use in veterinary medicine, and adverse effects have not been reported. In people, coagulopathies are possible because of decreased platelet function. Anaphylactic shock also has occurred.	Used primarily in critical care situations. Delivered via constant rate infusion slowly. Monitor patient's cardiopulmonary status carefully during administration.	Injectable solution 250, 500, 1000 mL	Dog: 10–20 mL/kg IV over 30–60 min Cat: 5–10 mL/kg IV over 30–60 min
Dextrose solution 5% (D-5-W)	Sugar added to fluid solutions. Isotonic	High doses produce pulmonary edema.	Commonly used fluid solution administered via constant rate infusion. <i>Not a maintenance solution</i>	Fluid solution for IV administration	40–50 mL/kg q24h IV
Diazepam (Valium and generic)	Benzodiazepine. Central-acting CNS depressant. Mechanism of action appears to be via potentiation of GABA-receptor mediated effects in CNS. Used for sedation, anesthetic adjunct, anticonvulsant, and behavioral disorders. Diazepam metabolized to desmethyldiazepam (nordiazepam) and oxazepam.	Sedation is most common side effect. May cause paradoxical excitement in dogs. Causes polyphagia. In cats, idiopathic fatal hepatic necrosis has been reported.	Clearance in dogs is many times faster than in people (half-life in dogs less than 1 h); requires frequent administration. For treatment of status epilepticus, may be administered IV intranasal, or rectally. Avoid administration IM.	2, 5, 10 mg tablets; 5 mg/mL solution for injection	Preanesthetic: 0.5 mg/kg IV Status epilepticus: 0.5 mg/kg IV, 1 mg/kg rectal; repeat if necessary Appetite stimulant (cat): 0.2 mg/kg IV For behavior treatment in cats: 1–4 mg/cat q12–24h PO
Dichlorvos (Task)	Antiparasitic drug, used primarily to treat hookworms, roundworms, whipworms. Kills parasites by anticholinesterase action.	Do not use in heartworm-positive patients. Overdoses can cause organophosphate intoxication. (Treat with 2-PAM, atropine.)	Doses based on manufacturer's recommendations	10, 25 mg tablets	Dog: 26.4–33 mg/kg PO Cat: 11 mg/kg PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Diethylstilbestrol (DES)	Synthetic estrogen compound. Used for estrogen replacement in animals. DES is most commonly used to treat estrogen-responsive incontinence in dogs. Also has been used to induce abortion in dogs	Side effects may occur that are caused by excess estrogen. Estrogen therapy may increase risk of pyometra and estrogen-sensitive tumors.	Doses listed are for treating urinary incontinence and vary depending on response. Titrate dose to individual patients. Although used to induce abortion, it was <i>not</i> efficacious in one study that administered 75 µg/kg.	1, 5 mg tablets; 50 mg/mL injection (no longer manufactured in US, but available from compounding pharmacist)	Dog: 0.1–1.0 mg/dog q24h PO. After initial response, reduce frequency to 2–3× per week. Cat: 0.05–0.1 mg/cat q24h PO
Digoxin (Lanoxin, Cardoxin)	Cardiac ionotropic agent. Increases cardiac contractility and decreases heart rate. Mechanism is via inactivation of cardiac muscle sodium-potassium ATPase. Beneficial effects for heart failure may occur via neuroendocrine effects (alters sensitivity of baroreceptors). Used in heart failure for ionotropic effect and to decrease heart rate. Used in supraventricular arrhythmias to decrease ventricular response to atrial stimulation.	Digitalis glycosides have narrow therapeutic index. May cause variety of arrhythmias in patients (e.g., heart block, ventricular tachycardia). Causes vomiting, anorexia, diarrhea. Adverse effects potentiated by hypokalemia, reduced by hyperkalemia. Some breeds of dogs (Doberman pinschers) and cats are more sensitive to adverse effects.	Monitor patients carefully. Optimum plasma concentration is 1–2 ng/mL. Adverse effects common at concentration above 3.5 ng/mL. When dosing, calculate dose on lean body weight. Doses should be 10% less for elixir because of increased absorption.	0.0625, 0.125, 0.25 mg tablets; 0.05 and 0.15 mg/mL elixir	Dog: 0.0025–0.005 mg/kg q12h PO Cat: 0.008–0.01 mg/kg q48h PO (approximately 1/4 of a 0.125 mg tablet/cat)
Dihydrotachysterol (Vitamin D, Hytakerol)	Treatment of hypocalcemia, especially hypoparathyroidism associated with thyroidectomy. The most common use is for replacement in cats that have had thyroidectomy for treatment of hyperthyroidism.	Overdose may cause hypercalcemia.	Doses for individual patients should be adjusted by monitoring serum calcium concentrations.	No formulations are currently available in the US. It can only be obtained from some compounding pharmacies.	0.01 mg/kg/day PO. Acute treatment: 0.02 mg/kg initially, then 0.01–0.02 mg/kg q24–48h PO thereafter. The dose should be adjusted on the basis of measuring calcium concentrations. Effective doses can range from 0.1 to 0.3 mg/kg.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Diltiazem (Cardizem, Dilacor)	Calcium channel-blocking drug. Blocks calcium entry into cells via blockade of slow channel. Produces vasodilation, negative chronotropic effects. Used for supraventricular arrhythmias in dogs; hypertrophic cardiomyopathy in cats	Hypotension, cardiac depression, bradycardia, AV block. May cause anorexia in some patients	Higher doses of 5 mg/kg PO q8h has been used in some dogs for atrial fibrillation.	30, 60, 90, 120 mg tablets. 5 mg/mL injection. Extended release capsules are 60, 90, 120, 180, 240, 300 mg.	Dog: 0.5–1.5 mg/kg q8h PO, 0.25 mg/kg over 2 min IV (repeat if necessary) Cat: 1.75–2.4 mg/kg q8h PO. For Dilacor XR or Cardizem CD, dose is 10 mg/kg once daily PO. In cats use either Dilacor XR 30 or Dilacor XR 60 per cat.
Dimenhydrinate (Dramamine, [Gravol in Canada])	Antihistamine drug. Converted to active diphenhydramine. Used for antiemetic treatment.	Primary side effect is sedation.	There have been no clinical studies on the use of dimenhydrinate. It is primarily used empirically for treatment of vomiting.	50 mg tablets and 50 mg/mL injection	Dog: 4–8 mg/kg q8h PO, IM, IV Cat: 12.5 mg/cat q8h IV, IM, PO
Dimercaprol (BAL) (BAL in Oil)	Chelating agent, used to treat lead, gold, arsenic toxicity.	Adverse effects not reported in veterinary medicine. In people, sterile abscesses occur at injection site. High doses have caused seizures, drowsiness, and vomiting.	Use as soon as possible after intoxicant exposure. Alkalization of urine will increase toxin removal. For lead intoxication, may be used with edetate calcium.	Injection, usually prepared by compounding	4 mg/kg q4h IM
Dinoprost tromethamine	See Prostaglandin F2α.				
Diocetyl calcium sulfosuccinate	See Docusate calcium.				
Diocetyl sodium sulfosuccinate	See Docusate sodium.				
Diphenhydramine hydrochloride (Benadryl)	Antihistamine used for allergy treatment and antiemetic	Primary side effect is sedation.	Antihistamine used primarily for allergic disease in animals.	Available OTC; 2.5 mg/mL elixir; 25, 50 mg capsules and tablets; 50 mg/mL injection	Dog: 2.2 mg/kg q8–12h PO, IM, SC Cat: 2–4 mg/kg q6–8h PO, or 1 mg/kg q6–8h IM, IV
Diphenoxylate (Lomotil)	Opiate agonist. Stimulates smooth muscle segmentation in intestine, as well as electrolyte absorption. Used for acute treatment of nonspecific diarrhea.	Adverse effects have not been reported in veterinary medicine. Diphenoxylate is poorly absorbed systemically and produces few systemic side effects. Excessive use can cause constipation.	Doses are based primarily on empiricism or extrapolation of human dose. Clinical studies have not been performed in animals. Contains atropine, but dose is not high enough for significant systemic effects.	2.5 mg tablets	Dog: 0.1–0.2 mg/kg q8–12h PO Cat: 0.05–0.1 mg/kg q12h PO
Diphenylhydantoin	See Phenytoin.				
Diphosphonate disodium etidronate	See Etidronate disodium.				

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Dipyridamole (Persantine)	Platelet inhibitor. Mechanism of action is attributed to increased levels of cyclic adenosine monophosphate (cAMP) in platelet, which decreases platelet activation. Indicated to prevent thromboembolism	Adverse effects have not been reported in animals.	Used primarily in people to prevent thromboembolism. Use in animals has not been reported. When used in people, it is combined with other antithrombotic agents (e.g., warfarin).	25, 50, 75 mg tablets; 5 mg/mL injection	4–10 mg/kg q24h PO
Dirlotapide (Slentrol)	Dirlotapide is one of the microsomal triglyceride transfer protein (MTP) inhibitors used to treat obesity in dogs. The MTP inhibitors block the processing of lipid molecules in the enterocytes of the intestine. Release of lipids from enterocytes is blocked, causing decreased appetite in dogs.	It will decrease appetite in all dogs in which it is effective (the mechanism for producing weight loss). Anorexia and vomiting will be observed in some animals. Diarrhea also is possible. Liver enzymes may become elevated in some dogs.	The dosing regimen must be followed closely and a program of regular evaluation (weighing the dog) and dose adjustment with each visit is necessary for successful therapy.	Oral oil-based solution 5 mg/mL	Dog: Start with 0.01 mL/kg/day PO. Adjust by doubling the dose in two weeks. monthly adjustments to dose should be done on the basis of animal's weight loss. Do not exceed 0.2 mL/kg/day Cat: do not administer to cats
Disopyramide (Norpace [Rythmodan in Canada])	Antiarrhythmic agent of Class 1. Depresses myocardial electrophysiologic conduction rate	Adverse effects have not been reported in animals. High doses may cause cardiac arrhythmias.	Not commonly used in veterinary medicine. Other antiarrhythmic drugs are preferred.	100, 150 mg capsules (10 mg/mL injection in Canada only)	Dog: 6–15 mg/kg q8h PO
Dithiazanine iodide (generic)	Microfilaricidal drug for dogs. Also effective for hookworms, roundworms, and whipworms	Adverse effects are rare. Causes vomiting in some dogs. Causes discoloration of feces	Before ivermectin and similar drugs, this was the only microfilaricidal agent for dogs. Not commonly used and may not be commercially available anymore	10, 50, 100, 200 mg tablets	Dog: (heartworm) 6.6–11 mg/kg q24h PO for 7–10 days; (other parasites) 22 mg/kg PO Cat: no dose established
Dobutamine hydrochloride (Dobutrex)	Adrenergic agonist. Action is primarily to stimulate myocardium via action on cardiac β_1 -receptors. Increases heart contraction without increase in heart rate. Some action may occur via α -receptors. Primarily used for acute treatment of heart failure	May cause tachycardia and ventricular arrhythmias at high doses or in sensitive individuals.	Dobutamine has a rapid elimination half-life (minutes) and therefore must be administered via carefully monitored constant rate infusion. When mixing, avoid alkalinizing solutions. Usually dilute in 5% dextrose solution (e.g., 250 mg in 1 L 5% dextrose).	250 mg/20 mL vial for injection (12.5 mg/mL)	Dog: 5–20 μ g/kg/min IV infusion Cat: 2 μ g/kg/min IV infusion

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Docusate calcium (Surfak, Doxidan)	Stool softener (surfactant). Acts to decrease surface tension to allow more water to accumulate in the stool	No adverse effects reported in animals. In people, high doses have caused abdominal discomfort.	Doses are based on extrapolations from humans or empiricism. No clinical studies reported for animals. Docusate calcium products may contain stimulant cathartic phenolphthalein, which should be used cautiously in cats.	60 mg tablets (and many others)	Dog: 50–100 mg/dog q12–24h PO Cat: 50 mg/cat q12–24h PO
Docusate sodium (Colace, Doxan, Doss; many OTC brands)	See Docusate calcium.	See Docusate calcium.	See Docusate calcium.	50, 100 mg capsules; 10 mg/mL liquid	Dog: 50–200 mg/dog q8–12h PO Cat: 50 mg/cat q12–24h PO
Dolasetron mesylate (Anzemet)	Antiemetic drug. Acts by inhibiting serotonin (5-HT, type 3) receptors. Used for antiemetic therapy, especially from vomiting induced by chemotherapy.	No adverse effects have been reported in animals.	The use of serotonin antagonists is based primarily on experience from human medicine. There have been no efficacy trials in veterinary medicine. It is more effective if used to prevent vomiting, rather than inhibiting on-going vomiting.	50, 100 mg tablets; 20 mg/mL injection	Prevention of nausea and vomiting: 0.6 mg/kg IV or PO q12–24h. Treating vomiting and nausea: 1.0 mg/kg PO or IV q24h
Dopamine hydrochloride (Intropin)	Adrenergic agonist. Action is primarily to stimulate myocardium via action on cardiac β_1 -receptors. There is no evidence to support the use for acute kidney injury.	May cause tachycardia and ventricular arrhythmias at high doses or in sensitive individuals. High doses cause vasoconstriction via α -receptor action.	Dopamine has a very rapid elimination half-life (minutes) and therefore must be administered via carefully monitored constant rate infusion. When mixing, avoid alkalinizing solutions. Administer in 5% dextrose solution or lactated Ringer's solution. Mix 200–400 mg in 250 to 500 mL of fluid.	40, 80, or 160 mg/mL for IV injection	2–10 μ g/kg/min IV infusion
Doxapram hydrochloride (Dopram, Respiram)	Respiratory stimulant via action on carotid chemoreceptors and subsequent stimulation of respiratory center. Used to treat respiratory depression or to stimulate respiration post anesthesia. May also increase cardiac output.	Adverse effects not reported in animals. Cardiovascular effects and convulsions have occurred with high doses in people. Contains benzyl alcohol as a vehicle.	Used for short-term treatment only. No longer available from manufacturer.	20 mg/mL injection	5–10 mg/kg IV; neonate: 1–5 mg SC, sublingual, or via umbilical vein

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Doxorubicin (Adriamycin)	Anticancer agent. Acts to intercalate between bases on DNA, disrupting DNA and RNA synthesis in tumor cell. Doxorubicin also may affect tumor cell membranes. Used for treatment of various neoplasias, including lymphoma	Most common acute effects are anorexia, vomiting, and diarrhea. Dose-related toxicity also includes bone marrow suppression, hair loss (in certain breeds), and cardiotoxicity. Cardiotoxicity limits the total dose administered (usually not to exceed 200 mg/m ²).	Regimen listed may differ for various tumors. Consult specific anticancer protocol for guidelines. Dose must be infused IV (over 20–30 min). Animals may require antiemetic and antihistamine (diphenhydramine) prior to therapy. Monitor ECG during therapy. Dose according to body weight may be more effective for small dogs.	2 mg/mL injection	Dog: 30 mg/m ² IV every 21 days, or: > 20 kg, use 30 mg/m ² and < 20 kg, use 1 mg/kg Cat: 20 mg/m ² (or approximately 1–1.25 mg/kg) every 3 weeks IV
Doxycycline (Vibramycin and generic forms)	Tetracycline antibiotic. Mechanism of action of tetracyclines is to bind to 30S ribosomal subunit and inhibit protein synthesis. Usually bacteriostatic. Broad spectrum of activity including bacteria, some protozoa, <i>Rickettsia</i> , <i>Ehrlichia</i> . Also used as adjunctive treatment for heartworm disease	Severe adverse reactions not reported with doxycycline. Tetracyclines in general may cause renal tubular necrosis at high doses. Tetracyclines can affect bone and teeth formation in young animals, but this is less likely with doxycycline.	Many pharmacokinetic and experimental studies have been conducted in small animals, but no clinical studies. Ordinarily considered the drug of choice for <i>Rickettsia</i> and <i>Ehrlichia</i> infections in dogs. Doxycycline IV infusion is stable for only 12 h at room temperature and 72 h if refrigerated.	10 mg/mL oral suspension; 100 mg injection vial doxycycline hydiate 50, 100 mg tablets or capsules. Doxycycline monohydrate 50 or 100 mg tablets or capsules	5 mg/kg q12h, or 10 mg/kg once daily For <i>Rickettsia</i> or <i>Ehrlichia</i> in dogs: 5 mg/kg q12h. Heartworm treatment: 10 mg/kg PO per day, intermittently at 4–6 week intervals; used with ivermectin or ivermectin + melarsomine.
Edetate calcium disodium (CaNa ₂ EDTA, Calcium Disodium Versenate)	Chelating agent. Indicated for treatment of acute and chronic lead poisoning. Sometimes used in combination with dimercaprol	No adverse effects reported in animals. In people, allergic reactions (release of histamine) occur after IV administration	May be used with dimercaprol. Equally effective when administered IV or IM, but IM injection may be painful. Ensure adequate urine flow before the first dose.	20 mg/mL injection	25 mg/kg q6h SC, IM, IV for 2–5 days
Edrophonium (Tensilon and others)	Cholinesterase inhibitor. Causes cholinergic effects by inhibiting metabolism of acetylcholine. Very short acting and ordinarily is only used for diagnostic purposes (e.g., for myasthenia gravis). Also has been used to reverse neuromuscular blockade of nondepolarizing agents (pancuronium)	Short acting, so side effects are minimal. Excessive muscarinic/cholinergic effects may occur with high doses (counteract with atropine).	Usually used only for determination of diagnosis of myasthenia gravis in patients.	10 mg/mL injection	Dog: 0.11–0.22 mg/kg IV Cat: 0.25–0.5 mg per cat IV

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Enalapril maleate (Enacard, Vasotec)	ACE inhibitor vasodilator via inhibition of angiotensin II synthesis. Used for vasodilation and treatment of heart failure. Primarily used in dogs, but may benefit some cats in heart failure.	May cause azotemia in some patients; carefully monitor patients receiving high doses of diuretics. <i>Drug interactions:</i> Use cautiously with other hypotensive drugs and diuretics. NSAIDs may decrease vasodilating effects.	Doses are based on clinical trials conducted in dogs by manufacturer. For dogs, start with once-daily administration and increase to q12h if needed. Other drugs used for treatment of heart failure may be used concurrently. Monitor electrolytes and renal function 3–7 days after initiating therapy and periodically thereafter.	2.5, 5, 10, 20 mg tablets	Dog: 0.5 mg/kg q12–24h PO Cat: 0.25–0.5 mg/kg q12–24h PO, or 1.0–1.25 mg/cat/day
Enilconazole (Imaverol, Clinafarm EC)	Azole antifungal agent for topical use only. Like other azoles, inhibits membrane synthesis (ergosterol) in fungus. Highly effective for dermatophytes	Administered topically. Adverse effects have not been reported.	Imaverol is available only in Canada as 10% emulsion. In the US, Clinafarm EC is available for use in poultry units as 13.8% solution. Dilute solution to at least 50:1, and apply topically every 3–4 days for 2–3 weeks. Enilconazole also has been instilled as 1:1 dilution into nasal sinus for nasal aspergillosis.	10% or 13.8% emulsion	Nasal aspergillosis: 10 mg/kg q12h instilled into nasal sinus for 14 days (10% solution diluted 50/50 with water) Dermatophytes: dilute 10% solution to 0.2%, and wash lesion with solution 4 times at 3–4 day intervals
Enoxaparin (Lovenox)	LMWH; anticoagulant; indicated for prevention of thromboembolism in at-risk patients. It has been used in cats with severe left atrial enlargement secondary to cardiomyopathy prior to and following embolism. Anti-Xa: anti-IIa ratio: 3.8:1	Bleeding may be a problem.	No need to monitor clotting times as with conventional (unfractionated) heparin when enoxaparin is used at recommended dosages. More consistent absorption and clearance than unfractionated (conventional) heparin.	30 mg/0.3 mL, 40 mg/0.4 mL, 60 mg/0.6 mL, 80 mg/0.8 mL, and 100 mg/1 mL prefilled syringes for injection	Dog: 0.8 mg/kg SQ q6h Cats: 1 mg/kg SQ, q12h, up to 1.25 mg/kg SQ, q6h

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Enrofloxacin (Baytril)	Fluoroquinolone antibacterial drug. Acts via inhibition of DNA gyrase in bacteria to inhibit DNA and RNA synthesis. Bactericidal. Broad spectrum of activity	Adverse effects include seizures in epileptic animals, arthropathy in dogs 4–28 weeks of age, vomiting in dogs and cats at high doses. Blindness in cats has been reported. Drug interactions: May increase concentrations of theophylline if used concurrently. Coadministration with di- and trivalent cations (e.g., sucralfate) may decrease absorption.	Solution is not approved for IV use but has been administered via this route safely if given slowly. Do not mix IV solutions with cation-containing fluids (e.g., Mg ⁺⁺ , Ca ⁺⁺).	22.7 and 68 mg tablets. Taste Tabs are 22.7, 68 and 136 mg. 22.7 mg/mL injection	Dog: 5–20 mg/kg/q24h PO, IV, IM Cat: 5 mg/kg q24h PO, IM. Do not administer to cats at doses higher than 5 mg/kg and do not administer to cats IV.
Ephedrine (many, generic)	Adrenergic agonist. Agonist on α - and β_1 -adrenergic receptors but not β_2 -receptors. Used as vasopressor, e.g., administered during anesthesia. CNS stimulant	Adverse effects related to excessive adrenergic activity (e.g., peripheral vasoconstriction and tachycardia)	Used primarily in acute situations to increase blood pressure	25, 50 mg/mL injection	Vasopressor: 0.75 mg/kg IM, SC, repeat as needed
Epinephrine hydrochloride (Adrenalin chloride and generic forms)	Adrenergic agonist. Nonselectively stimulates α -, β_1 and β_2 -adrenergic receptors. Used primarily for emergency situations to treat cardiopulmonary arrest and anaphylactic shock	Overdose will cause excessive vasoconstriction and hypertension. High doses can cause ventricular arrhythmias. When high doses are used for cardiopulmonary arrest, an electrical defibrillator should be available.	Doses are based on experimental studies, primarily in dogs. IV doses are ordinarily used, but endotracheal administration is acceptable when IV access is not available. Intraosseous route also has been used, and doses are equivalent to IV. When endotracheal route is used, the dose is higher and duration of effect may be longer than with IV administration. Avoid intracardiac injection.	1 mg/mL (1:1000) injection solution	Cardiac arrest: 10–20 μ g/kg IV or 100–200 μ g/kg endotracheal (may be diluted in saline before administration) The low dose (0.01 mg/kg) of epinephrine is recommended because high-dose therapy has not been associated with increased survival. A shortcut to calculate low-dose epinephrine volume for administration is 0.1 mL/10kg. The dose may be repeated at 3 to 5-minute intervals. Anaphylactic shock: 2.5–5 μ g/kg IV or 50 μ g/kg endotracheal (may be diluted in saline)

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Epoetin alfa (Erythropoietin) (Epogen, [r-HuEPO])	Human recombinant erythropoietin. Hematopoietic growth factor that stimulates erythropoiesis. Used to treat nonregenerative anemia.	Since this product is a human recombinant product, it may induce local and systemic allergic reactions in animals. Injection site pain and headache have occurred in people. Seizures also have occurred. Delayed anemia may occur because of crossreacting antibodies against animal erythropoietin (reversible when drug is withdrawn).	Use has been based on clinical reports in dogs and cats. The only form currently available is a human recombinant product.	2000 U/mL injection	Dog: Doses range from 35 or 50 U/kg 3 times/week to 400 U/kg/week SC (adjust dose to hematocrit of 30%–34%). Cat: start with 100 U/kg three times weekly SC. Adjust dose based on hematocrit.
Epsiprantel (Cestex)	Anticestodal agent	Anorexia and transient diarrhea. Vomiting at high doses.		12.5, 25, 50, or 100 mg tablets	Dog: 5.5 mg/kg PO Cat: 2.75 mg/kg PO
Ergocalciferol (vitamin D ₂) (Calciferol, Drisdol)	Vitamin D analogue. Used for vitamin D deficiency and as treatment of hypocalcemia, especially that associated with hypothyroidism. Vitamin D promotes absorption and utilization of calcium.	Overdose may cause hypercalcemia. Avoid use in pregnant animals because it may cause fetal abnormalities. Use cautiously with high doses of calcium-containing preparations.	Should not be used for renal hypoparathyroidism because of inability to convert to active compound. Available as oral solution, tablets, capsules, and injection. Doses for individual patients should be adjusted by monitoring serum calcium concentrations.	400 U tablets (OTC); 50,000 U tablets (1.25 mg); 500,000 U/mL (12.5 mg/mL) injection	500–2000 U/kg/day PO
Ertapenem (Invanz)	Carbapenem antibiotic of the β-lactam group. Like meropenem and imipenem, highly active against a broad spectrum of bacteria, including those resistant to other drugs. Ertapenem is not as active against <i>Pseudomonas</i> as meropenem or imipenem.	Well tolerated in animals. CNS toxicity may be possible with high doses. Allergy to β-lactam antibiotics is possible.	Dosing information is extrapolated from human medicine or limited empirical use in veterinary medicine. As with other carbapenems, use only when organisms are resistant to other drugs.	1 g vial for injection	30 mg/kg q8h IV or SC

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Erythromycin (many brands and generic)	Macrolide antibiotic. Inhibits bacteria by binding to 50S ribosome and inhibiting protein synthesis. Spectrum of activity limited primarily to gram-positive aerobic bacteria. Used for skin and respiratory infections.	Most common side effect is vomiting (probably caused by cholinergic-like effect or motilin-induced motility). May cause diarrhea in some animals. Do not administer PO to rodents or rabbits.	There are several forms of erythromycin, including the ethylsuccinate and estolate esters, and stearate salt for oral administration. There is no convincing data to suggest that one form is absorbed better than another, and one dose is included for all.	250 or 500 mg capsules or tablets	10–20 mg/kg q8–12h PO; GI motility effects at 0.5–1.0 mg/kg q8–12h PO or IV
Esmolol hydrochloride (Brevibloc)	β -blocker. Selective for β_1 -receptor. The difference between esmolol and other β -blockers is the short duration of action. Indicated for short-term control of heart rate and arrhythmias	Same as other precautions for β -blockers	Indicated for short-term IV therapy only. Doses are based primarily on empiricism or extrapolation of human dose. No clinical studies have been reported in animals.	10 mg/mL injection	50–100 μ g/kg IV bolus every 5 min (up to 500 μ g/kg max) 25–200 μ g/kg/min CRI
Estradiol cypionate (ECP, Depo-Estradiol Cypionate, generic)	Semisynthetic estrogen compound. Used primarily to induce abortion in animals	High risk of endometrial hyperplasia and pyometra. High doses can produce leukopenia, thrombocytopenia, and fatal aplastic anemia.	Ordinarily, 22 μ g/kg is administered once IM during days 3–5 of estrus or within 3 days of mating. However, in one study, a dose of 44 μ g/kg was more efficacious than 22 μ g/kg when given during estrus or diestrus.	2 mg/mL injection	Dog: 22–44 μ g/kg IM (total dose not to exceed 1.0 mg) Cat: 250 μ g/cat IM between 40 h and 5 days of mating
Estriol (Incurin)	Estrogen drug used to treat urinary incontinence in dogs.	May be better tolerated than other estrogens.	May be combined with phenylpropanolamine.	1 mg tablet	Dog: Starting dose – 2 mg/dog q24h PO. After 1 week reduce dose to 1.5 mg/dog/day for 1 week, then 1 mg/dog/day for 1 week, and gradually taper the dose and increase the interval (every other day, every third day, etc.) until a goal of 0.5 mg/dog, once per week is achieved.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Etidronate disodium (Didronel)	Bisphosphonate drug. Used to treat osteoporosis and hypercalcemia. Decreases bone turnover, inhibits osteoclast activity, retards bone resorption, and decreases rate of osteoporosis	Adverse effects not reported for animals. In people, GI problems are common.	At high doses, may inhibit mineralization of bone.	200, 400 mg tablets; 50 mg/mL injection	Dog: 5 mg/kg q24h PO Cat: 10 mg/kg q24h PO
Etodolac (EtoGesic, veterinary; Iodine, human)	An NSAID of the pyranocarboxylic acid group. Inhibits inflammatory prostaglandins.	NSAIDs may cause GI ulceration. Other adverse effects caused by NSAIDs include decreased platelet function and renal injury. Keratoconjunctivitis sicca has been reported in dogs. In clinical trials with etodolac, some dogs at recommended doses showed weight loss, loose stools, or diarrhea. At high doses, etodolac caused GI ulceration in dogs.	Studies in dogs showed etodolac to be more efficacious than placebo for treatment of arthritis.	150 and 300 mg tablets	Dog: 10–15 mg/kg q24h PO Cat: Dose not established
Famciclovir (Famvir)	Antiviral drug. Famciclovir is a synthetic purine analogue (acyclic nucleoside analogue). It is converted to the antiviral drug penciclovir via deacetylation and oxidation and is used to treat feline herpesvirus infections.	Possible adverse effects: mild anemia, mild increase in WBC.	It may produce improvement in some cats, but response can be variable.	125, 250, and 500-mg tablets.	Cat: Treatment of feline herpes: 62.5 mg/cat q8h PO, for 3 weeks. However, a higher dose of 125 mg/cat q8h may be more effective. Lower doses should be used in kittens (30–50 mg/kg oral, q12h).
Famotidine (Pepcid)	Histamine H ₂ -receptor antagonist. Used to suppress acid secretion for treatment and prevention of ulcers.	None reported for animals.	Clinical studies for famotidine have not been performed, therefore optimal dose for ulcer prevention and healing is not known.	10 mg tablet; 10 mg/mL injection; 8 mg/mL oral suspension	Dog: 0.1–0.2 mg/kg PO, IV, SC, IM q12h Cat: 0.2–0.25 mg/kg IM, IV, SC, PO q12–24h

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Felbamate (Felbatol)	Anticonvulsant. Usually used when dogs are refractory to other anticonvulsants. Mechanism may be via antagonism at the N-methyl-D-aspartate (NMDA) receptor and block effects of excitatory amino acids.	Not documented with use in dogs. In people, the most severe reactions have been hepatotoxicity and aplastic anemia. It may increase phenobarbital concentrations.	Dosing has been empirical.	120 mg/mL oral liquid; 400 and 600 mg tablets	Dog: Start with 15–20 mg/kg q8h PO. Or 200 mg/dog q8h for small dogs and 400 mg/dog q8h for larger dogs. Increase dose gradually by 200 mg increments until seizure control. Maximum dose for small dogs is 600 mg/dog q8h and for large dogs is 1200 mg/dog q8h Cat: No dose reported
Fenbendazole (Panacur, Safe-Guard)	Benzimidazole antiparasite drugs. Effective for treatment of <i>Giardia</i>	Good safety margin, but vomiting and diarrhea have been reported. No known contraindications.	Dose recommendations based on clinical studies by manufacturer. Granules may be mixed with food. In studies for treatment of <i>Giardia</i> , it was safer than other treatments.	Panacur granules 22.2% (222 mg/g); 100 mg/mL oral suspension	50 mg/kg/day × 3 days PO
Fentanyl citrate (Sublimaze, generic)	Synthetic opiate analgesic. Approximately 80–100 times more potent than morphine.	Adverse effects similar to morphine.	Doses are based on empiricism and experimental studies. No clinical studies have been reported. In addition to fentanyl injection, transdermal fentanyl is available (see below).	250 µg/5 mL injection	Anesthetic use: 0.02–0.04 mg/kg IV q2h IM, SC or 0.01 mg/kg IV, IM, SC (with acetylpromazine or diazepam) Analgesia: 0.005–0.01 mg/kg, q2h IV, IM, SC CRI: 0.003 mg/kg loading dose, followed by 0.005 mg/kg/h IV in dogs or 0.002 mg/kg/h in cats
Fentanyl transdermal (Recuvyra)	Synthetic opioid analgesic.	Same properties and adverse effects as other fentanyl products.	Approved for use in dogs to treat pain. After transdermal absorption, analgesia is maintained for 4 days.	10 mL amber-colored glass vials (50 mg fentanyl/mL).	Dog: 2.7 mg/kg (1.2 mg/pound) applied topically to the dorsal scapular area 2 to 4 hours prior to surgery. Cat: No dose established.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Fentanyl, transdermal (Duragesic)	Same as for fentanyl. Transdermal fentanyl incorporates fentanyl into adhesive patches applied to skin of dogs and cats. Studies have determined that patches release sustained levels of fentanyl for 72–108 hours in dogs and cats. One 100 µg/h patch is equivalent to 10 mg/kg of morphine q4h IM.	Adverse effects have not been reported. However, if adverse effects are observed (e.g., respiratory depression, excess sedation, excitement in cats), remove patch and, if necessary, administer naloxone.	Patches available in sizes of 25, 50, 75, and 100 µg/h. Patch size is related to release rate of fentanyl. Studies have determined that 25 µg/h patches are appropriate for cats; 50 µg/h patches are appropriate for dogs 10–20 kg. Follow manufacturer's recommendations carefully when applying patches.	25, 50, 75, and 100 µg/h patch	Dog: 10–20 kg, 50 µg/h patch q72h Cat: 25 µg patch q120h
Ferrous sulfate (many OTC brands)	Iron supplement	High doses cause stomach ulceration.	Recommendations based on dose needed to increase hematocrit	Many	Dog: 100–300 mg/dog q24h PO Cat: 50–100 mg/cat q24h PO
Finasteride (Proscar)	Inhibits conversion of testosterone to dihydrotestosterone (DHT). Since DHT stimulates prostate growth, this drug has been used for benign prostatic hypertrophy.	No adverse effects reported in dogs. Contraindicated in pregnancy	Doses based on study in dogs in which decrease in prostate size was reported.	5 mg tablets	Dog: 0.1 mg/kg PO q24h (or 5 mg tablet q24h in 10–50 kg dogs)
Firocoxib (Previcox)	Firocoxib is a Nonsteroidal Anti-inflammatory Drug (NSAID). Like other drugs in this class, firocoxib produces analgesic and anti-inflammatory effects by inhibiting the synthesis of prostaglandins. Firocoxib is highly selective for COX-2.	GI problems are the most common adverse effects associated with NSAIDs and can include vomiting, diarrhea, nausea, ulcers, and erosions of the GI tract.	Dose for cats has only been reported from one study. Not registered for cats.	Tablets 57 or 277 mg	Dog: 5 mg/kg PO, q24h Cat: 1.5 mg/kg, once. Long-term safety in cats has not been determined
Florfenicol (Nuflor)	Chloramphenicol derivative with same mechanism of action as chloramphenicol (inhibition of protein synthesis) and broad antibacterial spectrum. Use in small animals has been infrequent.	Use in dogs and cats has been limited, therefore adverse effects have not been reported. Chloramphenicol has been linked to dose-dependent bone marrow depression, and similar reactions may be possible with florfenicol. However, there does not appear to be a risk of aplastic anemia, as for chloramphenicol.	Dose form is only approved for use in cattle, and these doses have not been evaluated in small animals. Doses listed are derived from pharmacokinetic studies.	300 mg/mL injectable solution	Dog: 20 mg/kg q6h PO, IM Cat: 22 mg/kg q8h IM, PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Fluconazole (Diflucan)	Azole antifungal drug. Similar mechanism as other azole antifungal agents. Inhibits ergosterol synthesis in fungal cell membrane. Fungistatic. Active against dermatophytes and variety of systemic fungi, but not <i>Aspergillus</i> sp.	Adverse effects have not been reported from fluconazole administration. Compared to ketoconazole, has less effect on endocrine function. However, increased liver enzyme plasma concentrations and hepatopathy are possible. Compared to other oral azole antifungals, fluconazole is absorbed more predictably and completely, even on an empty stomach.	Doses for fluconazole are primarily based on studies performed in cats for treatment of cryptococcosis. Efficacy for other infections has not been reported. The primary difference between fluconazole and other azoles is that fluconazole attains higher concentrations in the CNS.	50, 100, 150, or 200 mg tablets; 10 or 40 mg/mL oral suspension; 2 mg/mL IV injection	Dog: 10–12 mg/kg q24h PO. For <i>Malassezia</i> , 5 mg/kg q12h PO has been used. Cat: 50 mg/cat q24h, PO
Flucytosine (Ancobon)	Antifungal drug. Used in combination with other antifungal drugs for treatment of cryptococcosis. Action is to penetrate fungal cells and is converted to fluorouracil, which acts as antimetabolite.	Anemia and thrombocytopenia are possible.	Flucytosine is used primarily to treat cryptococcosis in animals. Efficacy is based on flucytosine's ability to attain high concentrations in cerebrospinal fluid (CSF). Flucytosine may be synergistic with amphotericin B.	250 mg capsule; 75 mg/mL oral suspension	25–50 mg/kg q6–8h PO (up to a maximum dose of 100 mg/kg q12h PO)
Fludrocortisone Acetate (Florinef)	Mineralocorticoid. Used as replacement therapy in animals with adrenal atrophy/adrenocortical insufficiency. Has high potency of mineralocorticoid activity compared to glucocorticoid activity	Adverse effects are primarily related to glucocorticoid effects with high doses. Long-term treatment for hypoadrenocorticism may result in glucocorticoid side effects.	Dose should be adjusted by monitoring patient response (i.e., monitoring electrolyte concentrations). In some patients, it is administered with a glucocorticoid and sodium supplementation.	100 µg (0.1 mg) tablets	Dog: 15–30 µg/kg per day PO Cat: 0.1–0.2 mg per cat q24h PO; to test for primary aldosteronism 0.05 mg/kg q12h × 4 days
Flumazenil (Romazicon)	Benzodiazepine receptor antagonist. Used as reversal agent after benzodiazepine administration in people (not commonly used in veterinary medicine)	No adverse effects reported in animals	Used primarily to reverse effects of benzodiazepine drugs. May be used to treat toxicity caused by high doses of benzodiazepines (e.g., diazepam). Although used experimentally for hepatic encephalopathy, it is not recommended for this use.	100 µg/mL (0.1 mg/mL) injection	0.02 mg/kg (20 µg/kg) IV

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Flumethasone (Flucort)	Potent glucocorticoid anti-inflammatory drug. Potency is approximately 15× that of cortisol. Used to treat inflammatory disorders when a potent drug is needed.	Corticosteroids produce multiple systemic side effects. Adverse effects are common with chronic therapy.	Doses are based on severity of underlying disease.	0.5 mg/mL injection	Anti-inflammatory uses: 0.15–0.3 mg/kg q12–24h IV, IM, SC
Flunixin meglumine (Banamine)	NSAID. Acts to inhibit cyclooxygenase (COX) enzyme, which synthesizes prostaglandins. Other anti-inflammatory effects may occur (such as effects on leukocytes), but have not been well characterized. Used primarily for shortterm treatment of moderate pain and inflammation	Most severe adverse effects related to GI system. Causes gastritis, GI ulceration with high doses or prolonged use. Renal ischemia has also been documented. Therapy in dogs should be limited to 4 consecutive days. Avoid use in pregnant animals near term. <i>Drug interactions:</i> Ulcerogenic effects are potentiated when administered with corticosteroids.	Not approved for small animals, but has been shown in experimental studies to be an effective prostaglandin synthesis inhibitor. Usually other NSAIDs are preferred for dogs and cats.	250 mg packet granules; 10, 50 mg/mL injection	1.1 mg/kg once IV, IM, SC or 1.1 mg/kg/day 3 day/week PO Ophthalmic: 0.5 mg/kg once IV
5-Fluorouracil (Fluorouracil)	Anticancer agent. Antimetabolite. Action is via inhibition with nucleic acid synthesis.	Causes mild leukopenia, thrombocytopenia. CNS toxicity. Do not use in cats.	Used in anticancer protocols. Consult anticancer treatment protocol for precise dosage and regimen.	50 mg/mL vial	Dog: 150 mg/m ² once/week IV Cat: do not use
Fluoxetine (Reconcile [veterinary] Prozac [human])	Antidepressant drug. Used to treat behavioral disorders, such as obsessive-compulsive disorders and dominance aggression. Mechanism of action via selective inhibition of serotonin reuptake and down-regulation of 5-HT1 receptors.	Most common adverse effects during field trials were lethargy, reduced appetite, shaking, diarrhea, restlessness, aggression, and vocalization. In cats, nervousness and increased anxiousness have been observed.	Because of long half-life, accumulation in plasma may take several days to weeks.	Human formulations: 10 and 20 mg capsules; 4 mg/mL oral solution Veterinary formulations: 8, 16, 32, 64 mg chewable tablets (Veterinary formulation may no longer be available and human forms should be used instead.)	Dog: 1–2 mg/kg per day, PO Cat: 0.5–1.0 mg/kg per day, PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Fluticasone Propionate (Flovent)	Used as an inhaled (topical) corticosteroid for treatment of airway disease. Most of the use has been established for cats. Most common use is for inflammatory airway diseases such as asthma, bronchitis, or bronchospasm.	Although systemic absorption is low, some systemic exposure will occur in animals. Side effects can occur but are not expected to be as severe as with systemic corticosteroids.	It is delivered via a metered-dose inhaler. These inhalers can be used in animals if special adaptations, such as a spacer device, which are available for use in pediatrics or for cats and horses, are used.	Metered-dose inhaler at 44, 110, or 220 µg per puff	Dog: Start with 220 µg per dose, q12h Cat: Start with 44 µg per dose (one puff from a 44 µg inhaler), twice daily. Increase the dose as needed, to 110 µg, then to 220 µg
Follicle-stimulating hormone (FSH)	See Urofollitropin.				
Furosemide (Lasix, generic)	Loop diuretic. Inhibits sodium and water transport in ascending loop of Henle, which produces diuresis. Also may have vasodilating properties, increasing renal perfusion, and decreasing preload	Adverse effects primarily related to diuretic effect (loss of fluid and electrolytes). Administer conservatively in animals receiving ACE inhibitors to decrease risk of azotemia.	Furosemide may be used with other cardiovascular drugs, including pimobendan.	12.5, 20, 50 mg tablets; 10 mg/mL oral solution; 50 mg/mL injection	Dog: 2–6 mg/kg q8–12h (or as needed) IV, IM, SC, PO Cat: 1–4 mg/kg q8–24h IV, IM, SC, PO
Gabapentin (Neurontin)	Anticonvulsant and analgesic. Gabapentin is an analogue of the inhibitory neurotransmitter GABA. The mechanism of anticonvulsant action and analgesic effects are not known.	Warning: oral solution contains xylitol, which may be toxic to dogs.	Gabapentin has been used for treating refractory epilepsy and as adjunct for analgesia (with other drugs). It has not been effective for acute pain in dogs or cats.	100, 300, 400 mg capsules; 100, 300, 400, 600, 800 mg scored tablets; 50 mg/mL oral solution	Anticonvulsant dose: Dog: 2.5–10 mg/kg q8–12h, PO Cat: 5–10 mg q12h PO For analgesia: Dog: 10–15 mg/kg q8h, PO Cat: 8 mg/kg q12h, PO
Gemfibrozil (Lopid)	Cholesterol-lowering agent	Adverse effects have not been reported in animals.	Used primarily in people to treat hyperlipidemia. Clinical studies have not been performed in animals.	300 mg capsules; 600 mg tablets	7.5 mg/kg q12h PO
Gentamicin sulfate (Gentocin)	Aminoglycoside antibiotic. Action is to inhibit bacteria protein synthesis via binding to 30S ribosome. Bactericidal. Broad spectrum of activity except streptococci and anaerobic bacteria	Nephrotoxicity is the most dose-limiting toxicity. Ensure that patients have adequate fluid and electrolyte balance during therapy. Ototoxicity, vestibulotoxicity also are possible. Do not mix in vial or syringe with other antibiotics.	Dosing regimens are based on sensitivity of organisms. Some studies have suggested that once-daily therapy (combining multiple doses into a single daily dose) is as efficacious as multiple treatments.	50 and 100 mg/mL solution for injection	Dog: 9–14 mg/kg q24h IV, IM, SC Cat: 5–8 mg/kg q24h IV, IM, SC
Glibenclamide	British name for glyburide				

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Glipizide (Glucotrol)	Sulfonylurea oral hypoglycemic agent. Used as oral treatment in the management of diabetes mellitus, particularly in cats. Response rate is approximately 50%. This drug acts to increase secretion of insulin from pancreas, probably by interacting with sulfonylurea receptors on β cells. These drugs also may increase sensitivity of existing insulin receptors.	It may cause dose-related vomiting, anorexia, increased bilirubin, and elevated liver enzymes in some cats. Causes hypoglycemia, but less so than insulin. <i>Drug interactions:</i> Many drug interactions have been reported in people. It is not known if these occur in animals. Use cautiously with β -blockers, antifungal drugs, anticoagulants, fluoroquinolones, sulfonamides, and others (consult package insert).	Oral hypoglycemic agents are successful in people only for non-insulin-dependent diabetes. Since response to oral hypoglycemic agents in cats is unpredictable, it is recommended to use a trial first of at least 4 weeks. If the cat responds, the drug can be continued; otherwise, insulin may be indicated. Feed cats a high-fiber diet when using oral hypoglycemic agents. Efficacy in cats is unpredictable.	5, 10 mg tablets	Cat: 2.5–7.5 mg/cat q12h PO. Start with 2.5 mg per cat and increase to 5 mg/cat, q12h Dog: not recommended
Glucosamine and Chondroitin sulfate (Cosequin)	Cosequin is brand name for combination of glucosamine HCl and chondroitin sulfate. According to manufacturer, these compounds stimulate synthesis of synovial fluid and inhibit degradation and improve healing of articular cartilage. Used primarily for degenerative joint disease.	Adverse effects have not been reported, although hypersensitivity is possible.	Doses are based primarily on empiricism and manufacturer's recommendations. May be used with NSAIDs for arthritis in dogs.	Regular (RS) and double strength (DS) capsules	Dog: 1–2 RS capsules per day (2–4 capsules of DS for large dogs) Cat: 1 RS capsule daily
Glyburide (DiaBeta, Micronase, Glynase)	Sulfonylurea hypoglycemic agent. See Glipizide.	Dose-related anorexia and vomiting and elevated liver enzymes	Response is unpredictable. Glipizide is usually preferred in cats.	1.25, 2.5, 5 mg tablets	Cat: 0.2 mg/kg daily PO or 0.625 mg (1/2 tab) per cat/day
Glycerin (generic)	Used to treat acute glaucoma	No adverse effects reported		Oral solution, 40 mg/mL emulsion	1–2 mL/kg, q8h PO
Glycopyrrrolate (Robinul-V)	Anticholinergic drug, Glycopyrrrolate may have less effect on CNS compared to atropine because of lower CSF levels. May have longer duration of action than atropine.	Adverse effects attributed to antimuscarinic (anticholinergic) effects.	Glycopyrrrolate is often used in combination with other agents, particularly anesthetic drugs.	0.2 mg/mL injection	0.005–0.01 mg/kg IV, IM, SC

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
GoLYTELY	Oral solution for producing catharsis	See Polyethylene glycol electrolyte solution.			
Gonadorelin (GnRH, LHRH) (Factrel)	Stimulates synthesis and release of luteinizing hormone (LH) and, to a lesser degree, follicle-stimulating hormone (FSH). Used to induce luteinization.	Adverse effects have not been reported in animals.	Gonadorelin has been used to manage various reproductive disorders. Consult specific reference on reproductive problems in animals to guide therapy.	50 µg/mL injection	Dog: 50–100 µg/dog q24–48h IM Cat: 25 µg/cat once IM
Gonadotropin, chorionic (HCG) (Profasi, Pregnyl, generic, A.P.L.)	Action of HCG is identical to that of leutinizing hormone (LH). Used to induce luteinization in animals.	Adverse effects have not been reported in animals.	Consult specific reference on reproductive problems in animals to guide therapy.	Injection sizes of 5000, 10,000, and 20,000 U vials	Dog: 22 U/kg q24–48h IM, or 44 U once IM Cat: 250 U/cat once IM
Gonadotropinreleasing hormone	See Gonadorelin.				
Granisetron (Kytril)	Antiemetic drug that acts by inhibiting serotonin (5-HT) receptors. Used primarily for antiemetic during chemotherapy	None reported in dogs or cats.	Doses extrapolated from human uses.	1 mg tablets and 1 mg/mL injection	0.01 mg/kg IV (in people, dose is 1 mg/person PO)
Griseofulvin (microsize) (Fulvicin U/F) or (ultra-microsize) (Fulvicin P/G, Gris-PEG)	Antifungal drug. Incorporates into skin layers and inhibits mitosis of fungi. Antifungal activity is limited to dermatophytes.	Adverse effects in animals include teratogenicity in cats; anemia and leukopenia in cats; anorexia, depression, vomiting, and diarrhea. Do not administer to pregnant cats.	A wide range of doses has been reported. Doses listed here represent the current consensus. Griseofulvin should be administered with food to enhance absorption. Ultra-microsize is absorbed to a greater extent, and doses should be less than microsize.	125, 250, 500 mg tablets; 25 mg/mL oral suspension; 125 mg/mL oral syrup or ultramicrosize 100, 125, 165, 250, 330 mg tablets	50 mg/kg q24h PO (up to a maximum dose of 110–132 mg/kg/day in divided treatments) Ultramicrosize: 30 mg/kg/day in divided treatments PO
Growth hormone (hGH, somatrem, somatropin) (Protropin, Humatrop, Nutropin)	Growth hormone, also known as human growth hormone. Used to treat growth hormone deficiencies	Growth hormone is diabetogenic in all animals. Excess growth hormone causes acromegaly.	There is only limited clinical experience in animals. Dose form must be reconstituted with sterile diluent before use. Prepared solution is stable for 14 days, if refrigerated.	5 and 10 mg per vial	0.1 U/kg 3 times/week for 4–6 weeks, SC IM (usual human pediatric dose is 0.18–0.3 mg/kg/week)
Guaifenesin (glyceryl guaiacolate, Guaiphenesin, Mucinex)	Expectorant and muscle relaxant. The mechanism for expectorant effects is not known, but may increase respiratory secretions.	A vagal effect (e.g., stimulation of secretions) may occur when the drug is used as an expectorant.	Guaifenesin oral use is primarily for respiratory problems. Intravenous solutions have been used as adjunct for anesthesia, but primarily in horses.	Tablets: 100, 200 mg; Extended release tablets: 600 mg; Oral solution: 20 mg/mL or 40 mg/mL	Dog: Expectorant: 3–5 mg/kg q8h PO Anesthetic adjunct: 2.2 mL/kg/h of a 5% solution IV Cat: Expectorant: 3–5 mg/kg q8h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Halothane (Fluothane)	Inhalent anesthetic	Adverse effects related to anesthetic effects (e.g., cardiovascular and respiratory depression). Hepatotoxicosis has been reported in people.	Use of inhalent anesthetics requires careful monitoring. Dose is determined by depth of anesthesia.	250 mL bottle	Induction: 3% Maintenance: 0.5%–1.5%
Heparin sodium (Liquaemin ([US]; Hepalean [Canada])	Anticoagulant. Potentiates anticoagulant effects of antithrombin III. Used primarily for prevention of thrombosis	Adverse effects caused by excessive inhibition of coagulation: bleeding	Dose adjustments should be performed by monitoring clotting times. For example, dose is adjusted to maintain activated partial thromboplastin time (APTT) to 1.5 to 2× normal.	1000 and 10,000 U/mL injection	Low-dose prophylaxis (dog and cat): 70 U/kg q8–12h SC. Dog: 100–200 U/kg IV loading dose, then 100–300 U/kg q6–8h SC Cat: 300 U/kg, q8h; then up to 500 U/kg, if necessary
Hycodan	See Hydrocodone bitartrate.				
Hydralazine (Apresoline)	Vasodilator. Antihypertensive. Used to dilate arterioles and decrease afterload. Primarily used for treatment of CHF and other cardiovascular disorders characterized by high peripheral vascular resistance.	Adverse effects attributed to excess vasodilation. Monitor patients for hypotension. May dangerously decrease cardiac output. Allergic reactions (lupus-like syndrome) have been reported in people and are related to acetylator status, but have not been reported in animals.	Use in heart failure may accompany other drugs, such as digoxin and diuretics. It is advised to monitor patient for hypotension to adjust dosage.	10 mg tablets; 20 mg/mL injection	Dog: 0.5 mg/kg (initial dose), titrate to 0.5–2 mg/kg q12h PO Cat: 2.5 mg/cat q12–24h PO
Hydrochlorothiazide (HydroDIURIL, generic)	Thiazide diuretic. Inhibits sodium reabsorption in distal renal tubules. Used as diuretic and antihypertensive. Since it decreases renal excretion of calcium, it also has been used to treat calcium containing uroliths.	Do not use in patient with elevated calcium. May cause electrolyte imbalance, such as hypokalemia	Not as potent as loop diuretics (such as furosemide). Clinical efficacy has not been established in veterinary patients.	10, 100 mg/mL oral solution and 25, 50, and 100 mg tablets	2–4 mg/kg q12h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Hydrocodone bitartrate (Hycodan)	Opiate agonist. Used primarily for antitussive action. Hycodan contains homatropine, but other combinations may contain guaifenesin or acetaminophen.	Oral opiate. May cause systemic opiate effects.	Hydrocodone is combined with atropine in the product Hycodan.	5 mg tablets and 1 mg/mL syrup	Dog: antitussive: 0.5 mg/kg, q8h PO; analgesic: 0.5 mg/kg, q8–12h, PO Cat: no dose available
Hydrocortisone (Cortef and generic)	Glucocorticoid anti-inflammatory drug. Hydrocortisone has weaker anti-inflammatory effects and greater mineralocorticoid effects compared with prednisolone or dexamethasone. Also used for replacement therapy	Adverse effects are attributed to excessive glucocorticoid effects.	Dose requirements are related to severity of disease.	5, 10, 20 mg tablets	Replacement therapy: 1–2 mg/kg q12h PO Anti-inflammatory: 2.5–5 mg/kg q12h PO
Hydrocortisone sodium succinate (Solu-Cortef)	Same as hydrocortisone, except that this is a rapid-acting, injectable product	Same as for hydrocortisone	Same as for hydrocortisone. Prepare vials according to manufacturer's recommendations.	Various size vials for injection	Shock: 50–150 mg/kg IV q8h for 2 days Anti-inflammatory: 5 mg/kg q12h IV
Hydromorphone (Dilaudid, Hydrostat, and generic)	Opiate analgesic. Like other opiates, it binds to mu-opiate and kappa-opiate receptors. Hydromorphone is 6 or 7 times more potent than morphine.	Hydromorphone is an opiate agonist, with effects similar to morphine. However it is more potent than morphine and should be used at lower doses.	Hydromorphone may be used interchangeably with morphine, provided that doses are adjusted for potency differences.	Injection: 1, 2, 4, 10 mg/mL; 1 mg/mL oral solution; and 1, 2, 3, 4, 8 mg tablets	Dog: 0.22 mg/kg IM or repeat q4–6h, or as needed for pain treatment. A dose of 0.1 mg/kg may be used with acepromazine Cat: 0.1–0.2 mg/kg, SC or IM or 0.05–0.1 mg/kg IV q2–6h
Hydroxyethyl starch	Synthetic colloid volume expander. Used primarily to treat acute hypovolemia and shock	Kidney injury is possible, but not reported widely in veterinary medicine. Most of the serious adverse effects reported, such as kidney injury and coagulation abnormalities have been observed in human studies, and have not been documented with the clinical use in veterinary medicine.	Used in critical care situations. Infused via constant rate infusion.	6%- to 10% injectable solution	Dogs: Small volume resuscitation: 5 mL/kg IV Large volume resuscitation: 5–15 mL/kg, IV CRI: 10–20 mL/kg/day IV (0.4–0.8 mL/kg/hr). Maximum dose is 33–50 mL/kg/day. Cats: Resuscitation: 2–5 mL/kg IV CRI: 5–10 mL/kg/day IV (0.2–0.4 mL/kg/hr).

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Hydroxyurea (Hydrea)	Antineoplastic agent. Used in combination with other anticancer modalities for treatment of certain tumors. Has been used to treat polycythemia vera	Only limited use in veterinary medicine. No adverse effects have been reported. In people, hydroxyurea causes leukopenia, anemia, thrombocytopenia.	Limited use in veterinary medicine	200, 300, 400, and 500 mg capsules	Dog: 50 mg/kg PO q24h, 3 days/week Cat: 25 mg/kg PO q24h, 3 days/week
Hydroxyzine (Atarax)	Antihistamine of the piperazine class. Used primarily to treat pruritus in animals	Side effects of therapy are related primarily to antihistamine effects. Sedation occurs in some animals.	Clinical studies have shown hydroxyzine to be somewhat effective for treatment of pruritus in dogs. Clinical effects of hydroxyzine are attributed to conversion to cetirizine.	10, 25, 50 mg tablets; 2 mg/mL oral solution	Dog: 2 mg/kg, q8–12h, IM or PO Cat: Effective dose not established
Ibuprofen (Motrin, Advil, Nuprin)	NSAID. Produces anti-inflammatory action via inhibition of prostaglandins.	Safe doses have not been established for dogs and cats. Vomiting and severe GI ulceration and hemorrhage have been reported in dogs.	Avoid use, especially in dogs.	200, 400, 600, 800 mg tablets	Safe dose not established
Imipenem (Primaxin)	β -lactam antibiotic with broad-spectrum activity. Action is similar to other β -lactams except that imipenem is the most active of all β -lactams. Used primarily for serious, multiple-resistant infections	Allergic reactions may occur with β -lactam antibiotics. With rapid infusion or in patients with renal insufficiency, neurotoxicity may occur (seizures). Vomiting and nausea are possible. IM or SC injections may cause pain in dogs.	Reserve the use of this drug for only resistant, refractory infections. Observe manufacturer's instructions carefully for proper administration. For IV administration, add to IV fluids. For IM administration, add 2 mL lidocaine (1%); suspension is stable for only 1 hour.	250 or 500 mg vials for injection	3–10 mg/kg q6–8h IV, SC or IM; usually 5 mg/kg q6–8h IV, IM, or SC
Imipramine (Tofranil)	Tricyclic antidepressant drug (TCA). Used in people to treat anxiety and depression. Used in animals to treat variety of behavioral disorders, including obsessive-compulsive disorders. Action is via inhibition of uptake of serotonin at presynaptic nerve terminals.	Multiple side effects are associated with TCAs, such as antimuscarinic effects (dry mouth, rapid heart rate) and antihistamine effects (sedation). Overdoses can produce life-threatening cardiotoxicity.	Doses are primarily based on empiricism. There are no controlled efficacy trials available for animals. There may be a 2–4 week delay after initiation of therapy before beneficial effects are seen.	10, 25, 50 mg tablets	Dog: 2–4 mg/kg q12–24h PO Cat: 0.5–1.0 mg/kg q12–24h, PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Insulin	Insulin has multiple effects associated with utilization of glucose. Used to treat diabetes mellitus in dogs and cats	Adverse effects primarily related to overdoses (hypoglycemia)	Doses should be carefully adjusted in each patient, depending on response. Monitor plasma/serum glucose concentrations.	100 U/mL injection or 40 U/mL injection	Insulin doses are specific for each species and formulation available. Consult specific information on each product to derive starting dose.
Interferon (interferon- α , HuIFN- α) (Roferon)	Human interferon. Used to stimulate the immune system in patients.	Adverse effects have not been reported in animals.	Doses and indications for animals have primarily been based on extrapolation of human recommendations or limited experimental studies. To prepare, add 3 million U to 1 L sterile saline and divide into aliquots and freeze. Thaw as needed for 30 U/mL solution.	5 and 10 million U/vial	Dog: 2.5 million U/kg IV once daily for 3 days Cat: 1 million U/kg IV once daily for 5 consecutive days on days 0, 14, and 60
Iodide	See Potassium iodide.				
Ipecac syrup (Ipecac)	Emetic drug. For emergency treatment of poisoning. Active ingredient is thought to be emetine.	No adverse effects with acute therapy for poisoning. Chronic administration can lead to myocardial toxicity.	Available as non-prescription drug. Onset of vomiting may require 20–30 min.	Oral solution; 30 mL bottle	Dog: 3–6 mL per dog PO Cat: 2–6 mL per cat PO
Ipodate or lopanoic acid.	Cholecystographic agent. Used as treatment for hyperthyroidism in cats. Used as alternative to methimazole, radiation therapy, or surgery.	No adverse effects reported	Use of ipodate has been experimental, and precise doses have not been evaluated. In one study, 2/3 of treated cats responded.	Formulated into 50 mg capsules (these may have to be formulated for cats)	Ipodate: Cat: 15 mg/kg q12h PO. Most common dose has been 50 mg/cat q12h lopanoic acid: 50 mg per cat q12h, PO
Iron	See Ferrous sulfate.				
Isoflurane (AErrane)	Inhalent anesthetic.			100 mL bottle	Induction: 5% Maintenance: 1.5%–2.5%
Isoniazid (INH)	Antibacterial agent that interferes with nucleic acid synthesis. Used for mycobacterium	Do not use in animals with hepatic disease.		100, 300, and 500 mg tablets or 10 mg/mL syrup	5 mg/kg/day, PO, IM, IV; 15 mg/kg 2–3 times/wk

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Isoproterenol (Isuprel)	Adrenergic agonist. Stimulates both β_1 - and β_2 -adrenergic receptors. Used to stimulate heart (inotropic and chronotropic). Also used to relax bronchial smooth muscle for acute treatment of bronchoconstriction.	Adverse effects are related to excessive adrenergic stimulation and are seen primarily as tachycardia and tachyarrhythmias.	Short half-life. Must be infused via constant rate infusion or repeated if administered IM or SC. Recommended for short-term use only.	Ampules for injection, 0.2 mg/mL	10 $\mu\text{g}/\text{kg}$ q6h IM, SC; or dilute 1 mg in 500 mL of 5% dextrose or Ringer's solution and infuse IV 0.5–1 mL/min (1–2 $\mu\text{g}/\text{min}$), or to effect
Isosorbide dinitrate (Isordil, Isorbid, Sorbitrate)	Nitrate vasodilator. Causes vasodilation via generation of nitric oxide. Relaxes vascular smooth muscle, especially venous. Reduces preload in patients with CHF.	Adverse effects are primarily related to overdoses that produce excess vasodilation and hypotension. Tolerance may develop with repeated doses.	Generally, doses are titrated to individual, depending on response.	2.5, 5, 10, 20, 30, 40 mg tablets; 40 mg capsules	2.5–5 mg/animal q12h PO (or 0.22–1.1 mg/kg q12h PO)
Isosorbide mononitrate (Monoket)	Same comments as for isosorbide dinitrate, except that this is a biologically active form of isosorbide dinitrate. Compared to isosorbide dinitrate, it does not undergo first-pass metabolism and is completely absorbed orally.	Same as for isosorbide dinitrate and nitroglycerin	Generally absorbed better than isosorbide dinitrate	10, 20 mg tablets	5 mg/dog two doses per day 7 hours apart PO
Isotretinoin (Accutane)	Keratinization stabilizing drug. Isotretinoin reduces sebaceous gland size, inhibits sebaceous gland activity, and decreases sebum secretion. In people, it is primarily used to treat acne. In animals, it has been used to treat sebaceous adenitis.	Absolutely contraindicated in pregnant animals. Adverse effects not reported for animals, although experimental studies have demonstrated that it can cause focal calcification (such as in myocardium and vessels)	Use in veterinary medicine is confined to limited clinical experience and extrapolation from human reports.	10, 20, 40 mg capsules	Dog: 1–3 mg/kg/day (up to a maximum recommended dose of 3–4 mg/kg/day PO) Cat: no dose established

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Itraconazole (Sporanox)	Azole (triazole) antifungal drug. Active against dermatophytes and systemic fungi, such as <i>Blastomyces</i> , <i>Histoplasma</i> , and <i>Coccidioides</i> . Also used for <i>Malassezia</i> dermatitis.	Itraconazole is better tolerated than ketoconazole. However, vomiting and hepatotoxicosis are possible, especially at high doses. High doses in cats may cause vomiting and anorexia.	Doses are based on studies in animals in which itraconazole has been used to treat blastomycosis in dogs. In cats, lower doses have been effective for dermatophytes (see dosage section). Other uses or doses are based on empiricism or extrapolation from human literature.	100 mg capsules and 10 mg/mL oral liquid. Compounded formulations are not be absorbed as well as proprietary formulations.	Dog: 2.5 mg/kg q12h, or 5 mg/kg q24h PO For <i>Malassezia</i> dermatitis: 5 mg/kg q24h PO for 2 days, repeated each week for 3 weeks Dermatophytes: 3 mg/kg/day PO for 15 days Cat: 5 mg/kg q12h PO For Dermatophytes: 1.5–3.0 mg/kg (up to 5 mg/kg) q24h PO for 15 days
Ivermectin (Heartgard, Ivermectin, Eqvalan liquid)	Antiparasitic drug. Neurotoxic to parasites by potentiating glutamate-gated chloride channels; used for anti-parasitic treatment and heartworm prevention.	Toxicity may occur at high doses, and in breeds in which ivermectin crosses blood–brain barrier. Sensitive breeds include collies, Australian shepherds, shelties, and Old English sheepdogs. Toxicity is neurotoxic, and signs include depression, ataxia, difficulty with vision, coma, and death. Ivermectin appears to be safe for pregnant animals. Do not administer to animals under 6 weeks of age. Animals with high microfilaremia may show adverse reactions to high doses.	Doses vary, depending on use. Heartworm prevention is lowest dose, other parasites require higher doses. Heartgard is only form approved for small animals; for other indications, large animal injectable products are often administered PO, IM, or SC to small animals.	1% (10 mg/mL) injectable solution; 10 mg/mL oral solution; 18.7 mg/mL oral paste; 68, 136, and 272 µg tablets; and 55 and 165 mg feline tablets	Heartworm preventative: 6 µg/kg every 30 days PO in dogs and 24 µg/kg every 30 days PO in cats Microfilaricide: 50 µg/kg PO 2 wks after adulticide therapy Ectoparasite therapy (dogs and cats): 200–300 µg/kg IM, SC, PO Endoparasites (dogs and cats): 200–400 µg/kg weekly SC, PO <i>Demodex</i> therapy: start with 100 µg/kg/day and increase dose by 100 µg/kg/day to 600 µg/kg/day for 60–120 days PO Heartworm prevention in cats: 25 µg/kg every 30 days, PO
Kanamycin (Kantrim)	Aminoglycoside antibiotic with broad-spectrum activity	Shares same properties with other aminoglycosides (see Amikacin, Gentamicin)	See Gentamicin.	200, 500 mg/mL injection	10 mg/kg q12h or 20 mg/kg q24h IV IM, SC

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Ketamine (Ketalar, Ketavet, Vetalar)	Anesthetic agent. NMDA receptor antagonist. Exact mechanism of action is not known, but appears to act as dissociative agent. Rapidly metabolized and eliminated in most animals.	Causes pain with IM injection. Tremors, spasticity, and convulsive seizures have been reported. Increases cardiac output compared to other anesthetic agents. Do not use in animals with head injury because it may elevate CSF pressure.	Often used in combination with other anesthetics and anesthetic adjuncts, such as alpha-2 agonists, acepromazine, or diazepam. IV doses generally less than IM doses.	100 mg/mL injection solution	Dog: 5.5–22 mg/kg IV, IM (recommend adjunctive sedative or tranquilizer treatment). Cat: 2–25 mg/kg IV, IM (recommend adjunctive sedative or tranquilizer treatment). Dog and cat: Dose for constant rate infusion: 0.3–0.5 mg/kg IV followed by 0.3–0.6 mg/kg/h. May be used in combination with other analgesics
Ketoconazole (Nizoral)	Azole (imidazole) antifungal drug. Similar mechanism of action as other azole antifungal agents. Inhibits ergosterol synthesis in fungal cell membrane. Fungistatic. Efficacious against dermatophytes and variety of systemic fungi, such as <i>Histoplasma</i> , <i>Blastomyces</i> , and <i>Coccidioides</i> . Also active against <i>Malassezia</i> .	Adverse effects in animals include dose-related vomiting, diarrhea, and hepatic injury. Enzyme elevations are common. Do not administer to pregnant animals. Ketoconazole causes endocrine abnormalities, especially, inhibition of cortisol synthesis. <i>Drug interactions:</i> Ketoconazole will inhibit metabolism of other drugs (anticonvulsants, cyclosporine, cisapride).	Oral absorption depends on acidity in stomach. Do not administer with antisecretory drugs or antacids. Because of endocrine effects, ketoconazole has been used for short-term treatment of hyperadrenocorticism.	200 mg tablets; 100 mg/mL oral suspension (only available in Canada)	Dog: 10–15 mg/kg q8–12h PO. For <i>Malassezia canis</i> infection: 5 mg/kg q24h PO. For hyperadrenocorticism: start with 5 mg/kg q12h for 7 days, then 12–15 mg/kg q12h PO. Cat: 5–10 mg/kg q8–12h PO
Ketoprofen (Orudis KT [human OTC tablet]; Ketofen [veterinary injection])	NSAID. Anti-inflammatory agent. Used to treat arthritis and other inflammatory disorders.	All NSAIDs share similar adverse effect of GI toxicity. Ketoprofen has been administered for 5 consecutive days in dogs, without serious adverse effects. Most common side effect is vomiting. GI ulceration is possible in some animals.	Although not approved in the US, ketoprofen is approved for small animals in other countries. Doses listed are based on approved use in those countries. It is available as OTC drug for humans in the US.	12.5 mg tablet OTC; 25, 50, 75 mg Rx' human form; 100 mg/mL injection for horses	1 mg/kg q24h PO for up to 5 days. Initial dose can be given via injection at up to 2 mg/kg SC, IM, IV

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Ketorolac tromethamine (Toradol)	NSAID. Used for short-term relief of pain and inflammation. Acts by inhibiting cyclooxygenase enzyme (COX). Use of ketorolac has been evaluated clinically in dogs but not cats.	NSAIDs may cause GI ulceration. Ketorolac may cause gastrointestinal lesions if administered more frequently than q8h. Do not administer more than 2 doses.	Available as 10 mg tablet and injection for IV or IM use. Dosing q12h is recommended to avoid GI problems.	10 mg tablets; 15 and 30 mg/mL injection in 10% alcohol	Dog: 0.5 mg/kg q8–12h PO, IM, IV Cat: safe dose not established
Lactated Ringer's solution (many)	Fluid solution for replacement. IV administration.	Administer IV fluids only in carefully monitored patients.	Fluid requirements vary depending on animal's needs (replacement vs maintenance). Consult fluid therapy reference for optimum rate. Rate listed here is for maintenance and shock.	250, 500, 1000 mL bags	Maintenance: 55–65 mL/kg/day IV Severe dehydration: 50 mL/kg/h, IV Shock: 90 mL/kg IV (dogs) and 60–70 mL/kg IV (cats)
Lactulose (Chronulac, generic)	Laxative. Produces laxative effect by osmotic effect in colon. Lactulose also has been used for treatment of hyperammonemia (hepatic encephalopathy) because it decreases blood ammonia concentrations via lowering pH of colon, thus ammonia in colon is not as readily absorbed.	Excessive use may cause fluid and electrolyte loss.	In veterinary medicine, clinical studies to establish efficacy are not available. In addition to doses cited, 20–30 mL/kg of 30% solution retention enema has been used in cats.	10 g/15 mL	Constipation: 1 mL/4.5 kg q8h (to effect) PO Hepatic encephalopathy—Dog: 0.5 mL/kg q8h PO Cat: 2.5–5 mL/cat q8h PO
L-Dopa	See Levodopa.				
Leflunomide (Arava)	Immunosuppressive agent. Used to suppress T- and β -cell proliferation. Used to treat immune-mediated disease in dogs.	No adverse effects reported in dogs, but may decrease appetite or cause diarrhea.	Usually used as alternative to other immunosuppressive agents.	5, 10, 20 mg tablets	Dogs: 4 mg/kg per day, usually in divided doses of 2 mg/kg q12h, tapered to 2 mg/kg q24h, PO Cats: 2 mg/kg per day, for 2 days, PO, then 2 mg/kg, q48h, PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Leucovorin calcium (folinic acid) (Wellcovorin and generic)	Leucovorin is a reduced form of folic acid, which is converted to active folic acid derivatives for purine and thymidine synthesis. It is used as antidote for folic acid antagonists.	Allergic reactions have been reported in people.	Used primarily as rescue for overdoses of folic acid antagonists (methotrexate). Clinical studies have not been reported in veterinary medicine. It is not established whether leucovorin will prevent toxicity from trimethoprim-sulfonamide administration.	5, 10, 15, 25 mg tablets; 3 or 5 mg/mL injection	With methotrexate administration: 3 mg/m ² IV, IM, PO As antidote for pyrimethamine toxicosis: 1 mg/kg q24h PO
Levamisole hydrochloride (Levasole, Tramisol, Ergamisol)	Antiparasitic drug of the imidazothiazole class. Mechanism of action due to neuromuscular toxicity to parasites. Levamisole has been used for endoparasites in dogs and as microfilaricide.	May produce cholinergic toxicity. May cause vomiting in some dogs.	In heartworm-positive dogs, it may sterilize female adult heartworms.	0.184 g bolus; 11.7 g per 13 g packet; 50 mg tablet (Ergamisol)	Dog: hookworms, 5–8 mg/kg once PO (up to 10 mg/kg PO for 2 days); microfilaricide, 10 mg/kg q24h PO for 6–10 days; immunostimulant, 0.5–2 mg/kg 3 times/week PO. Cat: endoparasites, 4.4 mg/kg once PO; lungworms, 20–40 mg/kg q48h for 5 treatments PO
Levetiracetam (Keppra)	Anticonvulsant. Used for treating epilepsy when other treatments have been ineffective. It inhibits burst firing of neurons without affecting normal neuronal excitement.	Weakness, lethargy, dizziness have been reported in people. No adverse effects have been reported in animals.	May be used with other anticonvulsants, such as KBR and phenobarbital.	250-, 500-, 750-, and 1,000-mg tablets. Extended-release formulation (XR) available in 500-, 750-, and 1,000 mg-tablets. Oral solution 100 mg/mL, and 100 and 500 mg/mL solution for injection	Dog: start with 20 mg/kg q8h PO and increase gradually as necessary. Oral extended-release tablets: 30 mg/kg q12h, PO Cat: 20 mg/kg q8h PO
Levodopa (L-dopa) (Larodopa)	Converted to dopamine after crossing blood-brain barrier. Stimulates CNS dopamine receptors. In people, used for treating Parkinson disease. In animals, has been used for treating hepatic encephalopathy.	Adverse effects in animals have not been reported. In people, dizziness, mental changes, difficult urination, and hypotension are among the reported adverse effects.	Clinical studies have not been reported in veterinary medicine. Titrate dose for each patient.	100, 250, 500 mg tablets or capsules	Hepatic encephalopathy: 6.8 mg/kg initially, then 1.4 mg/kg q6h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Levothyroxine sodium (Soxoloxine, Thyo-Tabs, Synthroid Leventa)	Replacement therapy for treating patients with hypothyroidism. Levothyroxine is T4, which is converted in most patients to the active T3.	High doses may produce thyrotoxicosis, which is uncommon (compared to people). Drug interactions: Patients receiving corticosteroids may have decreased ability to convert T4 to T3.	Thyroid supplementation should be guided by testing to confirm diagnosis and postmedication monitoring to adjust dose.	0.1–0.8 mg tablets (in 0.1 mg increments), 1 mg/mL oral solution	Dog: (tablets) 18–22 µg/kg q12h PO (adjust dose via monitoring) Dog (oral solution): 20 µg/kg q24h PO Cat: 10–20 µg/kg/day PO (adjust dose via monitoring)
Lidocaine (Xylocaine and generic brands)	Local anesthetic and Class I antiarrhythmic. Lidocaine is also used commonly for acute treatment of cardiac arrhythmias.	High doses cause CNS effects (tremors, twitches, and seizures). Lidocaine can produce cardiac arrhythmias, but has greater effect on abnormal cardiac tissue than normal tissue. Cats are more susceptible to adverse effects, and lower doses should be used.	When used for local infiltration, many formulations contain epinephrine to prolong activity at injection site. Avoid epinephrine in patients with cardiac arrhythmias. Note that human formulations may contain epinephrine, but no veterinary formulations contain epinephrine. To increase pH, increase onset of action, and decrease pain from injection, one may add 1 mEq sodium bicarbonate to 10 mL lidocaine (use immediately after mixing).	5, 10, 15, 20 mg/mL injection	Dog (antiarrhythmic): 2–4 mg/kg IV (to a maximum dose of 8 mg/kg over 10-min period); 25–75 µg/kg/min IV infusion; 6 mg/kg q1.5h IM Cat (antiarrhythmic): start with 0.1–0.4 mg/kg, then increase to 0.25–0.75 mg/kg IV slowly, or 10–20 µg/kg/min infusion. For epidural (dog and cat): 4.4 mg/kg of 2% solution
Lincomycin (Lincocin)	Lincosamide antibiotic, similar in mechanism to clindamycin and erythromycin. Spectrum includes primarily grampositive bacteria. Used for pyoderma and other soft tissue infections.	Adverse effects uncommon. Lincomycin has caused vomiting and diarrhea in animals. Do not administer orally to rodents and rabbits.	Action of lincomycin and clindamycin are similar enough that clindamycin can be substituted for lincomycin.	100, 200, 500 mg tablets	15–25 mg/kg q12h PO. For pyoderma, doses as low as 10 mg/kg q12h have been used.
Linezolid (Zyvox)	Oxazolidinone antibiotic. Gram-positive spectrum that includes drug resistant strains of <i>Enterococcus</i> and <i>Staphylococcus</i> . High expense limits routine use.	Adverse effects include diarrhea and nausea. Rarely in people anemia and leukopenia have been observed. Use cautiously with monoamine oxidase inhibitors and serotonergic drugs.	Use in animals is reserved for only drug resistant infections (e.g., methicillin-resistant <i>Staphylococcus</i> spp.) for which other drugs are ineffective.	400 and 600 mg tablets. 20 mg/mL oral suspension. 2 mg/ML injection	10 mg/kg, q8–12h PO or IV

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Liothyronine (Cytomel)	Thyroid supplement. Liothyronine is equivalent to T ₃ . Usually levothyroxine is preferred.	Adverse effects have not been reported (see Levothyroxine sodium).	Doses of liothyronine should be adjusted on the basis of monitoring T ₃ concentrations in patients.	5, 25, 50, and 60 µg tablets	4.4 µg/kg q8h PO. For T ₃ suppression test in cats: collect presample for T ₄ and T ₃ , administer 25 µg q8h for 7 doses, then collect postsamples for T ₃ and T ₄ after last dose.
Lisinopril (Prinivil, Zestril)	ACE inhibitor. Used for treatment of CHF and hypertension. Inhibits synthesis of angiotensin II, producing vasodilation and decreased aldosterone.	Lisinopril has not been used extensively in animals to document adverse effects.	Clinical studies using lisinopril in animals have not been reported. With all ACE inhibitors, monitor electrolytes and renal function 3–7 days after initiating therapy and periodically thereafter.	2.5, 5, 10, 20, 40 mg tablets	Dog: 0.5 mg/kg q24h PO Cat: 0.25 mg/kg q24h PO
Lithium carbonate (Lithotabs, Lithane)	Stimulates granulopoiesis and elevates neutrophil pool in animals. In people, it is used for treatment of depression. CNS effect is related to decreased concentrations of neurotransmitters.	Adverse effects have not been reported in animals. In people, cardiovascular problems, drowsiness, and diarrhea are among the adverse effects.	Use in animals is not common. It has been used experimentally to increase neutrophils following cancer therapy.	150, 300, 600 mg capsules; 300 mg tablets; 300 mg/5 mL syrup	Dog: 10 mg/kg q12h PO Cat: not recommended
Lomustine (CCNU) (CeeNU)	Anticancer drug—alkylating agent in the nitrosourea class. Highly lipid-soluble and crosses blood-brain barrier. Used for lymphoma and brain tumors	Myelosuppression, hepatotoxicosis, vomiting	Administering on empty stomach decreases nausea. Monitor hemogram for evidence of myelosuppression.	10, 40, 100 mg capsules	Dog: 70–90 mg/m ² every 4 weeks PO. For brain tumors: 60–80 mg/m ² q6–8 week PO Cat: 50–60 mg/m ² PO every 3–6 weeks or 10–20 mg per cat PO every 3–6 weeks
Loperamide (Imodium and generic)	Opiate agonist. Stimulates smooth muscle segmentation in intestine, as well as electrolyte absorption. Used for acute treatment of nonspecific diarrhea	Loperamide does not produce systemic opiate adverse effects. Its systemic effects are low and it does not cross the blood-brain barrier. However, some breeds (e.g., collies, Australian shepherds, and collie-mixed breeds) may be susceptible to adverse effects because of a deletion of the P-gp. In any animal, excessive use can cause constipation.	Doses are based primarily on empiricism or extrapolation of human dose. Clinical studies have not been performed in animals.	2 mg tablet; 0.2 mg/mL oral liquid	Dog: 0.1 mg/kg q8–12h PO Cat: 0.08–0.16 mg/kg q12h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Lorazepam (Ativan)	Is a benzodiazepine, may be considered for anxiety disorders in animals, but it has not been used as commonly as other drugs such as diazepam.	Sedation is the most common side effect. Lorazepam causes polyphagia. Some animals may experience paradoxical excitement. Chronic administration may lead to dependence and a withdrawal syndrome if discontinued.	There have been no clinical trials in veterinary medicine, although it is expected to produce effects similar to other benzodiazepines.	0.5, 1, and 2 mg tablets and 2 and 4 mg/mL injection	Dog: 0.05 mg/kg q12h PO Seizures: 0.2 mg/kg IV. Repeat every 3–4 hours for seizure control, if necessary Cat: 0.05 mg/kg q12–24h PO.
Lufenuron (Program)	Antiparasitic. Used for controlling fleas in animals. Inhibits development in hatching fleas. May be used for dermatophytes in dogs and cats, although efficacy has been questioned by some experts	Adverse effects have not been reported. Appears to be relatively safe during pregnancy and in young animals	Lufenuron may control flea development with administration once every 30 days in animals.	45, 90, 135, 204.9, 409.8 mg tablets; 135 and 270 mg suspension per unit pack	Flea control: Dog: 10 mg/kg PO every 30 days Cat: 30 mg/kg PO every 30 days Cat injection: 10 mg/kg SC every 6 months Antifungal dose: Dog: 80 mg/kg Cat: 100 mg/kg. In endemic areas (e.g., catteries) treat cats once a month
Lufenuron + milbemycin oxime (Sentinel tablets and Flavor Tabs)	Combination of two antiparasitic drugs. See Lufenuron or Milbemycin oxime. Used to protect against fleas, heartworms, roundworms, hookworms, and whipworms	See Lufenuron or Milbemycin oxime.	See Lufenuron or Milbemycin oxime.	Milbemycin oxime/lufenuron ratio is as follows: 2.3/46 mg tablets; 5.75/115, 11.5/230, and 23/460 mg Flavor Tabs	Dog: Administer one tablet every 30 days. Each tablet formulated for size of dog. Cat: This product is not registered for cats.
Luteinizing hormone	See Gonadorelin.				
L-Lysine (Enisyl-F)	Amino acid for treatment of herpes infections. Oral supplementation for cats with feline herpesvirus-1 (FHV-1) infection. In clinical trials, efficacy for FHV has not been demonstrated for controlling upper respiratory or ocular infections.	Well tolerated in cats	Powder can be mixed with food. Paste can be given directly.	250 mg/mL paste	Cat: 400 mg PO/day Paste formulation: 1–2 mL PO to adult cats and 1 mL to kittens

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Magnesium citrate (Citroma, Citro-Nesia [Citro-Mag in Canada])	Saline cathartic. Acts to draw water into small intestine via osmotic effect. Fluid accumulation produces distention, which promotes bowel evacuation. Used for constipation and bowel evacuation prior to certain procedures	Adverse effects have not been reported in animals. However, fluid and electrolyte loss can occur with overuse. Magnesium accumulation may occur in patients with renal impairment. <i>Drug interactions:</i> Magnesium-containing cathartics decrease oral absorption of ciprofloxacin and other fluoroquinolones.	Commonly used to evacuate bowel prior to surgery or diagnostic procedures. Onset of action is rapid.	Oral 6% suspension	2–4 mL/kg/day PO
Magnesium hydroxide (Milk of Magnesia)	Same as for magnesium citrate. Magnesium hydroxide also is used as oral antacid to neutralize stomach acid.	Magnesium accumulation in patients with renal failure is possible.	Same as Magnesium citrate.	Oral liquid 400 mg/5 mL	Antacid: 5–10 mL/kg q4–6h PO Cathartic (dog): 15–50 mL/kg q24h PO Cathartic (cat): 2–6 mL/cat q24h PO
Magnesium sulfate (Epsom salts)	Magnesium sulfate (Epsom salts) is used as cathartic when administered orally. It also has been used as a source of magnesium for treating refractory arrhythmias.	Same as Magnesium citrate.	See Magnesium citrate.	Crystals. Many generic preparations	Dog: 8–25 g/dog q24h PO For treating arrhythmias: 0.15–0.3 mEq/kg slowly IV over 5–15 minutes followed by 0.75–1.0 mEq/kg per day When supplementing fluid solutions: 0.75–1.0 mEq/kg/day Cat: 2–5 g/cat q24h PO
Mannitol (Osmotrol)	Hyperosmotic diuretic. Increases plasma osmolality, which draws fluid from tissues to plasma. Antiglaucoma agent. Used for treatment of edema and reducing intraocular pressure. Mannitol also has been used to promote urinary excretion of certain toxins.	Causes fluid and electrolyte imbalance. Do not use in dehydrated patients. Use cautiously when intracranial bleeding is suspected because it may increase bleeding. Administration that is too rapid may expand the extracellular volume excessively.	Use only in patients in which fluid and electrolyte balance can be monitored. Once solutions are prepared, discard unused portions.	5%–25% solution for injection	Diuretic: 1 g/kg of 5%–25% solution IV to maintain urine flow. Glaucoma or CNS edema: 0.25–2 g/kg of 15%–25% solution over 30–60 min IV (repeat in 6 h, if necessary). Fluid expansion: Dog: 0.5–2 g/kg IV Cat: 0.5–0.8 g/kg IV over 5 min followed by CRI of 1 mg/kg/min

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Marbofloxacin (Zeniquin)	Fluoroquinolone antimicrobial. Spectrum includes staphylococci, gram-negative bacilli, and some <i>Pseudomonas</i> .	May cause some nausea and vomiting at high doses. Avoid use in young animals. Safe for cats (ocular safety) at recommended dose.	Use susceptibility testing to guide therapy.	25, 50, 100, and 200 mg tablets	2.75–5.55 mg/kg q24h PO
Maropitant (Cerenia)	Antiemetic. Neurokinin (NK) type-1 inhibitor. Maropitant acts to prevent vomiting caused by chemotherapy and motion sickness. It is also effective for inhibiting vomiting from both central and peripheral stimulation.	In clinical trials, there were few adverse effects in dogs or cats. Salivation and muscle tremors occurred in some animals.	Studies have shown NK-1 inhibitors to be effective antiemetics for a variety of stimuli in both dogs and cats. Keep refrigerated to avoid pain from injection.	10 mg/mL injection; 16, 24, 60, or 160 mg tablets	Dog: 1 mg/kg SC q24h for up to 5 days; 2 mg/kg PO q24h for up to 5 days; for motion sickness, 8 mg/kg PO q24h for up to 2 days. Cat: 1 mg/kg, once per day SC or PO
MCT oil (medium chain triglyceride oil [many sources])	Medium chain triglycerides. Used to treat hepatic encephalopathy	Adverse effects not reported in veterinary medicine. May cause diarrhea in some patients.	Results of clinical trials using MCT oil have not been reported. Many enteral feeding formulas contain MCT oil (many polymeric formulations).	Oral liquid	1–2 mL/kg q24h in food
Meclizine (Antivert, generic)	Antiemetic and antihistamine. Used for treatment of motion sickness. Action may be caused by central anticholinergic actions. Also may suppress chemoreceptor trigger zone (CRTZ)	Adverse effects have not been reported in animals. Anticholinergic (atropine-like) effects may cause side effects.	Results of clinical studies in animals have not been reported. Use in animals is based on experience in people or anecdotal experiences in animals.	12.5, 25, 50 mg tablets	Dog: 25 mg q24h PO (for motion sickness, administer 1 h prior to traveling) Cat: 12.5 mg q24h PO, (1 h prior to traveling)
Meclofenamate sodium (Arquel, Meclofen)	NSAID. Used for treatment of arthritis and other inflammatory disorders. Use has diminished because of availability of other NSAIDs.	Adverse effects have not been reported in animals, but adverse effects common to other NSAIDs are possible.	Results of clinical studies in animals have not been reported. Use in animals is based on experience in people or anecdotal experiences in animals. Administer with food.	50, 100 mg capsules Formulations for dogs are rarely available any longer.	Dog: 1 mg/kg PO q24h for up to 5 days Cat: not recommended
Medetomidine (Domitor)	α_2 -adrenergic agonist. Used primarily as sedative, anesthetic adjunct, and analgesia. Use has diminished because of availability of dexmedetomidine (Dexdomitor), which is more specific.	α_2 -agonists decrease sympathetic output. Cardiovascular depression may occur. Medetomidine will cause an initial bradycardia and hypertension.	May be used for sedation, analgesia, and minor surgical procedures. Should be reversed with equal volume of atipamezole	1.0 mg/mL injection	750 μ g/m ² IV or 1000 μ g/m ² IM Lower doses may be used for short-term sedation and analgesia

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Medium chain triglycerides	See MCT oil.				
Medroxy-progesterone acetate (Depo-Provera [injection]; Provera [tablets])	Progesterin hormone. Derivative of acetoxyprogesterone. In animals, used as progesterone hormone treatment to control estrous cycle. Also used for management of some behavioral and dermatologic disorders (such as urine spraying in cats and alopecia)	Adverse effects include polyphagia, polydipsa, adrenal suppression (cats), increased risk of diabetes, pyometra, diarrhea, and increased risk of neoplasia.	Clinical studies in animals have studied primarily the reproductive use and effects on behavioral use. Medroxyprogesterone acetate may have fewer side effects than megestrol acetate.	150, 400 mg/mL suspension injection; 2.5, 5, 10 mg tablets	1.1–2.2 mg/kg q7d IM. For behavioral use, 10–20 mg/kg is injected SC. For prostatic disease in dogs, use 3–5 mg/kg IM, SC
Megestrol acetate (Ovaban)	Progesterin hormone	Long-term use may produce adverse effects including increased risk of neoplasia and diabetes.	Avoid chronic use. Use for controlling behavior problems or dermatologic therapy is discouraged.	5 mg tablets	Dog—proestrus: 2 mg/kg q24h PO for 8 days; anestrus: 0.5 mg/kg q24h PO for 30 days; behavior: 2–4 mg/kg q24h for 8 days (reduce dose for maintenance). Cat—dermatologic therapy or urine spraying: 2.5–5 mg/cat q24h PO for one week, then reduce to 5 mg once or twice/week; suppress estrus: 5 mg/cat/day for 3 days, then 2.5–5 mg once/week for 10 weeks
Melarsomine (Immiticide)	Organic arsenical compound used for heartworm therapy. Heartworm adulticide. Arsenicals alter glucose uptake and metabolism in heartworms.	Adverse effects: pulmonary thromboembolism (7–20 days after therapy), anorexia (13% incidence), injection site reaction (myositis) (32% incidence), lethargy or depression (15% incidence). Causes elevations of hepatic enzymes. High doses (3×) can cause pulmonary inflammation and death. If high doses are administered, dimercaprol (3 mg/kg IM) may be used as antidote.	Avoid human exposure. (Wash hands after handling, or wear gloves.) Do not freeze solutions after they are prepared.	25 mg/mL injection. After reconstitution, retains potency for 24 h	Dog: Administer via deep IM injection. 2.5 mg/kg q24h for two consecutive days. Three dose protocol includes 2.5 mg/kg once, then in 1 month, two additional doses 24 h apart. Doxycycline may be administered to improve efficacy and reduce pulmonary reaction.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Meloxicam (Mobic [human drug], Metacam [veterinary drug])	NSAID of the oxicam class. Meloxicam is relatively COX-1-sparing and has high COX-1: COX-2 ratio. It has been used in dogs and cats for pain and osteoarthritis.	Adverse effects are GI and include vomiting, diarrhea, and ulceration.	Oral suspension is in a palatable flavor, which may be added to pet's food. Use reduced dose in cats. OroCAM is a transmucosal spray applied to the oral mucosa of dogs (0.1 mg/kg).	0.5 mg/mL (0.02 mg per drop) oral suspension, 1.5 mg/mL (0.05 mg per drop) oral suspension, 0.5% (5 mg/mL) injection, and 7.5- and 15-mg tablets (human preparation). An oral transmucosal is available as a spray. The spray is available in 3 sizes: 0.25 mg, 0.5 mg, and 1.075 mg per spray	Dog: 0.2 mg/kg initial loading dose, then 0.1 mg/kg q24h PO. Injection: 0.2 mg/kg IV or SC. Cat: single antipyretic dose, 0.15–0.3 mg/kg single dose SC. Long-term dose, 0.05 mg/kg once daily, or extend interval to q48–72h PO
Melphalan (Alkeran)	Anticancer agent. Alkylating agent, similar in action to cyclophosphamide	Adverse effects related to its action as an anticancer agent. Causes myelosuppression.	Used to treat multiple myeloma and certain carcinomas.	2 mg tablets, 50 mg vials for injection	1.5 mg/m ² (or 0.1–0.2 mg/kg) q24h PO for 7–10 days (repeat every 3 weeks)
Meperidine (Demerol)	Synthetic opioid agonist with activity primarily at the μ -opiate receptor. Similar in action to morphine, except with approximately 1/7 of the potency. 75 mg meperidine IM or 300 mg PO has similar potency as 10 mg morphine.	Side effects similar to other opiates.	Although comparative clinical studies have not been conducted in animals, meperidine is considered an effective analgesic in dogs and cats, but with short duration.	50, 100 mg tablets; 10 mg/mL syrup; 25, 50, 75, 100 mg/mL injection	Dog: 5–10 mg/kg IV, IM as often as q2–3h (or as needed) Cat: 3–5 mg/kg IV, IM q2–4h (or as needed)
Mepivacaine (Carbocaine-V)	Local anesthetic of the amide class. Medium potency and duration of action, compared to bupivacaine. Compared to lidocaine, longer-acting, but equal potency	Mepivacaine may cause less irritation to tissues than lidocaine.	For epidural use, do not exceed 8 mg/kg total dose. Duration of epidural is 2.5–3 h.	2% (20 mg/mL) injection	Variable dose for local infiltration. For epidural, 0.5 mL of 2% solution every 30 sec until reflexes are absent
6-Mercaptopurine (Purinethol)	Anticancer agent. Antimetabolite agent that inhibits synthesis of purines in cancer cells.	Many side effects are possible that are common to anticancer therapy (many of which are unavoidable), including bone marrow suppression and anemia. Do not use in cats.	Used for various forms of cancer, including leukemia and lymphoma. Consult specific anticancer protocol for specific regimen.	50 mg tablets	Dog: 50 mg/m ² q24h PO Cat: do not use

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Meropenem (Merrem IV)	Broad-spectrum carbapenem antibiotic; indicated primarily for resistant infections caused by bacteria resistant to other drugs. Bactericidal. More active than imipenem and ertapenem.	Risks similar to those of other β -lactam antibiotics. Meropenem does not cause seizures as frequently as imipenem. SC injections may cause slight hair loss at injection site.	Dosage guidelines have been extrapolated from pharmacokinetic studies in animals and not tested for efficacy in animals. Meropenem is more soluble than imipenem and can be injected via bolus rather than administered in fluid solutions.	500 mg/20 mL or 1g/30 mL vial for injection	Dogs: 8.5 mg/kg q12h SC up to 12 mg/kg q8h SC or 24 mg/kg IV q12h For <i>Pseudomonas</i> : 12 mg/kg q8h, SC or 25 mg/kg q8h IV Cats: 10 mg/kg IV, or SC. q12h.
Mesalamine (Asacol, Mesalal, Pentasa)	5-Aminosalicylic acid. Used as treatment for colitis. Action is not precisely known, but suppresses inflammation in colon. Component of sulfasalazine.	Mesalamine alone has not been associated with side effects in animals.	Mesalamine use has not been reported in animals from clinical trials; however, it has been used as a substitute for sulfasalazine in animals that cannot tolerate sulfonamides.	400 mg tablets; 250 mg capsules	Veterinary dose has not been established. The usual human dose is 400–500 mg PO q6–8h which has been used to extrapolate animal dose of 5–10 mg/kg q8h PO (also see Sulfasalazine, Olsalazine)
Metaproterenol (Alupent, Metaprel)	β -adrenergic agonist. β_2 -specific. Used primarily for bronchodilation.	Adverse effects related to excessive β -adrenergic stimulation.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals. β_2 -agonists also have been used in people to delay labor (inhibit uterine contractions).	10, 20 mg tablets; 5 mg/mL syrup; and inhalers	0.325–0.65 mg/kg q4–6h PO
Methadone (Methadose, and generic)	Opiate analgesic. Methadone has analgesic properties via binding to opiate receptors, and may also produce some NMDA-receptor antagonism. Methadone is used as an adjunct to anesthesia protocols and for analgesia.	Adverse effects in dogs include sedation and vomiting (rarely). However, other opiate adverse effects in dogs have not been reported.	Oral doses that are available for humans have not been absorbed in dogs.	2 mg/mL oral solution; 10 and 20 mg/mL solution for injection; 5, 10, and 40 mg tablets.	Dog: 0.1–0.5 IV, or 0.5–2.2 mg/kg SC or IM q3–4h Cat: 0.05–0.1 mg/kg IV or 0.2–0.5 mg/kg SC or IM q3–4h
Methazolamide (Neptazane)	Carbonic anhydrase inhibitor. Produces less diuresis than others (See Dichlorphenamide and Acetazolamide).	Use cautiously in patients sensitive to sulfonamides. (See Acetazolamide, Dichlorphenamide.)	Used to treat glaucoma in patients. May be used with other glaucoma agents. (See Acetazolamide, Dichlorphenamide.)	25, 50 mg tablets	2–3 mg/kg q8h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Methenamine hippurate (Hiprex, Urex) (Mandelamine and generic)	Urinary antiseptic. Converted to formaldehyde in acidic urine to produce antibacterial/antifungal effect. Active against a wide range of bacteria. Resistance does not develop. Less effective against <i>Proteus</i> , which produces an alkaline urine pH. Not effective for systemic infections	Although formaldehyde formation in bladder may be irritating, in people, high doses were required (> 8 gm/day). In animals, no adverse effects have been reported.	Results of clinical studies in animals have not been reported. Use in animals is based on experience in people, or anecdotal experience in animals. Urine must be acidic for methenamine to convert to formaldehyde (monitor pH periodically). pH below 5.5 is optimal. Supplement with ascorbic acid or ammonium chloride to lower pH.	Methenamine hippurate: 0.6 and 1 g tablets. Methenamine mandelate is no longer available.	Methenamine hippurate: Dog: 500 mg/dog q12h PO Cat: 250 mg/cat q12h PO
Methimazole (Tapazole, Felimazole)	Antithyroid drug. Used for treating hyperthyroidism, primarily in cats. Action is to serve as substrate for thyroid peroxidase and decrease incorporation of iodide into tyrosine molecules.	In people, it has caused agranulocytosis and leukopenia. In cats, lupus-like reactions are possible, such as vasculitis and bone marrow changes. Well tolerated in dogs.	Use in cats is based on experimental studies in hyperthyroid cats. Methimazole has, for the most part, replaced propylthiouracil for use in cats. Transdermal formulations (compounded) have been used. They may be effective in some cats, but results are inconsistent. Cats should be monitored for response by measuring T4 levels periodically.	5 and 10 mg tablets (human form) and 2.5 and 5 mg tablets (veterinary form)	Cat: 2.5 mg per cat q12h PO × 7–14 days, then 5–10 mg per cat PO q12h, and monitor T ₄ concentrations
DL-Methionine	See Racemethionine.				
Methocarbamol (Robaxin-V)	Skeletal muscle relaxant. Depresses polysynaptic reflexes. Used for treatment of skeletal muscle spasms.	Causes some depression and sedation of the CNS.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	500, 750 mg tablets; 100 mg/mL injection	44 mg/kg q8h PO, IV on the first day, then 22–44 mg/kg q8h PO. Up to 130 mg/kg for severe conditions
Methohexitol (Brevital)	Barbiturate anesthetic. Methohexitol is about 2–3 × more potent than pentothal, but with shorter duration.	Similar to other barbiturates such as thiopental.	Monitor respiratory and cardiovascular function.	0.5, 2.5, and 5 g vials for injection	3–6 mg/kg IV (give slowly to effect)

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Methotrexate (MTX, Mexate, Folex, Rheumatrex, and generic)	Anticancer agent. Used for various carcinomas, leukemia, and lymphomas. Action is via antimetabolite action. Analogue of folic acid that binds dihydrofolate reductase. Inhibits DNA, RNA, and protein synthesis. In people, methotrexate is also commonly used for autoimmune diseases, such as rheumatoid arthritis.	Anticancer drugs cause predictable (and sometimes unavoidable) side effects that include bone marrow suppression, leukopenia, and immunosuppression. Hepatotoxicity has been reported in people from methotrexate therapy. <i>Drug interactions:</i> Concurrent use with NSAIDs may cause severe methotrexate toxicity. Do not administer with pyrimethamine, trimethoprim, or sulfonamides.	Use in animals has been based on experimental studies. There is only limited clinical information available. Consult specific anticancer protocols for precise dosage and regimen.	2.5 mg tablets; 2.5 or 25 mg/mL injection	2.5–5 mg/m ² q48h PO (dose depends on specific protocol) Dog: 0.3–0.5 mg/kg once/week IV Cat: 0.8 mg/kg IV every 2–3 weeks
Methoxamine (Vasoxyl)	Adrenergic agonist. Sympathomimetic. α_1 -adrenergic agonist. Specific for α_1 -receptors used as a vasopressor.	Adverse effects related to excessive stimulation of α_1 -receptor (prolonged peripheral vasoconstriction). Reflex bradycardia may occur.	Used primarily in critical care patients or during anesthesia to increase peripheral resistance and increase blood pressure. Short onset and duration of action	20 mg/mL injection is no longer available in the US. Some solutions have been compounded.	200–250 μ g/kg IM, or 40–80 μ g/kg IV; repeat dose as needed
Methylene blue 0.1% (generic, also called new methylene blue)	Antidote for intoxication. Used to treat methemoglobinemia. Methylene blue acts as reducing agent to reduce methemoglobin to hemoglobin.	Methylene blue can cause Heinz body anemia in cats, but is safe when used at therapeutic doses listed here.	Comparison of effects for intoxication has only been performed in experimental studies.	1% solution (10 mg/mL)	1.5 mg/kg IV, slowly, once
Methylprednisolone (Medrol)	Glucocorticoid anti-inflammatory drug. Compared to prednisolone, methylprednisolone is 1.25× more potent.	Same as for other glucocorticoids. Manufacturer suggests that methylprednisolone causes less PU/PD than prednisolone.	Use of methylprednisolone is similar to that of other corticosteroids. Dose adjustment should be made to account for difference in potency. (See dose section.)	1, 2, 4, 8, 18, 32 mg tablets	0.22–0.44 mg/kg q12–24h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Methylprednisolone acetate (Depo-Medrol)	Depot form of methylprednisolone. Slowly absorbed from IM injection site, producing glucocorticoid effects for 3–4 weeks in some animals. Used for intralesional therapy, intra-articular therapy, and inflammatory conditions	Many adverse effects are possible from use of corticosteroids. Cardiovascular problems (congestive heart failure) have been associated with use in cats. Chronic use of methylprednisolone acetate may cause long-term adverse effects.	Use of methylprednisolone acetate should be evaluated carefully because one injection will cause glucocorticoid effects that persist for several days to weeks.	20 or 40 mg/mL suspension for injection	Dog: 1 mg/kg (or 20–40 mg/dog) IM every 1–3 weeks Cat: 10–20 mg/cat IM every 1–3 weeks
Methylprednisolone sodium succinate (Solu-Medrol)	Same as methylprednisolone, except that this is a water-soluble formulation intended for acute therapy when high IV doses are needed for rapid effect. Used for treatment of shock and CNS trauma.	Adverse effects are not expected from single administration; however, with repeated use, other side effects are possible.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	1 and 2 g and 125 and 500 mg vials for injection	For emergency use: 30 mg/kg IV and repeat at 15 mg/kg in 2–6 h, IV
Methyltestosterone (Android, generic)	Anabolic androgenic agent. Used for anabolic actions or testosterone hormone replacement therapy (androgenic deficiency). Testosterone has been used to stimulate erythropoiesis.	Adverse effects caused by excessive androgenic action of testosterone. Prostatic hyperplasia is possible in male dogs. Masculinization can occur in female dogs. Hepatopathy is more common with oral methylated testosterone formulations.	See also Testosterone cypionate, Testosterone propionate. Use of testosterone androgens has not been evaluated in clinical studies in veterinary medicine. Use is based primarily on experimental evidence or experiences in people.	10, 25 mg tablets	Dog: 5–25 mg/dog q24–48h PO Cat: 2.5–5 mg/cat q24–48h PO
Metoclopramide (Reglan, Maxolon)	Prokinetic drug. Centrally acting antiemetic. Stimulates motility of upper GI tract. Action is to inhibit dopamine receptors and enhance action of acetylcholine in GI tract. Used primarily for gastroparesis and treatment of vomiting. It is not effective for dogs with gastric dilation.	Adverse effects are primarily related to blockade of central dopaminergic receptors. Adverse effects similar to phenothiazines (e.g., acepromazine) have been reported, in addition to behavioral changes. Do not use in epileptic patients or with diseases caused by GI obstruction.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals. Most use is for general antiemetic purposes, but doses as high as 2 mg/kg have been used to prevent vomiting during cancer chemotherapy.	5, 10 mg tablet; 1 mg/mL oral solution; 5 mg/mL injection	0.2–0.5 mg/kg q6–8h IV, IM, PO CRI: loading dose of 0.4 mg/kg IV, followed by 0.3 mg/kg/h IV. In refractory patients, rates up to 1.0 mg/kg/h have been used Antiemetic treatment with cancer chemotherapy: up to 2 mg/kg/24h

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Metoprolol tartrate (Lopressor)	Adrenergic-blocking agent, β_1 -adrenergic blocker. Similar properties to propranolol, except that metoprolol is specific for β_1 -receptor. Used to control tachyarrhythmias and slow heart rate.	Adverse effects are primarily caused by excessive cardiovascular depression (decreased inotropic effects). May cause heart block. Use cautiously in animals prone to bronchoconstriction.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	50, 100 mg tablets; 1 mg/mL injection	Dog: 5–50 mg/dog (0.5–1.0 mg/kg) q8h PO Cat: 2–15 mg/cat q8h PO
Metronidazole (Flagyl and generic) and Metronidazole benzoate	Antibacterial and antiprotozoal drug. Disrupts DNA in organism via reaction with intracellular metabolite. Action is specific for anaerobic bacteria and protozoa, such as <i>Giardia</i> .	Most severe adverse effect is caused by toxicity to CNS. High doses have caused lethargy, CNS depression, ataxia, vomiting, and weakness. Metronidazole may be mutagenic. Fetal abnormalities have not been demonstrated in animals with recommended doses, but use cautiously during pregnancy.	Metronidazole is one of the most commonly used drugs for anaerobic infections and for giardiasis. Maximum dose that should be administered is 50–65 mg/kg/day in any species. Although tablets have been broken or crushed for oral administration to cats, they find these unpalatable. When palatability is a problem in cats, consider metronidazole benzoate.	250, 500 mg tablet; 50 mg/mL suspension; 5 mg/mL injection; the benzoate form is not available commercially and must be obtained from compounding pharmacies. 20 mg of metronidazole benzoate = 12.4 mg metronidazole.	For anaerobes—Dog: 15 mg/kg q12h, or 12 mg/kg q8h PO Cat: 10–25 mg/kg q24h PO For <i>Giardia</i> —Dog: 12–15 mg/kg q12h for 8 days PO Cat: 17 mg/kg (1/3 tablet per cat) q24h for 8 days
Mexiletine (Mexitil)	Antiarrhythmic drug. Used for ventricular arrhythmias. Mechanism of action is to block fast sodium channel. Class IB antiarrhythmic agent. An additional use of mexiletine is its use for treating chronic pain. It is used to treat pain caused by diabetic neuropathy and nerve injury and lower doses than the antiarrhythmic dose.	May produce arrhythmias. Use cautiously in animals with liver disease. Do not use in cats.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	150, 200, 250 mg capsules	Dog: 6–10 mg/kg q8–12h PO Chronic pain caused by nerve injury: 4–10 mg/kg PO, q8h. Not recommended for cats

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Midazolam hydrochloride (Versed)	Benzodiazepine. Action is similar to other benzodiazepines. Used as anesthetic adjunct. Absorbed better from IM injection than other benzodiazepines	Use very cautiously IV, especially with opiates. IV midazolam may cause cardiorespiratory depression.	Clinical experience is based on anecdotal reports and experimental studies. Compared to other benzodiazepines, midazolam can be administered IM.	5 mg/mL injection	Dog: 0.1–0.25 mg/kg IV, IM or 0.1–0.3 mg/kg/h IV infusion Cat: (sedation) 0.05 mg/kg IV; (induction) 0.3–0.6 mg/kg IV; combined with 3 mg/kg ketamine
Milbemycin oxime (Interceptor, Interceptor Flavor Tabs, and SafeHeart)	Antiparasitic drug of the macrocyclic lactone group. Mechanism of action is similar to ivermectin. Used as heartworm preventative, miticide, and microfilaricide. Used to control infections of hookworm, roundworms, and whipworms. At high doses, it has been used to treat Demodex infections in dogs.	In susceptible dogs (collie breeds), milbemycin may cross the blood–brain barrier and produce CNS toxicosis (depression, lethargy, coma). At doses used for heartworm prevention, this effect is less likely.	Doses vary, depending on parasite treated. Consult dose column. Treatment of Demodex requires high dose administered daily. See also Lufenuron + milbemycin oxime.	2.3, 5.75, 11.5, and 23 mg tablet	Dog: microfilaricide: 0.5 mg/kg q30 days PO; Demodex: 2 mg/kg q24h PO for 60–120 days; heartworm prevention and control of endoparasites: 0.5 mg/kg every 30 days PO. Cat: for heartworm and endoparasite control, 2.0 mg/kg every 30 days PO
Mineral oil (generic)	Lubricant laxative. Increases water content of stool. Used to increase passage of feces for treatment of impaction and constipation.	Adverse effects have not been reported. Chronic use may decrease absorption of fat-soluble vitamins.	Use is empirical. No clinical results reported.	Oral liquid	Dog: 10–50 mL/dog q12h PO Cat: 10–25 mL/cat q12h PO
Minocycline hydrochloride (Minocin, Solodyn)	Tetracycline antibiotic. Similar to doxycycline.	Minocycline may cause vomiting and gastrointestinal disturbances, especially at high doses.	Clinical use has not been reported, but properties are similar to doxycycline. Used in dogs and cats as a substitute for minocycline. It has similar activity and clinical indications as for doxycycline.	50, 75 and 100 mg tablets; or capsules 10 mg/mL oral suspension	Dog: 5 mg/kg q12h PO Cat: 8.8 mg/kg (or 50 mg per cat) q24h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Mirtazapine (Remeron)	Used as an antiemetic and appetite stimulant. Action is via blockade of serotonin receptors and antagonism of alpha-2 receptors.	In cats, twitching and changes in behavior have been observed.	Doses and recommendations in animals are based primarily on studies performed in cats. Use in dogs is based primarily on anecdotal experience.	15 and 30 mg tablets	Dogs: 0.5 mg/kg q24h, PO. Generally in the range of 3.75–7.5 mg per dog, daily, PO Cats: 1.9 mg per cat, PO. Doses have ranged from 3.75 to 7.5 mg per cat, per day, PO (one fourth to one half of a 15-mg tablet). In healthy cats it can be administered once daily. In cats with chronic kidney disease, increase interval to q48h
Misoprostol (Cytotec)	Prostaglandin E ₂ analogue. Prostaglandins provide a cytoprotective role in the GI mucosa. Misoprostol is used to prevent gastritis and ulcers associated with NSAID therapy. Misoprostol also has been effective for atopic dermatitis in dogs.	Adverse effects are caused by effects of prostaglandins. Most common side effects are GI discomfort, vomiting, and diarrhea. Do not administer to pregnant animals; may cause abortion.	Doses and recommendations are based on clinical trials in which misoprostol was administered to prevent GI mucosal injury caused by aspirin.	0.1 mg (100 µg), 0.2 mg (200 µg) tablets	Dog: 2–5 µg/kg q12h PO Atopic dermatitis: 5 µg/kg q8h, PO Cat: dose not established
Mithramycin	Older name for plicamycin				
Mitotane (<i>o,p'</i> -DDD) (Lysodren)	Adrenocortical cytotoxic agent. Causes suppression of adrenal cortex. Used to treat adrenal tumors and pituitary-dependent-hyperadrenocorticism (PDH).	Adverse effects, especially during induction period, include lethargy, anorexia, ataxia, depression, vomiting. Corticosteroid supplementation (e.g., hydrocortisone or prednisolone) may be administered to minimize side effects.	Dose and frequency often are based on patient response. Adverse effects are common during initial therapy. Administration with food increases oral absorption. Maintenance dose should be adjusted on the basis of periodic cortisol measurements and ACTH stimulation tests. Cats usually have not responded to mitotane treatment.	500 mg tablets	Dog—for PDH: 50 mg/kg/day (in divided doses) PO for 5–10 days, then 50–70 mg/kg/week PO; for adrenal tumor: 50–75 mg/kg/day for 10 days, then 75–100 mg/kg/week PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Mitoxantrone hydrochloride (Novantrone)	Anticancer antibiotic. Similar to doxorubicin in action. Used for leukemia, lymphoma, and carcinomas.	As with all anticancer agents, certain adverse effects are predictable, unavoidable, and related to drug's action. Mitoxantrone produces myelosuppression, vomiting, anorexia, and GI upset, but may be less cardiotoxic than doxorubicin.	Proper use of mitoxantrone usually follows a specific anticancer protocol. Consult specific protocol for dosing regimen.	2 mg/mL injection	Dog: 5–5.5 mg/m ² IV every 21 days Cat: 6.0–6.5 mg/m ² IV every 21 days
Morphine sulfate (generic)	Opioid agonist, analgesic. Prototype for other opioid agonists. Action of morphine is to bind to μ - and κ -opiate receptors on nerves and inhibit release of neurotransmitters involved with transmission of pain stimuli (such as substance P). Morphine also may inhibit release of some inflammatory mediators. Central sedative and euphoric effects are related to μ -receptor effects in brain.	Like all opiates, side effects from morphine are predictable and unavoidable. Side effects from morphine administration include sedation, constipation, and bradycardia. Respiratory depression occurs with high doses. Tolerance and dependence occur with chronic administration. Cats are more sensitive to excitement than other species.	Effects from morphine administration are dose dependent. Low doses (0.1–0.25 mg/kg) produce mild analgesia. Higher doses (up to 1 mg/kg) produce greater analgesic effects and sedation. Usually morphine is administered IM, IV, or SC. Oral absorption is inconsistent and unreliable. Epidural administration has been used for surgical procedures.	1 and 15 mg/mL injection; 30, 60 mg delayed-release tablets	Dog: 0.1–1 mg/kg IV, IM, SC (dose is escalated as needed for pain relief) q4–6h. 0.5 mg/kg q2h has been used to provide consistent analgesia CRI: 0.2 mg/kg followed by 0.1 mg/kg/h, IV Epidural: 0.1 mg/kg Cat: 0.1 mg/kg IM, SC q3–6h (or as needed)
Moxidectin (canine form: ProHeart; equine oral gel: Quest; cattle pour-on: Cydectin)	Antiparasitic drug. Neurotoxic to parasites by potentiating glutamate-gated chloride ion channels in parasites. Used for endo- and ectoparasites, as well as heartworm prevention.	Toxicity may occur at high doses and in species in which ivermectin crosses blood–brain barrier (collie breeds). Toxicity is neurotoxic, and signs include depression, ataxia, difficulty with vision, coma, and death.	Similar use as ivermectin. Extreme caution is recommended if equine formulation is considered for use in small animals. Toxic overdoses are likely because the equine formulation is highly concentrated.	30, 68, 136 μ g tablets for dogs; 20 mg/mL equine oral gel; and 5 mg/mL cattle pour-on	Dog—heartworm prevention: 3 μ g/kg q30d PO Endoparasites: 25–300 μ g/kg Demodex: 400 μ g/kg/day PO and up to 500 μ g/kg/day for 21–22 weeks Long-acting: Proheart-6: 0.17 mg/kg SC as a single dose
Moxifloxacin (Avelox)	Fluoroquinolone antibiotic. Similar to other fluoroquinolones, except with greater activity against gram-positive and anaerobic bacteria.	Similar to those of other fluoroquinolones. Because of the increased spectrum of action on anaerobic bacteria, greater GI disturbance is possible from oral dose.	Doses and recommendations based primarily on limited clinical experience and extrapolation from human studies	400 mg tablet	10 mg/kg q24h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Mycophenolate (Cell Cept)	Mycophenolate is metabolized to mycophenolic acid. It is used to suppress immunity for transplantation and for treatment of immune-mediated diseases.	In dogs, gastrointestinal problems (diarrhea, vomiting) have been the most common effects reported.	Mycophenolate is used in some patients that cannot tolerate other immunosuppressive drugs such as azathioprine or cyclophosphamide.	250 and 500 mg capsule	Dog: 10 mg/kg q8h PO, or 20 mg/kg q12h PO Cats: 10 mg/kg q12h, PO
Naloxone (Narcan)	Opiate antagonist. Used to reverse effects from opiate agonists (such as morphine). Naloxone may be used to reverse sedation, anesthesia, and adverse effects caused from opiates.	Adverse effects are not reported. Tachycardia and hypertension have been reported in people.	Administration may have to be individualized based on response in each patient. Naloxone's duration of action is short in animals (60 min) and may have to be repeated.	20 or 400 µg/mL or 1 mg/mL injection	0.01–0.04 mg/kg IV, IM, SC, as needed, to reverse opiate
Naltrexone (Trexan)	Opiate antagonist. Similar to naloxone, except that it is longer acting and administered orally. Used in people for treatment of opiate dependence. In animals, it has been used for treatment of some obsessive-compulsive behavioral disorders.	Adverse effects have not been reported in animals.	Treatment for obsessive-compulsive disorders in animals has been reported with naltrexone. Relapse rates may be high.	50 mg tablets	Dog: For behavior problems: 2.2 mg/kg q12h PO
Nandrolone decanoate (Deca-Durabolin)	Anabolic steroid. Derivative of testosterone. Anabolic agents are designed to maximize anabolic effects while minimizing androgenic action. Anabolic agents have been used for reversing catabolic conditions, increasing weight gain, increasing muscling in animals, and stimulating erythropoiesis.	Adverse effects from anabolic steroids can be attributed to the pharmacologic action of these steroids. Increased masculine effects are common. Increased incidence of some tumors has been reported in people.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	50, 100, 200 mg/mL injection	Dog: 1–1.5 mg/kg/week IM Cat: 1 mg/kg/week IM

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Naproxen (Naprosyn, Naxen, Aleve [naproxen sodium])	NSAID. Action is via inhibition of prostaglandins. Used for treatment of inflammatory disorders (e.g., arthritis). Use in animals has declined because of availability of other NSAIDs.	Naproxen is a potent NSAID. Adverse effects attributed to GI toxicity are common to all NSAIDs. Naproxen has produced serious ulceration in dogs because elimination in dogs is much slower than in people or horses.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on pharmacokinetic studies in experimental animals. Use caution when using the OTC formulation designed for people because the tablet size is much larger than safe dose for dogs. 220 mg naproxen sodium is equivalent to 200 mg naproxen.	220 mg tablet (OTC); 25 mg/mL oral suspension; 250, 375, 500 mg tablets (Rx)	Dog: 5 mg initially, then 2 mg/kg q48h PO Cat: not recommended
Neomycin (Biosol)	Aminoglycoside antibiotic. Neomycin differs from other aminoglycosides because it is only administered topically or orally. Systemic absorption is minimal from oral absorption.	Although oral absorption is so small that systemic adverse effects are unlikely, some oral absorption has been demonstrated in young animals (calves). Alterations in intestinal bacterial flora from therapy may cause diarrhea.	Neomycin is primarily used for oral treatment of diarrhea. Efficacy for this indication (especially for nonspecific diarrhea) is questionable. Used also for treatment of hepatic encephalopathy.	500 mg bolus; 50 and 200 mg/mL oral liquid; 325 mg soluble powder	10–20 mg/kg q6–12h PO
Neostigmine bromide and Neostigmine methylsulfate (Prostigmin; Stiglyn)	Anticholinesterase drug. Cholinesterase inhibitor. Inhibits breakdown of acetylcholine at synapse. Antimyasthenic drug. Used primarily for treatment of myasthenia gravis or as an antidote for neuromuscular blockade caused by neuromuscular blocking drugs.	Adverse effects are related to drug's pharmacologic effects: excessive cholinergic stimulation (muscarinic effects), which include diarrhea, salivation, respiratory problems, vomiting, CNS effects, muscle twitching, or used to treat overdose.	Compared to other drugs in this class (e.g., pyridostigmine) produces more severe muscarinic effects. When injected for diagnosis or treatment of myasthenia, it is recommended to use atropine to counteract side effects.	15 mg tablet (neostigmine bromide); 0.25, 0.5 mg/mL injection (neostigmine methylsulfate)	2 mg/kg/day PO (in divided doses, to effect). Injection—antimyasthenic: 10 µg/kg IM, SC, as needed; antidote for neuromuscular block: 40 µg/kg IM or SC; diagnostic aid for myasthenia gravis: 40 µg/kg IM or 20 µg/kg IV

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Nifedipine (Adalat, Procardia)	Calcium channel-blocking drug of the dihydropyridine class. Action is similar to other calcium channel-blocking drugs, except nifedipine is more specific for vascular smooth muscle than cardiac tissue. Used for smooth muscle relaxation, vasodilation.	Adverse effects have not been reported in veterinary medicine. Most common side effect is hypotension.	Use of nifedipine is limited in veterinary medicine. Other calcium channel blockers, such as diltiazem, are used to control heart rhythm.	10, 20 mg capsules; and 30, 60, 90 extended release capsules	Animal dose not established. In people, the dose is 10 mg/person three times a day and increased in 10 mg increments to effect.
Nitenpyram (Capstar)	Antiparasitic drugs. It rapidly kills adult fleas.	No adverse reactions are reported. It was safe in studies in dogs and cats in which up to 10× dose was administered. Transient pruritus may be observed shortly after administration which coincides with rapid flea death.	Do not use in dogs or cats less than 1 kg (2 pounds) in weight. Do not use in cats or dogs less than 4 weeks of age.	Tablet: 11.4 or 57 mg	1 mg/kg, PO, daily as needed to kill fleas
Nitrofurantoin (Macrodantin, Furalan, Furatoxin, Furadantin, and generic)	Antibacterial drug. Urinary antiseptic. Action is via reactive metabolites that damage DNA. Therapeutic concentrations are reached only in the urine. Not to be used for systemic infections. May be active against some bacteria that are resistant to other antimicrobials.	Adverse effects include nausea, vomiting, and diarrhea. Turns urine color rust-yellow brown. Do not administer during pregnancy.	Two dosing forms exist. Microcrystalline is rapidly and completely absorbed. Macrocystalline (Macrodantin) is more slowly absorbed and causes less GI irritation. Urine should be at acidic pH for maximum effect. Administer with food to increase absorption.	Macrodantin and generic: 25, 50, 100 mg capsules; Furalan, Furatoxin, and generic: 50, 100 mg tablets; Furadantin: 5 mg/mL oral suspension	10 mg/kg/day divided into four daily treatments, for 10–14 days, then 1 mg/kg at night PO Macrocrystalline formulation: 2–3 mg/kg q8h PO, followed by 1–2 mg/kg once at night
Nitroglycerin ointment (Nitrol, Nitro-Bid, Nitrostat)	Nitrate. Nitrovasodilator. Relaxes vascular smooth muscle (especially venous) via generation of nitric oxide. Used primarily in heart failure to reduce preload or decrease pulmonary hypertension. In people, used to treat angina pectoris.	Most significant adverse effect is hypotension. Methemoglobinemia can occur with accumulation of nitrates, but is a rare problem.	Tolerance can develop with repeated, chronic use. Use should be intermittent for optimum effect. Nitroglycerin has high presystemic metabolism, and oral availability is poor. When using ointment, 1 inch of ointment is approximately 15 mg.	0.5, 0.8, 1, 5, 10 mg/mL injection; 2% ointment; transdermal systems (0.2 mg/h patch)	Dog: 4–12 mg (up to 15 mg) topically q12h Cat: 2–4 mg topically q12h (or 1/4 inch of ointment per cat)

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Nitroprusside (Sodium nitroprusside) (Nitropress)	Nitrate vasodilator. See Nitroglycerin ointment. Nitroprusside is used only as an IV infusion, and patients should be monitored carefully during administration.	Severe hypotension is possible during therapy. Monitor patients carefully during administration. Cyanide is generated via metabolism during nitroprusside treatment, especially at high infusion rates. Sodium thiosulfate has been used in people to prevent cyanide toxicity. Methemoglobinemia is possible, and if necessary, treated with methylene blue.	Nitroprusside is administered via IV infusion. IV solution should be delivered in 5% dextrose solution (e.g., add 50 mg to 250 mL of 5% dextrose). Protect from light. Discard solution if color change is observed. Titrate dose carefully in each patient.	50 mg vial for injection	1–5 µg/kg/min up to a maximum of 10 µg/kg/min IV infusion. Start with 2 µg/kg/min and increase gradually until desired blood pressure is achieved.
Nizatidine (Axit)	Histamine H ₂ blocking drug. Same as cimetidine, except up to 10× more potent. Inhibits acid secretion in stomach. Used for ulcers and gastritis.	Side effects from nizatidine have not been reported in animals.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals. Nizatidine and ranitidine have been shown to stimulate gastric emptying and colonic motility via anticholinesterase activity.	150, 300 mg capsules	Dog: 2.5–5 mg/kg q24h PO
Norfloxacin (Noroxin)	Fluoroquinolone antibacterial drug. Same action as ciprofloxacin, except spectrum of activity is not as broad as with enrofloxacin or ciprofloxacin.	Adverse effects have not been reported in animals. Some effects are expected to be similar to enrofloxacin and other veterinary fluoroquinolones.	Use in animals (and doses) is based on pharmacokinetic studies in experimental animals, experience in people, or anecdotal experience in animals.	400 mg tablets	22 mg/kg q12h PO
Oclacitinib (Apoquel)	A Janus kinase inhibitor used for control of pruritus in dogs associated with allergic dermatitis and atopic dermatitis.	Adverse effects are rare if the recommended dosing schedule is followed.	Oclacitinib has a rapid onset of effect to control pruritus in dogs.	3.6, 5.4 and 16 mg tablets.	Dog: 0.5 mg/kg (0.4–0.6 mg/kg, with or without food) PO q12h for 14 days, then decrease frequency to q24h. Cat: Dose not established.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Olsalazine sodium (Dipentum)	Anti-inflammatory drug for treating colitis. Two molecules of mesalamine joined by an azo bond.	No adverse effects reported in dogs.	Olsalazine is used in patients that cannot tolerate sulfasalazine.	500 mg tablets	Dose not established, but 5–10 mg/kg q8h PO has been used. (The usual human dose is 500 mg twice daily.)
Omeprazole (Prilosec)	Proton pump inhibitor. Omeprazole inhibits gastric acid secretion by inhibiting the K ⁺ /H ⁺ pump. Omeprazole is more potent and longer acting than most available antisecretory drugs. Used for treatment and prevention of GI ulcers.	Side effects have not been reported in animals. Drug interactions: Do not administer with drugs that depend on stomach acid for absorption (e.g., itraconazole or ketoconazole).	Due to omeprazole's potency and accumulation in gastric cells, once-daily administration is possible. Equine paste has been diluted to 40 mg/mL in oil and administered to dogs at a dose of 1 mg/kg PO.	20 or 40 mg capsules and equine paste (370 mg/g)	Dog: 20 mg/dog q24h PO (or 1–2 mg/kg q24h PO) Cat: 1 mg/kg q24h PO
Ondansetron (Zofran)	Antiemetic drug. Ondansetron's action is to inhibit action of serotonin (blocks 5-HT ₃ receptors). It is administered to treat or prevent vomiting caused by chemotherapy or GI disease.	Adverse effects have not been reported in animals.	Granisetron has similar action.	4, 8 mg tablets; 2 mg/mL injection; 4 mg/5 mL syrup and 2-mg/mL injection	0.5 to 1.0 mg/kg IV or PO 30 min prior to administration of cancer drugs. To control vomiting due to other causes, doses as low as 0.1–0.2 mg/kg IV q6–12h may be considered.
o,p'-DDD	See Mitotane				
Orbifloxacin (Orbax)	Fluoroquinolone antimicrobial. Same mechanism as enrofloxacin and ciprofloxacin. Spectrum includes staphylococci, gram-negative bacilli, and some Pseudomonas.	May cause some nausea and vomiting at high doses. Avoid use in young animals. Blindness in cats has not been reported with doses ≤ 15 mg/kg/day.	Dose range is wide to account for susceptibility of bacteria. Dosing should be guided by susceptibility tests.	5.7, 22.7, and 68 mg tablets and oral suspension 30 mg/mL	Tablets (dog and cat): 2.5 to 7.5 mg/kg q24h PO Oral suspension in cats: 7.5 mg/kg q24h PO
Ormetoprim + sulfadimethoxine	Trimethoprim-like drug used in combination with sulfadimethoxine. (See Primor.)				
Oxazepam (Serax)	Benzodiazepine. Central-acting CNS depressant. Mechanism of action appears to be via potentiation of GABA–receptor mediated effects in CNS. Used for sedation and to stimulate appetite.	Sedation is most common side effect. Causes polyphagia. In cats, fatal hepatic necrosis has been reported from diazepam.	Doses based on empiricism. There have been no clinical trials in veterinary medicine.	15, 30 mg tablets; 10, 15, 30 mg capsules	Dog: 0.2–1.0 mg/kg q12h PO but may be increased to q6h Cat: appetite stimulant, 2.5 mg/cat PO Cat: behavior treatment, 0.2–0.5 mg/kg q12–24h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Oxtriphylline (Choledyl-SA)	Choline theophyllinate. Methylxanthine bronchodilator, similar in mechanism to theophylline.	Same adverse effects as theophylline	Adverse effects similar to theophylline. Some formulations (Theocon) contain oxtriphylline and guaifenesin. When administering slow-release tablet, do not crush tablet.	400, 600 mg tablets (oral solutions and syrup available in Canada, but not US)	Dog: 47 mg/kg (equivalent to 30 mg/kg theophylline) q12h PO
Oxybutynin chloride (Ditropan)	Anticholinergic agent. Inhibits smooth muscle spasms via blocking action of acetylcholine. Used primarily to increase bladder capacity and to decrease spasms of urinary tract.	Adverse effects are related to anticholinergic effects but are less frequent compared to other anticholinergic drugs. Administer physostigmine for overdose.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	5 mg tablets; 1 mg/mL oral syrup	Dog: 5 mg/dog q6–8h PO, or 0.2 mg/kg q12h PO
Oxymetholone (Anadrol)	Anabolic steroid. Derivative of testosterone. Used to stimulate androgenic activity, increase weight gain, and stimulate erythropoiesis.	Produces androgenic side effects. Liver injury is possible.	Use is based primarily or anecdotal experience.	50 mg tablets	1–5 mg/kg q24h PO
Oxymorphone hydrochloride (Numorphan)	Opioid agonist. Action is similar to morphine, except that oxymorphone is more lipophilic than morphine and 10–15× more potent than morphine.	Same adverse effects and precautions as morphine.	There is some evidence that oxymorphone may have fewer cardiovascular effects compared to morphine. Since oxymorphone is more lipophilic, it is readily absorbed from epidural injection.	1.5 and 1 mg/mL injection	Analgesia: 0.1–0.2 mg/kg IV, SC, IM (as needed), redose with 0.05–0.1 mg/kg q1–2h Preanesthetic: 0.025–0.05 mg/kg IM or SC Sedation: 0.05–0.2 mg/kg (with or without acepromazine) IM, SC
Oxytetracycline (Terramycin)	Tetracycline antibiotic. Same mechanism and spectrum as tetracycline. Oxytetracycline may be absorbed to higher extent.	Generally safe. Use cautiously in young animals.	Oral dose forms are from large-animal use. Use of injectable long-acting forms has not been studied in small animals. For most indications, doxycycline or minocycline can be used as substitute.	250 mg tablets; 100, 200 mg/mL Injection; 500 mg bolus	7.5–10 mg/kg IV q12h; 20 mg/kg q12h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Oxytocin (Pitocin, Syntocinon [nasal solution] and generic)	Stimulates uterine muscle contraction via action on specific oxytoxin receptors. Used to induce or maintain normal labor and delivery in pregnant animals. Does not increase milk production but will stimulate contraction leading to milk ejection.	Adverse effects are uncommon if used carefully. Fetal stress and progression of normal labor should be monitored closely.	Used to induce labor. In people, oxytocin is administered via injection, constant IV infusion, and intranasal solution. Repeat up to 3x every 30–60 min. (maximum dose is 3 U/cat).	10, 20 U/mL injection; 40 U/mL nasal solution	Dog: 5–20 U/dog IM or SC (repeat every 30 min for primary inertia) Cat: 2.5–3 U/cat IM or IV, repeat up to 3 times, every 30–60 min
2-PAM	See Pralidoxime chloride.				
Pamidronate (Aredia)	Bisphosphonate drug; it slows the formation and dissolution of hydroxyapatite crystals. Is used in animals to decrease calcium in conditions that cause hypercalcemia, such as cancer and vitamin D toxicosis.	No serious adverse effects have been identified; however, use in animals has been uncommon.	Bisphosphonates may be effective in animals for treatment of hypercalcemia of cancer and vitamin D toxicosis. For IV infusion, dilute in fluid solution and administer over several hours (dilute 30 mg pamidronate in 250 mL of fluids).	Available as 30, 60, and 90 mg vials for injection; 1 mg/mL single use vial for injection.	Dog: Treatment of cholecalciferol toxicosis: 1.3–2 mg/kg IV or SC × 2 treatments after toxin exposure Treatment of hypercalcemia: 1–2 mg/kg IV, SC Treatment of malignancy: 1–2 mg/kg IV every 28 days (2 h infusion) Cat: 1–2 mg/kg IV
Pancrelipase (Viokase)	Pancreatic enzyme. Used to treat pancreatic exocrine insufficiency. Provides lipase, amylase, and protease.	Adverse effects not reported.	Mix with food when administering, approximately 20 minutes prior to feeding.	16,800 U of lipase, 70,000 U of protease, and 70,000 U of amylase per 0.7 g Also capsules and tablets	Dog: Mix 2 tsp powder with food per 20 kg body weight, or 1–3 tsp/0.45 kg of food Cat: 1/2 tsp per cat with food
Pancuronium bromide (Pavulon)	Nondepolarizing neuromuscular blocker (see Atracurium)	Similar precautions as atracurium.	Similar to atracurium.	1, 2 mg/mL injection	0.1 mg/kg IV, or start with 0.01 mg/kg and add 0.01 mg/kg doses every 30 min
Pantoprazole sodium (Protonix, Protonix IV)	Ulcer treatment. Proton pump inhibitor; indicated for treatment of gastroduodenal ulcer disease and gastroesophageal reflux. Pantoprazole is the first proton pump inhibitor for IV use. Antisecretory effects persist for > 24 h.	Side effects have not been reported in animals. However, in humans, there is concern about hypergastrinemia with chronic use.	Give IV dose over 15 minutes, and do not mix with other drugs that may interfere with stability.	20 and 40 mg delayed-release tablets; 4 mg/mL vials for IV injection	0.5 mg/kg q24h PO. IV use: 0.5–1 mg/kg IV infusion over 24 h, which may be delivered in 2 or 15 min, depending on dilution.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Paregoric (corrective mixture)	Paregoric (opium tincture) is an outdated product used to treat diarrhea. Paregoric contains 2 mg of morphine in every 5 mL of paregoric.	Same as other opiates.	Use of paregoric has been replaced by more specific products, such as loperamide or diphenoxylate.	2 mg morphine per 5 mL of paregoric	0.05–0.06 mg/kg q12h PO
Paroxetine (Paxil)	Selective serotonin reuptake inhibitor (SSRI) much like fluoxetine (Prozac) in action. Used for obsessive-compulsive disorders, anxiety disorders, aggression, and other behavioral problems.	Some effects similar to fluoxetine, but in some animals, paroxetine is better tolerated.	Dosing recommendations are empirical.	10, 20, 30, 40 mg tablets; 2 mg/mL oral suspension	Dog: 0.5–1 mg/kg q24h PO. Cat: 1/8 to 1/4 of a 10 mg tablet q24h PO
Penicillamine (Cuprimine, Depen)	Chelating agent for lead, copper, iron, and mercury. Used primarily in animals for treatment of copper toxicity and hepatitis associated with accumulation of copper. It also has been used to treat cystine calculi. Penicillamine has been used in people to treat rheumatoid arthritis.	Do not use in pregnant animals. In people, allergic reactions have been reported, as well as agranulocytosis and anemia.	Administer on an empty stomach (2 h before meals).	125, 250 mg capsules and 250 mg tablets	10–15 mg/kg q12h PO
Penicillin G potassium; Penicillin G sodium (many brands)	β -lactam antibiotic. Action is similar to other penicillins. Spectrum of penicillin G is limited to gram-positive bacteria and anaerobes.	Injections may induce allergic reactions.	Penicillin G does not have good activity against most small animal pathogens.	5–20 million U vials	20,000–40,000 U/kg q6–8h IV or IM
Penicillin G procaine (generic)	Same as other forms of penicillin G, except procaine penicillin is absorbed slowly, producing concentrations for 12–24 h after injection.	IM and SC injection can produce reactions at injection site.	Avoid SC injection with procaine penicillin G.	300,000 U/mL suspension	20,000–40,000 U/kg q12–24h IM
Penicillin V	Oral penicillin is not highly absorbed and is narrow spectrum in comparison with other penicillin derivatives.		Same as for other penicillins (amoxicillin). Penicillin V should be administered on an empty stomach for maximum absorption (250 mg = 400,000 U).	250, 500 mg tablets	10 mg/kg q8h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Pentobarbital (Nembutal and sodium generic)	Short-acting barbiturate anesthetic. Action is via nonselective CNS depression. Pentobarbital usually is used as IV anesthetic. Used to control severe seizures in animals. Duration of action may be 3–4 h.	Cardiac and respiratory depression is common.	Pentobarbital has narrow therapeutic index. When administering IV, inject first half of dose initially, then remainder of calculated dose gradually, until anesthetic effect is achieved.	50 mg/mL	25–30 mg/kg IV, to effect CRI: 2–15 mg/kg IV to effect, followed by 0.2–1.0 mg/kg/h Status epilepticus: 2–6 mg/kg IV
Pentoxifylline (Trental)	Methylxanthine. Pentoxifylline is used primarily as a rheological agent in people (increases blood flow through narrow vessels). It may have anti-inflammatory action via inhibition of cytokine synthesis. Used in dogs for some dermatoses (dermatomyositis) and vasculitis.	May cause signs similar to those of other methylxanthines. Nausea and vomiting have been reported in people. When broken tablet is administered to cats, the taste is unpleasant.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	400 mg tablets; IV solution 50 mg/mL	Dog—10 mg/kg q12h and up to 15 mg/kg q8h PO or 400 mg/dog for most animals. Use 25 mg/kg q12h PO for dermatologic conditions. Cat: 1/4 of a 400 mg tablet (100 mg) q8–12h PO
Pepto-Bismol	See Bismuth subsalicylate.				
Phenobarbital (Luminal and generic)	Long-acting barbiturate. Phenobarbital's major use is as an anticonvulsant, in which it potentiates inhibitory actions of GABA.	Adverse effects are dose-related. Phenobarbital causes polyphagia, sedation, ataxia, and lethargy. Some tolerance develops to side effects after initial therapy. Hepatotoxicity has been reported in some dogs receiving high doses.	Phenobarbital doses should be carefully adjusted via monitoring serum/plasma concentrations. Optimum range for therapeutic effect is 15–40 µg/mL	15, 30, 60, 100 mg tablets; 30, 60, 65, and 130 mg/mL injection; 4 mg/mL oral elixir solution	Dog: 2–8 mg/kg q12h PO Status epilepticus: administer in increments of 10–20 mg/kg IV (to effect) Cat: 2–4 mg/kg q12h PO
Phenoxybenzamine hydrochloride (Dibenzyline)	α1-adrenergic antagonist. Binds α1-receptor on smooth muscle, causing relaxation. Potent vasodilator. Used primarily to treat peripheral vasoconstriction. In some animals, has been used to relax urethral smooth muscle.	Causes prolonged hypotension in animals. Use carefully in animals with cardiovascular compromise.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or limited experimental experience in animals.	10 mg capsules	Dog: 0.25 mg/kg q8–12h PO, or 0.5 mg/kg q24h. Cat: 2.5 mg/cat q8–12h, or 0.5 mg/kg q12h PO. (In cats, doses as high as 0.5 mg/kg IV have been used to relax urethral smooth muscle.)

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Phentolamine mesylate (Regitine, [Rogitine in Canada])	Nonselective α -adrenergic blocker. Vasodilator. Blocks stimulation of α -receptors on vascular smooth muscle. Primarily used to treat hypertension.	May cause excess hypotension with high doses or in animals that are dehydrated. May cause tachycardia.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals. Titrate dose for each patient to produce desired vasodilation.	5 mg vials for injection	0.02–0.1 mg/kg IV
Phenylbutazone (Butazolidin and generic)	NSAID. Inhibits prostaglandin synthesis. Phenylbutazone is used primarily for arthritis and various forms of musculoskeletal pain and inflammation.	Phenylbutazone is generally well-tolerated in dogs, but there is no data for cats. Adverse effects possible are GI toxicity. Do not administer injectable formulation IM. Phenylbutazone causes bone marrow depression in people, which also is possible in dogs.	Doses are based primarily on manufacturer's recommendations and clinical experience. Use has declined in small animals because of availability of other NSAIDs.	100, 200, 400 mg and 1g tablets; 200 mg/mL injection	Dog: 15–22 mg/kg q8–12h (44 mg/kg/day) PO or IV (800 mg/dog maximum) Cat: 6–8 mg/kg q12h IV or PO
Phenylephrine hydrochloride (Neo-Synephrine)	Specific adrenergic agonist; specific for α_1 -receptor	Vasoconstriction and increased blood pressure	Phenylephrine also is used as topical vasoconstrictor (as in nasal decongestants).	10 mg/mL injection; 1% nasal solution	0.01 mg/kg every 15 min IV; 0.1 mg/kg every 15 min IM or SC
Phenylpropanolamine (PPA) (Proin PPA, Propalin syrup)	Adrenergic agonist. Used as decongestant, mild bronchodilator, and to increase tone of urinary sphincter.	Adverse effects are attributed to excess stimulation of adrenergic (α and β) receptors. Side effects: tachycardia, cardiac effects, CNS excitement, restlessness, and appetite suppression.	Phenylpropanolamine has been removed from human decongestant formulations. Only veterinary compounded formulations are available.	25, 50, 75 mg flavored tablet and 25 mg/mL vanilla flavored oral solution	Dog: 1 mg/kg, q8h, PO. Increase to 1.5–2.0 mg/kg as needed, q8h PO, or decrease to q12–24h in some animals.
Phenytoin (Dilantin)	Anticonvulsant. Depresses nerve conduction via blockade of sodium channels. Also classified as Class I antiarrhythmic. Commonly used as anticonvulsant in people, but not effective in dogs and not used in cats.	Adverse effects: sedation, gingival hyperplasia, skin reactions, CNS toxicity. Do not administer to pregnant animals.	Because of short half-life and poor efficacy in dogs and questionable safety in cats, other anticonvulsants are used as first choice before phenytoin.	30, 100 mg capsules; 50 mg/mL injection, 25 mg/mL oral suspension, and 50 mg chewable tablets	Dog: Antiepileptic: 20–35 mg/kg q8h. Antiarrhythmic: 30 mg/kg q8h PO or 10 mg/kg IV over 5 min Cat: do not use

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Physostigmine (Antilirium)	Cholinesterase inhibitor. Antidote for anticholinergic intoxication, especially intoxication that exhibits CNS signs. Major difference between physostigmine and neostigmine or pyridostigmine is that physostigmine crosses blood–brain barrier and the others do not.	Adverse effects attributed to excessive cholinergic effects (treat overdoses with atropine)	Physostigmine is indicated primarily only for treatment of intoxication. For routine systemic use of anticholinesterase drug, neostigmine and pyridostigmine have fewer side effects. When used, frequency of dose may be increased, based on observation of effects.	1 mg/mL injection	0.02 mg/kg q12h IV
Phytomenadione	See Vitamin K1.				
Phytonadione	See Vitamin K1.				
Pimobendan (Vetmedin)	Phosphodiesterase 3 inhibitor and a calcium sensitizer that acts as an inotropic vasodilator (inodilator). Licensed for treating CHF due to dilated cardiomyopathy and valvular insufficiency.	Safe in most dogs. Contraindicated with aortic stenosis and hypertrophic cardiomyopathy	May be used with furosemide and ACE inhibitors	Chewable tablets: 1.25 mg, 2.5 mg and 5 mg (US) Capsules: 2.5 mg and 5 mg (Canada, Europe, and Australia)	Dog: 0.25–0.3 mg/kg q12h PO Cat: 1.25 mg per cat q12h PO (0.1–0.3 mg/kg)
Piperacillin (Pipracil) and Zosyn (with tazobactam)	β-lactam antibiotic of the acylureidopenicillin class. Similar to other penicillins, except with high activity against <i>Pseudomonas aeruginosa</i> . Also good activity against streptococci.	Same precautions as for other injectable penicillins.	Reconstituted solution should be used within 24 hours (or 7 days if refrigerated). Piperacillin is combined with tazobactam (β-lactamase inhibitor) in Zosyn. Piperacillin and tazobactam has a broader spectrum of activity and is preferred when a beta-lactam and beta-lactamase inhibitor are needed.	2, 3, 4, 40 g vials for injection	50 mg/kg IV or IM q6h, or CRI using 2.4 mg/kg loading dose, followed by 3.2 mg/kg per hour infusion
Piperazine (many)	Antiparasitic compound. Produces neuromuscular blockade in parasite through inhibition of neurotransmitter, which causes paralysis of worms. Used primarily for treatment of helminth (ascaris) infections.	Remarkably safe in all species	Used to treat all species for roundworms	860 mg powder; 140 mg capsules; 120, 160, 170, 340, and 800 mg/mL oral solution; and 50, 250 mg tablets	44–66 mg/kg PO, administered once

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Piroxicam (Feldene and generic)	NSAID of the oxicam class. Prostaglandin synthesis inhibitor. Clinical effects are similar to other NSAIDs. Piroxicam has been used for treatment of transitional cell carcinoma in dogs.	Elimination of piroxicam is slow; use cautiously in dogs. Adverse effects are primarily GI toxicity (ulcers); see Flunixin meglumine.	Piroxicam is primarily used to treat arthritis and other musculoskeletal conditions, but there are reports of its activity for treating certain tumors (e.g., transitional cell carcinoma of bladder).	10 mg capsules	Dog: 0.3 mg/kg q48h PO; Cancer Tx: 0.3 mg/kg q24h PO Cat: 0.3 mg/kg q24h PO
Pitressin (ADH)	See Vasopressin and Desmopressin acetate.				
Plicamycin (old name is mithramycin) (Mithracin)	Anticancer agent. Action is to combine with DNA in presence of divalent cations and inhibit DNA and RNA synthesis. Lowers serum calcium. May have direct action on osteoclasts to decrease serum calcium. Used for carcinomas and treatment of hypercalcemia.	Adverse effects have not been reported in animals. In people, hypocalcemia and GI toxicity have been reported. May cause bleeding problems. <i>Drug interactions:</i> Do not use with drugs that may increase the risk of bleeding (e.g., NSAIDs, heparin, or anticoagulants).	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	2.5 mg injection	Antihypercalcemic (dogs or cats): 25 µg/kg q24h IV (slow infusion) over 4 h Antineoplastic (dogs): 25–30 µg/kg q24h IV (slow infusion) for 8–10 days
Polyethylene glycol electrolyte solution (GoLYTELY)	Saline cathartic. Nonabsorbable compounds that increase water secretion into bowel via osmotic effect. Used for bowel evacuation prior to surgical or diagnostic procedure.	Water and electrolyte loss with high doses or prolonged use.	Used primarily to evacuate bowel as preparation for procedures	Oral solution	25 mL/kg, repeat in 2–4 h PO
Polymyxin B sulfate	Antibiotic peptide; disrupts bacterial cell membrane. Active against a broad spectrum of bacteria	Renal injury is possible. IM injection is painful.	Use is primarily topical, but systemic use may be indicated for resistant infections.	Vials of 500,000 U per vial; 1 mg is equivalent to 10,000 U	Dog and Cat: 15,000–25,000 U/kg IV q12h
Polysulfated glycosaminoglycan (PSGAG) (Adequan Canine)	Large molecular weight compounds similar to normal constituents of healthy joints. Chondroprotective. Inhibits enzymes that may degrade articular cartilage. Used primarily to treat or prevent degenerative joint disease.	Adverse effects are rare. Allergic reactions are possible. PSGAG has heparin-like effects and may potentiate bleeding problems in some animals.	Doses are derived from empirical evidence, experimental studies, and clinical studies in dogs. Although effective for acute arthritis, may not be as effective for chronic arthropathy.	100 mg/mL injection in 5 mL vial	4.4 mg/kg IM, twice weekly for up to 4 weeks

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Potassium bromide (KBr)	Anticonvulsant. Anticonvulsant action is to stabilize neuronal cell membranes. Bromide ordinarily is used in patients refractory to phenobarbital, or added to phenobarbital treatment.	Adverse effects are related to high levels of bromide. Signs of toxicosis are CNS depression, weakness, ataxia. Consider using sodium bromide in patients with hypoadrenocorticism. Adverse effects in cats are more common than in dogs. Respiratory side effects similar to asthma have been reported in some cats.	Bromide usually is administered in combination with phenobarbital. Monitor serum bromide concentrations to adjust dose. Effective plasma concentrations should be 1–2 mg/mL, but if used alone (without phenobarbital), higher concentrations of 2–4 mg/mL may be needed. Diets high in chloride will cause shorter half-life and need for higher dose. Sodium bromide can be substituted for potassium bromide. Note that 30 mg/kg potassium bromide is equal to 20 mg/kg of elemental bromide.	Usually prepared as oral solution. (No commercial formulation, but can be formulated by a pharmacist)	Standard starting dose: 30–40 mg/kg q24h PO. If administered without phenobarbital, higher doses of up to 40–50 mg/kg may be needed by monitoring plasma concentrations. Rapid IV loading dose: 800 mg/kg (sodium bromide) given over 8 hours slowly IV. Rapid oral loading dose: 600 mg/kg PO divided over 3–5 days. Slow (60 day) oral loading dose: 60 mg/kg/day (30 mg/kg q12h), then monitor blood level. Cats: Not recommended for use in cats.
Potassium chloride (generic)	Potassium supplement. Used for treatment of hypokalemia. Usually added to fluid solutions.	Toxicity from high potassium concentrations can be dangerous. Hyperkalemia can lead to cardiovascular toxicity (bradycardia and arrest) and muscular weakness. Oral potassium supplements can cause nausea and stomach irritation.	1 g of potassium chloride provides 13.41 mEq of potassium. When potassium is supplemented in fluids, do not administer at a rate faster than 0.5 mEq/kg/h.	Various concentrations for injection (usually 2 mEq/mL). Oral suspension and oral solution.	0.5 mEq potassium/kg/day, or supplement 10–40 mEq/500 mL of fluids, depending on serum potassium
Potassium citrate (generic, Urocit-K)	Potassium supplement. Alkalizes urine and may increase urine citric acid. Used for calcium oxalate urolithiasis. Also used for renal tubular acidosis.	Same as potassium chloride.	1 g of potassium citrate provides 9.26 mEq of potassium.	5 mEq and 10 mEq tablets. Some forms are in combination with potassium chloride. 1,000 mg potassium citrate = 9.26 mEq potassium	0.5 mEq/kg/day PO
Potassium gluconate (Kaon, Tumil-K, generic)	Potassium supplement. Used for renal tubular acidosis.	Same as for potassium chloride	1 g of potassium gluconate provides 4.27 mEq of potassium.	2 mEq tablets; 500 mg tablets; Kaon is 20 mg/15 mL elixir.	Dog: 0.5 mEq/kg q12–24h PO Cat: 2–8 mEq/day divided twice daily, PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Potassium iodide	Iodine supplement, with some additional antimicrobial properties. It has been used to treat some fungal infections. It also may be used to protect the thyroid from radiation injury.	High doses produce iodism, which includes lacrimation, skin irritation, swelling of eye lids, cough, and poor hair coat.	Doses are purely empirical.	10% solution and 145 mg tablets	Dog and Cat: Start with 5 mg/kg q8h PO, and increase to 25 mg/kg q8h PO Radiation exposure: 2 mg/kg, per day, PO
Potassium phosphate	Phosphorus supplement. Used for severe hypophosphatemia associated with diabetic ketoacidosis.	May cause hypocalcemia		500 mg tablets contain 3.7 mmol (114 mg) phosphorus Injection contains 3 mmol (93 mg) phosphorus per mL	4 mg/kg phosphorus PO, up to 4x per day. 0.03–0.12 mmol/kg/h IV for acute treatment
Pradofloxacin (Vevafox)	Fluoroquinolone antimicrobial for dogs and cats. Increased activity against some Gram-positive and anaerobic bacteria compared to other fluoroquinolones	Use cautiously in young dogs. Oral treatment may cause vomiting and diarrhea.	New fluoroquinolone approved in Europe, but not yet available in US. Pradofloxacin is a 3rd generation fluoroquinolone with greater antimicrobial activity than other fluoroquinolones. It is approved in the U.S. for cats only, but in both dogs and cats in Europe.	Formulations contain pradofloxacin in a 2.5% oral suspension in the U.S. and Europe and 15, 60, and 120 mg tablets in Europe	Dog: 3–5 mg/kg q24h PO Cats: Tablets: 3–5 mg/kg q24h, PO Oral suspension: 5–7.5 mg/kg q24h, PO
Pralidoxime chloride (2-PAM) (Protopam)	Used for treatment of organophosphate toxicosis	Adverse effects have not been reported.	When treating intoxication, consult poison control center for precise guidelines. May be used with atropine (0.1 mg/kg).	50 mg/mL injection	20 mg/kg up to 50 mg/kg q8–12h; initial dose IV slow, or IM
Praziquantel (Droncit), and combined with pyrantel in Drontal	Antiparasitic drug. Action on parasites related to neuromuscular toxicity and paralysis via altered permeability to calcium. Used primarily to treat infections caused by tapeworms.	Vomiting occurs at high doses. Anorexia and transient diarrhea have been reported. Safe in pregnant animals.	Dose recommendations based on label dose supplied by manufacturer.	23, 34 mg tablet; 56.8 mg/mL injection. Also combined with pyrantel in tablets of 13.6/54.3, 18.2/72.6, and 27.2/108.6 of praziquantel/pyrantel.	Dog (oral dose): < 6.8 kg: 7.5 mg/kg PO, once; > 6.8 kg: 5 mg/kg PO, once. Dog (injection): ≤ 2.3 kg: 7.5 mg/kg IM or SC, once; 2.7–4.5 kg: 6.3 mg/kg IM or SC, once; ≤ 5 kg: 5 mg/kg IM or SC, once. Cat (oral dosage): < 1.8 kg: 6.3 mg/kg PO, once; > 1.8 kg: 5 mg/kg PO, once. For <i>Paragonimus</i> infection use 25 mg/kg q8h PO for 2–3 days. Cat (injection): 5 mg/kg IM or SC.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Prazosin (Minipress)	α_1 -adrenergic blocker. Relaxes smooth muscle, especially of vasculature. Prazocin is used as vasodilator and to relax smooth muscle (occasionally urethral muscle).	High doses cause vasodilation and hypotension.	Titrate dose to needs of individual patient. Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	1, 2, 5 mg capsules	0.5–2 mg/animal (1 mg/15 kg) q8–12h PO
Prednisolone (Delta-Cortef and many others)	Glucocorticoid anti-inflammatory drug. Potency is approximately 4× cortisol.	All glucocorticoids produce expected (and sometimes unavoidable) side effects. Chronic therapy may lead to several adverse effects.	Doses for prednisolone are based on severity of underlying condition.	5 and 20 mg tablets; 3 mg/mL syrup; 25 mg/mL acetate suspension injection	Dog (cats often require 2× dog dose)—anti-inflammatory: 0.5–1 mg/kg q12–24h IV, IM, PO initially, then taper to q48h; immunosuppressive: 2.2–6.6 mg/kg/day IV, IM, PO initially, then taper to 2–4 mg/kg q48h; replacement therapy: 0.2–0.3 mg/kg/day PO
Prednisolone sodium succinate (Solu-Delta-Cortef)	Same as for prednisolone, except that this is a water-soluble formulation intended for acute therapy when high IV doses are needed for rapid effect. Used for treatment of shock and CNS trauma	Adverse effects are not expected from single administration; however, with repeated use, other side effects are possible.	Although shock doses are listed, efficacy for treatment of shock is questionable.	100, 500 mg vials for injection (10 and 50 mg/mL)	Shock: 15–30 mg/kg IV (repeat in 4–6 h) CNS trauma: 15–30 mg/kg IV, taper to 1–2 mg/kg q12h Anti-inflammatory: 1 mg/kg/day IV Replacement therapy: 0.25–0.5 mg/kg/day IV
Prednisone (Deltasone and generic; Meticorten for injection)	Same as for prednisolone, except that, after administration, prednisone is converted to prednisolone	Adverse effects are same as for prednisolone.	Same as for prednisolone. In cats use prednisolone.	1, 2.5, 5, 10, 20, 25, and 50 mg tablets; 1 mg/mL syrup (Liquid Pred in 5% alcohol) and 1 mg/mL oral solution (in 5% alcohol)	Dogs convert prednisone to prednisolone, and doses are similar; in cats there is inadequate conversion of prednisone to prednisolone.
Pregabalin (Lyrica)	Analgesic and anticonvulsant, similar to gabapentin. Action is via stabilization of excitable neurons. Used to treat seizure disorders, and as adjunct for pain management.	Sedation is most common adverse effect, especially at high doses.	Clinical use is based primarily on anecdotal experience and extrapolation from human medicine.	25, 50, 75, 100, 150, 200, 225, and 300 mg capsules. Oral solution 20 mg/mL	Dog (anticonvulsant dose): 2 mg/kg q8h PO; (analgesic dose): 4 mg/kg q12h, PO maximum dose) Cat: 2 mg/kg q12h, PO and increase to 4 mg/kg if necessary

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Primidone (Mylepsin, Neurosyn [Mysoline in Canada])	Anticonvulsant. Primidone is converted to phenylethylmalonamide and phenobarbital, both of which have anticonvulsant activity, but most of activity (85%) is probably due to phenobarbital. See Phenobarbital for more details.	Adverse effects are same as for phenobarbital. Primidone has been associated with idiosyncratic hepatotoxicity in dogs. Although some labels caution its use in cats, one study in experimental cats determined that it is safe if used at recommended doses.	When monitoring therapy with primidone, phenobarbital plasma concentrations should be measured to estimate anticonvulsant effect.	50 and 250 mg tablets	8–10 mg/kg q8–12h as initial dose PO, then adjust via monitoring to 10–15 mg/kg q8h.
Primor (ormetoprim + sulfadimethoxine) (Primor)	Antibacterial drug. Ormetoprim inhibits bacterial dihydrofolate reductase; sulfonamide competes with <i>p</i> -aminobenzoic acid (PABA) for synthesis of nucleic acids. Bactericidal/bacteriostatic. Broad antibacterial spectrum and active against some coccidia.	Several adverse effects have been reported from sulfonamides. Ormetoprim has been associated with CNS adverse effects.	Doses listed are based on manufacturer's recommendations. Controlled trials have demonstrated efficacy for treatment of pyoderma on once-daily schedule.	Combination tablet (ormetoprim + sulfadimethoxine) 120, 240, 600 and 1200 mg tablets in 1:5 ratio	Dog: 55 mg/kg on first day, PO, followed by 27.5 mg/kg q24h PO. Daily doses can be divided into twice-daily.
Procainamide (Pronestyl, Procanbid, generic)	Antiarrhythmic drug. Class 1 antiarrhythmic used primarily for treatment of ventricular arrhythmias. Action is to inhibit sodium influx into cardiac cell via sodium channel blockade.	Adverse effects include cardiac arrhythmias, cardiac depression, tachycardia, and hypotension. In people, procainamide produces hypersensitivity effects (lupus-like reactions), but these have not been reported in animals. <i>Drug interactions:</i> Cimetidine may increase plasma concentrations.	Since dogs do not produce active metabolite (N-acetyl-procainamide), dose may be higher to control some arrhythmias compared to dose for people. Monitor plasma concentrations during chronic therapy (effective plasma concentration in experimental dogs is 20 µg/mL). In animals, slow-release oral formulations do not produce longer duration of sustained blood concentrations.	250, 375, 500 mg tablet or capsule; 100, 500 mg/mL injection, some oral formulations may be unavailable.	Dog: 10–30 mg/kg q6h PO to a maximum dose of 40 mg/kg; 8–20 mg/kg IV, IM; 25–50 µg/kg/min IV infusion. Cat: 3–8 mg/kg IM, PO q6–8h or CRI 1–2 mg/kg IV then 10–20 µg/kg/min IV.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Prochlorperazine + isopropamide (Darbazine)	Combination product. Chlorpromazine is a central-acting dopamine antagonist (antiemetic); isopropamide is an anticholinergic drug (atropine-like effects). Used primarily to control vomiting in animals.	Side effects are attributed to each component. Prochlorperazine produces phenothiazine-like effects. Isopropamide produces antimuscarinic effects. Use of antimuscarinic drugs is contraindicated in animals with gastroparesis and should be used cautiously in animals with diarrhea.	Doses are based on manufacturer's recommendations	No. 1, 2, and 3 capsules	Dog and Cat: 0.14–0.2 mL/kg q12h SC Dog 2–7 kg: 1–#1 capsule q12h PO Dog 7–14 kg: 1–#2 capsule q12h PO Dog > 14 kg: 1–#3 capsule q12h PO
Promethazine (Phenergan)	Phenothiazine with strong antihistamine effects. Used for treatment of allergy and as antiemetic (motion sickness).	Adverse effects include sedation and antimuscarinic (atropine-like) effects. Both phenothiazine effects and anticholinergic effects are possible in some patients.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	6.25 and 25 mg/5 mL syrup; 12.5, 25, 50 mg tablets; 25, 50 mg/mL injection	0.2–0.4 mg/kg q6–8h IV, IM, PO (up to a maximum dose of 1 mg/kg)
Propantheline bromide (Pro-Banthine)	Anticholinergic (antimuscarinic) drug. Blocks acetylcholine receptor to produce parasympatholytic effects (atropine-like effects). Used to decrease smooth muscle contraction and secretion of GI tract. Used to treat vagal-mediated cardiovascular effects.	Side effects are attributed to excess anticholinergic (antimuscarinic) effects. Treat overdoses with physostigmine. Use cautiously for treating gastrointestinal disease.	Propantheline has not been evaluated in clinical trials in animals, but propantheline is often the drug of choice for oral therapy in cases in which an anticholinergic effect is desired.	7.5, 15 mg tablet	0.25–0.5 mg/kg q8–12h PO
Propiopromazine Hydrochloride (Tranvet)	Phenothiazine sedative. Also has antiemetic, antihistaminic actions.	Adverse effects and precautions are similar to other phenothiazines such as acepromazine.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals. Do not confuse this drug with propiomazine (Largon), which is a discontinued human drug.	5–10 mg/mL injection, or 20 mg chewable tablet	1.1–4.4 mg/kg q12–24h PO 0.1–1.1 mg/kg IV, IM (Range of dose depends on degree of sedation needed.)

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Propofol (Rapinovet, Propoflo, [veterinary]; Diprivan [human])	Anesthetic. Used for induction or producing short-term general anesthesia. Mechanism of action is not well-defined, but may be barbiturate-like. Propofol may be used as induction agent, followed by inhalation with halothane or isoflurane.	Apnea and respiratory depression are most common adverse effects. Adverse effects attributed to general anesthetic properties.	Propofol is primarily used for general anesthesia, or adjunct for general anesthesia. Propofol's advantage over other agents is smooth, rapid recovery. Use strict aseptic technique for administration. Propofol may be diluted in 5% dextrose, lactated Ringer's solution, or 0.9% saline, but not to less than 2 mg/mL concentration.	1% (10 mg/mL) injection in 20 mL ampules	Dog: 6.6 mg/kg IV slowly over 60 sec. Constant rate IV CRI: 5 mg/kg slow IV followed by 100–400 µg/kg/min Cat: Anesthesia induction: 7 mg/kg IV slowly CRI: 6 mg/kg slow IV, then 200–300 µg/kg/min IV Short-term surgery: 10 mg/kg IV
Propranolol hydrochloride (Inderal)	β-adrenergic blocker. Nonselective for β ₁ - and β ₂ -adrenergic receptors. Class II antiarrhythmic. Used primarily to decrease heart rate, cardiac conduction, tachyarrhythmias, and blood pressure.	Adverse effects related to β ₁ -blocking effects on heart. Causes cardiac depression, decreases cardiac output. β ₂ -blocking effects can cause bronchoconstriction. Decreases insulin secretion.	Usually, dose is titrated according to patient's response. Start with low dose and increase gradually to desired effect. Clearance relies on hepatic blood flow; use cautiously in animals with impaired hepatic perfusion.	10, 20, 40, 60, 80, and 90 mg tablets; 1 mg/mL injection; 4 and 8 mg/mL oral solution	Dog: 20–60 µg/kg over 5–10 min IV; 0.2–1 mg/kg PO q8h (titrate dose to effect) Cat: 0.4–1.2 mg/kg (2.5–5 mg/cat) PO q8h
Propylthiouracil (PTU) (generic, Propyl-Thyracl)	Antithyroid drug. Compared to methimazole, PTU inhibits conversion of T ₄ to T ₃ .	Adverse effects in cats include hemolytic anemia, thrombocytopenia, and other signs of immune-mediated disease.	Use of PTU in most cats has been replaced with methimazole.	50 and 100 mg tablets	11 mg/kg q12h PO
Prostaglandin F _{2α} (dinoprost) (Lutalyse)	Prostaglandin induces luteolysis. Has been used to treat open pyometra in animals. Use for inducing abortion has been questioned.	Side effects include vomiting, diarrhea, and abdominal discomfort.	Use in treating pyometra should be monitored carefully.	5 mg/mL solution for injection	Pyometra (dog): 0.1–0.2 mg/kg, once daily for 5 days SC; (cat): 0.1–0.25 mg/kg, once daily for 5 days SC. Termination of pregnancy (dog): 0.025–0.05 mg (25–50 µg)/kg q12h IM; (cat): 0.5–1 mg/kg IM for 2 injections.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Pseudoephedrine hydrochloride (Sudafed, and many others [some formulations have other ingredients])	Adrenergic agonist. Similar to ephedrine, phenylpropanolamine in action. Used to increase peripheral resistance, as a decongestant, and in animals to treat urinary incontinence.	Side effects attributed to adrenergic effects (excitement, rapid heart rate, arrhythmias)	Although clinical trials have not been conducted for comparison, it is believed that pseudoephedrine's action and efficacy are similar to ephedrine and phenyl-propanolamine.	30, 60 mg tablets; 120 mg capsules; 6 mg/mL syrup. Most formulations have been removed from human market, because of risk of diversion to manufacture methamphetamine.	Dog: 0.2–0.4 mg/kg (or 15–60 mg/dog) q8–12h PO
Psyllium (Metamucil and others)	Bulk-forming laxative. Use for treatment of constipation and bowel evacuation. Action is to absorb water and expand to provide increased bulk and moisture content to the stool, which encourages normal peristalsis and bowel motility.	Adverse effects have not been reported in animals. Intestinal impaction can occur with overuse, or in patients with inadequate fluid intake.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	Available as powder 3.4 g per teaspoon	1 tsp/5–10 kg (added to each meal)
Pyrantel pamoate (Nemex, Strongid)	Antiparasitic drug. Acts to block ganglionic neurotransmission via cholinergic action.	No adverse effects reported	Dose recommendations based on manufacturer's recommendations	171, 180, 226 mg/mL paste; 50 mg/mL suspension 22.7, 113.5 mg tablets	Dog: 5 mg/kg once PO and repeat in 7–10 days Cat: 20 mg/kg once PO
Pyridostigmine bromide (Mestinon, Regonol)	Anticholinesterase. Same as for neostigmine, except that pyridostigmine has longer duration of action. Use to treat anticholinergic toxicity and treatment of myasthenia gravis.	Adverse effects caused by excessive anticholinesterase activity. Signs are attributed to acetylcholine. <i>Drug interactions:</i> Since this product contains bromide, use cautiously in patients already receiving bromide (e.g., potassium bromide for epilepsy).	Same as for neostigmine, except that adverse effects may persist longer.	12 mg/mL oral syrup; 60 mg tablets; 5 mg/mL injection	Antimyasthenic: 0.02–0.04 mg/kg q2h IV, or 0.5–3 mg/kg q8–12h PO Antidote for muscle blockade: 0.15–0.3 mg/kg IM, IV
Pyridoxine	Vitamin B ₆				

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Pyrimethamine (Daraprim)	Antibacterial, antiprotozoal drug. Blocks dihydrofolate reductase enzyme, which inhibits synthesis of reduced folate and nucleic acids. Activity of pyrimethamine is more specific against protozoa than bacteria.	When administered with trimethoprim-sulfonamide combinations, anemia has been observed. Folic or folinic acid has been supplemented to prevent anemia, but benefit of this treatment is unclear.	Used either alone or in combination with sulfonamides	25 mg tablets	Dog: 1 mg/kg q24h PO for 14–21 days (5 days for <i>Neosporum caninum</i>) Cat: 0.5–1 mg/kg q24h PO for 14–28 days
Quinidine gluconate (Quinaglute, Duraquin) Quinidine sulfate (Cin-Quin, Quinora) Quinidine polygalacturonate (Cardioquin)	Antiarrhythmic drug. Class I antiarrhythmic. Action is to inhibit sodium influx via blockade of sodium channels. Used to treat ventricular arrhythmias and occasionally atrial fibrillation. Mexilitine is often used as a Class I antiarrhythmic instead.	Side effects with quinidine are more common than procainamide and include nausea and vomiting. Adverse effects: hypotension, tachycardia (due to antivagal effect). <i>Drug interactions:</i> Coadministration with digoxin may increase digoxin concentrations.	Quinidine is not used as commonly as other Class I antiarrhythmic drugs. Doses calculated according to amount of quinidine base in each product. 324 mg quinidine gluconate = 202 mg quinidine base. 300 mg quinidine sulfate = 250 mg quinidine base. 275 mg quinidine polygalacturonate = 167 mg quinidine base	Many human formulations are no longer available due to diminished use. Quinidine gluconate 324 mg tablets; 80 mg/mL injection Quinidine polygalacturonate 275 mg tablets Quinidine sulfate 100, 200, 300 mg tablets; 200, 300 mg capsules; 200 mg/mL injection	Dog: 6–20 mg/kg q6h IM; 6–20 mg/kg q6–8h PO (of base)
Racemethionine (DL-methionine) (Uroeze, Methio-Form, and generic. Human forms include Pedameth, Uracid, and generic.)	Urinary acidifier. Lowers urinary pH. Also has been used to protect against acetaminophen overdose in people by restoring hepatic concentrations of glutathione. In people, it also is used to treat dermatitis caused by urinary incontinence (reduces urine ammonia).	Adverse effects have not been reported. Do not use in patients with metabolic acidosis or hepatic function impairment. Do not use in young cats.	Used for urinary acidification. Use for acetaminophen toxicity has been replaced by acetylcysteine.	500 mg tablets, powders added to animal's food; 75 mg/5 mL pediatric oral solution; 200 mg capsules	Dog: 150–300 mg/kg q24h PO Cat: 1–1.5g/cat PO (added to food each day)
Ranitidine hydrochloride (Zantac)	Histamine H ₂ -antagonist. Same as cimetidine except 4–10× more potent and longer acting.	Ranitidine may have fewer effects on endocrine function and drug interactions, compared to cimetidine.	Pharmacokinetic information in dogs suggests that ranitidine may be administered less often than cimetidine to achieve continuous suppression of stomach acid secretion. Ranitidine may stimulate stomach emptying and colon motility via anticholinesterase action.	75, 150, 300 mg tablets; 150, 300 mg capsules; 25 mg/mL injection	Dog: 2 mg/kg q8h IV, PO Cat: 2.5 mg/kg q12h IV; 3.5 mg/kg q12h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Retinoids	See Isotretinoin and Vitamin A.				
Retinol	See Vitamin A.				
Riboflavin (Vitamin B ₂)	See Vitamin B ₂ .				
Rifampin (Rifadin)	Antibacterial. Action is to inhibit bacterial RNA synthesis. Spectrum of action includes staphylococci and mycobacteria. Other susceptible bacteria include streptococci. Used in dogs treat staphylococcosis, including methicillin-resistant strains.	Adverse effects in dogs include gastrointestinal disturbance, increased liver enzymes, and hepatic injury. <i>Drug interactions:</i> Multiple drug interactions are possible. Induces cytochrome P-450 enzymes. Drugs affected include barbiturates, chloramphenicol, and corticosteroids.	Clinical trials in dogs indicate that rifampin is effective for treating Staphylococcal infections, including methicillin-resistant strains, even when used as monotherapy.	150, 300 mg capsules; injection solution: 600 mg Rifadin IV	5 mg/kg q12h PO, or 10 mg/kg per day PO
Ringer's solution, lactated (generic)	IV solution for replacement	Monitor pulmonary pressure when infusing high doses.	When administering IV fluid solution, monitor rate and electrolyte concentrations carefully.	250, 500, 1000 mL bags for infusion	55–65 mL/kg/day IV, SC 50 mL/kg/h IV for severe dehydration
Ronidazole	Antiprotozoal drug. Ronidazole has mechanism of action similar to other nitroimidazoles, such as metronidazole. Ronidazole has been used to treat tritrichomonas intestinal infections in cats.	Neurotoxicity is the most serious adverse effect, which is more likely at high doses.	Do not exceed 60 mg/kg per day in cats to avoid neurotoxicity. Doses are based only on experimental studies.	There are no commercial formulations; however, compounding pharmacies have prepared formulations for cats.	Dog: No established dose Cat: 30 mg/kg q24h PO for 2 weeks.
Salicylate	See Aspirin.				
Selamectin (Revolution)	Topical parasiticide and heartworm prevention	Transient localized alopecia with or without inflammation at or near the site of application was observed in approximately 1% of 691 treated cats. Other signs observed rarely included GI signs, anorexia, lethargy, salivation, tachypnea, and muscle tremors.	Recommended for use in dogs 6 weeks of age or older and in cats 8 weeks of age or older	Available in six separate dose strengths	6–12 mg/kg topically every 30 days

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Selegiline (Anipryl [also known as deprenyl and L-deprenyl]; human dose form is Eldepryl)	Action is to inhibit specific monoamine oxidase (MAO type B) to inhibit degradation of dopamine in CNS. In dogs, it is approved to control clinical signs of pituitary-dependent hyperadrenocorticism (Cushing's disease) and to treat cognitive dysfunction in geriatric dogs.	Adverse effects have not been reported in dogs. However, amphetamine-like signs can be produced in experimental animals. At high doses in dogs, hyperactivity has been observed (doses > 3 mg/kg). Do not use with other MAO-inhibitors or drugs that inhibit serotonin reuptake.	In the multicenter trial performed by Deprenyl Animal Health, Inc. selegiline controlled the clinical signs of > 70% of dogs with hyperadrenocorticism. However, other investigators have reported efficacy rates as low as 20%	2, 5, 10, 15, and 30 mg tablets; 5 mg capsules; 20, 30, and 40 cm ² transdermal patch	Dog: Treatment for Cushing's disease and cognitive dysfunction use the same dose. Begin with 1 mg/kg q24h PO. If there is no response within 2 months, increase dose to maximum of 2 mg/kg q24h PO. Cat: 0.25–0.5 mg/kg q12–24h PO
Senna (Senokot)	Laxative. Acts via local stimulation or via contact with intestinal mucosa	Adverse effects not reported for animals	Doses and indications are not well established for veterinary medicine. Use is strictly through anecdotal experience.	Granules in concentrate, or syrup	Dog (syrup): 5–10 mL/dog q24h PO; (granules): 1/2–1 tsp/dog q24h PO Cat (syrup): 5 mL/cat q24h; (granules) 1/2 teaspoon per cat q24h (with food)
Sevoflurane	Inhalant anesthetic	Action and adverse effects similar to other inhalant anesthetics.		100 mL bottle	Induction: 8% Maintenance: 3%–6% to effect
Sildenafil citrate (Viagra)	Phosphodiesterase 5 inhibiting vasodilator that preferentially vasodilates pulmonary circulation. Indicated for treatment of pulmonary hypertension	May cause hypotension especially if used in combination with nitrates; cutaneous flushing in inguinal area has been reported in dogs	Very expensive	25, 50, 100 mg tablets	Dog: 2 mg/kg q12h PO but dose interval may range from 8–24 hours. Cat: 1 mg/kg q8h PO
Silymarin (Silybin, Marin, "milk thistle")	Silymarin, contains silybin as the most active ingredient. It is also known as milk thistle, from which it is derived. Silymarin is a mixture of antihepatotoxic flavonolignans (derived from the plant <i>Silybum</i>).	No adverse reactions have been reported.	Silymarin is available in several dietary supplements. There may be variable content and absorption among products.	Silymarin tablets are widely available OTC. Commercial veterinary formulations (Marin) also contain zinc and Vitamin E in a phosphatidylcholine complex in tablets for dogs and cats.	5–15 mg/kg once daily, PO. Some sources recommend 30 mg/kg/day PO.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Sodium bicarbonate (NaHCO ₃) (generic, baking soda, Soda Mint)	Alkalizing agent. Antacid. Used to treat systemic acidosis or to alkalize urine. Increases plasma and urinary concentrations of bicarbonate	Adverse effects attributed to alkalizing activity. <i>Drug interactions:</i> When administered orally, interaction may occur to decrease absorption of other drugs (partial list includes anticholinergic drugs, ketoconazole, fluoroquinolones, tetracyclines).	When used for systemic acidosis, doses should be adjusted on basis of blood gas measurements or assessment of acidosis. Doses vary depending on underlying condition (see dosage section). Note: 8.5% solution = 1 mEq/mL of NaHCO ₃ .	325, 520, 650 mg tablets; injection of various strengths (4.2% to 8.4%); 8.4% solution is equivalent to 1 mEq/mL.	Acidosis: 0.5–1 mEq/kg IV Renal failure: 10 mg/kg q8–12h PO Alkalization of urine: 50 mg/kg q8–12h PO (1 tsp is approximately 2 g) Antacid: 2–5 g mixed with food or water
Sodium chloride 0.9% (generic)	Sodium chloride is used for IV infusion as replacement fluid.	Not a balanced electrolyte solution. Long-term infusion may cause electrolyte imbalance.	Rate of infusion varies depending on patient needs.	500, 1000 mL infusion	15–30 mL/kg/h IV for moderate dehydration
Sodium chloride 7.2% (generic) Hypertonic saline	Concentrated sodium chloride used for acute treatment of hypovolemia	Not a balanced electrolyte solution. Long-term infusion may cause electrolyte imbalance.	Hypertonic saline is used for short-term infusion for rapid replacement of vascular volume.	7.2% solution	3–8 mL/kg IV (do not administer at a rate > 1 mL/kg/min)
Sotalol hydrochloride (Betapace)	Nonspecific β-(β ₁ and β ₂) adrenergic blocker (Class II antiarrhythmic). Action is similar to propranolol (1/3 potency); however, its beneficial effect may be caused more by the other antiarrhythmic effects. In addition to being a Class II antiarrhythmic drug, Sotalol may have some Class III (potassium channel-blocking) activity.	Adverse effects have not been reported for animals but are expected to be similar to propranolol. Like many antiarrhythmics, it may have some proarrhythmic activity. Negative inotropic effects may cause concern in some animals with poor contractility.	It may be a more effective maintenance agent than other drugs for controlling arrhythmias. Sotalol may have pro arrhythmic effect in German shepherds.	80, 160, 240 mg tablets	Dog: 1–2 mg/kg q12h PO (medium-size dogs, start with 40 mg per dog, then increase to 80 mg if needed) Cat: 2 mg/kg PO q12h
Spinosad (Comfortis)	Antiparasite drug used for flea control. Fleas are killed rapidly after administration.	Occasional vomiting has been observed, but otherwise safe.	Administer with food.	140, 270, 560, 810, and 1620 mg tablets. Also combined with milbemycin in some formulations.	Dogs: 30 mg/kg (13.5 mg/pound), PO, administered once per month Cats: 50–100 mg/kg, PO, once per month

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Spironolactone (Aldactone)	Potassium-sparing diuretic. Spironolactone competitively inhibits the action of aldosterone. Used for treating high blood pressure and congestion caused by heart failure.	Can produce hyperkalemia in some patients. Do not use in dehydrated patients. Severe ulcerative facial dermatitis may occur in cats. <i>Drug interactions:</i> Avoid supplements that are high in potassium.	Spironolactone usually is used with diuretic agent for CHF. It may decrease cardiac remodeling and improve patient survival; no effect though on cardiac remodeling in Maine Coon cats with cardiomyopathy. Spironolactone will cause slight false increase in plasma digoxin concentrations measured by some assays.	25, 50, 100 mg tablets	Dog: 2–4 mg/kg q24h PO (or 1–2 mg/kg q12h PO) (European approved label dose is 2mg/kg/day, PO.) Cat: avoid use in cats, but 1–2 mg/kg q12h PO has been used in some cases.
Stanozolol (Winstrol-V)	Anabolic steroid. Stanozolol has been used to decrease negative nitrogen balance in animals with chronic renal failure.	Stanozolol will produce anabolic effects with chronic use. There is increased risk of hepatic toxicity, with cats being at higher risk.	Monitor liver enzymes in treated animals.	50 mg/mL injection; 2 mg tablets, some commercial forms withdrawn from market.	Dog: 2 mg/dog (or range of 1–4 mg/dog) q12h PO; 25–50 mg/dog/week IM Cat: 1 mg/cat q12h PO; 25 mg/cat/week IM
Succimer (Chemet)	Used in treatment of lead toxicosis. Chelates lead and other heavy metals, such as mercury and arsenic.	No known adverse effects	Doses based on studies in dogs but evidence for use in cats is lacking.	100 mg capsules	Dog: 10 mg/kg q8h PO for 5 days, then 10 mg/kg q12h PO for 2 more weeks Cat: 10 mg/kg q8h PO for 2 weeks
Sucralfate (Carafate, [Sucrulate in Canada])	Gastric mucosa protectant. Antiulcer agent. Action of sucralfate is to bind to ulcerated tissue in GI tract to aid healing of ulcers.	Adverse effects have not been reported. Not absorbed systemically. <i>Drug interactions:</i> Sucralfate may decrease absorption of other orally administered drugs (e.g., fluoroquinolones and tetracyclines) via chelation with aluminum.	Dosing recommendations are based largely on empiricism. There have not been clinical trials of efficacy in animals.	1 g tablets; 200 mg/mL oral suspension	Dog: 0.5–1 g q8–12h PO Cat: 0.25 g q8–12h PO
Sufentanil citrate (Sufenta)	Opioid agonist. Action of fentanyl derivatives is via μ -receptor. Sufentanil is 5–7 \times more potent than fentanyl. 13–20 μ g of sufentanil produces analgesia equal to 10 mg of morphine.	Adverse effects similar to other opiates. High potency requires careful calculation of dose.	When used for anesthesia, often animals are premedicated with acepromazine or benzodiazepine.	50 μ g/mL injection	2 μ g/kg IV, up to a maximum dose of 5 μ g/kg (0.005 mg/kg)

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Sulfadiazine (generic, combined with trimethoprim in Tribriksen)	Sulfonamides compete with PABA for enzyme that synthesizes dihydrofolic acid in bacteria. Synergistic with trimethoprim. Broad spectrum of activity, including some protozoa. Bacteriostatic.	Adverse effects associated with sulfonamides include allergic reactions, type II and III hypersensitivity, hypothyroidism (with prolonged therapy), keratoconjunctivitis sicca, and skin reactions.	Usually, sulfonamides are combined with trimethoprim or ormetoprim in 5:1 ratio to produce a synergistic effect.	500 mg tablets	100 mg/kg IV, PO (loading dose), followed by 50 mg/kg q12h IV, PO See Trimethoprim + sulfadiazine section for additional dosing.
Sulfasalazine (sulfapyridine + mesalamine) (Azulfidine [Salazopyrin in Canada])	Sulfonamide + anti-inflammatory drug. Used for treatment of colitis. Sulfonamide has little effect; salicylic acid (mesalamine) has anti-inflammatory effects.	Adverse effects are all attributed to sulfonamide component. Keratoconjunctivitis sicca has been reported.	Usually used for treatment of idiopathic colitis, often in combination with dietary therapy.	500 mg tablets	Dog: 10–30 mg/kg q8–12h PO (see also Mesalamine, Olsalazine) Cat: 20 mg/kg q12h PO
Tamoxifen citrate (Nolvadex)	Nonsteroid estrogen receptor blocker. Also has weak estrogenic effects. Tamoxifen may also increase release of gonadotropin-releasing hormone (Gn-RH). Used as adjunctive treatment for certain tumors	Adverse effects have not been thoroughly documented in animals. However, in people, tamoxifen causing increased tumor pain has been reported. Do not use in pregnant animals. <i>Drug interactions:</i> Reacts with antiulcer drugs	Consult specific anticancer protocols for doses and regimens.	10 and 20 mg tablets (tamoxifen citrate)	Veterinary dose not established. Human dose is 10 mg q12h PO.
Taurine (generic)	Nutritional supplement for cats. Used in prevention and treatment of ocular and cardiac disease (cardiomyopathy) caused by taurine deficiency	Adverse effects have not been reported.	Routine supplementation with taurine may not be necessary in cats that are receiving a balanced diet.	Available in powder	Dog: 500 mg q12h PO Cat: 250 mg/cat q12h PO
Telazol	See Tiletamine + zolazepam.				
Terbinafine hydrochloride (Lamisil)	Antifungal drug effective against dermatophytes and <i>Malassezia</i>	Vomiting and anorexia. Hepatotoxicity possible but not reported in animals	Doses used in dogs and cats much higher than those used in humans. Clinical results in dogs and cats for dermatophytes have been inconsistent.	250 mg tablets, 1% topical solution, 1% topical cream	Dog: 30–40 mg/kg PO (with food) q24h for 2–3 weeks Cats: 30–40 mg/kg/day PO for at least 2 weeks. Or, or 1/4 tablet for small cats (62.5 mg), 1/2 tablet for medium size cats (125 mg) and one tablet for large cats (250 mg), all administered once daily

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Terbutaline sulfate (Brethine, Bricanyl)	β -adrenergic agonist. β_2 -specific. Used primarily for bronchodilation.	Adverse effects related to excessive β -adrenergic stimulation. Tachycardia and tachyarrhythmias possible with high doses.	Used primarily for bronchodilation. May be administered orally, IM, or SC. Terbutaline (and other β_2 -agonists) have also been used in people to delay labor (dose in people is 2.5 mg q6h PO).	2.5, 5 mg tablets; 1 mg/mL injection (equivalent to 0.82 mg/mL)	Dog: 1.25–5 mg/dog q8h PO or 3–5 μ g/kg SC Cat: 0.1 mg/kg q8h, PO or 0.625 mg/cat (1/4 of 2.5 mg tablet) q12h PO For acute therapy in cats 5–10 μ g/kg (0.005–0.01 mg/kg) q4h SC, or IM
Testosterone cypionate ester (Andro-Cyp, Andronate, Depo-Testosterone, and other forms) and Testosterone propionate ester (Testex, [Malogen in Canada])	Testosterone ester. Similar effects as methyltestosterone. Testosterone esters are administered IM to avoid first-pass effects. Esters in oil are absorbed more slowly from IM injection. Esters are then hydrolyzed to free testosterone.	Adverse effects are attributed to androgenic and anabolic effects. Hepatic toxicity is also possible.	Clinical efficacy for chronic diseases has not been evaluated in small animals.	Testosterone cypionate: 100, 200 mg/mL injection Testosterone propionate: 100 mg/mL injection	Testosterone cypionate: 1–2 mg/kg every 2–4 weeks IM (see also Methyltestosterone). Testosterone propionate: 0.5–1 mg/kg 2–3 times/week IM
Tetracycline (Panmycin)	Tetracycline antibiotic. Mechanism of action of tetracyclines is to bind to 30S ribosomal subunit and inhibit protein synthesis. Usually bacteriostatic. Broad spectrum of activity, including bacteria, some protozoa, <i>Rickettsia</i> , <i>Ehrlichia</i> .	Tetracyclines can affect bone and teeth formation in young animals. Tetracyclines have been implicated in drug fever in cats. Hepatotoxicity may occur at high doses in susceptible individuals. <i>Drug interactions:</i> Tetracyclines bind to calcium-containing compounds, which decreases oral absorption.	Pharmacokinetic and experimental studies have been conducted in small animals, but no clinical studies. Do not use outdated solutions. For most indications, doxycycline can be substituted.	250, 500 mg capsules; 100 mg/mL suspension, 25 and 324 g/lb of powder	15–20 mg/kg q8h PO; or 4.4–11 mg/kg q8h IV, IM Rickettsial infection (dogs): 22 mg/kg for 14 days PO
Thenium closylate (Canopar)	Antiparasitic drug. Used to treat hookworms (<i>Ancylostoma</i> and <i>Uncinaria</i>).	Tablet is bitter if coating is broken. May cause occasional vomiting after oral administration.	Doses listed are based on recommendations from manufacturer.	500 mg tablets	Dogs > 4.5 kg: 500 mg PO once, repeat in 2–3 weeks; 2.5–4.5 kg: 250 mg PO q12h for 1 day, repeat in 2–3 weeks

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Theophylline	Methylxanthine bronchodilator. Mechanism of action is unknown, but may be related to increased cAMP or antagonism of adenosine. There is anti-inflammatory action as well as bronchodilating action.	Adverse effects: nausea, vomiting, diarrhea. With high doses, tachycardia, excitement, tremors, and seizures are possible. Cardiovascular and CNS adverse effects appear to be less frequent in dogs than in people.	Plasma concentrations of theophylline should be monitored in patients receiving chronic therapy to maintain plasma concentrations between 5 and 20 µg/mL. Many slow-release tablets are no longer available.	100, 125, 200, 250, 300 mg tablets; 27 mg/5 mL oral solution or elixir; injection in 5% dextrose. Extended-release forms are available as 100, 200, and 300 mg tablets. Availability of extended-release formulations may be variable.	Dog: 9 mg/kg q6–8h PO Extended-release formulations: 10 mg/kg q12h PO Cat: 4 mg/kg q8–12h PO Extended-release formulations: 20–25 mg/kg q24–48h PO
Thiamin (Vitamin B ₁ (Bewon and others)	Vitamin B ₁ used for treatment of vitamin deficiency	Adverse effects are rare because water-soluble vitamins are easily excreted. Riboflavin may discolor the urine.	Vitamin B supplements are administered often in combination.	250 µg/5 mL elixir; tablets of various size from 5 mg to 500 mg; 100 and 500 mg/mL injection	Dog: 10–100 mg/dog q24h PO 12.5–50 mg/dog IM, SC Cat: 5–30 mg/cat q24h PO (up to a maximum dose of 50 mg/cat q24h), 12.5–25 mg/cat IM or SC
Thioguanine (6-TG) (generic)	Anticancer agent. Antimetabolite of purine analog type. Inhibits DNA synthesis in cancer cells.	Adverse effects, as with any anticancer drugs, are expected (see 6-Mercaptopurine). Immunosuppression and leukopenia are common.	Thioguanine is often combined with other agents for treatment of cancer. Consult specific reference on cancer therapy for guidance.	40 mg tablets	Dog: 40 mg/m ² q24h PO Cat: 25 mg/m ² PO q24h × 1–5 days, then repeat every 30 days
Thiopental sodium (Pentothal)	Ultra-short-acting barbiturate. Used primarily for induction of anesthesia or for short duration of anesthesia (10–15 min procedures). Anesthesia is produced by CNS depression, without analgesia. Anesthesia is terminated by redistribution in the body.	Adverse effects are related to the anesthetic effects of the drug. Severe adverse effects are caused by respiratory and cardiovascular depression. Overdoses are caused by rapid or repeated injections. Avoid extravasation outside of vein.	Therapeutic index is low. Use only in patients in which it is possible to monitor cardiovascular and respiratory functions. Often administered with other anesthetic adjuncts.	Various size vials from 250 mg to 10 g (mix to desired concentration)	Dog: 10–25 mg/kg IV (to effect) Cat: 5–10 mg/kg IV (to effect)

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Thiotepa (generic)	Anticancer agent. Alkylating agent of the nitrogen mustard type (similar to cyclophosphamide). Used for various tumors, especially malignant effusions.	Adverse effects are similar to other anticancer agents and alkylating drugs (many of which are unavoidable). Bone marrow suppression is the most common effect.	One should consult specific cancer chemotherapy protocol for guidance on administration. Thiotepa usually is administered directly into body cavities.	15 mg injection (usually in solution of 10 mg/mL)	0.2–0.5 mg/m ² weekly, or daily for 5–10 days IM, intracavitory, or intratumor
Thyroid hormone	See Levothyroxine sodium and Liothyronine.				
Thyrotropin, Thyroid-stimulating hormone (TSH) (Thytopar, Thyrogen)	Thyroid-stimulating hormone is used for diagnostic testing. Stimulates normal secretion of thyroid hormone.	Adverse reactions rare. In people, allergic reactions have occurred.	For Thyrogen, reconstitute 1.1 mg vial with 6.0 mL sterile water, then divide into 12 aliquots. Administer 0.5 mL to each patient for testing. Remaining solution may be frozen for storage.	Old forms (Thytopar) are difficult to obtain. Human recombinant form (rh TSH) (Thyrogen) contains 1,000 µg/vial.	Dog: Collect baseline sample, followed by (human recombinant form) 50–100 µg per dog.
Ticarcillin disodium (Ticar, Ticillin)	β-lactam antibiotic. Action similar to ampicillin/amoxicillin. Spectrum similar to carbenicillin. Ticarcillin is primarily used for Gram-negative infections, especially those caused by <i>Pseudomonas</i> .	Adverse effects are uncommon. However, allergic reactions are possible. High doses can produce seizures and decreased platelet function. <i>Drug interactions:</i> Do not combine in same syringe or in vial with aminoglycosides.	Ticarcillin is synergistic and often combined with aminoglycosides (e.g., amikacin, gentamicin). 1% lidocaine may be used for reconstitution to decrease pain from IM injection.	Vials containing 1, 3, 6, 20, and 30 g for injection. 3 g vials with a final concentration of 384.6 mg/mL.	33–50 mg/kg q4–6h IV, IM
Tiletamine + zolazepam (Telazol, Zoletil)	Anesthetic. Combination of tiletamine (dissociative anesthetic agent similar in action to ketamine) and zolazepam (benzodiazepine similar in action to diazepam). Produces short duration (30 min) of anesthesia.	Wide margin of safety. Side effects include excessive salivation (may be antagonized with atropine), erratic recovery, and muscle twitching.	Administer by deep IM injection. (Consult manufacturer's package insert for dosing information for dogs and cats.)	50 mg of each component per mL	Dog (minor procedures): 6.6–10 mg/kg IM; (short-term anesthesia) 10–13 mg/kg IM Cat (minor procedures): 10–12 mg/kg IM; (surgery) 14–16 mg/kg IM
Tinidazole (Tindamax)	Antiprotozoal drug, similar to metronidazole, but considered a 2nd-generation drug. Used for <i>Trichomonas</i> , <i>Giardia</i> , and intestinal protozoa.	High doses can produce neurological adverse effects.	Dosing and use in dogs and cats are based on limited anecdotal information and extrapolation from human medicine.	250 and 500 mg tablets	Dog: 15 mg/kg q12h PO Cat: 15 mg/kg q24h PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Tobramycin sulfate (Nebcin)	Aminoglycoside antibacterial drug. Similar mechanism of action and spectrum as amikacin, gentamicin.	Adverse effects similar to those of amikacin, gentamicin.	Dosing requirements vary depending on bacterial susceptibility. See dose schedules for gentamicin and amikacin.	40 mg/mL injection	Dog: 9–14 mg/kg q24h IV, IM, SC Cat: 5–8 mg/kg q24h IV, IM, SC
Tocanide hydrochloride (Tonocard)	Antiarrhythmic drug. Considered an oral analogue of lidocaine. Class 1 antiarrhythmic.	In dogs, anorexia and GI toxicity have been reported. Arrhythmias, vomiting, ataxia also are possible. (In one study, 35% of dogs showed GI effects.)	Limited experience in animals. However, clinical studies demonstrate efficacy. Therapeutic concentrations are 6–10 µg/mL.	400, 600 mg tablets	Dog: 15–20 mg/kg q8h PO Cat: no dose established
Toceranib phosphate (Palladia)	Anticancer agent used for cutaneous mast cell tumors in dogs. It is a tyrosine kinase inhibitor that disrupts blood supply to tumors.	It has been associated with GI adverse effects, that include vomiting, decreased appetite, diarrhea, weight loss, and blood in feces.	Administer with antihistamines to decrease adverse effects. Proton pump inhibitors are also recommended. If adverse effects occur, discontinue for up to 2 weeks.	10, 15, and 50 mg tablets	Dog: 3.25 mg/kg PO every other day, or may be lowered to 2.5 mg/kg 3 days per week Cat: no dose established
Tramadol hydrochloride (Ultram, and generic)	Analgesic drug. Tramadol has some µ-opioid receptor action, and it may also inhibit the reuptake of norepinephrine (NE) and serotonin (5 HT). The metabolite (desmethyltramadol) may have greater opiate effects than the parent drug.	Sedation may occur in some animals, especially at high doses. In cats, some vomiting, behavior changes, and mydriasis may be observed at high doses. At very high doses in dogs, seizures may occur.	Tramadol has produced inconsistent results in both experimental studies and clinical studies in dogs. In most studies, it is a weak analgesic, or has effects not greater than a placebo. May be used with NSAIDs, other analgesics, and anesthetics.	Tramadol immediate release tablets are available in 50 mg tablets. Extended release tablets are 100, 200, and 300 mg.	Dog: 5 mg/kg q6–8h PO Cat: Start with 2 mg/kg, and increase up to 4 mg/kg q8–12h PO
Trandolapril (Mavik)	ACE inhibitor. Similar in mechanism to captopril and enalapril. Used for management of CHF. Converted to active trandolaprilat after administration.	Same adverse effects as for other ACE inhibitors	Not used extensively in veterinary patients	1, 2, 4 mg tablets	Not established for dogs. Dose in people is 1 mg/person/day to start, then increased to 2–4 mg/day.
Trazodone hydrochloride (Desyrel)	Antianxiety agent. Action is to alter serotonin action and reuptake at synapse. Used as a sedative, hypnotic, and antianxiety agent.	Causes sedation at high doses. High margin of safety.	Administer at least 1 hour prior to event that triggers anxiety. Trazodone has been used in dogs and cats to decrease anxiety associated with stressful events, or to facilitate confinement.	50, 100, 150, and 300 mg tablets	Dogs: 5 mg/kg, PO, as needed, but generally every 8 to 24 hours; or administer a single dose 1 hour prior to an anticipated event that may trigger anxiety. Cats: 50–100 mg per cat, PO (peak effect occurs in 2–2.5 hours).

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Triamcinolone and Triamcinolone acetonide (Vetalog, Triamtabs, Aristocort, generic)	Glucocorticoid anti-inflammatory drug. Triamcinolone has potency that is approximately equal to methylprednisolone (about 5× cortisol and 1.25× prednisolone), although some dermatologists suggest that potency is higher. Injectable suspension is slowly absorbed from IM or intralesional injection site. Used for intralesional therapy.	Adverse effects are similar to other corticosteroids. When used for ocular injections, there is some concern that granulomas may occur at injection site.	Note that cats may require higher doses than dogs (sometimes 2×).	Veterinary (Vetalog): 0.5 and 1.5 mg tablets. 2 or 6 mg/mL suspension injection; human form: 1, 2, 4, 8, 16 mg tablets; 10 mg/mL injection	Anti-inflammatory: 0.5–1 mg/kg q12–24h PO, then taper dose to 0.5–1 mg/kg q48h PO. (However, manufacturer recommends doses of 0.11 to 0.22 mg/kg/day.) Cat dose: start with 0.2 mg/kg per day, PO. Gradually taper to a dose of 0.1 mg/kg (0.5 mg per cat one tablet is a common dose), every other day. Triamcinolone acetonide injection: 0.1–0.2 mg/kg IM, SC, repeat in 7–10 days. Intralesional: 1.2–1.8 mg, or 1 mg for every cm diameter of tumor every 2 weeks
Triamterene (Dyrenium)	Potassium-sparing diuretic. Similar action as spironolactone, except that spironolactone has competitive inhibiting effect of aldosterone; triamterene does not.	Similar to spironolactone	Little clinical experience available for triamterene. There is no convincing evidence that triamterene is more effective than spironolactone.	50, 100 mg capsules	1–2 mg/kg q12h PO
Tribriissen	See Trimethoprim + sulfadiazine.				
Trentine hydrochloride (Syprine)	Chelating agent. Used to chelate copper when penicillamine cannot be tolerated in a patient.	Adverse effects have not been reported in animals.	Used only in patients that cannot tolerate penicillamine. Generally induces less cupruresis than penicillamine.	250 mg capsules	10–15 mg/kg q12h PO; 1–2h before feeding
Trifluoperazine (Stelazine)	Phenothiazine. Used for treatment of anxiety, to produce sedation, antiemetic. Action is believed to be via antagonism of dopamine (similar to acepromazine); antiemetic action may be via antimuscarinic action.	Adverse effects not reported in animals, but are expected to be similar to other phenothiazines.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals.	10 mg/mL oral solution; 1, 2, 5, 10 mg tablets; 2 mg/mL injection	0.03 mg/kg IM q12h

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Triflupromazine hydrochloride (Vesprin)	Phenothiazine. Similar action as other phenothiazines, except triflupromazine may have stronger antimuscarinic activity than other phenothiazines. Used for antiemetic action.	Adverse effects have not been reported in animals. Adverse effects possible include anticholinergic effects.	Same as for other phenothiazines.	10, 20 mg/mL injection	0.1–0.3 mg/kg IM, PO q8–12h
Triiodothyronine	See Liothyronine.				
Trilostane (Vetoryl)	Used for treatment of hypercortisolemia (Cushing's syndrome) in dogs. 3-β-hydroxysteroid dehydrogenase inhibitor, in dogs, for treatment of pituitary-dependent hyperadrenocorticism (PDH).	Adverse effects include transient lethargy, anorexia, and vomiting. Otherwise, it has been well tolerated. One should check electrolyte levels in treated patients because trilostane may decrease aldosterone.	Trilostane is an efficacious and safe medication for treatment of dogs with PDH. Dose can be adjusted in individual patients based on cortisol measurements. In some patients, twice-daily dosing with lower doses is better tolerated than once-daily dose.	10, 30, 60, and 120 mg capsules	Dog: 3–6 mg/kg, once per day PO. Many dogs are controlled with a lower dose of 2–3 mg/kg q12h, PO. Adjust dose based on cortisol measurements. Large dogs (>30 kg) may require lower dose compared to small dogs (<15 kg). Cats: 3–6 mg/kg q24h PO, and gradually increase (as needed) to 10 mg/kg q24h. Some cats are better controlled with twice-daily administration. In these cats, start with low dose q12h, PO, then increase dose to 5 mg/kg q12h, PO as needed.
Trimeprazine tartrate (Temaril [Panectyl in Canada])	Phenothiazine with antihistamine activity (similar to promethazine). Used for treating allergies and motion sickness.	Adverse effects similar to those of promethazine.	There is evidence that trimeprazine is more effective when combined with prednisone for treatment of pruritus. Combination product is Temaril-P.	2.5 mg/5 mL syrup; 2.5 mg tablet. Temaril-P is available in tablets with 5 mg trimeprazine + 2 mg prednisolone.	0.5 mg/kg q12h PO or 0.5 mg/kg prednisolone + 1.25 mg/kg trimeprazine/day and gradually lower dose to 0.3 mg/kg prednisolone + 0.75 mg/kg trimeprazine every other day, PO.
Trimethobenzamide (Tigan, and others)	Antiemetic. Mechanism of action is not understood.	Adverse effects not reported in animals.	Efficacy as antiemetic not reported in animals.	100 mg/mL injection; 100, 250 mg capsules	Dog: 3 mg/kg q8h IM, PO Cat: not recommended

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Trimethoprim + sulfadiazine (Tribrissen, Tucoprim, and others)	Combines the antibacterial drug action of Trimethoprim and a sulfonamide. Together, the combination is synergistic, with a broad spectrum of activity.	Adverse effects primarily caused by sulfonamide component.	Dosage recommendations vary. There is evidence that 30 mg/kg/day is efficacious for pyoderma; for other infections, 30 mg/kg twice daily has been recommended.	30, 120, 240, 480, 960 mg tablet (all formulations have ratio of 5:1 sulfa:trimethoprim). Some trimethoprim-sulfadiazine tablets are less available.	15 mg/kg q12h PO, or 30 mg/kg q12–24h PO (for <i>Toxoplasma</i>). 30 mg/kg q12h PO
Trimethoprim + sulfamethoxazole (Bactrim, Septra, and generic forms)	Combines the antibacterial drug action of trimethoprim and a sulfonamide. Together, the combination is synergistic, with a broad spectrum of activity.	Adverse effects primarily caused by sulfonamide component.	Dosage recommendations vary. There is evidence that 30 mg/kg/day is efficacious for pyoderma; for other infections, 30 mg/kg twice daily has been recommended.	480, 960 mg tablet; 240 mg/5 ml oral suspension (all formulations have ratio of 5:1 sulfa:trimethoprim)	15 mg/kg q12h PO, or 30 mg/kg q12–24h PO; 30 mg/kg q12h IV
Tripeptenamine citrate (Pelamine, PBZ)	Histamine (H_1) blocker. Similar in action as other antihistamines. Used to treat allergic disease	Adverse effects similar to other antihistamines. Members of this class (ethanolamines) have greater antimuscarinic effects than other antihistamines.	There are no clinical reports of use in veterinary medicine. No evidence that it is more efficacious than other drugs in this class.	25, 50 mg tablets; 20 mg/mL injection	1 mg/kg q12h PO
Tylosin (Tylocine, Tylan, Tylosin tartrate)	Macrolide antibiotic. Tylosin is not used systemically, but has been administered to treat chronic diarrhea in dogs.	May cause diarrhea in some animals. Do not administer orally to rodents or rabbits.	Tylosin is rarely used in small animals. Powdered formulation (Tylosin tartrate) has been administered with food for control of signs of colitis in dogs. Tablets are approved in Canada for treatment of colitis.	Available as soluble powder 3 g per teaspoon 50 and 200 mg/mL injection	Dog and cat: 7–15 mg/kg q12–24h PO; 8–11 mg/kg q12h IM Dog (for colitis): 10–20 mg/kg q8h with food; if there is a response, increase the interval to q12–24h
Urofollitropin (FSH) (Metrodin)	Stimulates ovulation. Contains FSH. In people, it is used in combination with HCG to stimulate ovulation and induce pregnancy.	Side effects have not been reported in animals. In people, thromboembolism or severe ovarian hyperstimulation syndrome has been reported.	Results of clinical studies in animals have not been reported. Use in animals is based on experience in people.	75 U per vial for injection	Doses not established (human dose is 75 U/day IM for 7 days)

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Ursodiol (ursodeoxy-cholate) (Actigall)	Hydrophilic bile acid. Anticholelithic. Used for treatment of liver diseases. Increases bile flow. In dogs, may alter pool of circulating bile acids, displacing the more hydrophobic bile acids. In people, it is used to prevent or treat gallstones.	Adverse effects not reported in animals. May cause diarrhea.	Results of clinical studies in animals have not been reported. Use in animals (and doses) is based on experience in people or anecdotal experience in animals. Administer with meals.	300 mg capsules and 250 or 500 mg tablets	10–15 mg/kg q24h PO
Valproic acid (Depakene [valproic acid]; Depakote [divalproex] [Epival is Canadian brand])	Anticonvulsant. Used, usually in combination with phenobarbital, to treat refractory epilepsy in animals. Action is not known, but it may increase GABA concentrations in the CNS.	Adverse effects have not been reported in animals, but hepatic failure has been reported in people. Sedation may be seen in some animals. Do not use in pregnant animals. <i>Drug interactions:</i> May cause bleeding if used with drugs that inhibit platelets.	Valproic acid is listed here with divalproex. Divalproex is composed of both valproic acid and sodium valproate. Equivalent oral doses of divalproex sodium and valproic acid deliver equivalent quantities of valproate ion.	125, 250, 500 mg tablets (Depakote); 250 mg capsules; 50 mg/mL syrup (Depakene); 100 mg/mL injection (Depacon)	Dog: 50–250 mg per dog (depending on size) q8h PO. For delayed-release forms, start with 250 mg per dog q12h PO, and increase to 500 mg per dog q12h, if needed. Cat: no dose established
Vancomycin (Vancocin, Vancoled)	Antibacterial drug. Mechanism of action is to inhibit cell wall and cause bacterial cell lysis (via mechanism different from that of β -lactams). Spectrum includes staphylococci, streptococci, and enterococci (but not Gram-negative bacteria). Used primarily for treatment of methicillin-resistant <i>Staphylococcus</i> spp. (e.g., MRSA, or MRSP).	Adverse effects have not been reported in animals. Administer IV; causes severe pain and tissue injury if administered IM or SC. Do not administer rapidly; use slow infusion, if possible (e.g., over 30 min).	Vancomycin can be used in animals for treatment of enterococci or staphylococci that are resistant to other antibiotics. Monitoring of trough plasma concentrations is recommended to ensure proper dose. Maintain trough concentration above 5–10 μ g/mL.	Vials for injection (0.5 to 10 g)	Dog: 15 mg/kg q6–8h IV infusion Cat: 12–15 mg/kg q8h IV infusion
Vasopressin (ADH) (Pitressin)	Antidiuretic hormone. Vasopressin is used for treatment of polyuria caused by central diabetes insipidus. Not effective for polyuria caused by renal disease. Also used as a vasopressor and during cardiac arrest (CPR).	Adverse effects have not been reported. Allergic reactions have been reported in people. Increase in blood pressure has been reported in people.	Doses are adjusted on the basis of monitoring of water intake and urine output. See also Desmopressin acetate. CPR: There is evidence that this drug may be equivalent to or even superior to epinephrine in some situations.	20 U/mL (aqueous)	Antidiuretic: 10 U IV, IM Vasopressor: 0.01–0.04 U/min CPR: 0.8 U/kg/IV. Dose may be repeated at 3- to 5-minute intervals.

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Verapamil hydrochloride (Calan, Isoptin)	Calcium channel blocking drug of the nondihydropyridine group. Blocks calcium entry into cells via blockade of slow channel. Produces vasodilation, negative chronotropic effects.	Hypotension, cardiac depression, bradycardia, AV block. May cause anorexia in some patients.	Diltiazem is preferred over verapamil in patients with heart failure because of less cardiac suppression. Oral formulation not absorbed sufficiently (of the active stereoisomer) for adequate effects.	40, 80, 120 mg tablet; 2.5 mg/mL injection	Dog: 0.05 mg/kg every 10–30 min IV (maximum cumulative dose is 0.15 mg/kg); oral dose is not established
Vinblastine sulfate (Velban)	Similar to vincristine. Sometimes used as an alternative to vincristine. Do not use to increase platelet numbers (may actually cause thrombocytopenia).	Does not produce neuropathy as vincristine does, but there may be a higher incidence of myelosuppression. Causes tissue necrosis if injected outside vein.	Vinblastine is used in cancer chemotherapy protocols for various tumors. Consult specific chemotherapy protocol for regimens.	1 mg/mL injection	2 mg/m ² IV (slow infusion) once/week
Vincristine sulfate (Oncovin, Vincasar, generic)	Anticancer agent. vincristine causes arrest of cancer cell division by binding to microtubules and inhibiting mitosis. Used in combination chemotherapy protocols. Vincristine also increases numbers of functional circulating platelets and is used for thrombocytopenia.	Generally well tolerated. Less myelosuppressive than other anticancer drugs. Neuropathy has been reported but is rare. Constipation can occur. Very irritating to tissues. Avoid extravasation outside vein during administration.	Vincristine is used in cancer chemotherapy protocols for various tumors. Consult specific chemotherapy protocol for regimens.	1 mg/mL injection	Antitumor: 0.5–0.7 mg/m ² IV (or 0.025–0.05 mg/kg) once/week Thrombocytopenia: 0.02 mg/kg IV once/week (with prednisolone)
Vitamin A (retinoids) (Aquasol A)	Vitamin A supplement. See also Isotretinoin for analogues used for other conditions.	Excessive doses can cause bone or joint pain, dermatitis.	Dosing of vitamin is expressed as U or retinol equivalents (RE), or μ g of retinol. 1 RE = 1 μ g of retinol. 1 RE of Vitamin A = 3.33 U of retinol.	Oral solution: 5000 U (1500 RE)/0.1 mL; 10,000, 25,000, and 50,000 U tablets	625–800 U/kg q24h PO (see dosing information section)
Vitamin B ₁	See Thiamin.				
Vitamin B ₂ (riboflavin)	Vitamin B ₂ supplement	Adverse effects are rare because water-soluble vitamins are easily excreted. Riboflavin may discolor the urine.	Not necessary to supplement in animals with well-balanced diets	Various size tablets in increments from 10–250 mg	Dog: 10–20 mg/day PO Cat: 5–10 mg/day PO

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Vitamin B ₁₂ (cyanocobalamin) and Cobalamin	Vitamin B ₁₂ supplement. Vitamin B ₁₂ has been used to treat some forms of anemia.	Adverse effects are rare because water-soluble vitamins are easily excreted.	Administered to animals with intestinal disease (e.g., IBD), or pancreatic insufficiency to prevent deficiency. Serum monitoring can determine optimum dose. Suggested range is 290–1, 500 ng/L for cats and 252–908 ng/L for dogs. Not necessary to supplement in animals with well-balanced diets	Various size tablets in increments from 25–1000 µg, and injection	Dog: 100–200 µg/day PO, SC or 250–500 µg/day IM or SC Cat: 50–100 µg/day PO, SC or 250 µg/cat IM or SC weekly and interval can be increased to every 2, 4, or 6 weeks.
Vitamin C (ascorbic acid) (see Ascorbic acid)	Used to treat Vitamin C deficiency and occasionally used as urine acidifier. Insufficient data to show that ascorbic acid is effective for preventing cancer or cardiovascular disease.	Adverse effects have not been reported in animals. High doses may increase risk of oxalate stones in bladder.	Not necessary to supplement in animals with well-balanced diets	Tablets of various sizes, and injection	100–500 mg/day
Vitamin D	See Dihydrotachysterol or Ergocalciferol.				
Vitamin E (alpha tocopherol) (Aquasol E and generic)	Vitamin considered as antioxidant. Used as supplement and as treatment of some immune-mediated dermatoses.	Side effects have not been reported.	Vitamin E has been proposed as treatment for a wide range of human illnesses, but evidence for efficacy in animals is lacking.	Wide variety of capsules, tablets, oral solution available (e.g., 1000 U/capsule)	100–400 U q12h PO (or 400–600 U q12h PO for immune-mediated skin disease)
Vitamin K ₁ (phytonadione, phytomenadione) (Aqua-MEPHYTON [injection], Mephylton [tablets]; Veta-K1 [capsules])	Vitamin K ₁ is used to treat coagulopathies caused by anticoagulant toxicosis (Warfarin or other rodenticides). (Anticoagulants deplete Vitamin K in the body, which is essential for synthesis of clotting factors.)	Do not administer IV.	Consult poison control center for specific protocol if specific rodenticide is identified. Use Vitamin K ₁ for acute therapy because it is more highly bioavailable. Administer with food to enhance absorption. Phytonadione and phytomenadione are synthetic lipid-soluble forms of Vitamin K ₁ . Menadiol is Vitamin K ₄ , which is converted in the body to Vitamin K ₃ (menadione).	2 or 10 mg/mL injection; Mephylton is 5 mg tablet; Veta-K1 is 25 mg capsule. Phytonadione is 2 mg/mL or 10 mg/mL injection.	Short-acting rodenticides: 1 mg/kg/day IM, SC, PO for 10–14 days Long-acting rodenticides: 2.5–5 mg/kg/day IM, SC, PO for 3–4 weeks, and up to 6 weeks

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Voriconazole (Vfend)	Azole (triazole) antifungal. Action is similar to other antifungal azole drugs, which inhibit ergosterol synthesis. Active against systemic fungi, dermatophytes, and Aspergillus.	In dogs, the clearance may increase with multiple dosing, thus diminishing the effectiveness. Liver enzyme elevations have been observed in dogs. Adverse effects in cats have been observed and include ocular problems and neurologic toxicity. May cause drug interactions by inhibiting cytochrome P 450 enzymes.	Clinical use is based on limited clinical experience, anecdotal use, and extrapolation from human medicine.	50 and 200 mg tablets, 10 mg/mL injection.	Dog: 5–6 mg/kg q12h PO Cat: A safe dose has not been established for cats. However, in some cats, a loading dose of 25 mg per cat PO, followed by 12.5 mg (2–2.3 mg/kg) every other day has been used. Observe for signs of adverse effects with multiple dosing.
Warfarin sodium (Coumadin, generic)	Anticoagulant. Depletes Vitamin K, which is responsible for generation of clotting factors. Used to treat hypercoagulable disease, prevent thromboembolism.	Adverse effects are attributable to decreased clotting. <i>Drug interactions:</i> Other drugs may potentiate warfarin's action (including aspirin, chloramphenicol, phenylbutazone, ketoconazole, cimetidine)	Warfarin response is individualistic. For optimum therapy, adjust dose by monitoring clotting time. For example, in some patients, dose is adjusted to maintain prothrombin time at 1.5–2 × to 2–2.5 × normal (or INR of 2–3).	1, 2, 2.5, 4, 5, 7.5, 10 mg tablets	Dog: 0.1–0.2 mg/kg q24h PO Cat (thromboembolism): Start with 0.25 or 0.5 mg/cat q24h PO and adjust dose based on clotting time assessment.
Xylazine hydrochloride (Rompun, and generic)	α_2 -adrenergic agonist. Used primarily for short-term anesthesia and analgesia.	Produces sedation and ataxia. Cardiac depression, heart block, and hypotension are possible with high doses. Produces emesis after IV injection, especially in cats.	Often used in combination with other drugs, e.g., ketamine	20 and 100 mg/mL injection	Dog: 1.1 mg/kg IV; 2.2 mg/kg IM Cat: 1.1 mg/kg IM (emetic [cats only] dose is 0.4–0.5 mg/kg IV)
Yohimbine (Yobine)	α_2 -adrenergic antagonist. Used primarily to reverse actions of xylazine or detomidine. Atipamezole is more specific as a reversing agent.	High doses can cause tremors and seizures.	Reverses signs of sedation and anesthesia caused by α_2 -agonists. Antipamezole may be more specific and is recommended for small animals.	2 mg/mL injection	0.11 mg/kg IV, or 0.25–0.5 mg/kg SC, IM

<i>Drug Name (Trade or Other Names)</i>	<i>Pharmacology and Indications</i>	<i>Adverse Effects and Precautions</i>	<i>Dosing Information and Comments</i>	<i>Formulations</i>	<i>Dosage (Unless Otherwise Indicated, Dose is the Same for Dogs and Cats)</i>
Zidovudine (AZT) (Retrovir)	Antiviral drug. In people, used to treat AIDS. In animals, has been experimentally used for treatment of feline leukemia virus (FeLV) and feline immunodeficiency virus (FIV) viral infection in cats. AZT acts to inhibit the viral enzyme, reverse transcriptase, which prevents conversion of viral RNA into DNA.	Anemia and leukopenia are adverse effects. Monitor the packed cell volume in treated cats, and perform a complete blood count periodically.	At this time, experience with using AZT for treating viral disease in animals is largely experimental or anecdotal. It may have helped some experimental cats with FIV and may prevent persistent FeLV, but evidence for convincing efficacy is lacking.	10 mg/mL syrup; 10 mg/mL injection	Cat: 5–10 mg/kg PO, or SC, q12h. If administered SC, dilute in saline first to avoid injection site irritation.
Zolazepam	See Tiletamine + zolazepam.				
Zoledronate (Zometa, zoledronic acid)	Bisphosphonate drug. Inhibits bone resorption and decreases bone turnover by inhibiting osteoclasts. Used to treat malignancy of bone and pathologic bone disease. May provide pain relief with bone disease.	Use in dogs has not produced adverse effects.	Administer by IV infusion by diluting in fluids.	4 mg per 5 mL vial for injection	Dog: 0.2–0.25 mg/kg IV over 15 min diluted in 50–100 mL saline q28 days. Cat: 0.2 mg/kg IV over 15 min diluted in 25 mL every 21–28 days.
Zonisamide (Zonegran)	Anticonvulsant. Mechanism of action is uncertain, but it may potentiate the action of GABA, an inhibitory neurotransmitter, or it may stabilize membranes via changes in sodium and calcium conductance.	Adverse reactions can include lethargy, ataxia, and vomiting.	Zonisamide is used to treat refractory seizures in dogs when other drugs have not been effective.	100 mg capsule	Dog: 5–10 mg/kg q12h PO Cat: 10 mg/kg q12h PO

Key to Table Abbreviations:

ACE	angiotensin converting enzyme
CHF	congestive heart failure
CNS	central nervous system
COX	cyclooxygenase
CSF	cerebrospinal fluid
g	gram
GABA	gamma amino butyric acid
GI	gastrointestinal
IM	intramuscular
INR	international normalization ratio
IV	intravenous
μ g	micrograms
mg	milligram
MIC	minimum inhibitory concentration
mL	milliliter
NSAID	nonsteroidal anti-inflammatory drug
OTC	over the counter (without prescription)
PO	per os (oral)
PU/PD	polyuria and polydipsia
q	every, as in q8h = every 8 hours
Rx	prescription only
SC	subcutaneous
U	units

DISCLAIMER FOR DOSE TABLES:

Note: Doses listed are for dogs and cats, unless otherwise listed. Many of the doses listed are extra-label, or are human drugs not approved for animals administered in an extra-label manner. Doses listed are based on best available information at the time of table editing. The author cannot ensure efficacy or absolute safety of drugs used according to recommendations in this table. Adverse effects may be possible from drugs listed in this table of which authors were not aware at the time of table preparation. Veterinarians using this table are encouraged to consult current literature, product labels and inserts, and the manufacturer's disclosure information for additional information on adverse effects, interactions, and efficacy that were not identified at the time these tables were prepared.

APPENDIX X

CONVERSION TABLES

Table X-A

Conversion table of weight to body surface area (in square meters) for dogs			
kg	m^2	kg	m^2
0.5	0.06	26.0	0.88
1.0	0.10	27.0	0.90
2.0	0.15	28.0	0.92
3.0	0.20	29.0	0.94
4.0	0.25	30.0	0.96
5.0	0.29	31.0	0.99
6.0	0.33	32.0	1.01
7.0	0.36	33.0	1.03
8.0	0.40	34.0	1.05
9.0	0.43	35.0	1.07
10.0	0.46	36.0	1.09
11.0	0.49	37.0	1.11
12.0	0.52	38.0	1.13
13.0	0.55	39.0	1.15
14.0	0.58	40.0	1.17
15.0	0.60	41.0	1.19
16.0	0.63	42.0	1.21
17.0	0.66	43.0	1.23
18.0	0.69	44.0	1.25
19.0	0.71	45.0	1.26
20.0	0.74	46.0	1.28
21.0	0.76	47.0	1.30
22.0	0.78	48.0	1.32
23.0	0.81	49.0	1.34
24.0	0.83	50.0	1.36
25.0	0.85		

Although the above chart was compiled for dogs, it can also be used for cats. More precise values are represented in the formula $BSA \text{ in } m^2 = (K \times W^{2/3}) \times 10^{-4}$; where m^2 = square meters, BSA = body surface area, W = weight in g, and K = constant of 10.1 in dogs and 10.0 in cats.

Table X-B

Approximate equivalents for degrees Fahrenheit and Celsius*			
$^{\circ}F$	$^{\circ}C$	$^{\circ}F$	$^{\circ}C$
0	-17.8	98	36.7
32	0	99	37.2
